FastIron and Turbolron 24X

Configuration Guide

Supporting FSX 05.1.00 for FESX, FWSX, and FSX; FGS 04.3.03 for FGS, FLS and FWS; FGS 05.0.02 for FGS-STK and FLS-STK; FCX 06.0.00 for FCX; and TIX 04.2.00 for TIX

Chapter 1  Feature Highlights

- Introduction to features ............................... 1
- Note regarding IPv6 feature support ............. 1
Supported features ..................................................... 2
  Supported management features .............................. 2
  Supported security features .................................... 3
  Supported system-level features ............................... 5
  Supported Layer 2 features ...................................... 8
  Supported base Layer 3 features on FastIron devices .... 11
  Supported Edge Premium (EPREM) features on
  FastIron devices .................................................. 12
  Supported full Layer 3 features on FastIron devices ..... 13
  Supported Layer 3 features on Tubolron devices ......... 14
  Supported IPv6 management features ......................... 15
  Unsupported features ............................................. 16

Chapter 2 Getting Familiar with Management Applications

Using the management port ....................................... 17
  How the management port works .............................. 17
  CLI Commands for use with the management port ........ 17

Logging on through the CLI ....................................... 19
  On-line help ...................................................... 19
  Command completion .......................................... 20
  Scroll control ................................................... 20
  Line editing commands ........................................ 20

Using stack-unit, slot number, and port number
with CLI commands ................................................ 21
  CLI nomenclature on FSX, FSX 800, and FSX 1600 devices 21
  CLI nomenclature on TIX, FESX, and FWSX devices .... 21
  CLI nomenclature on FGS and FLS devices ............... 22
  CLI nomenclature on FGS-STK, FLS-STK, and FCX devices 22
  CLI nomenclature on the FWS ............................... 22

Searching and filtering output from CLI commands .......... 26
  Using special characters in regular expressions .......... 28
  Creating an alias for a CLI command ....................... 29

Logging on through the Web Management Interface .......... 30
  Navigating the Web Management Interface ................. 31

Logging on through IronView Network Manager .............. 34
Chapter 3 Configuring Basic Software Features

Configuring basic system parameters ............................................ 35
Entering system administration information .................................. 36
Configuring Simple Network Management Protocol (SNMP) parameters ................................................................. 36
Displaying virtual routing interface statistics .............................. 40
Disabling Syslog messages and traps for CLI access .................. 40
Configuring an interface as the source for all Telnet packets ...... 41
Cancelling an outbound Telnet session ........................................ 42
Configuring an interface as the source for all TFTP packets ....... 43
Configuring an interface as the source for all Syslog packets ... 43
Configuring an interface as the source for all SNTP packets ... 44
Specifying a Simple Network Time Protocol (SNTP) server ... 44
Setting the system clock ............................................................ 46
Limiting broadcast, multicast, and unknown unicast traffic ... 48
Configuring CLI banners ............................................................ 53
Configuring basic port parameters ............................................ 56
Assigning a port name ............................................................... 56
Modifying port speed and duplex mode .................................... 56
Auto speed detect ................................................................. 58
Enabling auto-negotiation maximum port speed advertisement and down-shift ......................................................... 58
Modifying port duplex mode .................................................... 61
Configuring MDI/MDIX ............................................................. 62
Disabling or re-enabling a port .................................................. 63
Disabling or re-enabling flow control ........................................ 64
Auto-negotiation and advertisement of flow control ............... 64
Configuring PHY FIFO Rx and Tx depth .................................. 66
Configuring the Interpacket Gap (IPG) ..................................... 67
Enabling and disabling support for 100BaseTX ......................... 69
Enabling and disabling support for 100BaseFX ....................... 70
Changing the Gbps fiber negotiation mode ............................... 72
Modifying port priority (QoS) .................................................. 72
Dynamic configuration of Voice over IP (VoIP) phones ............ 72
Configuring port flap dampening ............................................. 74
Configuring a local MAC address for Layer 2 management traffic ................................................................. 77
Port loop detection ................................................................. 78

Chapter 4 Operations, Administration, and Maintenance

Overview ................................................................................. 83
Determining the software versions installed and running on a device ................................................................. 83
Determining the flash image version running on the device ........ 83
Determining the boot image version running on the device .... 85
Determining the image versions installed in flash memory ... 86
Flash image verification ........................................................... 86
Image file types ................................................................. 88
Upgrading software .......................................................... 88
  Note regarding upgrading from FGS 02.4.00 .......................... 89
  to the new release ....................................................... 89
  Migrating to the new release (FESX and FSX devices only) .... 89
  Upgrading the boot code .............................................. 90
  Upgrading the flash code ............................................. 90
  Boot code synchronization feature .................................. 91

Important notes about downgrading from FSX 04.1.00 ............... 92

Using SNMP to upgrade software ......................................... 92

Changing the block size for TFTP file transfers ....................... 93

Rebooting ........................................................................ 94

Displaying the boot preference ............................................ 94

Loading and saving configuration files ................................. 95
  Replacing the startup configuration with the running configuration .......................... 96
  Replacing the running configuration with the startup configuration ......................... 96
  Logging changes to the startup-config file ............................................. 96
  Copying a configuration file to or from a TFTP server .............................. 96
  Dynamic configuration loading ............................................ 97
  Maximum file sizes for startup-config file and running-config ......................... 99

Loading and saving configuration files with IPv6 ...................... 100
  Copying a file to an IPv6 TFTP server .................................. 100
  Copying a file from an IPv6 TFTP server ................................ 101
  Using the IPv6 ncopy command .......................................... 102
  Uploading files from an IPv6 TFTP server ................................ 103
  Using SNMP to save and load configuration information .................. 104
  Erasing image and configuration files .................................. 105

Scheduling a system reload ................................................ 105
  Reloading at a specific time ............................................. 105
  Reloading after a specific amount of time ................................ 106
  Displaying the amount of time remaining before a scheduled reload ............ 106
  Canceling a scheduled reload .......................................... 106

Diagnostic error codes and remedies for TFTP transfers .......... 106

Chapter 5  Brocade Stackable Devices

Brocade IronStack overview .............................................. 109
  IronStack technology features ........................................ 109
  Brocade stackable models ............................................... 110
  Brocade IronStack terminology ...................................... 111
Building an IronStack ................................................. 113
Brocade IronStack topologies ................................. 113
Software requirements ........................................... 116
IronStack construction methods .............................. 116
Scenario 1 - Configuring a three-member IronStack
in a ring topology using secure-setup ....................... 117
Scenario 2 - Configuring a three-member IronStack
in a ring topology using the automatic setup process .... 121
Scenario 3 - Configuring a three-member IronStack
in a ring topology using the manual configuration process . 124
Configuring an FCX IronStack ................................. 125
Configuring FCX stacking ports ............................... 125
Verifying an IronStack configuration ....................... 136
IronStack management ............................................. 138
Managing your Brocade IronStack ........................... 139
Removing MAC address entries ............................... 143
CLI command syntax .............................................. 144
IronStack CLI commands ........................................ 145
Upgrading software ............................................... 146
Managing IronStack partitioning ............................. 152
MIB support for the IronStack ................................. 152
Persistent MAC address ......................................... 153
Unconfiguring an IronStack .................................... 154
Displaying IronStack information ......................... 156
Adding, removing, or replacing units in an IronStack ... 172
Renumbering stack units ......................................... 174
Syslog, SNMP, and traps ....................................... 176
Troubleshooting an IronStack ................................. 177
Troubleshooting an unsuccessful stack build ........... 177
Troubleshooting a stacking upgrade ....................... 179
Troubleshooting image copy issues ....................... 180
Stack mismatches .................................................. 180
Advanced feature mismatch .................................. 181
Image mismatch .................................................... 181
Configuration mismatch ........................................ 182
Memory allocation failure .................................... 182
Recovering from a mismatch .................................. 182
Troubleshooting secure-setup ................................. 184
Troubleshooting unit replacement issues ................ 184
More about IronStack technology ............................ 185
Configuration, startup configuration files and
stacking flash ...................................................... 185
Flexible stacking ports .......................................... 186
IronStack topologies ............................................. 186
Port down and aging ............................................. 186
Device roles and elections .................................... 186
Configuring the management port for an IPv6 automatic address configuration. .......................... 213

Configuring basic IPv6 connectivity on a Layer 3 switch. .......................................................... 214
  Enabling IPv6 routing. ........................................................................................................... 214
  Configuring IPv6 on each router interface ........................................................................... 214
  Configuring IPv4 and IPv6 protocol stacks. ........................................................................... 217

IPv6 management (IPv6 host support) ....................................................................................... 218
  IPv6 access control lists ...................................................................................................... 219
  Restricting SNMP access to an IPv6 node ......................................................................... 219
  Specifying an IPv6 SNMP trap receiver .............................................................................. 219
  SNMP V3 over IPv6 .............................................................................................................. 219
  SNTP over IPv6 ...................................................................................................................... 219
  Secure Shell, SCP, and IPv6 ................................................................................................. 220
  IPv6 Telnet ............................................................................................................................. 220
  IPv6 Web management using HTTP and HTTPS ................................................................. 220
  Restricting Web management access .................................................................................. 221
  Configuring name-to-IPv6 address resolution using IPv6 DNS resolver ........................... 221
  Defining an IPv6 DNS entry ................................................................................................. 222
  Using the IPv6 copy command ............................................................................................. 222
  Using the IPv6 ncopy command .......................................................................................... 224
  IPv6 ping ................................................................................................................................. 226
  Configuring an IPv6 Syslog server ....................................................................................... 227
  Viewing IPv6 SNMP server addresses ............................................................................... 227
  Disabling router advertisement and solicitation messages ................................................. 228
  IPv6 debug .............................................................................................................................. 228
  Disabling IPv6 on a Layer 2 switch ...................................................................................... 229

Configuring a static IPv6 route ................................................................................................. 229

IPv6 over IPv4 tunnels ............................................................................................................... 231
  Configuration notes .............................................................................................................. 231
  Configuring a manual IPv6 tunnel ....................................................................................... 232
  Clearing IPv6 tunnel statistics .............................................................................................. 233
  Displaying IPv6 tunnel information ..................................................................................... 233

ECMP load sharing for IPv6 ...................................................................................................... 235
  Disabling or re-enabling ECMP load sharing for IPv6 ......................................................... 236
  Changing the maximum load sharing paths for IPv6 ............................................................ 236
  Enabling support for network-based ECMP load sharing for IPv6 ....................................... 237
  Displaying ECMP load-sharing information for IPv6 .......................................................... 237

Configuring IPv6 ICMP features ............................................................................................. 237
  Configuring ICMP rate limiting ........................................................................................... 237
  Enabling IPv6 ICMP redirect messages ............................................................................. 238
Configuring IPv6 neighbor discovery ........................................... 238
Configuration notes ................................................................. 239
Neighbor solicitation and advertisement messages ................. 239
Router advertisement and solicitation messages ..................... 240
Neighbor redirect messages ..................................................... 240
Setting neighbor solicitation parameters for
duplicate address detection .................................................... 241
Setting IPv6 router advertisement parameters ...................... 242
Controlling prefixes advertised in IPv6 router
advertisement messages .......................................................... 243
Setting flags in IPv6 router advertisement messages ............... 244
Enabling and disabling IPv6 router advertisements ................. 244
Configuring reachable time for remote IPv6 nodes ................. 245
Changing the IPv6 MTU ............................................................. 245
Configuring static neighbor entries ......................................... 246
Limiting the number of hops an IPv6 packet can traverse ...... 246
Clearing global IPv6 information .............................................. 247
Clearing the IPv6 cache ............................................................ 247
Clearing IPv6 neighbor information ......................................... 247
Clearing IPv6 routes from the IPv6 route table ..................... 248
Clearing IPv6 traffic statistics .................................................. 248
Displaying global IPv6 information ............................................. 248
Displaying IPv6 cache information .......................................... 249
Displaying IPv6 interface information .................................... 250
Displaying IPv6 neighbor information .................................... 251
Displaying the IPv6 route table ............................................... 253
Displaying local IPv6 routers .................................................. 254
Displaying IPv6 TCP information ............................................ 255
Displaying IPv6 traffic statistics .............................................. 259

Chapter 9 Configuring Spanning Tree Protocol (STP) Related Features

STP overview ................................................................. 263
Configuring standard STP parameters .................................. 263
STP parameters and defaults ................................................ 263
Enabling or disabling the Spanning Tree Protocol (STP) ......... 265
Changing STP bridge and port parameters ......................... 266
STP protection enhancement ................................................. 268
Displaying STP information .................................................. 270
Configuring STP related features ............................................ 279
Fast port span ................................................................. 279
802.1W Rapid Spanning Tree (RSTP) .................................. 281
802.1W Draft 3 ................................................................. 319
Single Spanning Tree (SSTP) ................................................. 323
STP per VLAN group .......................................................... 325
PVST/PVST+ compatibility ........................................ 329
Overview of PVST and PVST+ .................................. 330
VLAN tags and dual mode ........................................ 331
Configuring PVST+ support ..................................... 332
Displaying PVST+ support information ....................... 332
Configuration examples .......................................... 333

PVRST compatibility .............................................. 336

BPDU guard ......................................................... 336
   Enabling BPDU protection by port ......................... 337
   Re-enabling ports disabled by BPDU guard ............... 337
   Displaying the BPDU guard status ....................... 338
   Example console messages ................................. 339

Root guard ........................................................ 340
   Enabling STP root guard .................................... 340
   Displaying the STP root guard ............................. 341
   Displaying the root guard by VLAN ...................... 341

Error disable recovery .......................................... 341
   Enabling error disable recovery ......................... 342
   Setting the recovery interval ............................... 342
   Displaying the error disable recovery state by interface.................. 342
   Displaying the recovery state for all conditions ........ 343
   Displaying the recovery state by port number and cause ... 343
   Errdisable Syslog messages ............................... 343

802.1s Multiple Spanning Tree Protocol ....................... 344
   Multiple spanning-tree regions ............................ 344
   Configuration notes .......................................... 346
   Configuring MSTP mode and scope ....................... 346
   Reduced occurrences of MSTP reconvergence ............. 347
   Configuring additional MSTP parameters ................. 349

Chapter 10 Configuring Basic Layer 2 Features

About port regions .............................................. 361

Enabling or disabling the Spanning Tree Protocol (STP) ........ 362
   Modifying STP bridge and port parameters ............... 362

Management MAC address for stackable devices .......... 363

MAC learning rate control ..................................... 363

Changing the MAC age time and disabling MAC address learning ........ 363
   Disabling the automatic learning of MAC addresses ... 364
   Displaying the MAC address table ......................... 365

Configuring static MAC entries ................................ 365
   Multi-port static MAC address ............................... 366

Configuring VLAN-based static MAC entries .............. 368

Clearing MAC address entries .................................. 369
Flow-based MAC address learning ............................ 369
Feature overview ........................................... 369
The benefits of flow-based learning ..................... 370
How flow-based learning works ............................ 370
Configuration considerations ............................. 371
Configuring flow-based MAC address learning ............ 371
Displaying information about flow-based MACs ........... 372
Clearing flow-based MAC address entries ............... 373

Enabling port-based VLANs ............................... 373
Assigning IEEE 802.1Q tagging to a port ............... 374

Defining MAC address filters ............................ 374
Configuration notes and limitations ...................... 375
Command syntax ........................................... 375
Enabling logging of management traffic permitted by MAC filters ............................... 377
MAC filter override for 802.1X-enabled ports ............. 378

Locking a port to restrict addresses ....................... 379
Configuration notes ........................................ 379
Command syntax ........................................... 380

Displaying and modifying system parameter default settings ..... 380
Configuration considerations ............................ 380
Displaying system parameter default values ............... 380
Modifying system parameter default values ............... 385

Dynamic buffer allocation for QoS priorities for
FastIron X Series devices ................................. 386
Default queue depth limits for FastIron X Series devices .... 387
Configuring the total transmit queue depth limit for
FastIron X Series devices ................................. 387
Configuring the transmit queue depth limit for a given
traffic class on FastIron X Series devices .................. 387
Removing buffer allocation limits on FastIron X Series devices 388
Generic buffer profiles for FastIron X Series devices ....... 388

Dynamic buffer allocation for FGS, FLS, FWS, and
FCX stackable and standalone devices ...................... 389
Configuring dynamic buffer allocation for FGS, FLS, FWS, and FCX
stackable and standalone devices ........................ 390
Removing buffer allocation limits on FGS, FLS, FWS, and
FCX stackable and standalone devices ...................... 392
Generic buffer profiles for FGS, FLS, FWS, and FCX stackable
and standalone devices .................................. 392
## Egress buffer thresholds for QoS priorities
Egress buffer thresholds for QoS priorities can be configured to ensure that traffic is properly managed across different classes of service. These thresholds determine how much data can be buffered before packets are dropped or transmitted. The default settings for egress buffer thresholds may be disabled or re-enabled, depending on the network's requirements. Setting the egress buffer threshold for all QoS priorities on a port or group of ports allows for fine-grained control over data flow, ensuring that critical traffic is given priority over less critical traffic.

### Cut-Through Switching Support on TurboIron 24X series switches
Cut-Through Switching Support on TurboIron 24X series switches enables devices to switch packets directly between input and output ports without the need for buffering. This can significantly reduce latency in high-speed networks. The default settings for cut-through switching can be modified to optimize performance and reliability.

### Default settings for egress buffer thresholds
By default, the egress buffer thresholds for different QoS priorities are set to a certain level to ensure that traffic is managed effectively. These default settings can be adjusted to accommodate specific network conditions or requirements.

### Disabling and re-enabling the default settings for egress buffer thresholds
Disabling the default settings for egress buffer thresholds allows for more granular control over the buffering process, which can be beneficial in scenarios where specific traffic conditions are known and can be managed more efficiently.

### Setting the egress buffer threshold for all QoS priorities on a port or group of ports
Setting the egress buffer threshold for all QoS priorities on a port or group of ports enables a uniform approach to managing traffic across different classes, ensuring that all QoS priorities are treated equally.

### Setting the egress buffer threshold for a specific QoS priority on a port or group of ports
Setting the egress buffer threshold for a specific QoS priority on a port or group of ports allows for targeted optimization of traffic management for that particular class.

### Remote Fault Notification (RFN) on 1G fiber connections
Remote Fault Notification (RFN) on 1G fiber connections allows devices to detect and report faults remotely, improving network reliability and reducing the time required to diagnose and repair issues.

### Enabling and disabling remote fault notification
Enabling and disabling remote fault notification can be useful in managing network configurations, ensuring that fault detection is aligned with network requirements.

### Link Fault Signaling (LFS) for 10G
Link Fault Signaling (LFS) for 10G provides an additional layer of fault detection, enhancing network resilience and reliability.

### Jumbo frame support
Jumbo frame support allows for the transmission of larger data packets, which can reduce the overhead associated with packet headers and improve network efficiency.

---

### Chapter 11 Configuring Metro Features

#### Topology groups
Topology groups are used to organize network devices into logical groups, allowing for more manageable and scalable configurations. Master VLAN and member VLANs, control ports and free ports, and configuration considerations are important aspects of managing topology groups.

#### Metro Ring Protocol (MRP)
Metro Ring Protocol (MRP) is a protocol used to create and manage metro rings in network deployments. Configuration notes, MRP rings without shared interfaces (MRP Phase 1), MRP rings with shared interfaces (MRP Phase 2), ring initialization, how ring breaks are detected and healed, and alarm RHP are critical aspects of implementing MRP.

#### Master VLANs and customer VLANs
Master VLANs and customer VLANs are integral to the configuration of MRP, ensuring that network services are properly segmented and managed.

#### Configuring MRP
Configuring MRP involves setting up the protocol on network devices to enable ring formation and operation. Using MRP diagnostics and displaying MRP information are essential for troubleshooting and monitoring MRP configurations.

#### Virtual Switch Redundancy Protocol (VSRP)
Virtual Switch Redundancy Protocol (VSRP) is a protocol used to provide redundant switching capabilities in network infrastructures. Configuration notes, layer 2 and layer 3 redundancy, master election and failover, VSRP-aware security features, VSRP parameters, configuring basic VSRP parameters, configuring optional VSRP parameters, displaying VSRP information, VSRP fast start, and VSRP and MRP signaling are key components in implementing VSRP.
Chapter 12: Configuring Uni-Directional Link Detection (UDLD) and Protected Link Groups

UDLD overview .......................................................... 455
  Configuration considerations ..................................... 456
  Enabling UDLD .......................................................... 456
  Changing the Keepalive interval .................................. 456
  Changing the Keepalive retries .................................... 457
  UDLD for tagged ports .............................................. 457
  Displaying UDLD information .................................... 458
  Clearing UDLD statistics .......................................... 460

Protected link groups .................................................. 460
  About active ports .................................................... 461
  Using UDLD with protected link groups ....................... 461
  Configuration notes .................................................. 461
  Creating a protected link group and assigning an active port ................................................................................ 462
  Viewing information about protected link groups .......... 463

Chapter 13: Configuring Virtual LANs (VLANs)

VLAN overview .......................................................... 465
  Types of VLANs .......................................................... 465
  Default VLAN .......................................................... 470
  802.1Q tagging .......................................................... 471
  Spanning Tree Protocol (STP) ....................................... 474
  Virtual routing interfaces ........................................... 475
  VLAN and virtual routing interface groups .................... 476
  Dynamic, static, and excluded port membership ............ 477
  Super aggregated VLANs ............................................ 479
  Trunk group ports and VLAN membership ................... 479
  Summary of VLAN configuration rules ......................... 480

Routing between VLANs .................................................. 481
  Virtual routing interfaces (Layer 3 Switches only) .......... 481
  Routing between VLANs using virtual routing interfaces
    (Layer 3 Switches only) ........................................... 481
  Dynamic port assignment (Layer 2 Switches and
    Layer 3 Switches) .................................................. 482
  Assigning a different VLAN ID to the default VLAN .... 482
  Assigning different VLAN IDs to reserved VLANs
    4091 and 4092 ..................................................... 483
  Assigning trunk group ports ...................................... 484
  Configuring port-based VLANs .................................... 484
  Modifying a port-based VLAN .................................... 488
  Enable spanning tree on a VLAN ................................ 489

Configuring IP subnet, IPX network and
  protocol-based VLANs .............................................. 490
  Configuration example .............................................. 490

Configuring IP subnet, IPX network, and protocol-based
  VLANs within port-based VLANs ................................. 492
Configuring an IPv6 protocol VLAN ............................................. 496
Routing between VLANs using virtual routing
interfaces (Layer 3 Switches only) ............................................ 497
Configuring protocol VLANs with dynamic ports ................. 503
   Aging of dynamic ports ................................................... 503
   Configuration guidelines ............................................... 504
   Configuring an IP, IPX, or AppleTalk Protocol
   VLAN with Dynamic Ports .............................................. 505
   Configuring an IP subnet VLAN with dynamic ports .......... 505
   Configuring an IPX network VLAN with dynamic ports ...... 506
Configuring uplink ports within a port-based VLAN .......... 506
   Configuration considerations ......................................... 507
   Configuration syntax .................................................... 507
Configuring the same IP subnet address on
multiple port-based VLANs ................................................ 508
Configuring VLAN groups and virtual routing interface groups ... 511
   Configuring a VLAN group .............................................. 511
   Configuring a virtual routing interface group .................... 513
   Displaying the VLAN group and virtual routing
   interface group information ........................................... 514
   Allocating memory for more VLANs or virtual
   routing interfaces .......................................................... 514
Configuring super aggregated VLANs ................................. 515
   Configuration note ......................................................... 518
   Configuring aggregated VLANs ....................................... 518
   Verifying the configuration ............................................. 520
   Complete CLI examples .................................................. 520
Configuring 802.1Q-in-Q tagging ........................................... 523
   Configuration rules ......................................................... 524
   Enabling 802.1Q-in-Q tagging ....................................... 524
   Example configuration .................................................. 525
   Configuring 802.1Q-in-Q tag profiles ............................... 526
   Example ................................................................. 527
   Configuring Q-in-Q tagging for stack devices ................. 527
Configuring private VLANs ................................................... 528
   Configuration notes ....................................................... 530
   Configuration notes and limitations for Turbolron devices ... 531
   Command syntax .......................................................... 532
   Enabling broadcast or unknown unicast traffic
to the private VLAN ....................................................... 534
   CLI example for Figure 90 .............................................. 534
   Enabling broadcast, unregistered multicast or unknown unicast
   traffic to the private VLAN on Turbolron device ............. 535
Dual-mode VLAN ports ......................................................... 535
Chapter 14 Configuring Trunk Groups and Dynamic Link Aggregation

Trunk group overview ............................................. 545
    Trunk group connectivity to a server ....................... 546
    Trunk group rules ........................................... 547
    Trunk group configuration examples ....................... 549
    Flexible trunk group membership ......................... 551
    Trunk group load sharing ................................... 553

Configuring a trunk group ...................................... 556
    CLI syntax ..................................................... 557
        Example 1: Configuring the trunk groups shown
                   in Figure 93 ........................................... 557
        Example 2: Configuring a trunk group that spans
                   two Gbps Ethernet modules in a chassis device .... 558
        Example 3: Configuring a multi-slot trunk group
                   with one port per module ............................ 558
        Example 4: Configuring a trunk group of 10 Gbps
                   Ethernet ports ......................................... 559
        Configuring trunk groups for FastIron stackable devices ... 559
        Additional trunking options ............................... 561

Displaying trunk group configuration information .......... 565

Dynamic link aggregation ...................................... 567
    IronStack LACP trunk group configuration example ...... 568
    Examples of valid LACP trunk groups ...................... 568
    Configuration notes and limitations ....................... 569
    Adaptation to trunk disappearance ........................ 572
    Flexible trunk eligibility .................................. 572
    Enabling dynamic link aggregation ......................... 573
    How changing the VLAN membership of a port
               affects trunk groups and dynamic keys ............ 575
    Additional trunking options for LACP trunk ports ........ 576
    Link aggregation parameters ............................... 576

Displaying and determining the status of aggregate links ... 581
    Events that affect the status of ports in an aggregate link 582
    Displaying link aggregation and port status information ... 582
    Displaying LACP status information ........................ 584

Clearing the negotiated aggregate links table ............... 585

Configuring single link LACP ................................ 585
    Configuration notes ....................................... 585
    CLI syntax .................................................. 585
Chapter 15  Configuring GARP VLAN Registration Protocol (GVRP)

GVRP overview .................................................. 587
Application examples ................................................. 587
  Dynamic core and fixed edge ............................... 588
  Dynamic core and dynamic edge ....................... 589
  Fixed core and dynamic edge ......................... 589
  Fixed core and fixed edge ............................... 589
VLAN names .......................................................... 590
Configuration notes ................................................... 590
Configuring GVRP .................................................... 591
  Changing the GVRP base VLAN ID ....................... 591
  Increasing the maximum configurable value
  of the Leaveall timer ................................... 592
  Enabling GVRP ................................................. 592
  Disabling VLAN advertising ............................. 593
  Disabling VLAN learning .................................. 593
  Changing the GVRP timers .................................. 593
Converting a VLAN created by GVRP into a
  statically-configured VLAN .............................. 595
Displaying GVRP information .................................... 596
  Displaying GVRP configuration information .......... 596
  Displaying GVRP VLAN information .................... 598
  Displaying GVRP statistics .............................. 600
  Displaying CPU utilization statistics ................ 601
  Displaying GVRP diagnostic information ............. 603
Clearing GVRP statistics ........................................ 603
CLI examples ....................................................... 603
  Dynamic core and fixed edge ......................... 604
  Dynamic core and dynamic edge ..................... 605
  Fixed core and dynamic edge ....................... 605
  Fixed core and fixed edge ............................ 606

Chapter 16  Configuring MAC-based VLANs

Overview .............................................................. 607
Static and dynamic hosts ....................................... 607
MAC-based VLAN feature structure .......................... 607
Dynamic MAC-based VLAN ................................. 608
Configuring MAC-based VLANs .................................................609
   Using MAC-based VLANs and 802.1X security
      on the same port .........................................................609
   Configuring generic and Brocade vendor-specific
      attributes on the RADIUS server .......................610
   Aging for MAC-based VLAN .............................................611
   Disabling aging for MAC-based VLAN sessions ..........612
   Configuring the maximum MAC addresses per port ........613
   Configuring a MAC-based VLAN for a static host ..613
   Configuring MAC-based VLAN for a dynamic host ....614
   Configuring dynamic MAC-based VLAN .................614

Configuration notes ..........................................................615
   Configuration example ....................................................616
   Configuring MAC-based VLANs using SNMP ..............617
   Displaying the MAC-VLAN table ....................617
   Displaying the MAC-VLAN table for a specific MAC address ..618
   Displaying allowed MAC addresses ..................619
   Displaying denied MAC addresses ..................620
   Displaying detailed MAC-VLAN data .................621
   Displaying MAC-VLAN information for a specific interface ..623
   Clearing MAC-VLAN information for a specific interface ..624
   Displaying MAC addresses in a MAC-based VLAN ....624
   Displaying MAC-based VLAN logging ...................625

Sample application ..........................................................625

Chapter 17 Configuring Rule-Based IP Access Control Lists (ACLs)

ACL overview .................................................................629
   Types of IP ACLs .................................................................629
   ACL IDs and entries ..........................................................629
   Numbered and named ACLs ..............................................631
   Default ACL action ..........................................................631

   How hardware-based ACLs work ........................................631
      How fragmented packets are processed ................631
      Hardware aging of Layer 4 CAM entries .................632

   Configuration considerations ...........................................632
   Configuring standard numbered ACLs ..................633
      Standard numbered ACL syntax .......................633
      Configuration example for standard numbered ACLs ....635
   Configuring standard named ACLs .......................635
      Standard named ACL syntax .......................635
      Configuration example for standard named ACLs ....637
   Configuring extended numbered ACLs ..................638
      Extended numbered ACL syntax ..................638
      Configuration examples for extended numbered ACLs ....642
   Configuring extended named ACLs .......................644
      Extended named ACL syntax .......................644
      Configuration example for extended named ACLs ....648

   Preserving user input for ACL TCP/UDP port numbers ....648
Chapter 18 Configuring IPv6 Access Control Lists (ACLs)

ACL overview ............................................. 679
Configuration notes .................................... 680
Configuring an IPv6 ACL .............................................. 681
  Example configurations ........................................... 681
  Default and implicit IPv6 ACL action .......................... 682
  ACL syntax .......................................................... 683
Applying an IPv6 ACL to an interface ......................... 688
Adding a comment to an IPv6 ACL entry ...................... 689
Deleting a comment from an IPv6 ACL entry .................. 689
Enabling ACL logging ............................................... 690
Displaying IPv6 ACLs .............................................. 690

Chapter 19 Configuring Power Over Ethernet

Power Over Ethernet overview ..................................... 693
  Terms used in this section ........................................ 693
  Methods for delivering POE and POE+ ......................... 693
  Autodiscovery ..................................................... 695
  Power class ......................................................... 695
  Power specifications .............................................. 696
  Cabling requirements .............................................. 696
  Supported powered devices ...................................... 696
  POE and CPU utilization .......................................... 698
Enabling or disabling Power over Ethernet ................... 698
Disabling support for POE legacy power consuming devices . 698
Enabling the detection of POE power requirements advertised through CDP ........................................ 699
  Configuration considerations .................................. 699
  Command syntax ................................................... 699
Setting the maximum power level for a POE power consuming device ............................................. 699
  Configuration notes ............................................... 700
  Command syntax ................................................... 700
Setting the power class for a POE power consuming device ......................................................... 700
  Configuration notes ............................................... 701
  Command syntax ................................................... 701
Setting the in-line power priority for a POE port ............ 702
  Command syntax ................................................... 702
Resetting POE parameters ...................................... 703
Displaying power over Ethernet information .................. 703
  Displaying POE operational status ............................ 703
  Displaying detailed information about POE power supplies ... 706

Chapter 20 Configuring Base Layer 3 and Enabling Routing Protocols

TCAM entries in FWS devices ...................................... 711
Adding a static IP route ............................................ 711
Adding a static ARP entry ........................................... 712
Modifying and displaying layer 3 system parameter limits ...... 713
  Configuration notes ............................................... 713
  FGS with base layer 3 ........................................... 713
  FastIron IPv4 models .......................................... 714
  FastIron IPv6 models .......................................... 716
  Displaying layer 3 system parameter limits .................... 716
Configuring RIP ..................................................... 717
  Enabling RIP ..................................................... 717
  Enabling redistribution of IP static routes into RIP ........... 718
  Enabling redistribution ......................................... 719
  Enabling learning of default routes .............................. 719
  Changing the route loop prevention method ...................... 720
Other layer 3 protocols ........................................... 720
  Enabling or disabling routing protocols ......................... 720
  Enabling or disabling layer 2 switching ........................ 721
    Configuration notes ........................................... 721
    Command syntax ............................................... 721
Chapter 21 Configuring Port Mirroring and Monitoring
Mirroring support by platform ..................................... 723
Configuring port mirroring and monitoring ........................ 723
  Configuration notes ............................................. 724
  Monitoring a port .............................................. 725
  Monitoring an individual trunk port ................................ 726
Configuring mirroring on an IronStack. ............................ 727
  Configuration notes ............................................. 727
ACL-based inbound mirroring ....................................... 728
  Creating an ACL-based inbound mirror clause for FGS, FGS-STK, FLS, FLS-STK, and FWS devices .............. 728
  Creating an ACL-based inbound mirror clause for TurboIron X Series devices ....................................... 729
  Creating an ACL-based inbound mirror clause for FastIron X Series devices ........................................... 729
MAC filter-based mirroring ......................................... 733
  Configuring MAC filter-based mirroring on FGS, FLS, FWS, FGS-STK, and FLS-STK devices ..................... 733
  Configuring MAC filter-based mirroring on TurboIron X Series devices ............................................. 734
VLAN-based mirroring ............................................... 735
  Configuration notes ............................................. 736
Chapter 22 Configuring Quality of Service
Classification ....................................................... 737
  Processing of classified traffic .................................. 737
QoS for Brocade stackable devices ........................................... 740
Stacking QoS profile restrictions ............................................. 740
QoS behavior for trusting layer 2 (802.1p) in an IronStack ........ 741
QoS behavior for trusting layer 3 (DSCP) in an IronStack ....... 741
QoS behavior on port priority and VLAN priority
in an IronStack .............................................................. 741
QoS behavior for 802.1p marking in an IronStack ................. 741
QoS queues ................................................................. 741
Assigning QoS priorities to traffic ........................................ 742
Buffer allocation/threshold for QoS queues ......................... 743
Marking ...................................................................... 743
Configuring DSCP-based QoS .............................................. 743
Application notes .......................................................... 744
Using ACLs to honor DSCP-based QoS ......................... 744
Configuring the QoS mappings ............................................ 745
Default DSCP –> Internal forwarding priority mappings ...... 745
Changing the DSCP –> internal forwarding priority mappings .. 746
Changing the internal forwarding priority –> hardware forwarding queue mappings .......................... 747
Scheduling ................................................................. 747
QoS Queuing methods .................................................... 747
Selecting the QoS queuing method ...................................... 749
Configuring the QoS queues .............................................. 749
Viewing QoS settings .......................................................... 752
Viewing DSCP-based QoS settings .................................... 752

Chapter 23  Configuring Rate Limiting and Rate Shaping on the FastIron X Series, FCX Series, and TurboIron Series

Rate limiting overview ..................................................... 755
Rate limiting in hardware .................................................. 755
How Fixed Rate Limiting works ........................................ 756
Configuration notes ......................................................... 756
Configuring a port-based rate limiting policy .................... 757
Configuring an ACL-based rate limiting policy .................. 757
Displaying the fixed rate limiting configuration ................. 757
Rate shaping overview ..................................................... 758
Configuration notes ......................................................... 758
Configuring outbound rate shaping for a port .................. 759
Configuring outbound rate shaping for a specific priority .... 759
Configuring outbound rate shaping for a trunk port .......... 760
Displaying rate shaping configurations ............................ 761
Chapter 24 Configuring Rate Limiting on FGS, FGS-STK, FLS, FLS-STK, and FWS Devices

Overview ................................................................. 763
  Rate limiting in hardware ...................................... 763
  How fixed rate limiting works .................................. 763
Configuring fixed rate limiting on inbound ports ............... 764
  Minimum and maximum rates .................................... 764
  Configuration notes ................................................ 765
  Configuration syntax .............................................. 765
Configuring fixed rate limiting on outbound ports ............... 765
  Minimum and maximum rates .................................... 766
  Configuration notes ................................................ 766
  Port-based rate limiting ........................................ 766
  Port- and priority-based rate limiting ......................... 767
Configuring an ACL-based rate limiting policy ................. 767
Displaying the fixed rate limiting configuration .......... 768
  Inbound ports .................................................... 768
  Outbound ports .................................................. 768

Chapter 25 Configuring Traffic Policies

About traffic policies .................................................. 771
Configuration notes and feature limitations .................. 771
Maximum number of traffic policies supported on a device ... 772
  Setting the maximum number of traffic policies
    supported on a Layer 3 device .............................. 773
ACL-based rate limiting using traffic policies ............... 773
  Support for fixed rate limiting and adaptive rate limiting 774
Configuring ACL-based fixed rate limiting .................. 774
Configuring ACL-based adaptive rate limiting .............. 775
Specifying the action to be taken for packets that are
  over the limit .................................................. 777
ACL and rate limit counting ........................................ 778
  Enabling ACL statistics ...................................... 778
  Enabling ACL statistics with rate limiting traffic policies 779
Viewing ACL and rate limit counters .......................... 780
Clearing ACL and rate limit counters ......................... 781
Viewing traffic policies ........................................... 781
Chapter 26  
Configuring IP Multicast Traffic Reduction for FastIron Devices

IGMP snooping for FGS and FGS-STK, FLS and FLS-STK, FWS, and FCX devices ........................................ 783
IGMP snooping overview ........................................ 783
PIM SM traffic snooping overview ............................... 787
Configuring IGMP snooping ..................................... 789
Displaying IGMP snooping information ................. 796
Clear IGMP snooping commands ............................. 802

Chapter 27  
Configuring IP Multicast Traffic Reduction for FastIron X Series and Turbolron Series Switches

IGMP snooping overview ........................................ 803
MAC-based implementation on FastIron X Series devices ... 804
IGMP V1, V2, and V3 snooping support ..................... 804
Queriers and non-queriers .................................... 805
IGMP snooping enhancements in software release 04.1.00 ........................................ 805
Configuration notes and feature limitations for
Fastiron X Series devices ...................................... 806
Configuration notes and feature limitations for Turbolron X Series devices ........................................ 807
PIM SM traffic snooping overview ........................................ 808
PIM SM snooping support ........................................ 808
Application examples ............................................. 809
Configuration notes and limitations ........................ 810
Configuring IGMP snooping ........................................ 811
Enabling IGMP snooping globally on the device ............ 813
Configuring the IGMP mode .................................... 813
Configuring the IGMP version ................................ 814
Disabling IGMP snooping on a VLAN ..................... 815
Disabling transmission and receipt of IGMP packets on a port ........................................ 815
Modifying the age interval for group membership entries ... 816
Modifying the query interval (active IGMP snooping mode only) ........................................ 816
Modifying the maximum response time .................... 816
Configuring report control .................................... 817
Modifying the wait time before stopping traffic when receiving a leave message ........................................ 817
Modifying the multicast cache age time .................... 817
Enabling or disabling error and warning messages ......... 818
Configuring static router ports ................................ 818
Turning off static group proxy ................................ 818
IGMP V3 membership tracking and fast leave ............. 818
Fast leave for IGMP V2 ........................................ 819
Fast convergence ........................................ 819
Chapter 28 Configuring IP Multicast Protocols

Overview of IP multicasting ................................. 833
IPv4 multicast group addresses ...................... 833
Mapping of IPv4 Multicast group addresses to Ethernet MAC addresses .......... 834
Supported Layer 3 multicast routing protocols .......... 834
Multicast terms ................................................. 834
Changing global IP multicast parameters .......... 835
Changing dynamic memory allocation for IP multicast groups .................. 835
Changing IGMP V1 and V2 parameters ................. 837
Adding an interface to a multicast group .............. 838
IP multicast boundaries ................................. 839
Configuration considerations ...................... 839
Configuring multicast boundaries .................. 839
Displaying multicast boundaries .................. 839

Configuring PIM SM snooping ...................... 820
Enabling or disabling PIM SM snooping .................. 820
Enabling PIM SM snooping on a VLAN .................. 821
Disabling PIM SM snooping on a VLAN .................. 821
IGMP snooping show commands ...................... 821
Displaying the IGMP snooping configuration .......... 821
Displaying IGMP snooping errors ...................... 822
Displaying IGMP group information .................. 823
Displaying IGMP snooping mcach e information .......... 824
Displaying usage of hardware resource by multicast groups .................. 825
Displaying software resource usage for VLANs ........ 826
Displaying the status of IGMP snooping traffic .......... 827
PIM SM snooping show commands ........ 828
Displaying PIM SM snooping information .............. 828
Displaying PIM SM snooping information on a Layer 2 switch .................. 828
Displaying PIM SM snooping information for a specific group or source group pair ........ 830
Clear commands for IGMP snooping ............. 830
Clearing the IGMP mcach e ...................... 831
Clearing the mcach e on a specific VLAN ........ 831
Clearing traffic on a specific VLAN ............... 831
Clearing IGMP counters on VLANs .............. 831
PIM Dense ......................................................... 840
  Initiating PIM multicasts on a network .................. 841
  Pruning a multicast tree .................................. 841
  Grafts to a multicast tree ................................ 843
  PIM DM versions ............................................. 843
  Configuring PIM DM ......................................... 844
  Failover time in a multi-path topology ................. 848
  Modifying the TTL ......................................... 848

PIM Sparse ...................................................... 849
  PIM Sparse switch types ................................... 850
  RP paths and SPT paths .................................... 851
  Configuring PIM Sparse .................................... 851
  Anycast RP ................................................... 856
  Displaying PIM Sparse configuration information
  and statistics .............................................. 863

PIM Passive ...................................................... 875

Multicast Source Discovery Protocol (MSDP) ............ 876
  Peer Reverse Path Forwarding (RPF) flooding .......... 878
  Source active caching ..................................... 878
  Configuring MSDP .......................................... 879
  Designating an interface IP address as
  the RP IP address ......................................... 880
  Filtering MSDP source-group pairs ..................... 880
  MSDP mesh groups ......................................... 883
  Displaying MSDP information ............................ 890
  Clearing MSDP information ................................ 894

Passive multicast route insertion ........................ 895

DVMRP overview .............................................. 896
  Initiating DVMRP multicasts on a network ............ 896
  Pruning a multicast tree .................................. 897
  Grafts to a multicast tree ................................ 898
  Configuring DVMRP ......................................... 898
  Enabling DVMRP on the Layer 3 Switch and interface .. 898
  Modifying DVMRP global parameters .................... 899
  Modifying DVMRP interface parameters ................ 901
  Displaying information about an upstream neighbor device 902

Configuring an IP tunnel ................................... 903

Using ACLs to control multicast features ............... 904
  Using ACLs to limit static RP groups .................. 904
  Using ACLs to limit PIM RP candidate advertisement . 906

Disabling CPU processing for select multicast groups .. 907
  CLI command syntax ....................................... 907
  Viewing disabled multicast addresses .................. 908

Configuring a static multicast route ..................... 908

Tracing a multicast route .................................. 910

Displaying the multicast configuration for
another multicast router .................................. 911
IGMP V3 ................................................................. 912
  Default IGMP version ........................................... 913
  Compatibility with IGMP V1 and V2 ......................... 913
  Globally enabling the IGMP version ......................... 914
  Enabling the IGMP version per interface setting .......... 914
  Enabling the IGMP version on a physical port within a virtual routing interface ......................... 914
  Enabling membership tracking and fast leave .............. 915
  Setting the query interval ................................... 916
  Setting the group membership time ......................... 916
  Setting the maximum response time ........................ 916
  IGMP V3 and source specific multicast protocols .......... 916
  Displaying IGMP V3 information on Layer 3 Switches .... 917
  Clearing IGMP statistics ....................................... 921
IGMP Proxy .......................................................... 921
  Configuration notes ............................................ 921
  Configuring IGMP Proxy ........................................ 922
  Displaying IGMP Proxy traffic ............................... 922
IP multicast protocols and IGMP snooping on the same device ........................................ 922
  Configuration example ........................................ 923
CLI commands ...................................................... 924

Chapter 29 Configuring LLDP and LLDP-MED

Terms used in this chapter ...................................... 927
LLDP overview ...................................................... 928
  Benefits of LLDP ............................................... 929
LLDP-MED overview ............................................... 930
  Benefits of LLDP-MED .......................................... 930
  LLDP-MED class .................................................. 931
General operating principles ................................... 931
  Operating modes ................................................ 931
  LLDP packets .................................................... 932
  TLV support ...................................................... 933
MIB support ....................................................... 936
Syslog messages ................................................... 936
Configuring LLDP .................................................. 936
  Configuration notes and considerations ..................... 937
  Enabling and disabling LLDP ................................. 937
  Enabling support for tagged LLDP packets ................. 937
  Changing a port LLDP operating mode ...................... 938
  Specifying the maximum number of LLDP neighbors ...... 940
  Enabling LLDP SNMP notifications and syslog messages .... 941
  Changing the minimum time between LLDP transmissions .. 942
  Changing the interval between regular LLDP transmissions 943
  Changing the holdtime multiplier for transmit TTL ........ 943
  Changing the minimum time between port reinitializations .. 943
  LLDP TLVs advertised by the Brocade device ............... 944
Configuring LLDP-MED ............................................. 953
Enabling LLDP-MED ............................................. 953
Enabling SNMP notifications and syslog messages
for LLDP-MED topology changes ............................ 954
Changing the fast start repeat count ......................... 954
Defining a location id ............................................. 955
Defining an LLDP-MED network policy ..................... 961
LLDP-MED attributes advertised by the Brocade device ........................ 963
Extended power-via-MDI information ......................... 964
Displaying LLDP statistics and configuration settings ........ 966
LLDP configuration summary .................................. 966
LLDP statistics .................................................... 967
LLDP neighbors ................................................... 969
LLDP neighbors detail .......................................... 970
LLDP configuration details ................................... 971
Resetting LLDP statistics ...................................... 973
Clearing cached LLDP neighbor information ............... 973

Chapter 30 Configuring IP

Basic configuration ............................................. 975
Overview ......................................................... 975
IP interfaces ..................................................... 976
IP packet flow through a Layer 3 Switch ................. 977
IP route exchange protocols ................................. 981
IP multicast protocols ....................................... 982
IP interface redundancy protocols ......................... 982
Access Control Lists and IP access policies .............. 982
Basic IP parameters and defaults – Layer 3 Switches .... 983
When parameter changes take effect ....................... 983
IP global parameters – Layer 3 Switches ................. 985
IP interface parameters – Layer 3 Switches ............... 989
Basic IP parameters and defaults – Layer 2 Switches .... 990
IP global parameters – Layer 2 Switches ................. 991
Interface IP parameters – Layer 2 Switches ............... 992
Chapter 31  Configuring Multicast Listening Discovery (MLD) Snooping on FGS, FGS-STK, FLS, FLS-STK, FWS, and FCX devices

Overview .................................................. 1107
  Platform support ........................................ 1108
  Configuration notes ..................................... 1109
  Configuring queriers and non-queriers .................. 1110
  VLAN specific configuration ............................. 1110
  Using MLDv1 with MLDv2 ............................... 1110

Configuring MLD snooping ................................. 1111
  Configuring the hardware and software resource limits . 1111
  Disabling transmission and receipt of MLD packets on a port ........................................... 1112
  Configuring the global MLD mode ....................... 1112
  Modifying the age interval .............................. 1112
  Modifying the query interval (Active MLD snooping mode only) .......................................... 1113
  Configuring the global MLD version ..................... 1113
  Configuring report control .............................. 1113
  Modifying the wait time before stopping traffic when receiving a leave message .................. 1114
  Modifying the multicast cache (mcache) aging time . 1114
  Disabling error and warning messages .................. 1114
  Configuring the MLD mode for a VLAN .................. 1114
  Disabling MLD snooping for the VLAN .................. 1115
  Configuring the MLD version for the VLAN ............. 1115
  Configuring the MLD version for individual ports .... 1115
  Configuring static groups to the entire VLAN or to individual ports .................................. 1115
  Configuring static router ports ......................... 1116
  Turning off static group proxy .......................... 1116
  Enabling MLDv2 membership tracking and fast leave for the VLAN ...................................... 1116
  Configuring fast leave for MLDv1 ....................... 1117
  Enabling fast convergence ................................ 1117
  Displaying MLD snooping information ................... 1118
  Clear MLD snooping commands ........................... 1122

Chapter 32  Configuring Multicast Listening Discovery (MLD) Snooping on the FastIron X Series

Overview .................................................. 1125
  How MLD snooping uses MAC addresses to forward multicast packets ................................. 1126
  Configuration notes and feature limitations .......... 1127
  Queriers and non-queriers ............................. 1128
  VLAN specific configuration ............................. 1128
  Using MLDv1 with MLDv2 ............................... 1129
Chapter 33 Configuring RIP

RIP overview .................................................. 1143
ICMP host unreachable message for undeliverable ARPs . 1143
RIP parameters and defaults ................................. 1144
RIP global parameters ...................................... 1144
RIP interface parameters .............................. 1145
Configuring RIP parameters ................................. 1145
Enabling RIP .................................................. 1145
Configuring metric parameters ......................... 1146
Changing the administrative distance ................. 1147
Configuring redistribution .............................. 1147
Configuring route learning and advertising parameters . 1150
Changing the route loop prevention method ............... 1151
Suppressing RIP route advertisement on a VRRP or VRRPE backup interface ......................................... 1152
Configuring RIP route filters ............................... 1152
Displaying RIP filters ........................................ 1153
Displaying CPU utilization statistics ....................... 1154

Chapter 36 Configuring OSPF Version 3 (IPv6)

Overview ................................................. 1223
Differences between OSPF V2 and OSPF V3 ............... 1223
Link state advertisement types for OSPF V3. ............... 1224
Configuring OSPF V3 ..................................... 1224
   Enabling OSPF V3 .................................. 1224
   Assigning OSPF V3 areas .......................... 1225
   Assigning interfaces to an area .................. 1226
   Configuring virtual links .......................... 1227
   Changing the reference bandwidth for the cost on
   OSPF V3 interfaces ................................ 1229
   Redistributing routes into OSPF V3 ............... 1230
   Filtering OSPF V3 routes .......................... 1234
   Configuring default route origination .............. 1237
   Modifying shortest path first timers ............... 1238
   Modifying administrative distance ................ 1238
   Configuring the OSPF V3 LSA pacing interval ....... 1239
   Modifying exit overflow interval .................. 1240
   Modifying external link state database limit ....... 1240
   Modifying OSPF V3 interface defaults .............. 1241
   Disabling or re-enabling event logging ............. 1241
Displaying OSPF V3 Information .......................... 1242
   Displaying OSPF V3 area information .............. 1242
   Displaying OSPF V3 database information .......... 1243
   Displaying OSPF V3 interface information ......... 1248
   Displaying OSPF V3 memory usage ................ 1251
   Displaying OSPF V3 neighbor information ........... 1252
   Displaying routes redistributed into OSPF V3 ...... 1254
   Displaying OSPF V3 route information .............. 1255
   Displaying OSPF V3 SPF information ................. 1257
   Displaying IPv6 OSPF virtual link information ..... 1259
   Displaying OSPF V3 virtual neighbor information 1260
Chapter 37  Configuring VRRP and VRRPE

Overview ..................................................... 1261
  Overview of VRRP ........................................ 1261
  Overview of VRRPE ..................................... 1266
  Configuration note ...................................... 1268

Comparison of VRRP and VRRPE .................. 1269
  VRRP ..................................................... 1269
  VRRPE .................................................. 1269
  Architectural differences ............................. 1269

VRRP and VRRPE parameters ...................... 1270

Configuring basic VRRP parameters .......... 1273
  Configuring the Owner ................................. 1273
  Configuring a Backup ................................ 1273
  Configuration rules for VRRP ....................... 1273

Configuring basic VRRPE parameters ........ 1273
  Configuration rules for VRRPE ...................... 1274

Note regarding disabling VRRP or VRRPE .... 1274

Configuring additional VRRP and VRRPE parameters 1274

Forcing a Master router to abdicate to a standby router 1281

Displaying VRRP and VRRPE information .......... 1282
  Displaying summary information ..................... 1282
  Displaying detailed information .................... 1284
  Displaying statistics ................................ 1289
  Clearing VRRP or VRRPE statistics ............... 1290
  Displaying CPU utilization statistics ............ 1290

Configuration examples .......................... 1292
  VRRP example ....................................... 1292
  VRRPE example ..................................... 1293

Chapter 38  Configuring BGP4

Overview of BGP4 ........................................ 1295
  Relationship between the BGP4 route table and
  the IP route table .................................... 1296
  How BGP4 selects a path for a route ................ 1297
  BGP4 message types .................................. 1298

Basic configuration and activation for BGP4 1300
  Note regarding disabling BGP4 ..................... 1301

BGP4 parameters ....................................... 1301
  When parameter changes take effect ............... 1302

Memory considerations .......................... 1304
  Memory configuration options obsoleted by
dynamic memory ..................................... 1304
Basic configuration tasks ............................................. 1305
   Enabling BGP4 on the router ................................ 1305
   Changing the router ID ......................................... 1305
   Setting the local AS number ................................. 1306
   Adding a loopback interface ................................. 1306
   Adding BGP4 neighbors ..................................... 1307
   Adding a BGP4 peer group .................................. 1313

Optional configuration tasks .................................... 1317
   Changing the Keep Alive Time and Hold Time ........... 1317
   Changing the BGP4 next-hop update timer .............. 1318
   Enabling fast external fallover ............................ 1318
   Changing the maximum number of paths for BGP4 load sharing ........................................ 1319
   Customizing BGP4 load sharing ............................. 1320
   Specifying a list of networks to advertise ............ 1321
   Changing the default local preference ................. 1322
   Using the IP default route as a valid next hop for a BGP4 route ........................................ 1323
   Advertising the default route .............................. 1323
   Changing the default MED (Metric) used for route redistribution ...................................... 1323
   Enabling next-hop recursion ................................. 1324
   Changing administrative distances ....................... 1327
   Requiring the first AS to be the neighbor AS ....... 1328
   Disabling or re-enabling comparison of the AS-Path length ........................................ 1328
   Enabling or disabling comparison of the router IDs ........................................ 1329
   Configuring the Layer 3 Switch to always compare Multi-Exit Discriminators (MEDs) ............ 1329
   Treating missing MEDs as the worst MEDs .......... 1330
   Configuring route reflection parameters ............... 1330
   Configuration notes .......................................... 1334
   Aggregating routes advertised to BGP4 neighbors .......... 1337

BGP null0 routing .................................................. 1338
   Configuration steps ........................................... 1338
   Configuration examples ...................................... 1339
   Show commands ................................................. 1340

Modifying redistribution parameters ........................ 1342
   Redistributing connected routes ......................... 1342
   Redistributing RIP routes .................................. 1343
   Redistributing OSPF external routes ..................... 1343
   Redistributing static routes ............................... 1344
   Disabling or re-enabling re-advertisement of all learned BGP4 routes to all BGP4 neighbors .......... 1344
   Redistributing IBGP routes into RIP and OSPF ......... 1344
Filtering .......................................................... 1345
  Filtering specific IP addresses ......................... 1345
  Filtering AS-paths ....................................... 1346
  Filtering communities .................................. 1349
  Defining IP prefix lists ................................ 1352
  Defining neighbor distribute lists .................... 1353
  Defining route maps .................................... 1353
  Using a table map to set the rag value ................ 1361
  Configuring cooperative BGP4 route filtering .......... 1362

Configuring route flap dampening ....................... 1365
  Globally configuring route flap dampening ............ 1366
  Using a route map to configure route flap dampening for specific routes ......................... 1367
  Using a route map to configure route flap dampening for a specific neighbor ...................... 1367
  Removing route dampening from a route ............... 1368
  Removing route dampening from a neighbor routes suppressed due to aggregation .................. 1369
  Displaying and clearing route flap dampening statistics . 1370

Generating traps for BGP ................................ 1371

Displaying BGP4 information ............................. 1372
  Displaying summary BGP4 information ................. 1372
  Displaying the active BGP4 configuration ............ 1374
  Displaying CPU utilization statistics ................... 1375
  Displaying summary neighbor information ............. 1376
  Displaying BGP4 neighbor information .................. 1378
  Displaying peer group information ...................... 1389
  Displaying summary route information ................ 1390
  Displaying the BGP4 route table ....................... 1391
  Displaying BGP4 route-attribute entries .............. 1397
  Displaying the routes BGP4 has placed in the IP route table ........................................... 1398
  Displaying route flap dampening statistics .......... 1399
  Displaying the active route map configuration ........ 1400

Updating route information and resetting a neighbor session .................. 1401
  Using soft reconfiguration ............................. 1401
  Dynamically requesting a route refresh from a BGP4 neighbor ........................................... 1404
  Closing or resetting a neighbor session .............. 1407
  Clearing and resetting BGP4 routes in the IP route table .............................................. 1407

Clearing traffic counters ................................ 1408
Clearing route flap dampening statistics ................ 1408
Removing route flap dampening .......................... 1408
Clearing diagnostic buffers .............................. 1409

### Chapter 40 Configuring SSH1 and SCP

- Configuring SSH1 ....................................................... 1483
  - Setting the host name and domain name .............. 1484
  - Generating a host I key pair .............................. 1484
  - Configuring RSA challenge-response authentication ... 1486
  - Setting optional parameters .............................. 1488
- Terminating an SSH session ................................. 1491
- Displaying SSH connection information ................. 1491
- Sample SSH configuration .................................. 1492
- Using secure copy with SSH1 .............................. 1494

### Chapter 41 Configuring SSH2 and SCP

- SSH version 2 support ........................................ 1495
  - Tested SSH2 clients ......................................... 1495
  - Supported features .......................................... 1496
  - Unsupported features ....................................... 1496
  - AES encryption for SSH2 ................................... 1496
- Configuring SSH2 ................................................. 1497
  - Recreating SSH keys ......................................... 1498
  - Generating a host key pair ............................... 1498
  - Configuring DSA challenge-response authentication .... 1499
Setting optional parameters ........................................ 1501
Setting the number of SSH authentication retries ............ 1502
Deactivating user authentication ..................................... 1502
Enabling empty password logins .................................... 1502
Setting the SSH port number ........................................ 1503
Setting the SSH login timeout value ................................. 1503
Designating an interface as the source for all SSH packets (Layer 3 code only) ........................................... 1503
Configuring the maximum idle time for SSH sessions ....... 1504
Filtering SSH access using ACLs .................................... 1504
Terminating an active SSH connection .......................... 1504
Displaying SSH connection information ......................... 1505
Using Secure copy with SSH2 ....................................... 1506
Enabling and disabling SCP ......................................... 1506
Example file transfers using SCP .................................... 1506

Chapter 42 Configuring 802.1X Port Security

IETF RFC support .................................................. 1509
How 802.1X port security works .................................... 1509
Device roles in an 802.1X configuration .......................... 1509
Communication between the devices .............................. 1510
Controlled and uncontrolled ports .................................. 1511
Message exchange during authentication ......................... 1512
Authenticating multiple hosts connected to the same port .... 1515
802.1X port security and sFlow ..................................... 1518
802.1X accounting .................................................. 1518
Configuring 802.1X port security ................................... 1519
Configuring an authentication method list for 802.1X .......... 1520
Setting RADIUS parameters ........................................ 1520
Configuring dynamic VLAN assignment for 802.1X ports ... 1523
Dynamically applying IP ACLs and MAC filters to 802.1X ports ......................................................... 1527
Enabling 802.1X port security ........................................ 1530
Setting the port control ............................................. 1531
Configuring periodic re-authentication ............................. 1532
Re-authenticating a port manually ................................... 1532
Setting the quiet period .............................................. 1533
Specifying the wait interval and number of EAP-request/identity frame retransmissions from the Brocade device 1533
Specifying the wait interval and number of EAP-request/identity frame retransmissions from the RADIUS server ... 1534
Specifying a timeout for retransmission of messages to the authentication server ........................................ 1535
Initializing 802.1X on a port ......................................... 1535
Allowing access to multiple hosts ................................... 1535
Defining MAC filters for EAP frames .............................. 1537
Configuring VLAN access for non-EAP-capable clients ....... 1538
Configuring 802.1X accounting .................................. 1539
802.1X Accounting attributes for RADIUS .................. 1540
Enabling 802.1X accounting .................................. 1540
Displaying 802.1X information ................................. 1540
Displaying 802.1X configuration information .............. 1540
Displaying 802.1X statistics ................................ 1543
Clearing 802.1X statistics .................................. 1544
Displaying dynamically assigned VLAN information ...... 1544
Displaying information about dynamically applied
MAC filters and IP ACLs .................................. 1545
Displaying 802.1X multiple-host authentication
information .................................................. 1548
Sample 802.1X configurations ................................ 1551
Point-to-point configuration ................................. 1552
Hub configuration ........................................ 1553
802.1X Authentication with dynamic VLAN assignment ... 1554
Using multi-device port authentication and 802.1X
security on the same port .................................. 1555
Configuring Brocade-specific attributes on the
RADIUS server ........................................... 1556
Example configurations .................................. 1557

Chapter 43 Using the MAC Port Security Feature

Overview .................................................. 1561
Local and global resources ................................ 1561
Configuration notes and feature limitations .............. 1562
Configuring the MAC port security feature .............. 1562
Enabling the MAC port security feature .................. 1562
Setting the maximum number of secure MAC addresses
for an interface ........................................... 1563
Setting the port security age timer ......................... 1563
Specifying secure MAC addresses ......................... 1563
Autosaving secure MAC addresses to the
startup-config file ....................................... 1564
Specifying the action taken when a security
violation occurs ......................................... 1564
Clearing port security statistics ............................ 1566
Clearing restricted MAC addresses ....................... 1566
Clearing violation statistics ................................ 1566
Displaying port security information .................... 1566
Displaying port security settings ......................... 1566
Displaying the secure MAC addresses .................. 1567
Displaying port security statistics ....................... 1568
Displaying restricted MAC addresses on a port ........ 1568
Chapter 44 Configuring Multi-Device Port Authentication

How multi-device port authentication works
RADIUS authentication
Authentication-failure actions
Supported RADIUS attributes
Support for dynamic VLAN assignment
Support for dynamic ACLs
Support for authenticating multiple MAC addresses on an interface
Support for dynamic ARP inspection with dynamic ACLs
Support for DHCP snooping with dynamic ACLs
Support for source guard protection
Using multi-device port authentication and 802.1X security on the same port
Configuring Brocade-specific attributes on the RADIUS server
Configuring multi-device port authentication
Enabling multi-device port authentication
Specifying the format of the MAC addresses sent to the RADIUS server
Specifying the authentication-failure action
Generating traps for multi-device port authentication
Defining MAC address filters
Configuring dynamic VLAN assignment
Dynamically applying IP ACLs to authenticated MAC addresses
Enabling denial of service attack protection
Enabling source guard protection
Clearing authenticated MAC addresses
Disabling aging for authenticated MAC addresses
Changing the hardware aging period for blocked MAC addresses
Specifying the aging time for blocked MAC addresses
Specifying the RADIUS timeout action
Multi-device port authentication password override
Limiting the number of authenticated MAC addresses
Displaying multi-device port authentication information
Displaying authenticated MAC address information
Displaying multi-device port authentication configuration information
Displaying multi-device port authentication information for a specific MAC address or port
Displaying the authenticated MAC addresses
Displaying the non-authenticated MAC addresses
Displaying multi-device port authentication information for a port
Displaying multi-device port authentication settings and authenticated MAC addresses
Displaying the MAC authentication table for FCX devices.
Example configurations ........................................ 1600
Multi-device port authentication with dynamic VLAN assignment. ......................... 1600
Examples of multi-device port authentication and 802.1X authentication configuration on the same port. ........ 1602

Chapter 45 Configuring Web Authentication

Overview ...................................................... 1607
Configuration considerations ................................. 1608
Configuration tasks ............................................. 1609
Enabling and disabling web authentication .................... 1611
Configuring the web authentication mode ...................... 1611
Using local user databases .................................. 1611
Using passcodes ............................................. 1615
Using automatic authentication .............................. 1619
Configuring web authentication options ...................... 1620
Enabling RADIUS accounting for web authentication .... 1620
Changing the login mode (HTTPS or HTTP) .................. 1621
Specifying trusted ports ..................................... 1621
Specifying hosts that are permanently authenticated .... 1621
Configuring the re-authentication period ................. 1622
Defining the web authentication cycle ...................... 1622
Limiting the number of web authentication attempts .... 1622
Clearing authenticated hosts from the web authentication table ................................ 1623
Setting and clearing the block duration for web authentication attempts ................... 1623
Manually blocking and unblocking a specific host ......... 1623
Limiting the number of authenticated hosts ................ 1624
Filtering DNS queries ....................................... 1624
Forcing re-authentication when ports are down ............ 1624
Forcing re-authentication after an inactive period ........ 1625
Defining the web authorization redirect address .......... 1625
Deleting a web authentication VLAN ....................... 1626
Web authentication pages .................................... 1626
Displaying web authentication information .................. 1633
Displaying the web authentication configuration ............ 1633
Displaying a list of authenticated hosts .................... 1635
Displaying a list of hosts attempting to authenticate .... 1636
Displaying a list of blocked hosts .......................... 1636
Displaying a list of local user databases .................... 1637
Displaying a list of users in a local user database ........ 1637
Displaying passcodes ....................................... 1638
Chapter 46  Protecting Against Denial of Service Attacks

Protecting against Smurf attacks ................................. 1639
  Avoiding being an intermediary in a Smurf attack .... 1639
  Avoiding being a victim in a Smurf attack ............ 1640
  Protection against ICMP attacks in TurboIron devices 1640

Protecting against TCP SYN attacks .......................... 1641
  Protection against TCP-SYN attacks in TurboIron devices 1642
  TCP security enhancement .................................. 1643
  Displaying statistics about packets dropped because of DoS attacks .................................. 1644
  Displaying statistics about packets dropped because of DoS attacks in TurboIron device 1645

Chapter 47  Inspecting and Tracking DHCP Packets

Dynamic ARP inspection ......................................... 1647
  ARP poisoning .................................................. 1647
  How DAI works ............................................... 1647
  Configuration notes and feature limitations .......... 1649
  Configuring DAI .............................................. 1649
  Displaying ARP inspection status and ports ........ 1650
  Displaying the ARP table .................................. 1651

DHCP snooping .................................................... 1651
  How DHCP snooping works ................................ 1652
  System reboot and the binding database ............... 1653
  Configuration notes and feature limitations .......... 1653
  Configuring DHCP snooping ............................... 1653
  Clearing the DHCP binding database ................... 1654
  Displaying DHCP snooping status and ports .......... 1655
  Displaying the DHCP snooping binding database ..... 1655
  Displaying DHCP binding entry and status .......... 1655
  DHCP snooping configuration example .................. 1655

DHCP relay agent information (DHCP Option 82) ........... 1656

About This Document

Introduction

This guide describes the following product families from Brocade:

- FastIron X Series devices:
  - FastIron Edge Switch X-Series (FESX) Layer 2/Layer 3 switch
  - FastIron Edge Switch X-Series Expanded (FESXE) Layer 2/Layer 3 switch
  - FastIron Workgroup Switch X Series (FWSX) Layer 2 switch
  - FastIron SuperX Switch (FSX) Layer 2/Layer 3 switch
  - FastIron SX 800, 1600, and 1600-ANR Layer 2/Layer 3 switch
- Turbolon X Series (TIX) Layer 2 switch
- FastIron CX Series Stackable Switches

This guide includes procedures for configuring the software. The software procedures show how to perform tasks using the CLI. This guide also describes how to monitor Brocade products using statistics and summary screens.

This guide applies to the FastIron and Turbolon X Series models listed in Table 1.

Device nomenclature

Table 1 lists the terms (product names) contained in this guide and the specific set of devices to which each term refers.

**Audience**

This document is designed for system administrators with a working knowledge of Layer 2 and Layer 3 switching and routing.

If you are using a Brocade Layer 3 Switch, you should be familiar with the following protocols if applicable to your network – IP, RIP, OSPF, BGP, ISIS, IGMP, PIM, DVMRP, and VRRP.
What new in this document

The following changes have been made since this document was last released:

- Information that was added:
  - For the FESX, FESXE, FSX, FSX 800, FSX 1600, FSX 1600-ANR, and FWSX:
    - FSX 05.1.00
  - For the FastIron GS and LS products:
    - 04.3.03
  - For the FastIron GS-STK and LS-STK products:
    - 05.0.02
  - For the FastIron WS products:
    - 04.3.03
  - For the FastIron CX products:
    - 06.0.00
  - For the TurboIron X Series products:
    - 04.2.00

Features that are not documented in this guide are not supported.

For further information about new features and documentation updates for this release, refer to the Knowledge Portal at kp.foundrynet.com.

Summary of features in FGS R04.3.03

New hardware in FGS R04.3.03

The RPS12 External Redundant Power Supply is introduced in R04.3.03. The power supply can supply backup power to one of four connected FWS POE switches in the event of an AC loss or failure of an internal power supply. The system supplies the failed switch with up to 120 W for primary 12 VDC power, and up to 780 W of -54 VDC PoE power (for PoE devices connected to the failed switch). See the Brocade FastIron WS Hardware Installation Guide for details on the RPS12.

Software enhancement in FGS 04.3.03

FGS, FLS, and FWS devices can be configured to operate as DHCP server beginning with R04.3.03. A DHCP server allocates IP addresses for specified periods of time (known as leases) and manages the IP address pools and the binding (leased addresses) database. For details, see “DHCP Server” on page 1037.
Summary of features in FCX R06.0.00

New hardware in FCX R06.0.00

FastIron CX stackable switches provide high 10/100/1000 port density and Gigabit Ethernet uplinks in a compact form factor. FCX R06.0.00 introduces the following FastIron CX models:

- **FCX624S**: Twenty 10/100/1000 Mbps ports plus four combo 100/1000 Mbps (SFP) Ethernet Fiber ports. The switch has two management interfaces, a serial port (Console) on the front panel and an RJ45 port (Outband Management Interface) on the rear panel. Two rear-panel power supply receptacles allow for up to two power supply units. Two dedicated 16GbE CX4 ports on the rear panel allow stacking for up to eight units. The front panel also has a module slot for an optional two-port 10GbE XFP module.

- **FCX648S**: Forty four 10/100/1000 Mbps ports plus four combo 100/1000 Mbps (SFP) Ethernet Fiber ports. The switch has two management interfaces, a serial port (Console) on the front panel and an RJ45 port (Outband Management Interface) on the rear panel. Two rear-panel power supply receptacles allow for up to two power supply units. Two dedicated 16GbE CX4 ports on the rear panel allow stacking for up to eight units. The front panel also has a module slot for an optional two-port 10GbE XFP module.

- **FCX624S-ADV**: The FCX624S model with Premium software features factory-loaded.

- **FCX648S-ADV**: The FCX648S model with Premium software features factory-loaded.

- **FCX624S-HPOE**: Twenty 10/100/1000 Mbps POE ports plus four combo 100/1000 Mbps (SFP) Ethernet Fiber ports. The switch has two management interfaces, a serial port (Console) on the front panel and an RJ45 port (Outband Management Interface) on the rear panel. Two rear-panel power supply receptacles allow for up to two power supply units. Two dedicated 16GbE CX4 ports on the rear panel allow stacking for up to eight units. The front panel also has a module slot for an optional two-port 10GbE XFP module.

- **FCX648S-HPOE**: Forty four 10/100/1000 Mbps POE ports plus four combo 100/1000 Mbps (SFP) Ethernet Fiber ports. The switch has two management interfaces, a serial port (Console) on the front panel and an RJ45 port (Outband Management Interface) on the rear panel. Two rear-panel power supply receptacles allow for up to two power supply units. Two dedicated 16GbE CX4 ports on the rear panel allow stacking for up to eight units. The front panel also has a module slot for an optional two-port 10GbE XFP module.

- **FCX624S-HPOE-ADV**: The FCX624S-HPOE model with Premium software factory-loaded.

- **FCX648S-HPOE-ADV**: The FCX648S-HPOE model with Premium software factory-loaded.

Software enhancements in FCX R06.0.00

FastIron CX switches support many of the Layer 2, Base Layer 3, Full Layer 3 and Premium features supported by the FESX switches. For specific details on supported features, refer to the Chapter 1, "Feature Highlights".

Summary of enhancements in TIX R04.2.00

The following tables present a summary of the enhancements in TIX R04.2.00
### TABLE 2  Enhancements in TIX R04.2.00

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>See details in...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAV</td>
<td>This enhancement improves SAV interoperability between Brocade devices and other vendors’ devices that support the 802.1Q tag-types.</td>
<td>“Support for 802.1Q-in-Q tagging” on page 473</td>
</tr>
<tr>
<td>Q-in-Q</td>
<td>802.1Q-in-Q tagging provides finer granularity for configuring 802.1Q tagging and enables you to configure 802.1Q tag-types on a group of ports.</td>
<td>“Configuring 802.1Q-in-Q tagging” on page 523</td>
</tr>
<tr>
<td>MRP 1 and MRP 2</td>
<td>Brocade proprietary protocol that prevents Layer 2 loops and provides fast reconvergence in Layer 2 ring topologies.</td>
<td>“Metro Ring Protocol (MRP)” on page 405</td>
</tr>
<tr>
<td>VSRP</td>
<td>Brocade proprietary protocol that provides redundancy and sub-second failover in Layer 2 and Layer 3 mesh topologies.</td>
<td>“Virtual Switch Redundancy Protocol (VSRP)” on page 428</td>
</tr>
<tr>
<td>Hardware-based private VLAN</td>
<td>A private VLAN is a standard Layer 2 port-based VLANs, which provides additional control over flooding packets on a VLAN. Private VLANs on the TurboIron device forwards unknown-unicast, unregistered multicast, and broadcast in hardware.</td>
<td>“Configuring private VLANs” on page 528</td>
</tr>
<tr>
<td>Topology and VLAN groups</td>
<td>VLAN group supports creating multiple port-based VLANs with identical port members.</td>
<td>“Configuring VLAN groups and virtual routing interface groups” on page 511</td>
</tr>
<tr>
<td>Hardware-based DoS attack prevention</td>
<td>Supports DoS attack monitoring and detection performed in the hardware.</td>
<td>“Protection against ICMP attacks in TurboIron devices” on page 1640</td>
</tr>
<tr>
<td>Mac authentication</td>
<td>Supports configuring MAC authentication and 802.1X authentication on the same port.</td>
<td>“Configuring Multi-Device Port Authentication” on page 1571</td>
</tr>
<tr>
<td>Dot1x security</td>
<td>Supports IEEE 802.1X standard for authenticating devices attached to LAN ports.</td>
<td>“Configuring 802.1X Port Security” on page 1509</td>
</tr>
<tr>
<td>Port MAC security</td>
<td>Supports forwarding only packets that match secure addresses.</td>
<td>“Using the MAC Port Security Feature” on page 1561</td>
</tr>
<tr>
<td>Dynamic Vlan assignment</td>
<td>This feature supports placing a port in one or more VLANs based on the MAC address learned on that interface.</td>
<td>“Support for dynamic VLAN assignment” on page 1573</td>
</tr>
<tr>
<td>Mac filter enhancements</td>
<td>Supports filtering packets based on the etype optional keyword.</td>
<td>“Defining MAC address filters” on page 374</td>
</tr>
<tr>
<td>Virtual Ethernet interface</td>
<td>TurboIron device can locally route IP, IPX, and Appletalk between VLANs defined within a single route.</td>
<td>“Routing between VLANs” on page 481</td>
</tr>
<tr>
<td>VRRP and VRRPE</td>
<td>This release supports the standard router redundancy protocol described in RFC 233.</td>
<td>“Configuring VRRP and VRRPE” on page 1261</td>
</tr>
<tr>
<td>Proxy ARP</td>
<td>Proxy ARP allows the TurboIron device to answer ARP requests from devices on one network on behalf of devices in another network.</td>
<td>“Enabling proxy ARP” on page 1008</td>
</tr>
<tr>
<td>IP Load Sharing</td>
<td>This release supports one route to many next hop relationships. It supports 2K ECMP table.</td>
<td>“Configuring IP load sharing” on page 1025</td>
</tr>
<tr>
<td>RIP V1, V2</td>
<td>Dynamic protocol described in RFC 1058 and RFC 2453.</td>
<td>“Configuring RIP” on page 1143</td>
</tr>
<tr>
<td>OSPF V2</td>
<td>Dynamic routing protocol described in RFC 2328.</td>
<td>“Configuring OSPF Version 2 (IPv4)” on page 1167</td>
</tr>
</tbody>
</table>
### Summary of enhancements in FSX R05.1.00

The following tables present a summary of the enhancements in FSX R05.1.00.

#### Layer 3 enhancements in FSX R05.1.00

**TABLE 3** Layer 3 enhancements in FSX R05.1.00

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>See details in...</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGMP V1, V2, V3</td>
<td>This release introduces the support of IGMP version 3 on Layer 3 Switches</td>
<td>“IGMP V3” on page 912</td>
</tr>
<tr>
<td>PIM-SM</td>
<td>Supports features described in RFC 2362.</td>
<td>“PIM Sparse” on page 849</td>
</tr>
<tr>
<td>PIM-DM</td>
<td>Supports features described in RFC 1075.</td>
<td>“PIM Dense” on page 840</td>
</tr>
<tr>
<td>MSDP</td>
<td>You must configure a fully meshed topology between MSDP peers. This is mandated for this release because of lack of any EGP that provides a peer RPF check for SA messages.</td>
<td>“Multicast Source Discovery Protocol (MSDP)” on page 876</td>
</tr>
<tr>
<td>Anycast RP</td>
<td>Anycast RP is a method of providing intra-domain redundancy and load-balancing between multiple Rendezvous Points (RP) in a Protocol Independent Multicast Sparse mode (PIM-SM) network.</td>
<td>“Anycast RP” on page 856</td>
</tr>
<tr>
<td>ACL for RP candidate</td>
<td>Limits the multicast groups that are covered by a static (RP). It control the multicast groups for which candidate RPs send advertisement messages to bootstrap routers.</td>
<td>“Using ACLs to limit static RP groups” on page 904 “Using ACLs to limit PIM RP candidate advertisement” on page 906</td>
</tr>
<tr>
<td>Auto-negotiation of 1G/10G</td>
<td>In this release, if the speed is set to Auto for a 1G port, the port auto-negotiates the flow control with the neighboring port.</td>
<td>“Modifying port speed and duplex mode” on page 56</td>
</tr>
<tr>
<td>I Pv6 Host Support</td>
<td>This release supports IPv6 host management.</td>
<td>“IPv6 management (IPv6 host support)” on page 218</td>
</tr>
<tr>
<td>L3 SNMP and MIB support</td>
<td>This release supports AES encryption. The SNMP group to which the user account is mapped should be configured before creating the user accounts; otherwise, the group will be created without any views.</td>
<td>“Defining an SNMP user account” on page 1673</td>
</tr>
</tbody>
</table>

---

**TABLE 3** Layer 3 enhancements in FSX R05.1.00

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>See details in...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point-to-Point GRE IP Tunnels</td>
<td>This release supports the tunneling of packets over an IP network using the Generic Router Encapsulation (GRE) mechanism as described in RFC 2784.</td>
<td>“IPv4 point-to-point GRE tunnels” on page 1067</td>
</tr>
<tr>
<td>GRE keepalive</td>
<td>GRE keepalive enables GRE to maintain or place a tunnel in an UP or DOWN state based upon the periodic sending of keepalive packets and the monitoring of responses to the packets.</td>
<td>“Configuring GRE link keepalive” on page 1076</td>
</tr>
</tbody>
</table>
**TABLE 3  Layer 3 enhancements in FSX R05.1.00**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>See details in...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path MTU Discovery for GRE tunnels</td>
<td>The following RFCs are supported for handling large packets over a GRE tunnel: RFC 1191, Path MTU Discovery RFC 4459, MTU and Fragmentation Issues with In-the-Network Tunneling</td>
<td>“Path MTU discovery (RFC 1191) support” on page 1002</td>
</tr>
<tr>
<td>Support for up to 64 GRE tunnels</td>
<td>You can configure a FastIron IPv6 device to support up to 64 GRE tunnels. By default, 16 tunnels are supported.</td>
<td>“Changing the maximum number of entries the static ARP table can hold” on page 1010</td>
</tr>
<tr>
<td>IPv4 multicast routing with GRE</td>
<td>PIM-DM and PIM-SM multicast protocols and multicast data traffic are supported over GRE tunnels. When a multicast protocol is enabled on both ends of a GRE tunnel, multicast packets can be sent from one tunnel endpoint to another.</td>
<td>“Support for IPv4 multicast routing over GRE tunnels” on page 1070</td>
</tr>
<tr>
<td>ACL support with GRE</td>
<td>Traffic coming from a GRE tunnel can be filtered and classified by an ACL, both before and after the tunnel is terminated.</td>
<td>“ACL, QoS, and PBR support for traffic through a GRE tunnel” on page 1070</td>
</tr>
<tr>
<td>PBR support with GRE</td>
<td>Traffic coming from a GRE tunnel can be redirected by PBR, both before and after the tunnel is terminated.</td>
<td>“ACL, QoS, and PBR support for traffic through a GRE tunnel” on page 1070</td>
</tr>
<tr>
<td>MSDP</td>
<td>Multicast Source Discovery Protocol (MSDP) is used by Protocol Independent Multicast (PIM) Sparse routers to exchange source information across PIM Sparse domains. Routers running MSDP can discover PIM Sparse sources that are in other PIM Sparse domains.</td>
<td>“Passive multicast route insertion” on page 895</td>
</tr>
<tr>
<td>Anycast RP</td>
<td>Anycast RP is a method of providing intra-domain redundancy and load-balancing between multiple Rendezvous Points (RP) in a Protocol Independent Multicast Sparse mode (PIM-SM) network. It is accomplished by configuring all RPs within a domain with the same anycast RP address which is typically a loopback IP address.</td>
<td>“Anycast RP” on page 856</td>
</tr>
<tr>
<td>PIM passive (multicast stub routing)</td>
<td>PIM Passive reduces and minimizes unnecessary PIM Hello and other PIM control messages.</td>
<td>“PIM Passive” on page 875</td>
</tr>
<tr>
<td>MAC filters on tagged ports in Layer 3 software images</td>
<td>MAC filters are now supported on tagged ports in the base layer 3 and full Layer 3 images.</td>
<td>“Defining MAC address filters” on page 374</td>
</tr>
<tr>
<td>Support for forwarding IP packets with bad header checksum in hardware</td>
<td>In releases prior to FSX 05.1.00, certain packets could be treated as a bad checksum, even if the checksum is correct. In this case, the packets would be dropped in hardware. Starting in release FSX 05.1.00, packets can be trapped at the CPU and if the checksum is correct, the packets are forwarded.</td>
<td>“Disabling IP checksum check” on page 1104</td>
</tr>
</tbody>
</table>
Layer 2 enhancement in FSX R05.1.00

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>See details in...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flow-based MAC address learning</td>
<td>With flow-based MAC address learning, the FastIron switch programs MAC addresses selectively on packet processors, rather than globally, on all packet processors. This method enables efficient management of the hardware MAC table, and enables support for up to 32K MAC addresses.</td>
<td><em>Flow-based MAC address learning</em> on page 369</td>
</tr>
</tbody>
</table>

System-Level enhancement in FSX R05.1.00

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>See details in...</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv6 support for LLDP</td>
<td>This release adds support for advertisement of IPv6 management addresses. Prior releases support advertisement of IPv4 management addresses only (or a MAC address, if no IPv4 address is configured).</td>
<td><em>LLDP-MED attributes advertised by the Brocade device</em> on page 963</td>
</tr>
</tbody>
</table>

Management enhancement in FSX R05.1.00

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>See details in...</th>
</tr>
</thead>
<tbody>
<tr>
<td>sFlow version 5</td>
<td>sFlow version 5 modifies and enhances the format of the data sent to the sFlow collector. sFlow version 5 introduces several new sFlow features and also defines a new datagram syntax used by the sFlow agent to report flow samples and interface counters to the sFlow collector.</td>
<td><em>Support for sFlow version 5</em> on page 1744</td>

Summary of enhancements in FGS R05.0.02

FGS R05.0.02 is designed for the devices listed below. You cannot use this software on other FastIron devices:
• FastIron GS and FastIron LS switches that have been upgraded to operate as stacking devices
• FastIron GS-STK and FastIron LS-STK stackable devices
This release includes Layer 2 and Base Layer 3 images.

Software enhancements in FGS R05.0.02

The software features available in FGS R05.0.02 that are available on your device depend on the type of software image the device is running. You can run Layer 2 or Base Layer 3 software images. The Edge Layer 3 software image is not available for these platforms.

The following table presents a summary of the features supported in FGS R05.0.02. For more information about supported features for FGS R05.0.02, see Chapter 1, “Feature Highlights”.

<table>
<thead>
<tr>
<th>Feature Description</th>

<td>AES is the 128-bit encryption standard adopted by the U.S. government. This standard is a symmetric cipher algorithm chosen by the National Institute of Standards and Technology (NIST) as the replacement for DES. &quot;Defining an SNMP group&quot; on page 1672</td>
</tr>
</tbody>
</table>

Summary of enhancements in 04.1.00

Software release 04.1.00 is designed for FGS-STK and FLS-STK devices, and FGS and FLS devices that have been upgraded to support stacking. This release also introduces support for standalone Edge Premium models of FGS and FLS devices with Edge Layer 3 (EPREM) features, and for standard and Edge Premium FWS POE models. Non-POE Edge Premium FWS models were introduced in FGS R04.3.00.

For more information about how to upgrade FGS or FLS devices, see the Brocade FastIron GS and GS-STK Switch Hardware Installation Guide, the Brocade FastIron LS and LS-STK Switch Hardware Installation Guide, or the installation instructions that ship with the upgrade kits.

NOTE
Memory DIMMs and EEPROMs are not interchangeable between FGS and FLS devices. See the upgrade instructions that shipped with your upgrade kit for more information.
The following sections list the feature enhancements for 04.1.00. The features that are available on your device depend on the type of software image the device is running. You can run Layer 2 or Base Layer 3 software images. The Edge Layer 3 software image is not available for these platforms.

**Hardware introduced in 04.1.00**

This release introduces support for standalone Edge Premium models of FGS and FLS devices with Edge Layer 3 (EPREM) features. This release also introduces support for standard and Edge Premium FWS POE models. Non-POE Edge Premium FWS models were introduced in FGS R04.3.00.

Table 9 lists the new hardware models introduced in 04.1.00.

**Document conventions**

This section describes text formatting conventions and important notice formats used in this document.
Text formatting

The narrative-text formatting conventions that are used are as follows:

**bold text**
- Identifies command names
- Identifies the names of user-manipulated GUI elements
- Identifies keywords
- Identifies text to enter at the GUI or CLI

*italic text*
- Provides emphasis
- Identifies variables
- Identifies document titles

**code text**
- Identifies CLI output

For readability, command names in the narrative portions of this guide are presented in bold: for example, `show version`.

Command syntax conventions

Command syntax in this manual follows these conventions:

**command and parameters**
- Commands and parameters are printed in bold.

[ ]
- Optional parameter.

*variable*
- Variables are printed in italics enclosed in angled brackets `< >`.

...  
- Repeat the previous element, for example “member[:;member...]”

|  
- Choose from one of the parameters.

Notes, cautions, and danger notices

The following notices and statements are used in this manual. They are listed below in order of increasing severity of potential hazards.

**NOTE**
- A note provides a tip, guidance or advice, emphasizes important information, or provides a reference to related information.
Notice to the reader

This document may contain references to the trademarks of the following corporations. These trademarks are the properties of their respective companies and corporations.

Chapter 1

Feature Highlights

Introduction to features

The features that are available on a device depend on the type of software image the device is running. You can run one of the following types of software images on these devices:

- Layer 2 is supported on all models
- Base Layer 3 is supported on the FESX, FSX, FSX 800, FSX 1600, FGS, FLS, FWS standard, and FGS-STK and FLS-STK models
- Edge Layer 3 is supported on FGS, FLS, and FWS EPREM models
- Full Layer 3 is supported on FESX, FESX6FSX, FSX 800, FCX, and FSX 1600 premium models only
- Layer 3 features supported on Turbolron devices only.

Table 11 lists the software that is loaded into the primary and secondary flash areas at the factory. All of the flash images are included on the CD-ROM that ships with each device.

<table>
<thead>
<tr>

Note regarding IPv6 feature support

The following IPv6 Layer 3 features are supported only with the IPv6 Layer 3 PROM and the full Layer 3 image:

- IPv6 unicast routing (multicast routing is not supported)
1 Supported features

- OSPF V3
- RIPvng
- IPv6 ICMP redirect messages
- IPv6 route redistribution
- IPv6 static routes
- IPv6 over IPv4 tunnels in hardware
- IPv6 Layer 3 forwarding

Supported features

The tables in this section list the feature highlights in the FastIron and TurboIron software.

Supported management features

Table 12 lists the supported management features. These features are supported in the Layer 2, Base Layer 3, Edge Layer 3 (EPREM), and full Layer 3 software images.

### Supported features

**Fixed rate limiting:**
- FESX, FSX, SX, and TIX devices support:
  - Port-based rate limiting on inbound ports
  - Not supported on 10 GbE ports on FESX, FSX, and SX devices. Supported on GbE and 10 GbE ports on TurboIron X Series devices.
  - Fixed rate limiting is not supported on tagged ports in the full Layer 3 router image
- FGS, FLS, FWS, FGS-STK, FLS-STK and FCX devices support:
  - Port-based fixed rate limiting on inbound ports
  - Port-based and port- and priority-based rate limiting on outbound ports
  - The above are supported on Gbps and 10 Gbps Ethernet ports.

**Supported base Layer 3 features on FastIron devices**

Base Layer 3 software images include all of the management, security, system, and Layer 2 features listed in the previous tables, plus the features listed in **Table 16**.

**NOTE**

FCX devices will not contain a base Layer 3 image. The features in this table will be supported on the full Layer 3 image for these devices.
Supported Edge Premium (EPREM) features on FastIron devices

Edge Premium Layer 3 software images include all of the management, security, system, Layer 2 and base Layer 3 features listed in the previous tables, plus the features shown in Table 17.

NOTE
EPREM Layer 3 images are supported on FGS, FLS, and FWS edge premium (EPREM) models.

</table>
Supported Layer 3 features on TurboIron devices

- ECMP
- RIP V1 and V2 (advertising only): Static RIP support only. The TurboIron does not learn RIP routes from other Layer 3 devices. However, the device does advertise directly connected routes.
- Routing for directly connected IP subnets
- Static IP routing:
- Virtual Interfaces: Up to 255 virtual interfaces
- VRRP
- OSPF V2 (IPv4)
- Route-only support (Global configuration level only)
- VRRP
- Anycast RP
- IGMP V1, V2, and V3 (for multicast routing scenarios)
- IP multicast routing protocols (DVMRP, PIM-SM, PIM-DM): TurboIron X Series devices support PIM-SM and PIM-DM (DVMRP is not supported)
- ICMP Redirect messages
- Multicast Source Discovery Protocol (MSDP)
- Route-only support:
  - Disabling Layer 2 Switching at the CLI Interface level as well as the Global CONFIG level.
  - This feature is not supported on virtual interfaces
- VRRP-E
- DHCP relay
- IP helper

**Supported IPv6 management features**

*Table 19* shows the IPv6 management features that are supported for Brocade devices that can be configured as IPv6 hosts in an IPv6 network, and in devices that support IPv6 routing.

Using the management port

The management port is an out-of-band port that customers can use to manage their devices without interfering with the in-band ports. The management port is widely used to download images and configurations, for Telnet sessions, and for Web management.

The MAC address for the management port is derived from the base MAC address of the unit, plus the number of ports in the base module. For example, on a 48-port FCX standalone device, the base MAC address is 0000.1234.2200. The management port MAC address for this device would be 0000.1234.2200 plus 0x30, or 0000.1234.2230. The 0x30 in this case equals the 48 ports on the base module.

How the management port works

The following rules apply to management ports:

- Any packets that are specifically addressed to the management port MAC address or the broadcast MAC address are forwarded accordingly. All other packets are filtered out.
- No packet received on a management port is sent to any in-band ports, and no packets received on in-band ports are sent to a management port.
- A management port is not part of any VLAN
- Protocols are not supported on the management port.
- Creating a management VLAN disables the management port on the device.
- All features that can be configured from the global configuration mode can also be configured from the interface level of the management port. Features that are configured through the management port take effect globally, not on the management port itself (on switches only).

For switches, any in-band port may be used for management purposes. A Router sends Layer 3 packets using the MAC address of the port as the source MAC address.

For stacking devices, (for example, an FCX stack) each stack unit has one out-of-band management port. Only the management port on the Active Controller will actively send and receive packets. If a new Active Controller is elected, the new Active Controller management port will become the active management port. In this situation, the MAC address of the old Active Controller and the MAC address of the new controller will be different.

CLI Commands for use with the management port

The following CLI commands can be used with a management port.

To display the current configuration, use the `show running-config interface management` command.

**Syntax:** show running-config interface management `num`
Using the management port

FCX624S Router(config-if-mgmt)#ip addr 10.44.9.64/24
FCX624S Router(config)#show running-config interface management 1
interface management 1
  ip address 10.44.9/64 255.255.255.0

To display the current configuration, use the show interfaces management command.

Syntax: show interfaces management num

FCX624S Switch(config)#show interfaces management 1
GigEthemetmgmt1 is up, line protocol is up
Hardware is GigEthemet, address is 0000.9876.544a (bia 0000.9876.544a)
Configured speed auto, actual 10bit, configured duplex fdx, actual fdx
Configured mdi mode AUTO, actual none
BPRU guard is disabled, ROOT protect is disabled
Link Error Dampening is Disabled
STP configured to OFF, priority is level0, mac-learning is enabled
Flow Control is config disabled, oper enabled
Mirror disabled, Monitor disabled
Not member of any active trunks
Not member of any configured trunks
No port name
IPG MII 0 bits-time, IPG GMII 0 bits-time
IP MTU 1500 bytes
300 second input rate: 83728 bits/sec, 130 packets/sec, 0.01% utilization
300 second output rate: 24 bits/sec, 0 packets/sec, 0.00% utilization
39926 packets input, 3210077 bytes, 0 no buffer
Received 4353 broadcasts, 32503 multicasts, 370 unicsats
0 input errors, 0 CRC, 0 frame, 0 ignored
0 runts, 0 giants
22 packets output, 1540 bytres, 0 underruns
Transmitted 0 broadcasts, 6 multicasts, 16 unicasts
0 output errors, 0 collisions

To display the management interface information in brief form, enter the show interfaces brief management command.

Syntax: show interfaces brief management num

Port Link State Dupl Speed Trunk Tag Pvid Pri MAC Name
mgmt1 Up None Full 100M None No 1 0 000d.5200.0118

To display management port statistics, enter the show statistics management command.

Syntax: show statistics management num

FastIron(config)# show statistics management 1
Port Link State Dupl Speed Trunk Tag Pvid Pri MAC Name
mgmt1 Up None Full 100M None No 1 0 000d.5200.0118

To display the management interface statistics in brief form, enter the **show statistics brief management** command.

**Syntax:** `show statistics brief management num`

FCX624S Switch(config)#show statistics brief management 1
PortIn PacketsOut PacketsTrunkIn ErrorsOut Errors
mgmt1399452200
Total399452200

Logging on through the CLI

Once an IP address is assigned to a Brocade device running Layer 2 software or to an interface on a Brocade device running Layer 3 software, you can access the CLI either through the direct serial connection to the device or through a local or remote Telnet session.

You can initiate a local Telnet or SNMP connection by attaching a cable to a port and specifying the assigned management station IP address.

The commands in the CLI are organized into the following levels:

- **User EXEC** – Lets you display information and perform basic tasks such as pings and traceroutes.
- **Privileged EXEC** – Lets you use the same commands as those at the User EXEC level plus configuration commands that do not require saving the changes to the system-config file.
- **CONFIG** – Lets you make configuration changes to the device. To save the changes across reboots, you need to save them to the system-config file. The CONFIG level contains sub-levels for individual ports, for VLANs, for routing protocols, and other configuration areas.

**NOTE**

By default, any user who can open a serial or Telnet connection to the Brocade device can access all these CLI levels. To secure access, you can configure Enable passwords or local user accounts, or you can configure the device to use a RADIUS or TACACS/TACACS+ server for authentication. Refer to **Chapter 39, “Securing Access to Management Functions”**.

On-line help

To display a list of available commands or command options, enter “?” or press Tab. If you have not entered part of a command at the command prompt, all the commands supported at the current CLI level are listed. If you enter part of a command, then enter “?” or press Tab, the CLI lists the options you can enter at this point in the command string.

If you enter an invalid command followed by ?., a message appears indicating the command was unrecognized. An example is given below.
Logging on through the CLI

```
FastIron(config)#rooter ip
Unrecognized command
```

**Command completion**

The CLI supports command completion, so you do not need to enter the entire name of a command or option. As long as you enter enough characters of the command or option name to avoid ambiguity with other commands or options, the CLI understands what you are typing.

**Scroll control**

By default, the CLI uses a page mode to paginate displays that are longer than the number of rows in your terminal emulation window. For example, if you display a list of all the commands at the global CONFIG level but your terminal emulation window does not have enough rows to display them all at once, the page mode stops the display and lists your choices for continuing the display. An example is given below.

```
aaa
all-client
appletalk
arp
boot
some lines omitted for brevity...

ipx
lock-address
logging
mac
--More--, next page: Space, next line:
Return key, quit: Control-c
```

The software provides the following scrolling options:

- Press the **Space bar** to display the next page (one screen at a time).
- Press the **Return** or **Enter** key to display the next line (one line at a time).
- Press **Ctrl+C** or **Ctrl+Q** to cancel the display.

**Line editing commands**

The CLI supports the following line editing commands. To enter a line-editing command, use the CTRL+key combination for the command by pressing and holding the CTRL key, then pressing the letter associated with the command.

**TABLE 21** CLI line editing commands

<table>
<thead>
<tr>
<th>Ctrl+Key combination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl+A</td>
<td>Moves to the first character on the command line.</td>
</tr>
<tr>
<td>Ctrl+B</td>
<td>Moves the cursor back one character.</td>
</tr>
<tr>
<td>Ctrl+C</td>
<td>Escapes and terminates command prompts and ongoing tasks (such as lengthy displays), and displays a fresh command prompt.</td>
</tr>
<tr>
<td>Ctrl+D</td>
<td>Deletes the character at the cursor.</td>
</tr>
<tr>
<td>Ctrl+E</td>
<td>Moves to the end of the current command line.</td>
</tr>
</tbody>
</table>
Using stack-unit, slot number, and port number with CLI commands

Many CLI commands require users to enter port numbers as part of the command syntax, and many show command outputs display port numbers. The port numbers are entered and displayed in one of the following formats:

- port number only
- slot number and port number
- stack-unit, slot number, and port number

The following sections show which format is supported on which devices. The ports are labelled on the front panels of the devices.

**CLI nomenclature on FSX, FSX 800, and FSX 1600 devices**

Chassis-based models use port numbering that consists of a slot number and a port number. When you enter CLI commands on these devices, you must specify both the slot number and the port number. The slot numbers used in the FSX CLI examples apply only to Chassis devices.

Here is an example. The following commands change the CLI from the global CONFIG level to the configuration level for the first port on the device:

- FSX commands
  ```
  FastIron(config)#interface e 1/1
  FastIron(config-if-1/1)#
  ```

**CLI nomenclature on TIX, FESX, and FWSX devices**

The TIX, FESX, and FWSX devices use port numbers only. When you enter CLI commands that require port numbers as part of the syntax, just specify the port number.

Here are some examples. The following commands change the CLI from the global CONFIG level to the configuration level for the first port on the device:

---

  FastIron(config)#interface e1
  FastIron(config-if-e1000-1)#

• TIX commands
  TurboIron 24X(config)#interface e1
  TurboIron 24X(config-if-e1000-1)#

**CLI nomenclature on FGS and FLS devices**

The CLI uses stack number and chassis-based port numbering (stacknum/slot/port). However, stacking is not supported for the FastIron GS and FastIron LS devices. For an explanation of CLI nomenclature for stackable devices, see the next section.

**CLI nomenclature on FGS-STK, FLS-STK, and FCX devices**

The stacking CLI uses stack unit IDs and chassis-based port numbering (<stack-unit>/<slot>/<port>). Refer to Chapter 5, “Brocade Stackable Devices” for more information about FGS-STK, FLS-STK and FCX devices and their command structure.

**CLI nomenclature on the FWS**

The FWS uses stack-unit/slot/port nomenclature. Stacking is not currently supported on the FWS, although the CLI supports the full stacking nomenclature.

**Slot and port number labeling on FGS and FLS devices**

When you enter CLI commands that include the port number as part of the syntax, you must specify the stack number (0 in current releases), the slot number, and the port number.

The slot and port numbers are labelled on the front of the FGS624XGP, FGS624XGP-POE, and other FGS and FLS models that are shipped in accordance with the new port numbering scheme. For older models, an upgrade label kit is available.

**FGS624P and FGS624P-POE**

**Figure 1** shows port numbers on the FGS624P and FGS624P-POE models as they appeared prior to release 02.5.00.

</table>
Using FGS and FLS port nomenclature

For FGS and FLS devices running software release 02.5.00 and later, when you enter a CLI command that includes the port number as part of the syntax, you must use the stack-unit/slot/port number format. For example, the following commands change the CLI from the global CONFIG level to the configuration level for the first port on the device:

- **FGS commands prior to release 02.5.00**
  
  FGS624(config)#interface e 1
  FGS624(config-if-e1000-1)#

- **FGS commands starting in release 02.5.00**
  
  FGS624(config)#interface e 0/1/1
  FGS624(config-if-e1000-0/1/1)#

**NOTE**
The stack-unit number is always 0 as long as the device is operating in standalone mode.

- **FGS-STK and FLS-STK commands starting in release 05.0.00**
  
  FGS624(config)#interface e 2/1/1
  FGS624(config-if-e1000-2/1/1)#

**Syntax:** ethernet stack-unit/slotnum/portnum
The <stack-unit> parameter is required on FGS devices running software release 02.5.00 or later. This number for these devices is currently always 0 when they are operating in standalone mode. These devices must be upgraded to support stacking.

The <slotnum> parameter is required on chassis devices and on FastIron GS devices running software release 02.5.00 or later.

The <portnum> parameter is a valid port number.

Using the FWS, FGS-STK, FLS-STK, and FCX port nomenclature

For FWS devices, and FGS-STK and FLS-STK devices, and FGS and FLS devices that have been upgraded to run the stacking features available with release 05.0.00, <stack-unit> is the ID number of the device within the stack and can be any number from 1 through 8. The <stack-unit> parameter is also required on all FastIron CX devices running software release 06.0.00 and later.

When you enter a CLI command that includes the port number as part of the syntax, you must use the stack-unit/slot/port number format. For example, the following commands change the CLI from the global CONFIG level to the configuration level for the first port on the device:

FWS624(config)#interface e 1/1/1
FWS624(config-if-e1000-1/1/1)#

**Syntax:** ethernet stack-unit/slotnum/portnum
The stack-unit and slotnum parameters are required on FWS, FGS and FLS devices, and FGS-STK, FLS-STK, and FCX stackable devices.

The portnum parameter is a valid port number.
Searching and filtering output from CLI commands

You can filter CLI output from `show` commands and at the --More-- prompt. You can search for individual characters, strings, or construct complex regular expressions to filter the output.

**Searching and filtering output from Show commands**

You can filter output from `show` commands to display lines containing a specified string, lines that do not contain a specified string, or output starting with a line containing a specified string. The search string is a regular expression consisting of a single character or string of characters. You can use special characters to construct complex regular expressions. Refer to "Using special characters in regular expressions" on page 28 for information on special characters used with regular expressions.

**Using include to display lines containing a specified string**

The `include` modifier filters the output of the `show interface` command for port 3/11 so it displays only lines containing the word “Internet”. This command can be used to display the IP address of the interface.

```
FastIron#show interface e 3/11 | include Internet
    Internet address is 192.168.1.11/24, MTU 1518 bytes, encapsulation ethernet
```

**Syntax:** `show-command | include regular-expression`

**NOTE**

The vertical bar ( | ) is part of the command.

The regular expression specified as the search string is case sensitive. In the example above, a search string of "Internet" would match the line containing the IP address, but a search string of "internet" would not.

**Using exclude to display lines that do not contain a specified string**

The `exclude` modifier filters the output of the `show who` command so it displays only lines that do not contain the word “closed”. This command can be used to display open connections to the Brocade device.

```
FastIron#show who | exclude closed
    Console connections:
        established
          you are connecting to this session
          2 seconds in idle
    Telnet connections (inbound):
        1 established, client ip address 192.168.9.37
          27 seconds in idle
    Telnet connection (outbound):
    SSH connections:
```

**Syntax:** `show-command | exclude regular-expression`

**Using begin to display lines starting with a specified string**

The `begin` modifier filters the output of the `show who` command so it displays output starting with the first line that contains the word “SSH”. This command can be used to display information about SSH connections to the Brocade device.
Using stack-unit, slot number, and port number with CLI commands

FastIron#show who | begin SSH
SSH connections:
  1 established, client ip address 192.168.9.210
      7 seconds in idle
  2 closed
  3 closed
  4 closed
  5 closed

Syntax:  show-command | begin regular-expression

Searching and filtering output at the --More-- prompt

The --More-- prompt displays when output extends beyond a single page. From this prompt, you can press the Space bar to display the next page, the Return or Enter key to display the next line, or Ctrl+C or Q to cancel the display. In addition, you can search and filter output from this prompt.

At the --More-- prompt, you can press the forward slash key (/) and then enter a search string. The Brocade device displays output starting from the first line that contains the search string, similar to the begin modifier for show commands. An example is given below.

--More--, next page: Space, next line: Return key, quit: Control-c
/telnet

The results of the search are displayed.

searching...
telnet     Telnet by name or IP address
temperature temperature sensor commands
terminal    display syslog
traceroute  TraceRoute to IP node
undebug     Disable debugging functions (see also 'debug')
undelete    Undelete flash card files
whois       WHOIS lookup
write       Write running configuration to flash or terminal

To display lines containing only a specified search string (similar to the include modifier for show commands) press the plus sign key (+) at the --More-- prompt and then enter the search string.

--More--, next page: Space, next line: Return key, quit: Control-c
+telnet

The filtered results are displayed.

filtering...
telnet     Telnet by name or IP address

To display lines that do not contain a specified search string (similar to the exclude modifier for show commands) press the minus sign key (-) at the --More-- prompt and then enter the search string.

--More--, next page: Space, next line: Return key, quit: Control-c
-telnet

The filtered results are displayed.
As with the modifiers for filtering output from `show` commands, the search string is a regular expression consisting of a single character or string of characters. You can use special characters to construct complex regular expressions. See the next section for information on special characters used with regular expressions.

## Using special characters in regular expressions

You use a regular expression to specify a single character or multiple characters as a search string. In addition, you can include special characters that influence the way the software matches the output against the search string. These special characters are listed in the following table.

### TABLE 25 Special characters for regular expressions

<table>
<thead>
<tr>
<th>Character</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>The period matches on any single character, including a blank space. For example, the following regular expression matches “aaZ”, “abZ”, “acZ”, and so on, but not just “az”: a.Z</td>
</tr>
<tr>
<td>*</td>
<td>The asterisk matches on zero or more sequential instances of a pattern. For example, the following regular expression matches output that contains the string “abc”, followed by zero or more Xs: abcX*</td>
</tr>
<tr>
<td>+</td>
<td>The plus sign matches on one or more sequential instances of a pattern. For example, the following regular expression matches output that contains ”de”, followed by a sequence of “g”s, such as “deg”, “degg”, “deggg”, and so on: deg+</td>
</tr>
<tr>
<td>?</td>
<td>The question mark matches on zero occurrences or one occurrence of a pattern. For example, the following regular expression matches output that contains “deg” or “deg”:\n\nde?g</td>
</tr>
<tr>
<td>^</td>
<td>A caret (when not used within brackets) matches on the beginning of an input string. For example, the following regular expression matches output that begins with “deg”: ^deg</td>
</tr>
<tr>
<td>$</td>
<td>A dollar sign matches on the end of an input string. For example, the following regular expression matches output that ends with “deg”: deg$</td>
</tr>
</tbody>
</table>
If you want to filter for a special character instead of using the special character as described in the table above, enter "\"" (backslash) in front of the character. For example, to filter on output containing an asterisk, enter the asterisk portion of the regular expression as "\*".

FastIron#show ip route bgp | include \*

**Creating an alias for a CLI command**

You can create *aliases* for CLI commands. An alias serves as a shorthand version of a longer CLI command. For example, you can create an alias called *shoro* for the CLI command *show ip route*. Then when you enter *shoro* at the command prompt, the *show ip route* command is executed.

To create an alias called *shoro* for *show ip route*, enter the following command.

FastIron(config)#alias shoro = show ip route

**Syntax: [no] alias alias-name = cli-command**

The <alias-name> must be a single word, without spaces.
After the alias is configured, entering `shoro` at either the Privileged EXEC or CONFIG levels of the CLI executes the `show ip route` command.

To create an alias called `wrsbc` for `copy running-config tftp 10.10.10.10 test.cfg`, enter the following command.

```
FastIron(config)#alias wrsbc = copy running-config tftp 10.10.10.10 test.cfg
```

To remove the `wrsbc` alias from the configuration, enter one of the following commands.

```
FastIron(config)#no alias wrsbc
```

or

```
FastIron(config)#unalias wrsbc
```

**Syntax: unalias alias-name**

The specified `alias-name` must be the name of an alias already configured on the Brocade device.

To display the aliases currently configured on the Brocade device, enter the following command at either the Privileged EXEC or CONFIG levels of the CLI.

```
FastIron#alias
wrsbc        copy running-config tftp 10.10.10.10 test.cfg
shoro        show ip route
```

**Syntax: alias**

**Configuration notes**

The following configuration notes apply to this feature:

- You cannot include additional parameters with the alias at the command prompt. For example, after you create the `shoro` alias, `shoro bgp` would not be a valid command.
- If configured on the Brocade device, authentication, authorization, and accounting is performed on the actual command, not on the alias for the command.
- To save an alias definition to the startup-config file, use the `write memory` command.

---

**Logging on through the Web Management Interface**

To use the Web Management Interface, open a Web browser and enter the IP address of the management port on the Brocade device in the Location or Address field. The Web browser contacts the Brocade device and displays a Login panel, such as the one shown below for the FESX.

**FIGURE 6  Web Management Interface login panel**
NOTE
If you are unable to connect with the device through a Web browser due to a proxy problem, it may be necessary to set your Web browser to direct Internet access instead of using a proxy. For information on how to change a proxy setting, refer to the on-line help provided with your Web browser.

To log in, click on the Login link. The following dialog box is displayed.

FIGURE 7  Web Management Interface login dialog

The login username and password you enter depends on whether your device is configured with AAA authentication for SNMP. If AAA authentication for SNMP is not configured, you can use the user name “get” and the default read-only password “public” for read-only access. However, for read-write access, you must enter “set” for the user name, and enter a read-write community string you have configured on the device for the password. There is no default read-write community string. You must add one using the CLI.

As an alternative to using the SNMP community strings to log in, you can configure the Brocade device to secure Web management access using local user accounts or Access Control Lists (ACLs).

Navigating the Web Management Interface

When you log into a device, the System configuration panel is displayed. This panel allows you to enable or disable major system features. You can return to this panel from any other panel by selecting the Home link.

The Site Map link gives you a view of all available options on a single screen.

NOTE
TurboIron devices do not support Web Management Interface.
Figure 8 displays the first Web Management Interface panel for Layer 3 Switch features, while Figure 9 displays the first panel for Layer 2 Switch features. These panels allow you to configure the features supported by the Layer 3 Switch and Layer 2 Switch software.

**FIGURE 8** First panel for Layer 3 Switch features

![First panel for Layer 3 Switch features](image)

**NOTE**
If you are using Internet Explorer 6.0 to view the Web Management Interface, make sure the version you are running includes the latest service packs. Otherwise, the navigation tree (the left-most pane in Figure 8) will not display properly. For information on how to load the latest service packs, refer to the on-line help provided with your Web browser.

**FIGURE 9** First panel for Layer 2 Switch features

![First panel for Layer 2 Switch features](image)

**NOTE**
If you are using Internet Explorer 6.0 to view the Web Management Interface, make sure the version you are running includes the latest service packs. Otherwise, the navigation tree (the left-most pane in Figure 8) will not display properly. For information on how to load the latest service packs, refer to the on-line help provided with your Web browser.
The left pane of the Web Management Interface window contains a “tree view,” similar to the one found in Windows Explorer. Configuration options are grouped into folders in the tree view. These folders, when expanded, reveal additional options. To expand a folder, click on the plus sign to the left of the folder icon.

You can configure the appearance of the Web Management Interface by using one of the following methods.

Using the CLI, you can modify the appearance of the Web Management Interface with the `web-management` command.

To cause the Web Management Interface to display the List view by default, enter the following command.

```
FastIron(config)#web-management list-menu
```

To disable the front panel frame, enter the following command.

```
FastIron(config)#no web-management front-panel
```

When you save the configuration with the `write memory` command, the changes will take place the next time you start the Web Management Interface, or if you are currently running the Web Management Interface, the changes will take place when you click the Refresh button on your browser.

**Using the Web Management Interface**

1. Click on the **plus sign** next to Configure in the tree view to expand the list of configuration options.
2. Click on the **plus sign** next to System in the tree view to expand the list of system configuration links.
3. Click on the **plus sign** next to Management in the tree view to expand the list of system management links.
4. Click on the **Web Preference** link to display the Web Management Preferences panel.
5. **Enable** or **disable** elements on the Web Management Interface by clicking on the appropriate radio buttons on the panel. The following figure identifies the elements you can change.
NOTE
The tree view is available when you use the Web Management Interface with Netscape 4.0 or higher or Internet Explorer 4.0 or higher browsers. If you use the Web Management Interface with an older browser, the Web Management Interface displays the List view only, and the Web Management Preferences panel does not include an option to display the tree view.

6. When you have finished, click the Apply button on the panel, then click the Refresh button on your browser to activate the changes.

7. To save the configuration, click the plus sign next to the Command folder, then click the Save to Flash link.

NOTE
The only changes that become permanent are the settings to the Menu Type and the Front Panel Frame. Any other elements you enable or disable will go back to their default settings the next time you start the Web Management Interface.

Logging on through IronView Network Manager

Refer to the IronView® Network Manager User Guide for information about using IronView Network Manager.
Configuring Basic Software Features

Configuring basic system parameters

Brocade devices are configured at the factory with default parameters that allow you to begin using the basic features of the system immediately. However, many of the advanced features such as VLANs or routing protocols for the device must first be enabled at the system (global) level before they can be configured. If you use the Command Line Interface (CLI) to configure system parameters, you can find these system level parameters at the Global CONFIG level of the CLI.

**NOTE**
Before assigning or modifying any router parameters, you must assign the IP subnet (interface) addresses for each port.

**NOTE**
For information about configuring IP addresses, DNS resolver, DHCP assist, and other IP-related parameters, refer to Chapter 30, “Configuring IP”.

For information about the Syslog buffer and messages, refer to Chapter 50, “Using Syslog”.

The procedures in this section describe how to configure the basic system parameters listed in Table 26.

**TABLE 26** Basic system parameters

**NOTE**
For information about the Syslog buffer and messages, refer to Chapter 50, “Using Syslog”.

**Entering system administration information**

You can configure a system name, contact, and location for a Brocade device and save the information locally in the configuration file for future reference. This information is not required for system operation but is suggested. When you configure a system name, the name replaces the default system name in the CLI command prompt.

The name, contact, and location each can be up to 32 alphanumeric characters.

Here is an example of how to configure a system name, system contact, and location.

```plaintext
FastIron(config)# hostname zappa
zappa(config)# snmp-server contact Support Services
zappa(config)# snmp-server location Centerville
zappa(config)# end
zappa# write memory
```

**Syntax:** hostname *string*

**Syntax:** snmp-server contact *string*

**Syntax:** snmp-server location *string*

The text strings can contain blanks. The SNMP text strings do not require quotation marks when they contain blanks but the host name does.

---

**NOTE**

The *chassis name* command does not change the CLI prompt. Instead, the command assigns an administrative ID to the device.

---

**Configuring Simple Network Management Protocol (SNMP) parameters**

Use the procedures in this section to perform the following configuration tasks:

- Specify an SNMP trap receiver.
- Specify a source address and community string for all traps sent by the device.
- Change the holdown time for SNMP traps
- Disable individual SNMP traps. (All traps are enabled by default.)
- Disable traps for CLI access that is authenticated by a local user account, a RADIUS server, or a TACACS/TACACS+ server.

---

**NOTE**

To add and modify “get” (read-only) and “set” (read-write) community strings, refer to Chapter 39, “Securing Access to Management Functions”.

---

**Specifying an SNMP trap receiver**

You can specify a trap receiver to ensure that all SNMP traps sent by the Brocade device go to the same SNMP trap receiver or set of receivers, typically one or more host devices on the network. When you specify the host, you also specify a community string. The Brocade device sends all the SNMP traps to the specified hosts and includes the specified community string. Administrators can therefore filter for traps from a Brocade device based on IP address or community string.
When you add a trap receiver, the software automatically encrypts the community string you associate with the receiver when the string is displayed by the CLI or Web Management Interface. If you want the software to show the community string in the clear, you must explicitly specify this when you add a trap receiver. In either case, the software does not encrypt the string in the SNMP traps sent to the receiver.

To specify the host to which the device sends all SNMP traps, use one of the following methods.

To add a trap receiver and encrypt the display of the community string, enter commands such as the following.

```
FastIron(config)# snmp-server host 2.2.2.2 0 mypublic port 200
FastIron(config)# write memory
```

Syntax: `snmp-server host ip-addr [0 | 1] string [port value]`

The `ip-addr` parameter specifies the IP address of the trap receiver.

The `0 | 1` parameter specifies whether you want the software to encrypt the string (1) or show the string in the clear (0). The default is 0.

The `string` parameter specifies an SNMP community string configured on the Brocade device. The string can be a read-only string or a read-write string. The string is not used to authenticate access to the trap host but is instead a useful method for filtering traps on the host. For example, if you configure each of your Brocade devices that use the trap host to send a different community string, you can easily distinguish among the traps from different Brocade devices based on the community strings.

The command in the example above adds trap receiver 2.2.2.2 and configures the software to encrypt display of the community string. When you save the new community string to the startup-config file (using the `write memory` command), the software adds the following command to the file.

```
snmp-server host 2.2.2.2 1 <encrypted-string>
```

To add a trap receiver and configure the software to encrypt display of the community string in the CLI and Web Management Interface, enter commands such as the following.

```
FastIron(config)# snmp-server host 2.2.2.2 0 FastIron-12
FastIron(config)# write memory
```

The `port value` parameter allows you to specify which UDP port will be used by the trap receiver. This parameter allows you to configure several trap receivers in a system. With this parameter, IronView Network Manager Network Manager and another network management application can coexist in the same system. Brocade devices can be configured to send copies of traps to more than one network management application.

**Specifying a single trap source**

You can specify a single trap source to ensure that all SNMP traps sent by the Brocade device use the same source IP address. When you configure the SNMP source address, you specify the Ethernet port, loopback interface, or virtual interface that is the source for the traps. The Brocade device then uses the lowest-numbered IP address configured on the port or interface as the source IP address in the SNMP traps sent by the device.

Identifying a single source IP address for SNMP traps provides the following benefits:
Configuring basic system parameters

- If your trap receiver is configured to accept traps only from specific links or IP addresses, you can use this feature to simplify configuration of the trap receiver by configuring the Brocade device to always send the traps from the same link or source address.

- If you specify a loopback interface as the single source for SNMP traps, SNMP trap receivers can receive traps regardless of the states of individual links. Thus, if a link to the trap receiver becomes unavailable but the receiver can be reached through another link, the receiver still receives the trap, and the trap still has the source IP address of the loopback interface.

To specify a port, loopback interface, or virtual interface whose lowest-numbered IP address the Brocade device must use as the source for all SNMP traps sent by the device, use the following CLI method.

To configure the device to send all SNMP traps from the first configured IP address on port 4, enter the following commands.

```
FastIron(config)# snmp trap-source ethernet 4
FastIron(config)# write memory
```

Syntax:  `snmp-server trap-source loopback num | ethernet [stack-unit][[slotnum][portnum] | ve num`

The `num` parameter is a loopback interface or virtual interface number.

If you specify an Ethernet port, the `slotnum` parameter is required on chassis devices.

If you specify an Ethernet port the `[stack-unit]` parameter is required on all FGS, FWS, FLS, FGS-STK and FLS-STK, and FCX devices.

To specify a loopback interface as the SNMP trap source for the device, enter commands such as the following.

```
FastIron(config)# int loopback 1
FastIron(config-lbif-1)# ip address 10.0.0.1/24
FastIron(config-lbif-1)# exit
FastIron(config)# snmp-server trap-source loopback 1
```

The commands in this example configure loopback interface 1, assign IP address 10.00.1/24 to the loopback interface, then designate the interface as the SNMP trap source for this device. Regardless of the port the Brocade device uses to send traps to the receiver, the traps always arrive from the same source IP address.

**Setting the SNMP trap holddown time**

When a Brocade device starts up, the software waits for Layer 2 convergence (STP) and Layer 3 convergence (OSPF) before beginning to send SNMP traps to external SNMP servers. Until convergence occurs, the device might not be able to reach the servers, in which case the messages are lost.

By default, a Brocade device uses a one-minute holddown time to wait for the convergence to occur before starting to send SNMP traps. After the holddown time expires, the device sends the traps, including traps such as “cold start” or “warm start” that occur before the holddown time expires.

You can change the holddown time to a value from one second to ten minutes.

To change the holddown time for SNMP traps, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)# snmp-server enable traps holddown-time 30
```
The command in this example changes the holddown time for SNMP traps to 30 seconds. The device waits 30 seconds to allow convergence in STP and OSPF before sending traps to the SNMP trap receiver.

**Syntax:** `[no] snmp-server enable traps holddown-time secs

The seconds parameter specifies the number of seconds and can be from 1 – 600 (ten minutes). The default is 60 seconds.

**Disabling SNMP traps**

Brocade devices come with SNMP trap generation enabled by default for all traps. You can selectively disable one or more of the following traps.

**NOTE**
By default, all SNMP traps are enabled at system startup.

**Layer 2 traps**

The following traps are generated on devices running Layer 2 software:

- SNMP authentication keys
- Power supply failure
- Fan failure
- Cold start
- Link up
- Link down
- Bridge new root
- Bridge topology change
- Locked address violation

**Layer 3 traps**

The following traps are generated on devices running Layer 3 software:

- SNMP authentication key
- Power supply failure
- Fan failure
- Cold start
- Link up
- Link down
- Bridge new root
- Bridge topology change
- Locked address violation
- BGP4
- OSPF
- VRRP
- VRRPE
To stop link down occurrences from being reported, enter the following.

FastIron(config)# no snmp-server enable traps link-down

Syntax: [no] snmp-server enable traps trap-type

Displaying virtual routing interface statistics

Platform Support:
- FastIron X Series devices running software release 03.2.00 and later – L2, BL3, L3

In software releases prior to FSX 04.1.00, this feature enables SNMP to extract and display virtual routing interface statistics from the ifTable (32-bit counters).

Starting with software release FSX 04.1.00, this feature enables SNMP to extract and display virtual routing interface statistics from the ifXTable (64-bit counters).

The following describes the limitations of this feature:
- The Brocade device counts traffic from all virtual interfaces (VEs). For example, in a configuration with two VLANs (VLAN 1 and VLAN 20) on port 1, when traffic is sent on VLAN 1, the counters (VE statistics) increase for both VE 1 and VE 20.
- The counters include all traffic on each virtual interface, even if the virtual interface is disabled.
- The counters include traffic that is denied by ACLs or MAC filters.

To enable SNMP to display VE statistics, enter the following command.

FastIron(config)# enable snmp ve-statistics

Syntax: [no] enable snmp ve-statistics

Use the no form of the command to disable this feature once it is enabled.

Note that the above CLI command enables SNMP to display virtual interface statistics. It does not enable the CLI or Web Management Interface to display the statistics.

Disabling Syslog messages and traps for CLI access

Brocade devices send Syslog messages and SNMP traps when a user logs into or out of the User EXEC or Privileged EXEC level of the CLI. The feature applies to users whose access is authenticated by an authentication-method list based on a local user account, RADIUS server, or TACACS/TACACS+ server.

NOTE
The Privileged EXEC level is sometimes called the “Enable” level, because the command for accessing this level is enable.

The feature is enabled by default.

Examples of Syslog messages for CLI access

When a user whose access is authenticated by a local user account, a RADIUS server, or a TACACS/TACACS+ server logs into or out of the CLI User EXEC or Privileged EXEC mode, the software generates a Syslog message and trap containing the following information:
- The time stamp
- The user name
- Whether the user logged in or out
- The CLI level the user logged into or out of (User EXEC or Privileged EXEC level)

**NOTE**
Messages for accessing the User EXEC level apply only to access through Telnet. The device does not authenticate initial access through serial connections but does authenticate serial access to the Privileged EXEC level. Messages for accessing the Privileged EXEC level apply to access through the serial connection or Telnet.

The following examples show login and logout messages for the User EXEC and Privileged EXEC levels of the CLI.

```
FastIron# show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
Buffer logging: level ACDMEINW, 12 messages logged
level code: A=alert C=critical D=debugging M=emergency E=error
I=informational N=notification W=warning
Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed

Dynamic Log Buffer (50 entries):
Oct 15 18:01:11:info:dg logout from USER EXEC mode
Oct 15 17:38:07:info:dg login to PRIVILEGE EXEC mode
Oct 15 17:38:03:info:dg login to USER EXEC mode
```

**Syntax:** show logging

The first message (the one on the bottom) indicates that user “dg” logged in to the CLI User EXEC level on October 15 at 5:38 PM and 3 seconds (Oct 15 17:38:03). The same user logged into the Privileged EXEC level four seconds later.

The user remained in the Privileged EXEC mode until 5:59 PM and 22 seconds. (The user could have used the CONFIG modes as well. Once you access the Privileged EXEC level, no further authentication is required to access the CONFIG levels.) At 6:01 PM and 11 seconds, the user ended the CLI session.

**Disabling the Syslog messages and traps**
Logging of CLI access is enabled by default. If you want to disable the logging, enter the following commands.

```
FastIron(config)# no logging enable user-login
FastIron(config)# write memory
FastIron(config)# end
FastIron# reload
```

**Syntax:** [no] logging enable user-login

**Configuring an interface as the source for all Telnet packets**
You can designate the lowest-numbered IP address configured on an interface as the source IP address for all Telnet packets from the device. Identifying a single source IP address for TelNet packets provides the following benefits:
If your Telnet server is configured to accept packets only from specific links or IP addresses, you can use this feature to simplify configuration of the Telnet server by configuring the Brocade device to always send the Telnet packets from the same link or source address.

If you specify a loopback interface as the single source for Telnet packets, Telnet servers can receive the packets regardless of the states of individual links. Thus, if a link to the Telnet server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

The software contains separate CLI commands for specifying the source interface for Telnet, TACACS/TACACS+, and RADIUS packets. You can configure a source interface for one or more of these types of packets.

To specify an interface as the source for all Telnet packets from the device, use the following CLI method. The software uses the lowest-numbered IP address configured on the interface as the source IP address for Telnet packets originated by the device.

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all Telnet packets, enter commands such as the following.

```
FastIron(config)# int loopback 2
FastIron(config-lbif-2)# ip address 10.0.0.2/24
FastIron(config-lbif-2)# exit
FastIron(config)# ip telnet source-interface loopback 2
```

The commands in this example configure loopback interface 2, assign IP address 10.0.0.2/24 to the interface, then designate the interface as the source for all Telnet packets from the device.

The following commands configure an IP interface on an Ethernet port and designate the address port as the source for all Telnet packets from the device.

```
FastIron(config)# interface ethernet 4
FastIron(config-if-e1000-4)# ip address 209.157.22.110/24
FastIron(config-if-e1000-4)# exit
FastIron(config)# ip telnet source-interface ethernet 4
```

### Cancelling an outbound Telnet session

If you want to cancel a Telnet session from the console to a remote Telnet server (for example, if the connection is frozen), you can terminate the Telnet session by doing the following.

1. At the console, press **Ctrl+^** (Ctrl+Shift-6).
2. Press the X key to terminate the Telnet session.

Pressing **Ctrl+^** twice in a row causes a single **Ctrl+^** character to be sent to the Telnet server. After you press **Ctrl+^**, pressing any key other than X or **Ctrl+^** returns you to the Telnet session.
Configuring an interface as the source for all TFTP packets

Platform Support:

• FastIron X Series devices running software release 02.5.00 and later

You can configure the device to use the lowest-numbered IP or IPv6 address configured on a loopback interface, virtual interface, or Ethernet port as the source for all TFTP packets from the device. The software uses the lowest-numbered IP or IPv6 address configured on the interface as the source IP address for the packets.

For example, to specify the lowest-numbered IP address configured on a virtual interface as the device source for all TFTP packets, enter commands such as the following.

```
FastIron(config)# int ve 1
FastIron(config-vif-1)# ip address 10.0.0.3/24
FastIron(config-vif-1)# exit
FastIron(config)# ip tftp source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface's address as the source address for all TFTP packets.

Syntax: `[no] ip tftp source-interface ethernet [stack-unit] [slotnum] | portnum | loopback num | ve <num>

If you specify an Ethernet port, the `slotnum` parameter is required on chassis devices.

If you specify an Ethernet port the `stack-unit` parameter is required on all FGS, FWS, FCX, and FLS devices.

The default is the lowest-numbered IP address configured on the port through which the packet is sent. The address therefore changes, by default, depending on the port.

Configuring an interface as the source for Syslog packets

Platform Support:

• FastIron X Series devices running software release 02.5.00 and later

You can configure the device to use the lowest-numbered IP or IPv6 address configured on a loopback interface, virtual interface, or Ethernet port as the source for all Syslog packets from the device. The software uses the lowest-numbered IP or IPv6 address configured on the interface as the source IP address for the packets.

For example, to specify the lowest-numbered IP address configured on a virtual interface as the device source for all Syslog packets, enter commands such as the following.

```
FastIron(config)# int ve 1
FastIron(config-vif-1)# ip address 10.0.0.4/24
FastIron(config-vif-1)# exit
FastIron(config)# ip syslog source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.4/24 to the interface, then designate the interface's address as the source address for all Syslog packets.

Syntax: `[no] ip syslog source-interface ethernet [stack-unit] | slotnum | portnum | loopback num | ve <num>

If you specify an Ethernet port, the `slotnum` parameter is required on chassis devices.
If you specify an Ethernet port the `stack-unit` parameter is required on all FGS, FWS, FCX, and FLS devices.

The default is the lowest-numbered IP or IPv6 address configured on the port through which the packet is sent. The address therefore changes, by default, depending on the port.

**Configuring an interface as the source for all SNTP packets**

**Platform Support:**
- FastIron X Series devices running software release 02.5.00 and later

You can configure the device to use the lowest-numbered IP or IPv6 address configured on a loopback interface, virtual interface, or Ethernet port as the source for all SNTP packets from the device. The software uses the lowest-numbered IP or IPv6 address configured on the interface as the source IP address for the packets.

For example, to specify the lowest-numbered IP address configured on a virtual interface as the device source for all SNTP packets, enter commands such as the following.

```plaintext
FastIron(config)# int ve 1
FastIron(config-vif-1)# ip address 10.0.0.5/24
FastIron(config-vif-1)# exit
FastIron(config)# ip sntp source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.5/24 to the interface, then designate the interface's address as the source address for all SNTP packets.

**Syntax:**

```
[no] ip sntp source-interface ethernet [slotnum]/portnum | loopback num | ve num
```

The default is the lowest-numbered IP or IPv6 address configured on the port through which the packet is sent. The address therefore changes, by default, depending on the port.

**Specifying a Simple Network Time Protocol (SNTP) server**

You can configure the Brocade device to consult SNTP servers for the current time and date.

**NOTE**

Brocade devices do not retain time and date information across power cycles. Unless you want to reconfigure the system time counter each time the system is reset, Brocade recommends that you use the SNTP feature.

To identify an SNTP server with IP address 208.99.8.95 to act as the clock reference for a Brocade device, enter the following.

```plaintext
FastIron(config)# sntp server 208.99.8.95
```

**Syntax:**

```
sntp server ip-addr | hostname [version]
```

The `version` parameter specifies the SNTP version the server is running and can be from 1 – 4. The default is 1. You can configure up to three SNTP servers by entering three separate `sntp server` commands.

By default, the Brocade device polls its SNTP server every 30 minutes (1800 seconds). To configure the Brocade device to poll for clock updates from a SNTP server every 15 minutes, enter the following.

```plaintext
FastIron(config)# sntp poll-interval 900
```
Syntax: `[no] snntp poll-interval 1-65535`

To display information about SNTP associations, enter the following command.

```
FastIron# show snntp associations
address ref clock st when poll delay disp
~207.95.6.102 0.0.0.0 16 202 4 0.0 5.45
~207.95.6.101 0.0.0.0 16 202 0 0.0 0.0
* synced, ~ configured
```

Syntax: `show snntp associations`

The following table describes the information displayed by the `show snntp associations` command.

**TABLE 27** Output from the `show snntp associations` command

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>

Configuring basic system parameters

### SNTP over IPv6

**Platform Support:**
- FastIron X Series devices running software release 02.4.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 and later

To enable the Brocade device to send SNTP packets over IPv6, enter a command such as the following at the Global CONFIG level of the CLI.

FastIron(config)# sntp server ipv6 3000::400

**Syntax:** `sntp server ipv6 ipv6-address`

The `ipv6-address` is the IPv6 address of the SNTP server. When you enter the IPv6 address, you do not need to specify the prefix length. A prefix length of 128 is implied.

### Setting the system clock

In addition to SNTP support, Brocade switches and routers also allow you to set the system time counter. The time counter setting is not retained across power cycles and is not automatically synchronized with an SNTP server. The counter merely starts the system time and date clock with the time and date you specify.

**NOTE**
You can synchronize the time counter with your SNTP server time by entering the `sntp sync` command from the Privileged EXEC level of the CLI.

**NOTE**
Unless you identify an SNTP server for the system time and date, you will need to re-enter the time and date following each reboot.

For more details about SNTP, refer to “Specifying a Simple Network Time Protocol (SNTP) server” on page 44.

To set the system time and date to 10:15:05 on October 15, 2003, enter the following command.

**Syntax:** `[no] clock set hh:mm:ss | mm-dd-yy | mm-dd-yyyy`

By default, Brocade switches and routers do not change the system time for daylight saving time. To enable daylight saving time, enter the following command.

FastIron# clock summer-time

**Syntax:** `clock summer-time`
Although SNTP servers typically deliver the time and date in Greenwich Mean Time (GMT), you can configure the Brocade device to adjust the time for any one-hour offset from GMT or for one of the following U.S. time zones:

- US Pacific
- Alaska
- Aleutian
- Arizona
- Central
- East-Indiana
- Eastern
- Hawaii
- Michigan
- Mountain
- Pacific
- Samoa

To change the time zone to Australian East Coast time (which is normally 10 hours ahead of GMT), enter the following command.

FastIron(config)# clock timezone gmt+10

**Syntax:** clock timezone gmt | us time-zone

You can enter one of the following values for `time-zone`:

- **US time zones (us):** alaska, aleutian, arizona, central, east-indiana, eastern, hawaii, michigan, mountain, pacific, samoa.
- **GMT time zones (gmt):** gmt+0:00 to gmt+12:00 in increments of 1, and gmt-0:00 to gmt-12:00 in decrements of 1 are supported.
- **FGS Release 03.0.00 adds support for the following additional time zones:** gmt+11:30, gmt+10:30, gmt+09:30, gmt+06:30, gmt+05:30, gmt+04:30, gmt+03:30, gmt-03:30, gmt-08:30, gmt-09:30.

**New start and end dates for US daylight saving time**

**NOTE**

This feature applies to US time zones only.

Starting in 2007, the system will automatically change the system clock to Daylight Saving Time (DST), in compliance with the new federally mandated start of daylight saving time, which is extended one month beginning in 2007. The DST will start at 2:00am on the second Sunday in March and will end at 2:00am on the first Sunday in November. The DST feature is automatic, but to trigger the device to the correct time, the device must be configured to the US time zone, not the GMT offset. To configure your device to use the US time zone, enter the following command.

FastIron(config)# clock timezone us pacific

**Syntax:** [no] clock timezone us timezone-type

Enter pacific, eastern, central, or mountain for `timezone-type`. 
This command must be configured on every device that follows the US DST.
To verify the change, run a `show clock` command.

```
FastIron# show clock
```

Refer to October 19, 2006 - Daylight Saving Time 2007 Advisory, posted on kp.foundrynet.com for more information

**Limiting broadcast, multicast, and unknown unicast traffic**

Brocade devices can forward all flooded traffic at wire speed within a VLAN. However, some third-party networking devices cannot handle high rates of broadcast, multicast, or unknown-unicast traffic. If high rates of traffic are being received by the Brocade device on a given port of that VLAN, you can limit the number of broadcast, multicast, or unknown-unicast packets or bytes received each second on that port. This can help to control the number of such packets or bytes that are flooded on the VLAN to other devices.

*Byte-based limiting* for broadcast, multicast, and unknown unicast traffic provides the ability to rate limit traffic based on byte count instead of packet count. When the byte mode is enabled, packets will be received on a port as long as the number of bytes received per second is less than the corresponding limit. Once the limit is reached, further packets will be dropped.

**NOTE**

Byte-based limiting is not supported on FCX, FGS, FLS, FGS-STK, and FLS-STK devices.

FastIron devices support packet-based and byte-based limiting simultaneously on the same port. For example, you can configure the broadcast limit in packet-based mode and the unknown unicast limit in the byte-based mode on the same port. TurboIron devices do not support packet-based and byte-based limiting simultaneously on the same port. For example, if you configure packet-based limiting for broadcast traffic, you must also configure packet-based limiting for multicast and unknown unicast traffic. Likewise, if you configure byte-based limiting for broadcast traffic, you must also configure byte-based limiting for multicast and unknown unicast traffic.

With FastIron devices, unknown unicast limiting is independent of broadcast and multicast limiting. When you enable broadcast limiting, the total number of broadcast packets or bytes received on the port will not exceed the corresponding limit. To also limit multicast packets on FastIron devices, enable limiting after enabling broadcast limiting. In this case, the total number of broadcast and multicast packets or bytes received on the port will not exceed the corresponding limit. With TurboIron devices, broadcast, multicast, and unknown unicast limiting are independent features. Thus, on TurboIron devices, you can configure separate rate limit values for all three types of traffic.

**NOTE**

On FastIron CX devices, if you enable unknown-unicast limiting, the device uses the limit defined in broadcast limiting. You cannot set a separate limit for unknown-unicast limiting.
Configuration considerations

- On FastIron X Series devices, when you configure unknown-unicast limiting, the rate applies to all ports in the port range for which unknown unicast is enabled. A 1-Gbps port range consists of 12 ports. For example, the FESX424 has 2 port ranges; ports 1 – 12 are one port range, and ports 13 – 24 are another port range. If you enable unknown unicast limiting on port 2, the configuration applies to the ports from 1 – 12 that have unknown unicast limiting enabled. 10-Gbps ports are not grouped into ranges. So if your device has two 10-Gbps uplinks, you can configure different unknown-unicast limits for each 10-Gbps port.

- This feature is not supported on trunk ports on TurboIron X Series devices.

Command syntax for packet-based limiting

Platform Support:

- FGS, FWS, and FLS – all software releases
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FastIron X Series – all software releases
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

To enable broadcast limiting on a group of ports by counting the number of packets received, enter commands such as the following.

FastIron(config)# interface ethernet 1 to 8
FastIron(config-mif-e1000-1-8)# broadcast limit 65536

These commands configure packet-based broadcast limiting on ports 1 – 8. On each port, the maximum number of broadcast packets per second cannot exceed 65,536 packets per second.

The commands for a FastIron GS or LS device will be slightly different, using the <stack-unit>/slotnum/portnum nomenclature, as shown here.

FGS624(config)# interface ethernet 0/1/1 to 0/1/8
FGS634(config-mif-e1000-0/1/1-0/1/8)# broadcast limit 65536

The commands for a FastIron GS-STK, and FastIron LS-STK or FCX device operating in a stack will resemble the following.

FastIron(config)# interface ethernet 1/1/1 to 1/1/8
FastIron(config-mif-e1000-1/1/1-1/1/8)# broadcast limit 65536

For FastIron devices, to include multicasts in the 65536 packets per second limit on each of the ports, enter the following command after enabling broadcast limiting.

FastIron(config-mif-e1000-1-8)#multicast limit

On TurboIron devices, multicast limiting is independent of broadcast limiting. To enable multicast limiting on TurboIron devices, enter commands such as the following.

TurboIron 24X(config)# interface ethernet 1 to 8
TurboIron 24X(config-mif-e1000-1-8)# multicast limit 65536

To enable unknown unicast limiting by counting the number of packets received, enter commands such as the following.
Configuring basic system parameters

FastIron(config)# interface eth 1
FastIron(config-if-e1000-1)# unknown-unicast limit 65536
The combined number of inbound Unknown Unicast packets permitted for ports 1 to 12 is now set to 65536
FastIron((config-if-e1000-1)#

Syntax:
[no] broadcast limit <num>

Syntax: [no] unknown-unicast limit <num>

Syntax: [no] multicast limit <num>

NOTE
On FCX, FGS, FLS, FGS-STK, and FLS-STK devices, if you enter the multicast limit or unknown-unicast limit commands, multicast packets and unknown-unicast packets are configured in the corresponding broadcast limit.

NOTE
The multicast limit command applies to FastIron devices only. The multicast limit <num> command applies to TurboIron devices only.

The <num> variable specifies the maximum number of packets per second. Acceptable values differ depending on the device you are configuring:

• On FastIron devices, <num> can be any number that is a multiple of 65536, up to a maximum value of 2147418112. If you enter the multicast limit command, multicast packets are included in the corresponding limit. If you specify 0, limiting is disabled. If you specify a number that is not a multiple of 65536, the software rounds the number to the next multiple of 65536. Limiting is disabled by default.

• On TurboIron devices, <num> can be any number between 1 and 8388607 (packets per second). The actual value will be determined by the system. Once you enter the value, the CLI will display a message indicating the actual value. The following shows an example configuration.

TurboIron(config)# interface ethernet 9
TurboIron(config-mif-e1000-9)# multicast limit 50
Multicast limit in pkts/sec set to 31

If you specify 0, limiting is disabled. Limiting is disabled by default.

Command syntax for byte-based limiting

Platform Support:
• FastIron X Series devices running software release 04.0.00 and later – L2, BL3, L3
• TurboIron X Series devices running software release 04.1.00 and later

FastIron devices can limit traffic based on bytes per second, whereas TurboIron devices limit traffic based on kilobits per second (kbps). To enable limiting, refer to the appropriate section, below.

FastIron devices
To enable broadcast limiting on a group of ports by counting the number of bytes received, enter commands such as the following.
Configuring basic system parameters

FastIron(config)# interface ethernet 9 to 10
FastIron(config-mif-e1000-9-10)# broadcast limit 131072 bytes

These commands configure byte-based broadcast limiting on ports 9 and 10. On each port, the total number of bytes received from broadcast packets cannot exceed 131,072 per second.

To include multicasts in the 131072 bytes per second limit on each of the ports, enter the following command after enabling broadcast limiting.

FastIron(config-mif-e1000-1-8)# multicast limit

To enable unknown unicast limiting, enter commands such as the following.

FastIron# config terminal
FastIron(config)# int e 13
FastIron(config-if-e1000-13)# unknown-unicast limit 65536 bytes

The combined number of bytes of inbound Unknown Unicast packets permitted for ports 13 to 24 is now set to 65536

Syntax: [no] broadcast limit num bytes

Syntax: [no] multicast limit

Syntax: [no] unknown-unicast limit num bytes

The num variable can be any number that is a multiple of 65536, up to a maximum value of 2147418112. If you enter the multicast limit command, multicast packets are included in the limit you specify. If you specify 0, limiting is disabled. If you specify a number that is not a multiple of 65536, the software rounds the number to the next multiple of 65536. Limiting is disabled by default.

TurboIron devices

To enable broadcast limiting on a group of ports by counting the number of kilobits received, enter commands such as the following.

TurboIron 24X(config)# interface ethernet 9 to 10
TurboIron 24X(config-mif-e1000-9-10)# broadcast limit 131072 kbps
Broadcast limit in kbits/sec set to 130000

These commands configure broadcast limiting on ports 9 and 10. On each port, the total number of kilobits received from broadcast packets cannot exceed 130,000 per second.

To enable multicast limiting, enter commands such as the following.

TurboIron 24X(config)# interface ethernet 8
TurboIron 24X(config-mif-e1000-1-8)# multicast limit 9000 kbps
Multicast limit in kbits/sec set to 8064

To enable unknown unicast limiting, enter commands such as the following.

TurboIron 24X(config)# int e 13
TurboIron 24X(config-if-e1000-13)# unknown-unicast limit 65536 kbps
Unknown unicast limit in kbits/sec set to 64000

Syntax: [no] broadcast limit num kbps

Syntax: [no] multicast limit num kbps

Syntax: [no] unknown-unicast limit num kbps
The `num` variable can be any number between 1 and 10000000. The actual value will be determined by the system. Once you enter the value, the CLI will display a message indicating the actual value, as shown in the configuration examples above. If you specify 0, limiting is disabled. Limiting is disabled by default.

### Viewing broadcast, multicast, and unknown unicast limits

You can use the `show run interface` command to display the broadcast, multicast, and unknown-unicast limits configured on the device.

Starting in software release FSX 04.2.00, you can use the following commands, in addition to the `show run interface` command, to display the broadcast, multicast, and unknown-unicast limits configured on the device:

- `show rate-limit unknown-unicast`
- `show rate-limit broadcast`

Use the `show run interface` command to view the broadcast, multicast, and unknown-unicast limit configured on each port.

```
FastIron# show run interface
interface ethernet 4
broadcast limit 1245184 bytes
multicast limit
!
interface ethernet 5
broadcast limit 1245184 bytes
multicast limit
!
interface ethernet 12
unknown-unicast limit 524288
!
interface ethernet 13
unknown-unicast limit 65536 bytes
!
interface ethernet 14
broadcast limit 65536
!
interface ethernet 23
broadcast limit 131072
multicast limit
!
```

**Syntax:** `show run interface`

Use the `show rate-limit unknown-unicast` command to display the unknown unicast limit for each port region to which it applies.

```
FastIron# show rate-limit unknown-unicast
Unknown Unicast Limit Settings:
Port Region Combined Limit Packets/Bytes
  1 - 12          524288       Packets
  13 - 24         65536        Bytes
```

**Syntax:** `show rate-limit unknown-unicast`
Use the `show rate-limit broadcast` command to display the broadcast limit or broadcast and multicast limit for each port to which it applies.

```
FastIron# show rate-limit broadcast
Broadcast/Multicast Limit Settings:
  Port    Limit   Packets/Bytes   Packet Type(s)
  4     1245184   Bytes   Broadcast + Multicast
  5     1245184   Bytes   Broadcast + Multicast
 14      65536   Packets   Broadcast only
 23     131072   Packets   Broadcast + Multicast
```

Syntax: `show rate-limit broadcast`

**Configuring CLI banners**

Brocade devices can be configured to display a greeting message on users’ terminals when they enter the Privileged EXEC CLI level or access the device through Telnet. In addition, a Brocade device can display a message on the Console when an incoming Telnet CLI session is detected.

**Setting a message of the day banner**

You can configure the Brocade device to display a message on a user terminal when he or she establishes a Telnet CLI session. For example, to display the message “Welcome to FESX!” when a Telnet CLI session is established.

```
FastIron(config)# banner motd $
(Press Return)
Enter TEXT message, End with the character '$'.
Welcome to FESX! $
```

A delimiting character is established on the first line of the `banner motd` command. You begin and end the message with this delimiting character. The delimiting character can be any character except “ (double-quotation mark) and cannot appear in the banner text. In this example, the delimiting character is $ (dollar sign). The text in between the dollar signs is the contents of the banner. FastIron X Series devices running software release FSX 04.2.00 or later support banner text of up to 4000 characters long, which can consist of multiple lines. FGS, FLS, FGS-STK, FLS-STK, FWS, and FCX devices also support up to 4000 characters. TurboIron X Series and FastIron X Series devices running a software release prior to FSX 04.2.00 support up to 2048 characters, which can consist of multiple lines.

Syntax: `[no] banner motd delimiting-character | banner motd delimiting-character`

To remove the banner, enter the `no banner motd` command.

**NOTE**
The `banner delimiting-character` command is equivalent to the `banner motd delimiting-character` command.

When you access the Web Management Interface, the banner is displayed.
NOTE
If you are using a Web client to view the message of the day, and your banners are very wide, with large borders, you may need to set your PC display resolution to a number greater than the width of your banner. For example, if your banner is 100 characters wide and the display is set to 80 characters, the banner may distort, or wrap, and be difficult to read. If you set your display resolution to 120 characters, the banner will display correctly.

Requiring users to press the Enter key after the message of the day banner

In releases prior to 03.0.01a for FastIron X Series devices, users were required to press the Enter key after the Message of the Day (MOTD) was displayed, prior to logging in to the Brocade device on a console or from a Telnet session. Beginning with release 03.0.01a, this requirement is disabled by default. Unless configured, users do not have to press Enter after the MOTD banner is displayed.

For example, if the MOTD "Authorized Access Only" is configured, by default, the following messages are displayed when a user access the Brocade device from a Telnet session.

```
Authorized Access Only ...
Username:
```

The user can then login to the device.

However, if the requirement to press the Enter key is enabled, the following messages are displayed when accessing the switch from Telnet.

```
Authorized Access Only ...
Press <Enter> to accept and continue the login process....
```

The user must press the Enter key before the login prompt is displayed.

Also, on the console, the following messages are displayed if the requirement to press the Enter key is disabled.

```
Press Enter key to login
Authorized Access Only ...
User Access Verification
Please Enter Login Name:
```

However, if the requirement to press the Enter key after a MOTD is enabled, the following messages are displayed when accessing the switch on the console.

```
Press Enter key to login
Authorized Access Only ...
Press <Enter> to accept and continue the login process....
```

The user must press the Enter key to continue to the login prompt.
To enable the requirement to press the **Enter key** after the MOTD is displayed, enter a command such as the following.

```
FastIron(config)# banner motd require-enter-key
```

**Syntax:** `[no] banner motd require-enter-key`

Use the **no** form of the command to disable the requirement.

**Setting a privileged EXEC CLI level banner**

You can configure the Brocade device to display a message when a user enters the Privileged EXEC CLI level.

```
FastIron(config)# banner exec_mode # (Press Return)
Enter TEXT message, End with the character '#'.
You are entering Privileged EXEC level
Do not foul anything up! #
```

As with the **banner motd** command, you begin and end the message with a delimiting character; in this example, the delimiting character is `#`(pound sign). The delimiting character can be any character except " (double-quotation mark) and cannot appear in the banner text. The text in between the pound signs is the contents of the banner. Fastiron X Series devices running software release FSX 04.2.00 or later support banner text of up to 4000 characters, which can consist of multiple lines. FGS, FLS, FWS, FGS-STK, FLS-STK, and FCX devices, TurboIron X Series devices, as well as Fastiron X Series devices running a software release prior to FSX 04.2.00 support up to 2048 characters, which can consist of multiple lines.

**Syntax:** `[no] banner exec_mode delimiting-character`

To remove the banner, enter the **no banner exec_mode** command.

**Displaying a console message when an incoming Telnet session is detected**

You can configure the Brocade device to display a message on the Console when a user establishes a Telnet session. This message indicates where the user is connecting from and displays a configurable text message.

```
FastIron(config)# banner incoming $ (Press Return)
Enter TEXT message, End with the character '}'.
Incoming Telnet Session!! $
```

When a user connects to the CLI using Telnet, the following message appears on the Console.

```
Telnet from 209.157.22.63
Incoming Telnet Session!!
```

As with the **banner motd** command, you begin and end the message with a delimiting character; in this example, the delimiting character is `$`(dollar sign). The delimiting character can be any character except " (double-quotation mark) and cannot appear in the banner text. The text in between the dollar signs is the contents of the banner. Fastiron X Series devices running software release FSX 04.2.00 or later support banner text of up to 4000 characters, which can consist of multiple lines. FGS, FLS, FWS, FGS-STK, FLS-STK, and FCX devices, Turboiron X Series devices, as well as Fastiron X Series devices running a software release prior to FSX 04.2.00, support up to 2048 characters, which can consist of multiple lines.

**Syntax:** `[no] banner incoming delimiting-character`

To remove the banner, enter the **no banner incoming** command.
Configuring basic port parameters

The procedures in this section describe how to configure the port parameters shown in Table 29.

### TABLE 29 Basic port parameters

<table>
<thead>
<tr>
<th>Port parameter</th>
<th>See page</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>page 56</td>
</tr>
<tr>
<td>Speed</td>
<td>page 56</td>
</tr>
<tr>
<td>Auto-negotiation maximum port speed advertisement and down-shift</td>
<td>page 58</td>
</tr>
<tr>

<td>page 74</td>
</tr>
</tbody>
</table>

All Brocade ports are pre-configured with default values that allow the device to be fully operational at initial startup without any additional configuration. However, in some cases, changes to the port parameters may be necessary to adjust to attached devices or other network requirements.

### Assigning a port name

A port name can be assigned to help identify interfaces on the network. You can assign a port name to physical ports, virtual interfaces, and loopback interfaces.

To assign a name to a port.

```
FastIron(config)# interface e 2
FastIron(config-if-e1000-2)# port-name Marsha
```

#### Syntax: `port-name text`

The `text` parameter is an alphanumeric string. The name can be up to 64 characters long. The name can contain blanks. You do not need to use quotation marks around the string, even when it contains blanks.

### Modifying port speed and duplex mode

This section describes how to modify port speed and duplex mode on FastIron and TurboIron devices.
Copper ports

The Gigabit Ethernet copper ports are designed to auto-sense and auto-negotiate the speed and duplex mode of the connected device. If the attached device does not support this operation, you can manually enter the port speed to operate at either 10, 100, or 1000 Mbps. The default and recommended setting is 10/100/1000 auto-sense.

**NOTE**

On FastIron devices, you can modify the port speed of copper ports only; this feature does not apply to fiber ports. On TurboIron devices, you can modify the port speed of copper ports and the 24 fiber ports.

**NOTE**

For optimal link operation, copper ports on devices that do not support 803.3u must be configured with like parameters, such as speed (10, 100, 1000), duplex (half, full), MDI/MDIX, and Flow Control.

Fiber ports on the TurboIron

The fiber ports on the TurboIron support 1 GbE and 10 GbE connections, depending on the SFP optic installed in the port. SFP+ optics are used for 10 GbE fiber connections, and SFP optics are used for 1 GbE fiber connections. The default setting is 10 GbE full-duplex mode with SFP+ optics. To use 1 GbE in a 10 GbE port, insert an SFP optic and change the speed-duplex to 1 GbE (speed-duplex 1000).

Configuration syntax

The following commands change the port speed of copper interface 8 on a FastIron from the default of 10/100/1000 auto-sense, to 100 Mbps operating in full-duplex mode.

```bash
FastIron(config)# interface e 8
FastIron(config-if-e1000-8)# speed-duplex 100-full
```

The following commands change the port speed of fiber interface 8 on a TurboIron from the default of 10 Gbps to 1 Gbps.

```bash
TurboIron 24X(config)# interface e 8
TurboIron 24X(config-if-e10000-8)# speed-duplex 1000
```

**Syntax:** `speed-duplex value`

where `value` can be one of the following:

- 10-full – 10 Mbps, full duplex
- 10-half – 10 Mbps, half duplex
- 100-full – 100 Mbps, full duplex
- 100-half – 100 Mbps, half duplex
- 1000 – 1 Gbps, full duplex (supported on TurboIron X Series 10-GbE ports only)
- 1000-full-master – 1 Gbps, full duplex master (not supported on the TurboIron X Series)
- 1000-full-slave – 1 Gbps, full duplex slave (not supported on the TurboIron X Series)
- 10000 – 10 Gbps, full duplex (supported on TurboIron X Series 10-GbE ports only)
- auto – auto-negotiation
The default for copper ports is **auto** (auto-negotiation).

The default for fiber ports on the TurboIron X Series is **10000** (10 Gbps, full duplex).

Use the **no** form of the command to restore the default.

**NOTE**

On FastIron devices, when setting the speed and duplex-mode of an interface to **1000-full** (1000 full duplex), configure one side of the link as master (1000-full-master) and the other side as slave (1000-full-slave).

On TurboIron X Series devices, when **10/100/1000** copper ports (ports 25 – 28) auto-negotiate to either 1 Gbps or 100 Mbps, the green and amber LEDs will be lit solid (ON) when the link is up, and the amber LED will blink when traffic flows through the port. On TurboIron X Series devices running software release **04.2.00** and later, if the speed is set to Auto for a 1G port, the port auto-negotiates the flow control with the neighboring port.

**Auto speed detect**

**Platform Support:**

- TurboIron X Series devices running software release **04.2.00** and later

On TurboIron X Series devices running software release **04.2.00** and later, if you insert a 1G SFP, the device detects the media change and automatically change the speed to support 1G for that port. This happens when the configured speed is 10G. The configured speed continues to be 10G, but the port comes up with operational speed of 1G. This removes the need for explicitly configuring **speed-duplex 1000** for SFPs where the device is able to detect the media type.

**NOTE**

All the ports with 1G SFPs which need to form a trunk (static or dynamic), need to use either the Auto speed detect feature to come up in 1G mode or use the **speed-duplex 1000** command. Configuring **speed-duplex 1000** on only few of the ports to be part of the trunk will prevent trunk creation.

**Enabling auto-negotiation maximum port speed advertisement and down-shift**

**Platform Support:**

- FastIron X Series devices running software release **2.3.01** and later
- FGS and FLS devices running software release **02.5.00** and later
- FGS-STK and FLS-STK devices running software release **05.0.00** and later
- FWS devices running software release **04.3.00** or later

**NOTE**

This feature is not supported on TurboIron X Series devices.

**NOTE**

For optimal link operation, link ports on devices that do not support 803.3u must be configured with like parameters, such as speed (10, 100, 1000), duplex (half, full), MDI/MDIX, and Flow Control.
Maximum Port speed advertisement and Port speed down-shift are enhancements to the auto-negotiation feature, a mechanism for accommodating multi-speed network devices by automatically configuring the highest performance mode of inter-operation between two connected devices.

Port speed down-shift enables Gbps copper ports on the Brocade device to establish a link at 1000 Mbps over a 4-pair wire when possible, or to down-shift to 100 Mbps if the medium is a 2-pair wire.

Maximum port speed advertisement enables you to configure an auto-negotiation maximum speed that Gbps copper ports on the Brocade device will advertise to the connected device. You can configure a port to advertise a maximum speed of either 100 Mbps or 10 Mbps. When the maximum port speed advertisement feature is configured on a port that is operating at 100 Mbps maximum speed, the port will advertise 10/100 Mbps capability to the connected device. Similarly, if a port is configured at 10 Mbps maximum speed, the port will advertise 10 Mbps capability to the connected device.

The port speed down-shift and maximum port speed advertisement features operate dynamically at the physical link layer between two connected network devices. They examine the cabling conditions and the physical capabilities of the remote link, then configure the speed of the link segment according to the highest physical-layer technology that both devices can accommodate.

The port speed down-shift and maximum port speed advertisement features operate dynamically at the physical link layer, independent of logical trunk group configurations. Although Brocade recommends that you use the same cable types and auto-negotiation configuration on all members of a trunk group, you could utilize the auto-negotiation features conducive to your cabling environment. For example, in certain circumstances, you could configure each port in a trunk group to have its own auto-negotiation maximum port speed advertisement or port speed down-shift configuration.

Application notes

- Port speed down-shift and maximum port speed advertisement work only when auto-negotiation is enabled (CLI command speed-duplex auto). If auto-negotiation is OFF, the device will reject the port speed down-shift and maximum port speed advertisement configuration.
- When port speed down-shift or maximum port speed advertisement is enabled on a port, the device will reject any configuration attempts to set the port to a forced speed mode (100 Mbps or 1000 Mbps).
- When the port speed down-shift feature is enabled on a combo port, the port will not support true media automatic detection, meaning the device will not be able to detect and select the fiber or copper connector based on link availability.

Enabling port speed down-shift

Platform Support:

- FastIron X Series devices running software release 04.0.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later

To enable port speed down-shift on a port that has auto-negotiation enabled, enter a command such as the following at the Global CONFIG level of the CLI.
Configuring basic port parameters

FastIron(config)# link-config gig copper autoneg-control down-shift e 1 e 2

The above command configures Gbps copper ports 1 and 2 to establish a link at 1000 Mbps over a 4-pair wire when possible, or to down-shift (reduce the speed) to 100 Mbps when the medium is a 2-pair wire.

Syntax: [no] link-config gig copper autoneg-control down-shift ethernet

[stack-unit/slotnum/portnum] | ethernet [stack-unit/slotnum/portnum]

The slotnum parameter is required on chassis devices and on FastIron GS devices.

The portnum parameter is a valid port number.

You can enable port speed down-shift on one or two ports at a time.

To disable port speed down-shift after it has been enabled, enter the no form of the command.

Configuring port speed down-shift and auto-negotiation for a range of ports

Port speed down-shift and auto-negotiation can be configured for an entire range of ports with a single command.

For example, to configure down-shift on ports 0/1/1 to 0/1/10 and 0/1/15 to 0/1/20 on the device, enter the following.

FastIron(config)# link-config gig copper autoneg-control down-shift ethe 0/1/1 to 0/1/10 ethe 0/1/15 to 0/1/20

To configure down-shift on ports 5 to 13 and 17 to 19 on a compact switch, enter the following.

FastIron(config)# link-config gig copper autoneg-control down-shift ethe 5 to 13 ethe 17 to 19

Syntax: [no] link-config gig copper autoneg-control | down-shift | 100m-auto | 10m-auto port-list

The port-list is the list of ports to which the command will be applied.

For port-list, specify the ports in one of the following formats:

- FastIron chassis devices – slotnum/portnum
- FESX, and FWSX compact switches – portnum

You can list all of the ports individually, use the keyword to to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword all instead of listing the ports individually.

The output from the show run command for this configuration will resemble the following.
To disable selective auto-negotiation of 100m-auto on ports 0/1/21 to 0/1/25 and 0/1/30, enter the following.

```
FastIron(config)# no link-config gig copper autoneg-control 100m-auto ethe 0/1/21 to 0/1/25 ethe 0/1/30
```

**NOTE**
This feature works with Layer 2 and Layer 3 images.

### Configuring maximum port speed advertisement

To configure a maximum port speed advertisement of 10 Mbps on a port that has auto-negotiation enabled, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)# link-config gig copper autoneg-control 10m e 1
```

To configure a maximum port speed advertisement of 100 Mbps on a port that has auto-negotiation enabled, enter the following command at the Global CONFIG level of the CLI.

```
FastIron(config)# link-config gig copper autoneg-control 100m-auto ethe 0/1/21 to 0/1/25 ethe 0/1/30
```

**Syntax:**

```
[no] link-config gig copper autoneg-control 10m | 100m ethernet [stack-unit/slotnum/] portnum> [ethernet [stack-unit/slotnum/] portnum]
```

The **slotnum** parameter is required on chassis devices and on FastIron GS devices.

The **portnum** parameter is a valid port number.

You can enable maximum port speed advertisement on one or two ports at a time.

To disable maximum port speed advertisement after it has been enabled, enter the **no** form of the command.

### Modifying port duplex mode

You can manually configure a 10/100 Mbps port to accept either full-duplex (bi-directional) or half-duplex (uni-directional) traffic.
NOTE
You can modify the port duplex mode of copper ports only. This feature does not apply to fiber ports.

Port duplex mode and port speed are modified by the same command.

**Configuration syntax**

To change the port speed of interface 8 from the default of 10/100/1000 auto-sense to 10 Mbps operating at full-duplex, enter the following.

```
FastIron(config)# interface e 8
FastIron(config-if-e1000-8)# speed-duplex 10-full
```

**Syntax:** `speed-duplex value`

The `value` can be one of the following:

- 10-full
- 10-half
- 100-full
- 100-half
- auto (default)

**Configuring MDI/MDIX**

**NOTE**
This feature is not supported on TurboIron devices.

Brocade devices support automatic Media Dependent Interface (MDI) and Media Dependent Interface Crossover (MDIX) detection on all Gbps Ethernet Copper ports.

MDI/MDIX is a type of Ethernet port connection using twisted pair cabling. The standard wiring for end stations is MDI, whereas the standard wiring for hubs and switches is MDIX. MDI ports connect to MDIX ports using straight-through twisted pair cabling. For example, an end station connected to a hub or a switch uses a straight-through cable. MDI-to-MDI and MDIX-to-MDIX connections use crossover twisted pair cabling. So, two end stations connected to each other, or two hubs or switches connected to each other, use crossover cable.

The auto MDI/MDIX detection feature can automatically correct errors in cable selection, making the distinction between a straight-through cable and a crossover cable insignificant.

**Configuration notes**

- This feature applies to copper ports only.
- The `mdi-mdix auto` command works only when auto-negotiation is ON. If auto-negotiation is OFF and you enter the command `mdi-mdix auto`, the device automatically resets the port to an MDIX only port. In this case, although the Brocade device does not apply the `mdi-mdix auto` configuration, it accepts and saves it. Consequently, when auto-negotiation is turned back ON, the Brocade device applies the `mdi-mdix auto` configuration.
- The `mdi-mdix mdi` and `mdi-mdix mdix` commands work independently of auto-negotiation. Thus, these commands work whether auto-negotiation is turned ON or OFF.
Do not use the `mdi-mdix` commands on ports that are manually configured with a speed/duplex of 100-full. In this case, make sure the other port (remote end of the connection) is also configured to 100-full and a cross-over cable is used if the connected device is another switch, hub, or router, or a straight-through cable if the connected device is a host NIC.

**Configuration syntax**

The auto MDI/MDIX detection feature is enabled on all Gbps copper ports by default. For each port, you can disable auto MDI/MDIX, designate the port as an MDI port, or designate the port as an MDIX port.

To turn off automatic MDI/MDIX detection and define a port as an MDI only port.

```
FastIron(config-if-e1000-2)# mdi-mdix mdi
```

To turn off automatic MDI/MDIX detection and define a port as an MDIX only port.

```
FastIron(config-if-e1000-2)# mdi-mdix mdix
```

To turn on automatic MDI/MDIX detection on a port that was previously set as an MDI or MDIX port.

```
FastIron(config-if-e1000-2)# mdi-mdix auto
```

Syntax: `mdi-mdix <mdi | mdix | auto`

After you enter the `mdi-mdix` command, the Brocade device resets the port and applies the change.

To display the MDI/MDIX settings, including the configured value and the actual resolved setting (for `mdi-mdix auto`), enter the command `show interface` at any level of the CLI.

**Disabling or re-enabling a port**

A port can be made inactive (disable) or active (enable) by selecting the appropriate status option. The default value for a port is enabled.

To disable port 8 of a Brocade device, enter the following.

```
FastIron(config)# interface e 8
FastIron(config-if-e1000-8)# disable
```

Syntax: `disable`

You also can disable or re-enable a virtual interface. To do so, enter commands such as the following.

```
FastIron(config)# interface ve v1
FastIron(config-vif-1)# disable
```

Syntax: `disable`

To re-enable a virtual interface, enter the `enable` command at the Interface configuration level. For example, to re-enable virtual interface v1, enter the following command.

```
FastIron(config-vif-1)#enable
```

Syntax: `enable`
Disabling or re-enabling flow control

You can configure full-duplex ports on a system to operate with or without flow control (802.3x). Flow control is enabled by default.

To disable flow control on full-duplex ports on a system, enter the following.

FastIron(config)# no flow-control

To turn the feature back on.

FastIron(config)# flow-control

Syntax:  [no] flow-control

NOTE
For optimal link operation, link ports on devices that do not support 803.3u must be configured with like parameters, such as speed (10,100,1000), duplex (half, full), MDI/MDIX, and Flow Control.

Auto-negotiation and advertisement of flow control

Platform Support:

- FastIron X Series devices running software release 03.2.00 and later
- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later

Auto-negotiation of flow control can be enabled and advertised for 10/100/1000M ports. To enable and advertise flow control capability, enter the following commands.

FastIron(config)# interface ethernet 0/1/21
FastIron(config-if-e1000-0/1/21)# flow-control

To also enable auto-negotiation of flow control, enter the following commands.

FastIron(config)# interface ethernet 0/1/21
FastIron(config-if-e1000-0/1/21)# flow-control neg-on

Syntax:  #[no] flow-control [neg-on]

- flow-control [default] - Enable flow control, advertise flow control and disable negotiation of flow control
- flow-control neg-on - Advertise flow control and enable negotiation of flow control
- no flow-control - Disable flow control, disable advertising flow control and also disable negotiation of flow control

Commands may be entered in IF (single port) or MIF (multiple ports at once) mode.

FastIron(config)# interface ethernet 0/1/21
FastIron(config-if-e1000-0/1/21)# flow-control

This command enables flow-control on port 0/1/21.

FastIron(config)# interface e 0/1/11 to 0/1/15
FastIron(config-mif-0/1/11-0/1/15)# flow-control

This command enables flow-control on ports 0/1/11 to 0/1/15.
Asynchronous flow control

The TurboIron X Series devices running software release 04.2.00 and later supports asynchronous flow control. By default, PAUSE frames are honored when you stop or start sending traffic to a switch when another switch sends a PAUSE frame.

Flow control supports honor-only mode and generate-only mode. Honor-only is the default mode. To change the default mode to generate-only mode use the `flow-control generate-only` command.

To set the mode to support both honor and generate modes use the `flow-control both` command. To set the mode to default, use the `flow-control honor-only` command.

Displaying flow-control status

The `show interface port` command displays configuration, operation, and negotiation status where applicable.

For example, on a device running the FGS software release 03.0.00 and later, issuing the command for 10/100/1000M port 0/1/21 displays the following output.

```
FastIron# show interfaces ethernet 0/1/21
GigabitEthernet0/1/21 is up, line protocol is up
Hardware is GigabitEthernet, address is 00e0.5204.4014 (bia 00e0.5204.4014)
Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
Configured mdi mode AUTO, actual MDIX
Member of 0 L2 VLANs, port is untagged, port state is LISTENING
BPDU Guard is disabled, Root Protect is disabled
STP configured to ON, priority is level0
Flow Control is config enabled, oper enabled, negotiation disabled
Mirror disabled, Monitor disabled
No port name
Inter-Packet Gap (IPG) is 96 bit times
300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
300 second output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 multicasts, 0 unicasts
0 input errors, 0 CRC, 0 frame, 0 ignored
0 runts, 0 giants
5 packets output, 320 bytes, 0 underruns
Transmitted 0 broadcasts, 5 multicasts, 0 unicasts
0 output errors, 0 collisions
```

Issuing the command on a device running the FSX software release 03.2.00 and later displays the following output.

```
FastIron# show interface ethernet 18/1
GigabitEthernet18/1 is up, line protocol is up
Hardware is GigabitEthernet, address is 0012.f228.0600 (bia 0012.f228.0798)
Configured speed auto, actual 1Gbit, configured duplex fdx, actual fdx
Configured mdi mode AUTO, actual MDIX
Member of 4 L2 VLANs, port is tagged, port state is FORWARDING
BPDU guard is Disabled, ROOT protect is Disabled
Link Error Dampening is Disabled
STP configured to ON, priority is level0, flow control enabled
Flow Control is config enabled, oper enabled, negotiation disabled
Mirror disabled, Monitor disabled
Not member of any active trunks
```
Configuring basic port parameters

Not member of any configured trunks
No port name
IPG MII 96 bits-time, IPG GMII 96 bits-time
IP MTU 1500 bytes, encapsulation ethernet
300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
300 second output rate: 848 bits/sec, 0 packets/sec, 0.00% utilization
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 multicasts, 0 unicasts
0 input errors, 0 CRC, 0 frame, 0 ignored
0 runts, 0 giants
10251 packets output, 1526444 bytes, 0 underruns
Transmitted 1929 broadcasts, 8293 multicasts, 29 unicasts
0 output errors, 0 collisions

The line highlighted in bold will resemble one of the following, depending on the configuration:

- If flow control and auto-negotiation are enabled (and a neighbor does not negotiate flow control), the display shows:
  
  Flow Control is config enabled, oper disabled, negotiation enabled

- If flow control is enabled, and auto-negotiation is disabled, the output shows.

  Flow Control is config enabled, oper enabled, negotiation disabled

- If flow control is disabled, the display shows.

  Flow Control is config disabled, oper disabled

**NOTE**

For 10 Gbps ports, the display shows Flow Control is enabled, or Flow Control is disabled, depending on the configuration.

**NOTE**

Auto-negotiation of flow control is not supported on 10 Gbps ports and copper/fiber combination ports.

**NOTE**

When any of the commands are applied to a port that is up, the port will be disabled and re-enabled.

**NOTE**

When flow-control is enabled, the hardware can only advertise Pause. It does not advertise Asym.

### Configuring PHY FIFO Rx and Tx depth

**Platform Support:**

- FGS and FLS devices running software release 03.1.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later

FGS Release 03.1.00 adds a new command to increase the FIFO (First In, First Out) depth to adjust for clock differences between connecting devices, if necessary.
PHY devices on FGS, FLS, FWS, FGS-STK, FLS-STK, and FCX devices contain transmit and receive synchronizing FIFOs to adjust for frequency differences between clocks. The `phy-fifo-depth` command allows you to configure the depth of the transmit and receive FIFOs. There are 4 settings (0-3) with 0 as the default. A higher setting indicates a deeper FIFO.

The default setting works for most connections. However, if the clock differences are greater than the default will handle, CRCs and errors will begin to appear on the ports. Raising the FIFO depth setting will adjust for clock differences.

Brocade recommends that you disable the port before applying this command, and re-enable the port. Applying the command while traffic is flowing through the port can cause CRC and other errors for any packets that are actually passing through the PHY while the command is being applied.

**Syntax:**

```
[no] phy-fifo-depth setting
```

- `setting` is a value between 0 and 3. (0 is the default.)

This command can be issued for a single port from the IF config mode or for multiple ports from the MIF config mode.

**NOTE**

Higher settings give better tolerance for clock differences with the partner phy, but may marginally increase latency as well.

---

### Configuring the Interpacket Gap (IPG)

**Platform Support:**

- FastIron X Series devices running software release 03.0.00 and later
- FGS and FLS devices running software release 03.0.00 and later (refer to “Configuring IPG on FGS, FWS, FLS, FGS-STK and FLS-STK, and FCX devices” on page 68)
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- Turbolron X Series devices running software release 04.1.00 and later
- FastIron GS-STK and FastIron LS-STK devices running software version 05.0.00 and later
- FCX-S devices running software release 06.0.00 and later

IPG is the time delay, in bit time, between frames transmitted by the device. You configure IPG at the interface level. The command you use depends on the interface type on which IPG is being configured.

The default interpacket gap is 96 bits-time, which is 9.6 microseconds for 10 Mbps Ethernet, 960 nanoseconds for 100 Mbps Ethernet, 96 nanoseconds for 1 Gbps Ethernet, and 9.6 nanoseconds for 10 Gbps Ethernet.

**Configuration notes**

- When configuring IPG on a FastIron switch, note the following:

  IPG configuration commands are based on "port regions". All ports within the same port region should have the same IPG configuration. If a port region contains two or more ports, changes to the IPG configuration for one port are applied to all ports in the same port region. When you enter a value for IPG, the CLI displays the ports to which the IPG configuration is applied.
Configuring basic port parameters

```
FastIron(config-if-e1000-7/1)# ipg-gmii 120
IPG 120(120) has been successfully configured for ports 7/1 to 7/12
```

- When you enter a value for IPG, the device applies the closest valid IPG value for the port mode to the interface. For example, if you specify 120 for a 1 Gbps Ethernet port in 1 Gbps mode, the device assigns 112 as the closest valid IPG value to program into hardware.

### Configuring IPG on a Gbps Ethernet port

On a Gbps Ethernet port, you can configure IPG for 10/100 mode and for Gbps Ethernet mode.

**10/100M mode**

To configure IPG on a Gbps Ethernet port for 10/100M mode, enter the following command.

```
FastIron(config)# interface ethernet 7/1
FastIron(config-if-e1000-7/1)# ipg-mii 120
IPG 120(120) has been successfully configured for ports 7/1 to 7/12
```

**Syntax:** `[no] ipg-mii <bit time>`

Enter 12-124 for `<bit time>`. The default is 96 bit time.

**1G mode**

To configure IPG on a Gbps Ethernet port for 1-Gbps Ethernet mode, enter commands such as the following.

```
FastIron(config)# interface ethernet 7/1
FastIron(config-if-e1000-7/1)# ipg-mii 120
IPG 120(112) has been successfully configured for ports 0/7/1 to 7/12
```

**Syntax:** `[no] ipg-gmii <bit time>`

Enter 48 - 112 for `<bit time>`. The default is 96 bit time.

### Configuring IPG on a 10 Gbps Ethernet interface

To configure IPG on a 10 Gbps Ethernet interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 9/1
FastIron(config-if-e10000-9/1)# ipg-xgmii 120
IPG 120(128) has been successfully configured for port 9/1
```

**Syntax:** `[no] ipg-xgimi <bit time>`

Enter 96-192 for `<bit time>`. The default is 96 bit time.

### Configuring IPG on FGS, FWS, FLS, FGS-STK and FLS-STK, and FCX devices

**Platform Support:**
- FGS and FLS devices running software release 03.0.00
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later

On FGS, FLS, FWS, FGS-STK, FLS-STK, and FCX devices, you can configure an IPG for each port. An IPG is a configurable time delay between successive data packets.
You can configure an IPG with a range from 48-120 bit times in multiples of 8, with a default of 96. The IPG may be set from either the interface configuration level or the multiple interface level.

When an IPG is applied to a trunk group, it applies to all ports in the trunk group. When you are creating a new trunk group, the IPG setting on the primary port is automatically applied to the secondary ports.

**Syntax:** [no] ipg value

To configure an IPG of 112 on Ethernet interface 0/1/21, for example, enter the following command.

```plaintext
FGS624P Switch(config)# interface ethernet 0/1/21
FGS624P Switch(config-if-e1000-0/1/21)# ipg 112
```

or, for multiple interface levels, to configure IPG for ports 0/1/11 and 0/1/14 through 0/1/17, enter the following commands.

```plaintext
FGS624P Switch(config)# interface ethernet 0/1/11 e 0/1/14 to 0/1/17
FGS624P Switch(config-mif-0/1/11,0/1/14-0/1/17)# ipg 104
```

As a result of this configuration, the output from the show interface e 0/1/21 command is.

```plaintext
FGS624P Switch# show interfaces ethernet 0/1/21
GigabitEthernet 0/1/21 is up, line protocol is up
Hardware is GigabitEthernet, address is 00e0.5204.4014 (bia 00e0.5204.4014)
Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
Configured mdi mode AUTO, actual MDIX
Member of L2 VLAN ID 1, port is untagged, port state is FORWARDING
BPDGU Guard is disabled, Root Protect is disabled
STP configured to ON, priority is level0
Flow Control is config enabled, oper enabled, negotiation disabled
Mirror disabled, Monitor disabled
Not member of any active trunks
Not member of any configured trunks
No port name
Inter-Packet Gap (IPG) is 112 bit times
IP MTU 10222 bytes
300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
300 second output rate: 248 bits/sec, 0 packets/sec, 0.00% utilization
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 multicasts, 0 unicasts
0 input errors, 0 CRC, 0 frame, 0 ignored
0 runts, 0 giants
80 packets output, 5120 bytes, 0 underruns
Transmitted 0 broadcasts, 80 multicasts, 0 unicasts
0 output errors, 0 collisions
```

This feature is supported on 10/100/1000M ports.

### Enabling and disabling support for 100BaseTX

**Platform Support:**

- FastIron X Series compact switches running software release 03.1.00 and later

You can configure a 1000Base-TX SFP (part number E1MG-TX) to operate at a speed of 100 Mbps. To do so, enter the following command at the Interface level of the CLI.

```plaintext
FastIron(config-if-e1000-11)# 100-tx
```

After the link is up, it will be in 100M/full-duplex mode, as shown in the following example.
The *show media* command will display the SFP transceiver as *1G M-TX*.

**Syntax:**  

```
[no] 100-tx
```

To disable support, enter the *no* form of the command.

**Configuration notes**

- This feature requires that autonegotiation be enabled on the other end of the link.
- Although combo ports (ports 1 – 4) on Hybrid Fiber (HF) models support the 1000Base-TX SFP, they cannot be configured to operate at 100Mbps. The 100Mbps operating speed is supported only with non-combo ports.
- 1000Base-TX modules must be configured individually, one interface at a time.
- 1000Base-TX modules do not support Digital Optical Monitoring.
- This module requires a Cat5 cable and uses an RJ45 connector.
- Hotswap is supported for this module when it is configured in 100M mode.

**Enabling and disabling support for 100BaseFX**

Some Brocade devices support 100BaseFX fiber transceivers. After you physically install a 100BaseFX transceiver, you must enter a CLI command to enable it.

**NOTE**

The CLI syntax for enabling and disabling 100BaseFX support on a Stackable device differs from the syntax for a Chassis device. Follow the appropriate instructions below.

**Compact device**

This section shows how to enable 100BaseFX on a Compact device.

The Brocade device supports the following types of SFPs for 100BaseFX:

- Multimode SFP – maximum distance is 2 kilometers
- Bidirectional singlemode SFP – maximum distance is 10 kilometers
- Long Reach (LR) – maximum distance is 40 kilometers (introduced in software release FSX 03.1.00)
- Intermediate Reach (IR) – maximum distance is 15 kilometers (introduced in software release FSX 03.1.00)

**NOTE**

Connect the 100BaseFX fiber transceiver after configuring both sides of the link. Otherwise, the link could become unstable, fluctuating between up and down states.

To enable 100BaseFX on a fiber port, enter the following command at the Global CONFIG level of the CLI.

```
FastIron(config)# link-config gig fiber 100base-fx e 4
```
The above command enables 100BaseFX on port 4.
The following command enables 100BaseFX on ports 3 and 4

FastIron(config)# link-config gig fiber 100base-fx e 3 e 4

Syntax: [no] link-config gig fiber 100base-fx ethernet [stack-unit/slotnum/] portnum ethernet
[stacknum/slotnum/]portnum

The stack-unit parameter is required on FastIron GS and LS devices, and FastIron GS-STK and

The slotnum parameter is required on chassis devices and on FastIron GS devices.

The portnum parameter is a valid port number.

You can specify one or two ethernet ports at a time, as shown in the above examples.

To disable 100BaseFX support on a fiber port, enter the no form of the command. Note that you
must disable 100BaseFX support before inserting a different type of module In the same port.
Otherwise, the device will not recognize traffic traversing the port.

**FSX 100/1000 interface module**

The FSX 100/1000 Interface module and 100BaseFX SFP was introduced in software release FSX
02.4.00.

**NOTE**
The following procedure applies to the FSX 100/1000 Fiber interface module only. The CLI syntax
for enabling and disabling 100BaseFX support on the FSX differs than on a Compact device. Make
sure you refer to the appropriate procedures.

The FSX 100/1000 fiber interface module supports the following types of SFPs for 100BaseFX:

- Multimode SFP – maximum distance is 2 kilometers
- Bidirectional single mode SFP – maximum distance is 10 kilometers
- Long Reach (LR) – maximum distance is 40 kilometers (introduced in software release FSX
03.1.00)
- Intermediate Reach (IR) – maximum distance is 15 kilometers (introduced in software release
FSX 03.1.00)

**NOTE**
Connect the 100BaseFX fiber transceiver after configuring both sides of the link. Otherwise, the
link could become unstable, fluctuating between up and down states.

To enable support for 100BaseFX on an FSX fiber port, enter commands such as the following.

FastIron(config)# interface e 1/6
FastIron(config-if-1/6)# 100-fx

The above commands enable 100BaseFX on port 6 in slot 1.

Syntax: [no] 100-fx

To disable 100BaseFX support on a fiber port, enter the no form of the command. Note that you
must disable 100BaseFX support before inserting a different type of module In the same port.
Otherwise, the device will not recognize traffic traversing the port.
Changing the Gbps fiber negotiation mode

The globally configured Gbps negotiation mode is the default mode for all Gbps fiber ports. You can override the globally configured default and set individual ports to the following:

- **Negotiate-full-auto** – The port first tries to perform a handshake with the other port to exchange capability information. If the other port does not respond to the handshake attempt, the port uses the manually configured configuration information (or the defaults if an administrator has not set the information). This is the default.

- **Auto-Gbps** – The port tries to perform a handshake with the other port to exchange capability information.

- **Negotiation-off** – The port does not try to perform a handshake. Instead, the port uses configuration information manually configured by an administrator.

To change the mode for individual ports, enter commands such as the following.

```
FastIron(config)# int ethernet 1 to 4
FastIron(config-mif-1-4)# gig-default auto-gig
```

This command overrides the global setting and sets the negotiation mode to auto-Gbps for ports 1 – 4.

**Syntax:** `gig-default neg-full-auto | auto-gig | neg-off`

**NOTE**

When Gbps negotiation mode is turned off (CLI command `gig-default neg-off`), the Brocade device may inadvertently take down both ends of a link. This is a hardware limitation for which there is currently no workaround.

Modifying port priority (QoS)

You can give preference to the inbound traffic on specific ports by changing the Quality of Service (QoS) level on those ports. For information and procedures, refer to Chapter 22, “Configuring Quality of Service”.

Dynamic configuration of Voice over IP (VoIP) phones

**Platform Support:**

- FastIron X Series devices running software release 02.2.00 and later
- FCX-S devices running software release 06.0.00 and later
- FastIron GS-STK and FastIron LS-STK devices running software version 05.0.00 and later

You can configure a FastIron device to automatically detect and re-configure a VoIP phone when it is physically moved from one port to another within the same device. To do so, you must configure a **voice VLAN ID** on the port to which the VoIP phone is connected. The software stores the voice VLAN ID in the port database for retrieval by the VoIP phone.

The dynamic configuration of a VoIP phone works in conjunction with the VoIP phone discovery process. Upon installation, and sometimes periodically, a VoIP phone will query the Brocade device for VoIP information and will advertise information about itself, such as, device ID, port ID, and platform. When the Brocade device receives the VoIP phone query, it sends the voice VLAN ID in a reply packet back to the VoIP phone. The VoIP phone then configures itself within the voice VLAN.
As long as the port to which the VoIP phone is connected has a voice VLAN ID, the phone will configure itself into that voice VLAN. If you change the voice VLAN ID, the software will immediately send the new ID to the VoIP phone, and the VoIP phone will re-configure itself with the new voice VLAN.

**Configuration notes**

- This feature works with any VoIP phone that:
  - Runs CDP
  - Sends a VoIP VLAN query message
  - Can configure its voice VLAN after receiving the VoIP VLAN reply
- Automatic configuration of a VoIP phone will not work if one of the following applies:
  - You do not configure a voice VLAN ID for a port with a VoIP phone
  - You remove the configured voice VLAN ID from a port without configuring a new one
  - You remove the port from the voice VLAN
- Make sure the port is able to intercept CDP packets (`cdp run` command).
- Some VoIP phones may require a reboot after configuring or re-configuring a voice VLAN ID. For example, if your VoIP phone queries for VLAN information only once upon boot up, you must reboot the VoIP phone before it can accept the VLAN configuration. If your phone is powered by a PoE device, you can reboot the phone by disabling then re-enabling the port.
- Brocade devices do not currently support Cisco 7970 VOIP phones.

**Enabling dynamic configuration of a Voice over IP (VoIP) phone**

You can create a voice VLAN ID for a port, or for a group of ports.

To create a voice VLAN ID for a port, enter commands such as the following.

```
FastIron(config)# interface e 2
FastIron(config-if-e1000-2)# voice-vlan 1001
```

To create a voice VLAN ID for a group of ports, enter commands such as the following.

```
FastIron(config)# interface e 1-8
FastIron(config-mif-1-8)# voice-vlan 1001
```

**Syntax:** `[no] voice-vlan voice-vlan num`  
where `voice-vlan-num` is a valid VLAN ID between 1 – 4095.

To remove a voice VLAN ID, use the `no` form of the command.

**Viewing voice VLAN configurations**

You can view the configuration of a voice VLAN for a particular port or for all ports.

To view the voice VLAN configuration for a port, specify the port number with the `show voice-vlan` command. The following example shows the command output results.

```
FastIron# show voice-vlan ethernet 2
Voice vlan ID for port 2: 1001
```
Configuring basic port parameters

The following example shows the message that appears when the port does not have a configured voice VLAN.

```
FastIron# show voice-vlan ethernet 2
Voice vlan is not configured for port 2.
```

To view the voice VLAN for all ports, use the `show voice-vlan` command. The following example shows the command output results.

```
FastIron# show voice-vlan
Port ID   Voice-vlan
  2       1001
  8       150
 15       200
```

**Syntax:** `show voice-vlan ethernet [stacknum/slotnum/]portnum`

If you specify an Ethernet port, note the following.

- The `slotnum` parameter is required on chassis devices and on FastIron GS devices.
- The `portnum` parameter is a valid port number.

### Configuring port flap dampening

**Platform Support:**

- FastIron X Series devices running software release 03.0.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- Turbolron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

Port Flap Dampening increases the resilience and availability of the network by limiting the number of port state transitions on an interface.

If the port link state toggles from up to down for a specified number of times within a specified period, the interface is physically disabled for the specified wait period. Once the wait period expires, the port link state is re-enabled. However, if the wait period is set to zero (0) seconds, the port link state will remain disabled until it is manually re-enabled.

**Configuration notes**

- When a flap dampening port becomes a member of a trunk group, that port, as well as all other member ports of that trunk group, will inherit the primary port configuration. This means that the member ports will inherit the primary port flap dampening configuration, regardless of any previous configuration.
- The Brocade device counts the number of times a port link state toggles from "up to down", and not from "down to up".

• The sampling time or window (the time during which the specified toggle threshold can occur before the wait period is activated) is triggered when the first "up to down" transition occurs.
• "Up to down" transitions include UDLD-based toggles, as well as the physical link state.

Configuring port flap dampening on an interface

This feature is configured at the interface level.

```bash
FastIron(config)# interface ethernet 2/1
FastIron(config-if-e10000-2/1)# link-error-disable 10 3 10
```

**Syntax:** `[no] link-error-disable toggle-threshold sampling-time-in-sec wait-time-in-sec`

The **toggle-threshold** is the number of times a port link state goes from up to down and down to up before the wait period is activated. The default is 0. Enter a valid value range from 1-50.

The **sampling-time-in-sec** is the amount of time during which the specified toggle threshold can occur before the wait period is activated. The default is 0 seconds. Enter 0 – 65535 seconds.

The **wait-time-in-sec** is the amount of time the port remains disabled (down) before it becomes enabled. Entering 0 – 65535 seconds; 0 indicates that the port will stay down until an administrative override occurs.

Configuring port flap dampening on a trunk

You can configure the port flap dampening feature on the primary port of a trunk using the **link-error-disable** command. Once configured on the primary port, the feature is enabled on all ports that are members of the trunk. You cannot configure port flap dampening on port members of the trunk.

Enter commands such as the following on the primary port of a trunk.

```bash
FastIron(config)# interface ethernet 2/1
FastIron(config-if-e10000-2/1)# link-error-disable 10 3 10
```

**Re-enabling a port disabled by port flap dampening**

A port disabled by port flap dampening is automatically re-enabled once the wait period expires; however, if the wait period is set to zero (0) seconds, you must re-enable the port by entering the following command on the disabled port.

```bash
FastIron(config)# interface ethernet 2/1
FastIron(config-if-e10000-2/1)# no link-error-disable 10 3 10
```

Displaying ports configured with port flap dampening

Ports that have been disabled due to the port flap dampening feature are identified in the output of the **show link-error-disable** command. The following shows an example output.

```bash
FastIron# show link-error-disable
Port 2/1 is forced down by link-error-disable.
```

Use the **show link-error-disable all** command to display the ports with the port flap dampening feature enabled.

For FSX software releases prior to release 03.2.00 and for FGS software releases, the output of the command shows the following.
Configuring basic port parameters

FastIron# show link-error-disable all
Port8/1 is configured for link-error-disable
  threshold:1, sampling_period:10, waiting_period:0
Port8/2 is configured for link-error-disable
  threshold:1, sampling_period:10, waiting_period:0
Port8/3 is configured for link-error-disable
  threshold:1, sampling_period:10, waiting_period:0
Port8/4 is configured for link-error-disable
  threshold:1, sampling_period:10, waiting_period:0
Port8/5 is configured for link-error-disable
  threshold:4, sampling_period:10, waiting_period:2
Port8/9 is configured for link-error-disable
  threshold:2, sampling_period:20, waiting_period:0

For TurboIron X Series devices, and FastIron X Series devices running software release 03.2.00, the output of the command shows the following.

FastIron# show link-error-disable all

<table>
<thead>
<tr>
<th>Port #</th>
<th>Threshold</th>
<th>Sampling-Time</th>
<th>Shutoff-Time</th>
<th>State</th>
<th>Counter</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>3</td>
<td>120</td>
<td>600</td>
<td>Idle</td>
<td>N/A</td>
</tr>
<tr>
<td>12</td>
<td>3</td>
<td>120</td>
<td>500</td>
<td>Down</td>
<td>424</td>
</tr>
</tbody>
</table>

Table 30 defines the port flap dampening statistics displayed by the show link-error-disable all command.

**TABLE 30** Output of show link-error-disable

<table>
<thead>
<tr>
<th>This column...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port #</td>
<td>The port number.</td>
</tr>
<tr>
<td>Threshold</td>
<td>The number of times the port link state will go from up to down and down to up before the wait period is activated.</td>
</tr>
<tr>
<td>Sampling-Time</td>
<td>The number of seconds during which the specified toggle threshold can occur before the wait period is activated.</td>
</tr>
<tr>
<td>Shutoff-Time</td>
<td>The number of seconds the port will remain disabled (down) before it becomes enabled. A zero (0) indicates that the port will stay down until an administrative override occurs.</td>
</tr>
</tbody>
</table>
| State          | The port state can be one of the following:
  - **Idle** – The link is normal and no link state toggles have been detected or sampled.
  - **Down** – The port is disabled because the number of sampled errors exceeded the configured threshold.
  - **Err** – The port sampled one or more errors. |
| Counter        | If the port state is **Idle**, this field displays N/A.
  - If the port state is **Down**, this field shows the remaining value of the shutoff timer.
  - If the port state is **Err**, this field shows the number of errors sampled. |
Also, in TurboIron X Series devices, and in FastIron X Series devices running software release 03.2.00 and later, the `show interface` command indicates if the port flap dampening feature is enabled on the port.

```
FastIron# show interface ethernet 15
GigabitEthernet15 is up, line protocol is up
  Link Error Dampening is Enabled
    Hardware is GigabitEthernet, address is 00e0.5200.010e (bia 00e0.5200.010e)
    Configured speed auto, actual 1Gbit, configured duplex fdx, actual fdx
    Configured mdi mode AUTO, actual MDIX
```

```
FastIron# show interface ethernet 17
GigabitEthernet17 is ERR-DISABLED, line protocol is down
  Link Error Dampening is Enabled
    Hardware is GigabitEthernet, address is 00e0.5200.010e (bia 00e0.5200.010e)
    Configured speed auto, actual unknown, configured duplex fdx, actual unknown
```

The line “Link Error Dampening” displays “Enabled” if port flap dampening is enabled on the port or “Disabled” if the feature is disabled on the port. The feature is enabled on the ports in the two examples above. Also, the characters “ERR-DISABLED” is displayed for the “GbpsEthernet” line if the port is disabled because of link errors.

**Syntax:** `show interface ethernet port-number`

In addition to the show commands above, the output of the `show interface brief` command for TurboIron X Series devices, and FastIron X Series devices running software release 03.2.00 and later, indicates if a port is down due to link errors.

```
FastIron# show interface brief e17

   Port  Link    State     Dupl     Speed  Trunk  Tag Priori MAC            Name
 17    ERR-DIS None     None      None  15    Yes level0 00e0.5200.010e
```

The ERR-DIS entry under the “Link” column indicates the port is down due to link errors.

**Syslog messages for port flap dampening**

The following Syslog messages are generated on devices running FSX software release 03.2.00 and later.

- If the threshold for the number of times that a port link toggles from “up” to “down” then “down” to “up” has been exceeded, the following Syslog message is displayed.
  
  `0d00h02m10s:I:ERR_DISABLE: Link flaps on port ethernet 16 exceeded threshold; port in err-disable state`

- If the wait time (port is down) expires and the port is brought up the following Syslog message is displayed.
  
  `0d00h02m41s:I:ERR_DISABLE: Interface ethernet 16, err-disable recovery timeout`

**Configuring a local MAC address for Layer 2 management traffic**

**Platform Support:**

- FGS and FLS devices running software release 04.0.00 and later
• FGS-STK and FLS-STK devices running software release 05.0.00 and later
• FWS devices running software release 04.3.00 or later

By default, Brocade Layer 2 devices use the MAC address of the first port as the MAC address for Layer 2 management traffic. For example, when the Brocade device receives an ARP request for its management IP address, it responds with the first port MAC address. This may cause problems in some configurations where the Brocade device uses the same MAC address for management traffic as for switched traffic.

Starting with the software releases listed above, you can configure the Brocade device to use a different MAC address for Layer 2 management traffic than for switched traffic. When you issue the `use-local-management-mac`, the Brocade device changes a local bit in the first port MAC address and uses this MAC address for management traffic. The second bit of the first port MAC address is changed to 2. For example, if the MAC address is 00e0.5201.9900 after the feature is enabled, the switch uses 02e0.5201.9900 for management functions. Switched traffic will continue to use the first port MAC address without the local bit setting.

Example

FastIron(config)# use-local-management-mac
FastIron(config)# write memory
FastIron(config)# end
FastIron# reload

Syntax: [no] use-local-management-mac

**NOTE**
You must save the configuration and reload the software to place the change into effect.

**NOTE**
This feature is only available for the switch code. It is not available for router code.

### Port loop detection

**Platform Support:**

• FGS and FLS devices running software release 04.0.00 and later
• FGS-STK and FLS-STK devices running software release 05.0.00 and later
• FWS devices running software release 04.3.00 or later
• FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
• FCX-S devices running software release 06.0.00 and later
• TurboIron X Series devices running software release 04.1.00 and later

This feature allows the Brocade device to disable a port that is on the receiving end of a loop by sending test packets. You can configure the time period during which test packets are sent.

#### Strict mode and loose mode

There are two types of loop detection; Strict Mode and Loose Mode. In Strict Mode, a port is disabled only if a packet is looped back to that same port. Strict Mode overcomes specific hardware issues where packets are echoed back to the input port. In Strict Mode, loop detection must be configured on the physical port.
In Loose Mode, loop detection is configured on the VLAN of the receiving port. Loose Mode disables the receiving port if packets originate from any port or VLAN on the same device. The VLAN of the receiving port must be configured for loop detection in order to disable the port.

**Recovering disabled ports**

Once a loop is detected on a port, it is placed in Err-Disable state. The port will remain disabled until one of the following occurs:

- You manually disable and enable the port at the Interface Level of the CLI.
- You enter the command `clear loop-detection`. This command clears loop detection statistics and enables all Err-Disabled ports.
- The device automatically re-enables the port. To set your device to automatically re-enable Err-Disabled ports, refer to “Configuring the device to automatically re-enable ports” on page 80.

**Configuration notes**

- Loopback detection packets are sent and received on both tagged and untagged ports. Therefore, this feature cannot be used to detect a loop across separate devices.
- On TurboIron devices running software release 04.2.00, the port loop detection feature works only on untagged ports.

The following information applies to Loose Mode loop detection:

- With Loose Mode, two ports of a loop are disabled.
- Different VLANs may disable different ports. A disabled port affects every VLAN using it.
- Loose Mode floods test packets to the entire VLAN. This can impact system performance if too many VLANs are configured for Loose Mode loop detection.

**NOTE**

Brocade recommends that you limit the use of Loose Mode. If you have a large number of VLANs, configuring loop detection on all of them can significantly affect system performance because of the flooding of test packets to all configured VLANs. An alternative to configuring loop detection in a VLAN-group of many VLANs is to configure a separate VLAN with the same tagged port and configuration, and enable loop detection on this VLAN only.

**NOTE**

When loop detection is used with L2 loop prevention protocols, such as spanning tree (STP), the L2 protocol takes higher priority. Loop detection cannot send or receive probe packets if ports are blocked by L2 protocols, so it does not detect L2 loops when STP is running because loops within a VLAN have been prevented by STP. Loop detection running in Loose Mode can detect and break L3 loops because STP cannot prevent loops across different VLANs. In these instances, the ports are not blocked and loop detection is able to send out probe packets in one VLAN and receive packets in another VLAN. In this way, loop detection running in Loose Mode disables both ingress and egress ports.
**Enabling loop detection**

Use the `loop-detection` command to enable loop detection on a physical port (Strict Mode) or a VLAN (Loose Mode). Loop detection is disabled by default. The following example shows a Strict Mode configuration.

```
FastIron(config)# interface ethernet 1/1
FastIron(config-if-e1000-1/1)# loop-detection
```

The following example shows a Loose Mode configuration.

```
FastIron(config)# vlan20
FastIron(config-vlan-20)# loop-detection
```

By default, the port will send test packets every one second, or the number of seconds specified by the `loop-detection-interval` command. Refer to “Configuring a global loop detection interval” on page 80.

**Syntax:**  
\[no\] loop-detection

Use the `[no]` form of the command to disable loop detection.

**Configuring a global loop detection interval**

The loop detection interval specifies how often a test packet is sent on a port. When loop detection is enabled, the loop detection time unit is 0.1 second, with a default of 10 (one second). The range is from 1 (one tenth of a second) to 100 (10 seconds). You can use the `show loop-detection status` command to view the loop detection interval.

To configure the global loop detection interval, enter a command similar to the following.

```
FastIron(config)# loop-detection-interval 50
```

This command sets the loop-detection interval to 5 seconds (50 x 0.1).

To revert to the default global loop detection interval of 10, enter one of the following.

```
FastIron(config)# loop-detection-interval 10
OR
FastIron(config)# no loop-detection-interval 50
```

**Syntax:**  
\[no\] loop-detection-interval *number*

where *number* is a value from 1 to 100. The system multiplies your entry by 0.1 to calculate the interval at which test packets will be sent.

**Configuring the device to automatically re-enable ports**

To configure the Brocade device to automatically re-enable ports that were disabled because of a loop detection, enter the following command.

```
FastIron(config)# errdisable recovery cause loop-detection
```

The above command will cause the Brocade device to automatically re-enable ports that were disabled because of a loop detection. By default, the device will wait 300 seconds before re-enabling the ports. You can optionally change this interval to a value from 10 to 65535 seconds. Refer to “Specifying the recovery time interval” on page 81.

**Syntax:**  
\[no\] errdisable recovery cause loop-detection
Use the \[\text{no}\] form of the command to disable this feature.

**Specifying the recovery time interval**

The recovery time interval specifies the number of seconds the Brocade device will wait before automatically re-enabling ports that were disabled because of a loop detection. (Refer to “Configuring the device to automatically re-enable ports” on page 80.) By default, the device will wait 300 seconds. To change the recovery time interval, enter a command such as the following.

```
FastIron(config)# errdisable recovery interval 120
```

This command configures the device to wait 120 seconds (2 minutes) before re-enabling the ports.

To revert to the default recovery time interval of 300 seconds (5 minutes), enter one of the following commands.

```
FastIron(config)# errdisable recovery interval 300
```

OR

```
FastIron(config)# no errdisable recovery interval 120
```

**Syntax:** \[\text{no}\] errdisable recovery interval \textit{seconds}

where \textit{seconds} is a number from 10 to 65535.

**Clearing loop-detection**

To clear loop detection statistics and re-enable all ports that are in Err-Disable state because of a loop detection, enter the following command.

```
FastIron# clear loop-detection
```

**Displaying loop-detection information**

Use the \texttt{show loop-detection status} command to display loop detection status, as shown.

```
FastIron# show loop-detection status
loop detection packets interval: 10 (unit 0.1 sec)
Number of err-disabled ports: 3
You can re-enable err-disable ports one by one by "disable" then "enable"
under interface config, re-enable all by "clear loop-detect", or
configure "errdisable recovery cause loop-detection" for automatic recovery

index | port/vlan | status | #errdis | sent-pkts | recv-pkts |
--- | --- | --- | --- | --- | --- |
1 | 1/13 | untag, LEARNING | 0 | 0 | 0 |
2 | 1/15 | untag, BLOCKING | 0 | 0 | 0 |
3 | 1/17 | untag, DISABLED | 0 | 0 | 0 |
4 | 1/18 | ERR-DISABLE by itself | 6 | 1 | 1 |
5 | 1/19 | ERR-DISABLE by vlan 12 | 0 | 0 | 0 |
6 | vlan12 | 2 ERR-DISABLE ports | 24 | 2 |

If a port is errdisabled in Strict mode, it shows “ERR-DISABLE by itself”. If it is errdisabled due to its associated vlan, it shows “ERR-DISABLE by vlan ?”

The following command displays the current disabled ports, including the cause and the time.

```
FastIron# show loop-detection disable
Number of err-disabled ports: 3
You can re-enable err-disable ports one by one by "disable" then "enable"
under interface config, re-enable all by "clear loop-detect", or
3 Configuring basic port parameters

configure "errdisable recovery cause loop-detection" for automatic recovery

<table>
<thead>
<tr>
<th>index</th>
<th>port</th>
<th>caused-by</th>
<th>disabled-time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1/18</td>
<td>itself</td>
<td>00:13:30</td>
</tr>
<tr>
<td>2</td>
<td>1/19</td>
<td>vlan 12</td>
<td>00:13:30</td>
</tr>
<tr>
<td>3</td>
<td>1/20</td>
<td>vlan 12</td>
<td>00:13:30</td>
</tr>
</tbody>
</table>

This example shows the disabled ports, the cause, and the time the port was disabled. If loop-detection is configured on a physical port, the disable cause will show “itself”. For VLANs configured for loop-detection, the cause will be a VLAN.

The following command shows the hardware and software resources being used by the loop-detection feature.

Vlans configured loop-detection use 1 HW MAC
Vlans not configured but use HW MAC: 1 10

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Syslog message**

The following message is logged when a port is disabled due to loop detection. This message also appears on the console.

`loop-detect: port ?\\?\? vlan ?, into errdisable state`

The Errdisable function logs a message whenever it re-enables a port.
Overview

For easy software image management, all Brocade devices support the download and upload of software images between the flash modules on the devices and a Trivial File Transfer Protocol (TFTP) server on the network.

Brocade devices have two flash memory modules:

- **Primary flash** – The default local storage device for image files and configuration files.
- **Secondary flash** – A second flash storage device. You can use the secondary flash to store redundant images for additional reload reliability or to preserve one software image while testing another one.

Only one flash device is active at a time. By default, the primary image will become active upon reload.

You can update the software contained on a flash module using TFTP to copy the update image from a TFTP server onto the flash module. In addition, you can copy software images and configuration files from a flash module to a TFTP server.

**NOTE**
Brocade devices are TFTP clients but not TFTP servers. You must perform the TFTP transaction from the Brocade device. You cannot “put” a file onto the Brocade device using the interface of your TFTP server.

**NOTE**
Brocade FGS-STK and FLS-STK devices do not support booting from TFTP.

**NOTE**
If you are attempting to transfer a file using TFTP but have received an error message, refer to “Diagnostic error codes and remedies for TFTP transfers” on page 106.

Determining the software versions installed and running on a device

Use the following methods to display the software versions running on the device and the versions installed in flash memory.

**Determining the flash image version running on the device**

To determine the flash image version running on a device, enter the `show version` command at any level of the CLI. Some examples are shown below.
**Compact devices**

To determine the flash image version running on a Compact device, enter the `show version` command at any level of the CLI. The following shows an example output.

```
FastIron#show version
SW: Version 03.0.00T53 Copyright (c) 2009 Brocade Communications Systems, Inc.
   Compiled on Mar 26 2003 at 13:50:31 labeled as FER03000
   (3089381 bytes) from Primary fer03000.bin
HW: Stackable FES2402-PREM-ILP
==========================================================================
330 MHz Power PC processor 8245 (version 129/1014) 66 MHz bus
512 KB boot flash memory
16384 KB code flash memory
128 MB DRAM
Monitor Option is on
The system uptime is 4 days 4 hours 8 minutes 33 seconds
The system : started=warm start
```

The version information is shown in bold type in this example:

- “03.0.00T53” indicates the flash code version number. The “T53” is used by Brocade for record keeping.
- “labeled as FER03000” indicates the flash code image label. The label indicates the image type and version and is especially useful if you change the image file name.
- “Primary fer03000.bin” indicates the flash code image file name that was loaded.

**Chassis devices**

To determine the flash image version running on a chassis device, enter the `show version` command at any level of the CLI. The following is an example output.

```
FastIron Switch# show version
==========================================================================
Active Management CPU:
SW: Version 03.1.00aT3e3 Copyright (c) 2009 Brocade Communications Systems, Inc.
   Compiled on Nov 07 2006 at 10:20:07 labeled as SXR03100a
   (3613675 bytes) from Primary sxr03100a.bin
BootROM: Version 03.0.01T3e5 (FEv2)
HW: Chassis FastIron SX 1600-PREM
Serial #: TE15065544
==========================================================================
Standby Management CPU:

P-ASIC 25: type 00D1, rev D2

SL 18: SX-F42XG 2-port 10G
Serial #: CH13050374
P-ASIC 34: type 01D1, rev 00
P-ASIC 35: type 01D1, rev 00

Active Management Module:
660 MHz Power PC processor 8541 (version 32/0020) 66 MHz bus
512 KB boot flash memory
16384 KB code flash memory
512 MB DRAM

Standby Management Module:
660 MHz Power PC processor 8541 (version 32/0020) 66 MHz bus
512 KB boot flash memory
16384 KB code flash memory
512 MB DRAM

The system uptime is 2 days 4 hours 33 minutes 52 seconds
The system : started=warm start reloaded=by "reload"

The version information is shown in bold type in this example:

- "03.1.00aT3e3" indicates the flash code version number. The "T3e3" is used by Brocade for record keeping.
- "labeled as SXR03100a" indicates the flash code image label. The label indicates the image type and version and is especially useful if you change the image file name.
- "Primary SXR03100a.bin" indicates the flash code image file name that was loaded.

Determining the boot image version running on the device

To determine the boot image running on a device, enter the `show flash` command at any level of the CLI. The following shows an example output.

FastIron# show flash
Active Management Module (Slot 9):
Compressed Pri Code size = 3613675, Version 03.1.00aT3e3 (sxr03100a.bin)
Compressed Sec Code size = 2250218, Version 03.1.00aT3e1 (sxs03100a.bin)
Compressed BootROM Code size = 524288, `Version 03.0.01T3e5`
Code Flash Free Space = 9699328

Standby Management Module (Slot 10):
Compressed Pri Code size = 3613675, Version 03.1.00aT3e3 (sxr03100a.bin)
Compressed Sec Code size = 2250218, Version 03.1.00aT3e1 (sxs03100a.bin)
Compressed BootROM Code size = 524288, `Version 03.0.01T3e5`
Code Flash Free Space = 524288

The boot code version is shown in bold type.
Determining the software versions installed and running on a device

Determining the image versions installed in flash memory

Enter the `show flash` command to display the boot and flash images installed on the device. An example of the command output is shown in “Determining the boot image version running on the device” on page 85:

- The “Compressed Pri Code size” line lists the flash code version installed in the primary flash area.
- The “Compressed Sec Code size” line lists the flash code version installed in the secondary flash area.
- The “Boot Monitor Image size” line lists the boot code version installed in flash memory. The device does not have separate primary and secondary flash areas for the boot image. The flash memory module contains only one boot image.

**NOTE**
To minimize the boot-monitor image size on FastIron devices, the `ping` and `tftp` operations performed in the boot-monitor mode are restricted to copper ports on the FastIron Chassis management modules and to copper ports on the FastIron stackable switch combination copper and fiber ports. The fiber ports on these devices do not have the ability to `ping` or `tftp` from the boot-monitor mode. This applies to FastIron devices only; it does not apply to TurboIron X Series devices.

Flash image verification

**Platform Support:**
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FastIron X Series devices running software release 04.0.00 and later
- TurboIron X Series devices running software release 04.1.00 and later

The Flash Image Verification feature allows you to verify boot images based on hash codes, and to generate hash codes where needed. This feature lets you select from three data integrity verification algorithms:

- **MD5** - Message Digest algorithm (RFC 1321)
- **SHA1** - US Secure Hash Algorithm (RFC 3174)
- **CRC** - Cyclic Redundancy Checksum algorithm

**CLI commands**

Use the following command syntax to verify the flash image:

**Syntax:** `verify md5 | sha1 | crc32 ASCII string | primary | secondary [hash code]`
Determining the software versions installed and running on a device

- **md5** – Generates a 16-byte hash code
- **sha1** – Generates a 20-byte hash code
- **crc32** – Generates a 4 byte checksum
- **ascii string** – A valid image filename
- **primary** – The primary boot image (primary.img)
- **secondary** – The secondary boot image (secondary.img)
- **hash code** – The hash code to verify

The following examples show how the `verify` command can be used in a variety of circumstances.

To generate an MD5 hash value for the secondary image, enter the following command.

```
FastIron# verify md5 secondary
FastIron#.........................Done
Size = 2044830, MD5 01c410d6d153189a4a5d36c955653862
```

To generate a SHA-1 hash value for the secondary image, enter the following command.

```
FastIron# verify sha secondary
FastIron#.........................Done
Size = 2044830, SHA1 49d12d26552072337f7f5fcaef4cf4b742a9f525
```

To generate a CRC32 hash value for the secondary image, enter the following command.

```
FastIron# verify crc32 secondary
FastIron#.........................Done
Size = 2044830, CRC32 b31fcbc0
```

To verify the hash value of a secondary image with a known value, enter the following commands.

```
FastIron# verify md5 secondary 01c410d6d153189a4a5d36c955653861
FastIron#.........................Done
Size = 2044830, MD5 01c410d6d153189a4a5d36c955653862
```

Verification FAILED.

In the previous example, the codes did not match, and verification failed. If verification succeeds, the output will look like this.

```
FastIron# verify md5 secondary 01c410d6d153189a4a5d36c955653861
FastIron#.........................Done
Size = 2044830, MD5 01c410d6d153189a4a5d36c955653861
```

Verification SUCEEDED.

The following examples show this process for SHA-1 and CRC32 algorithms.

```
FastIron# verify sha secondary 49d12d26552072337f7f5fcaef4cf4b742a9f525
FastIron#.........................Done
Size = 2044830, sha 49d12d26552072337f7f5fcaef4cf4b742a9f525
```

Verification SUCCEEDED.

and

```
FastIron# verify crc32 secondary b31fcbc0
FastIron#.........................Done
Size = 2044830, CRC32 b31fcbc0
```

Verification SUCCEEDED.
Image file types

This section lists the boot and flash image file types supported on the FastIron and Turbolron X Series family of switches and how to install them. For information about a specific version of code, refer to the release notes.

**TABLE 31** Software image files

1. These images are applicable to these devices only and are not interchangeable. For example, you cannot load FWSX boot or flash images on a FSX device, and vice versa. Also, you cannot load other images, such as B2R or B2S, for BigIron devices, on the FastIron family of switches.

Upgrading software

Use the following procedures to upgrade the software.

**NOTE**

This section does not describe how to upgrade a FESX or FSX base model to a premium (PREM) model. To perform this upgrade, you need an upgrade kit. Contact Brocade for information.
Note regarding upgrading from FGS 02.4.00 to the new release

When upgrading to release 02.5.00, the software automatically converts the saved system configuration to the new stack/slot/port nomenclature (refer to “CLI nomenclature on FGS and FLS devices” on page 22). The software makes the configuration change only for the saved configuration when the device is started. Software release 02.5.00 is not backward-compatible. If the software is downgraded from release 02.5.00, the configuration must be reloaded.

Migrating to the new release (FESX and FSX devices only)

Beginning with release 02.3.01, FESX and FSX devices share the same flash images. In releases prior to 02.3.01, FESX and FSX flash images were separate and were issued through separate software releases. Starting with release 02.3.01, the flash images for these devices were merged and are now issued in the same software release.

The new, combined flash images may create unique software upgrade circumstances for FESX and FSX devices. (FWSX devices are not affected by the software merge.) If your device is currently running software release 02.2.00 or later (FESX devices), or 02.2.01a or later (FSX devices), your device is not affected by the software merge. However, if your FESX or FSX device is running a release earlier than these versions, you must first upgrade the software on your device to FESX release 02.2.00 or later, or FSX release 02.2.01a or later, before loading the new software image. Earlier releases will not allow you to load the 02.3.01 or later software image.

To determine which software version is running on your device, use the show version command. See the following sections for information on how to upgrade the software images on your device.

Upgrading from FESX pre-02.2.00 or FSX pre-02.2.01a to the new release

If your device is running a software release earlier than FESX 02.2.00 or FSX 02.2.01a, you must first upgrade it to FESX 02.2.00 or later, or FSX 02.2.01a or later, before you can upgrade it to the new release. Follow the instructions, below.

1. Upgrade your device to software release FESX 02.2.00 or later, or FSX 02.2.01a or later. Follow the steps presented in “Upgrading software” on page 88 and “Upgrading the flash code” on page 90. Make sure you reload the software after loading the flash code.

2. Upgrade your device to the new software release. Refer to one of the following sections:
   - FESX – “Upgrading from FESX 02.2.00 or later to the new release” on page 89.
   - FSX – “Upgrading from FSX 02.2.01a or later to the new release” on page 90.

Upgrading from FESX 02.2.00 or later to the new release

Follow the instructions, below.

1. Upgrade the boot code to the new version (FEXZ0xxxx.bin) using the steps presented in “Upgrading software” on page 88.

2. Upgrade the flash code to the new version using the steps presented in “Upgrading the flash code” on page 90.
Upgrading from FSX 02.2.01a or later to the new release

Follow the instructions, below.

1. Upgrade the boot code to the new version (SXZ0xxxx.bin) using the steps presented in “Upgrading software” on page 88.
2. Upgrade the flash code to the new version using the steps presented in “Upgrading the flash code” on page 90.

Upgrading the boot code

NOTES:

- If you are upgrading a FESX or FSX device, refer to “Migrating to the new release (FESX and FSX devices only)” on page 89 before performing the steps in this section.
- If you are upgrading an FGS device from release 02.4.00, refer to “Note regarding upgrading from FGS 02.4.00 to the new release” on page 89 before performing the steps in this section.

Follow the steps given below to upgrade the boot code.

1. Place the new boot code on a TFTP server to which the Brocade device has access.
2. Enter the following command at the Privileged EXEC level of the CLI (example: FastIron Switch#) to copy the boot code from the TFTP server into flash memory:
   
   ```
   copy tftp flash ip-addr image-file-name bootrom
   ```

   **NOTE**
   
   Use the `copy tftp flash` command to copy the boot code to the Brocade device only during a maintenance window. Attempting to do so during normal networking operations can cause disruption to the network.

3. Verify that the code has been successfully copied by entering the following command at any level of the CLI:
   
   ```
   show flash
   ```
   
   The output will display the compressed boot ROM code size and the boot code version.
4. Upgrade the flash code as instructed in the following section.

Upgrading the flash code

**NOTE**

If you are upgrading a FESX or FSX device, refer to “Migrating to the new release (FESX and FSX devices only)” on page 89 before performing the steps in this section.

Follow the steps given below to upgrade the flash code.

1. Place the new flash code on a TFTP server to which the Brocade device has access.
2. Enter the following command at the Privileged EXEC level of the CLI (example: FastIron Switch#) to copy the flash code from the TFTP server into the flash memory.
   
   ```
   copy tftp flash ip-addr image-file-name primary | secondary
   ```
3. Verify that the flash code has been successfully copied by entering the following command at any level of the CLI.

   show flash

4. If the flash code version is correct, go to step 5. Otherwise, go to step 1.

5. Reload the software by entering one of the following commands:
   - **reload** (this command boots from the default boot source, which is the primary flash area by default)
   - **hitless-reload primary | secondary**
   - **boot system flash primary | secondary**

   **NOTE**
   The **hitless-reload** command is supported on FSX 800 and FSX 1600 devices running software release FSX 05.0.00 or later, and applies to Layer 2 switching and protocols only. Prior to using this command, see the section **Hitless Management Support** in the Brocade FastIron Chassis Hardware Installation Guide for complete details of the command, including some important configuration considerations.

   **NOTE**
   Release 03.1.00a added a confirmation step in the boot system flash process. This step occurs after a boot system flash primary/secondary command is entered and gives an administrator the opportunity to make last minute changes or corrections before performing a reload. The example below shows the confirmation step.

   FastIron Switch# boot system flash primary
   Are you sure? (enter 'Y' or 'N'): y

---

**Boot code synchronization feature**

Release 03.1.00a added support for automatic synchronization of the boot image in the active and redundant management modules. When the new boot image is copied into the active module, it is automatically synchronized with the redundant management module.

   **NOTE**
   There is currently no option for manual synchronization of the boot image.

   To activate the boot synchronization process, enter the following command.

   FastIron# copy tftp flash 192.168.255.102 superx/boot/sxz03001.bin bootrom

   The system responds with the following message.

   FastIron# Load to buffer (8192 bytes per dot)
   ......................Write to boot flash......................
   TFTP to Flash Done.
   FastIron# Synchronizing with standby module...
   Boot image synchronization done.
Important notes about downgrading from FSX 04.1.00

When downgrading from software release FSX 04.1.00 to an earlier release, you must do the following:

- If the `system-max ip-route` configuration is present, prior to downgrading the software, you must modify the value to reflect the maximum value supported in the earlier release. This is because software release 04.1.00 supports a maximum value of 524288, which is a higher value than in previous releases. For more information, refer to “Modifying system parameter default values” on page 385.

- If the Layer 3 switch has an IPv6 PROM installed, you must remove the following IPv6 configurations from the system, as these features are not supported in release FSX 04.0.01:

  **Global CONFIG commands:**
  - ipv6 unicast-routing
  - ipv6 router rip
  - ipv6 router ospf
  **Interface level commands:**
  - ipv6 rip
  - ipv6 ospf
  **Tunnel Interface command:**
  - tunnel mode ipv6ip

Using SNMP to upgrade software

You can use a third-party SNMP management application such as HP OpenView to upgrade software on a Brocade device.

**NOTE**
The syntax shown in this section assumes that you have installed HP OpenView in the “/usr” directory.

**NOTE**
Brocade recommends that you make a backup copy of the startup-config file before you upgrade the software. If you need to run an older release, you will need to use the backup copy of the startup-config file.

1. Configure a read-write community string on the Brocade device, if one is not already configured. To configure a read-write community string, enter the following command from the global CONFIG level of the CLI.

   `snmp-server community string ro | rw`

   where `string` is the community string and can be up to 32 characters long.

2. On the Brocade device, enter the following command from the global CONFIG level of the CLI.

   `no snmp-server pw-check`
This command disables password checking for SNMP set requests. If a third-party SNMP management application does not add a password to the password field when it sends SNMP set requests to a Brocade device, by default the Brocade device rejects the request.

3. From the command prompt in the UNIX shell, enter the following command.

```
/usr/0V/bin/snmpset -c rw-community-string fdry-ip-addr 1.3.6.1.4.1.1991.1.1.2.1.5.0 ipaddress tftp-ip-addr 1.3.6.1.4.1.1991.1.1.2.1.6.0 octetstringascii file-name 1.3.6.1.4.1.1991.1.1.2.1.7.0 integer command-integer
```

where

- `rw-community-string` is a read-write community string configured on the Brocade device.
- `fdry-ip-addr` is the IP address of the Brocade device.
- `tftp-ip-addr` is the TFTP server IP address.
- `file-name` is the image file name.
- `command-integer` is one of the following.
  - **20** – Download the flash code into the device primary flash area.
  - **22** – Download the flash code into the device secondary flash area.

## Changing the block size for TFTP file transfers

When you use TFTP to copy a file to or from a Brocade device, the device transfers the data in blocks of 8192 bytes by default. You can change the block size to one of the following if needed:

- 4096
- 2048
- 1024
- 512
- 256
- 128
- 64
- 32
- 16

To change the block size for TFTP file transfers, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)# flash 2047
set flash copy block size to 2048
```

**Syntax:** `[no] flash num`

The software rounds up the `num` value you enter to the next valid power of two, and displays the resulting value. In this example, the software rounds the value up to 2048.

**NOTE**

If the value you enter is one of the valid powers of two for this parameter, the software still rounds the value up to the next valid power of two. Thus, if you enter 2048, the software rounds the value up to 4096.
Rebooting

You can use boot commands to immediately initiate software boots from a software image stored in primary or secondary flash on a Brocade device or from a BootP or TFTP server. You can test new versions of code on a Brocade device or choose the preferred boot source from the console boot prompt without requiring a system reset.

**NOTE**
It is very important that you verify a successful TFTP transfer of the boot code *before* you reset the system. If the boot code is not transferred successfully but you try to reset the system, the system will not have the boot code with which to successfully boot.

By default, the Brocade device first attempts to boot from the image stored in its primary flash, then its secondary flash, and then from a TFTP server. You can modify this booting sequence at the global CONFIG level of the CLI using the `boot system`... command.

To initiate an immediate boot from the CLI, enter one of the `boot system`... commands.

**NOTE**
In FastIron X Series devices running software release 03.0.00 and higher, the `boot system tftp` command is supported on ports e1 through e12 only.

**NOTE**
If you are booting the device from a TFTP server through a fiber connection, use the following command: `boot system tftp ip-address filename fiber-port`.

Displaying the boot preference

Use the `show boot-preference` command to display the boot sequence in the startup config and running config files. The boot sequence displayed is also identified as either user-configured or the default.

The following example shows the default boot sequence preference.

```
FastIron# show boot-preference
Boot system preference (Configured):
    Use Default
Boot system preference (Default):
    Boot system flash primary
    Boot system flash secondary
```

The following example shows a user-configured boot sequence preference.

```
FastIron# show boot-preference
Boot system preference (Configured):
    Boot system flash secondary
    Boot system tftp 10.1.1.1 FGS04000b1.bin
    Boot system flash primary
Boot system preference (Default):
    Boot system flash primary
    Boot system flash secondary
```

**Syntax:** `show boot-preference`
Platform Support:

- FastIron X Series devices running software release 04.0.00
- FGS and FLS devices running software release 04.0.00
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later

The results of the `show run` command for the configured example above appear as follows.

```
FastIron# show run
Current Configuration:
!
ver 04.0.00x1T7el
!
module 1 fgs-48-port-copper-base-module
module 2 fgs-xfp-1-port-10g-module
module 3 fgs-xfp-1-port-10g-module
!
alias cp=copy tf 10.1.1.1 FGS04000bl.bin pri
!
boot sys fl sec
boot sys df 10.1.1.1 FGS04000bl.bin
boot sys fl pri
ip address 10.1.1.4 255.255.255.0
snmp-client 10.1.1.1
!
end
```

**Loading and saving configuration files**

For easy configuration management, all Brocade devices support both the download and upload of configuration files between the devices and a TFTP server on the network.

You can upload either the startup configuration file or the running configuration file to the TFTP server for backup and use in booting the system:

- **Startup configuration file** – This file contains the configuration information that is currently saved in flash. To display this file, enter the `show configuration` command at any CLI prompt.

- **Running configuration file** – This file contains the configuration active in the system RAM but not yet saved to flash. These changes could represent a short-term requirement or general configuration change. To display this file, enter the `show running-config` or `write terminal` command at any CLI prompt.

Each device can have one startup configuration file and one running configuration file. The startup configuration file is shared by both flash modules. The running configuration file resides in DRAM.

When you load the startup-config file, the CLI parses the file three times.

1. During the first pass, the parser searches for `system-max` commands. A `system-max` command changes the size of statically configured memory.

2. During the second pass, the parser implements the `system-max` commands if present and also implements trunk configuration commands (trunk command) if present.
3. During the third pass, the parser implements the remaining commands.

**Replacing the startup configuration with the running configuration**

After you make configuration changes to the active system, you can save those changes by writing them to flash memory. When you write configuration changes to flash memory, you replace the startup configuration with the running configuration.

To replace the startup configuration with the running configuration, enter the following command at any Enable or CONFIG command prompt.

`FastIron# write memory`

**Replacing the running configuration with the startup configuration**

If you want to back out of the changes you have made to the running configuration and return to the startup configuration, enter the following command at the Privileged EXEC level of the CLI.

`FastIron# reload`

**Logging changes to the startup-config file**

You can configure a Brocade device to generate a Syslog message when the startup-config file is changed. The trap is enabled by default.

The following Syslog message is generated when the startup-config file is changed.

`startup-config was changed`

If the startup-config file was modified by a valid user, the following Syslog message is generated.

`startup-config was changed by <username>`

To disable or re-enable Syslog messages when the startup-config file is changed, use the following command.

**Syntax:** `[no] logging enable config-changed`

**Copying a configuration file to or from a TFTP server**

To copy the startup-config or running-config file to or from a TFTP server, use one of the following methods.

**NOTE**

You can name the configuration file when you copy it to a TFTP server. However, when you copy a configuration file from the server to a Brocade device, the file is always copied as “startup-config” or “running-config”, depending on which type of file you saved to the server.

To initiate transfers of configuration files to or from a TFTP server using the CLI, enter one of the following commands:
• **copy startup-config tftp tftp-ip-addr filename** – Use this command to upload a copy of the startup configuration file from the Layer 2 Switch or Layer 3 Switch to a TFTP server.

• **copy running-config tftp tftp-ip-addr filename** – Use this command to upload a copy of the running configuration file from the Layer 2 Switch or Layer 3 Switch to a TFTP server.

• **copy tftp startup-config tftp-ip-addr filename** – Use this command to download a copy of the startup configuration file from a TFTP server to a Layer 2 Switch or Layer 3 Switch.

**Dynamic configuration loading**

You can load dynamic configuration commands (commands that do not require a reload to take effect) from a file on a TFTP server into the running-config on the Brocade device. You can make configuration changes off-line, then load the changes directly into the device running-config, without reloading the software.

**Usage considerations**

• Use this feature only to load configuration information that does not require a software reload to take effect. For example, you cannot use this feature to change statically configured memory (**system-max** command) or to enter trunk group configuration information into the running-config.

• Do not use this feature if you have deleted a trunk group but have not yet placed the changes into effect by saving the configuration and then reloading. When you delete a trunk group, the command to configure the trunk group is removed from the device running-config, but the trunk group remains active. To finish deleting a trunk group, save the configuration (to the startup-config file), then reload the software. After you reload the software, then you can load the configuration from the file.

• Do not load port configuration information for secondary ports in a trunk group. Since all ports in a trunk group use the port configuration settings of the primary port in the group, the software cannot implement the changes to the secondary port.

**Preparing the configuration file**

A configuration file that you create must follow the same syntax rules as the startup-config file the device creates.

• The configuration file is a script containing CLI configuration commands. The CLI reacts to each command entered from the file in the same way the CLI reacts to the command if you enter it. For example, if the command results in an error message or a change to the CLI configuration level, the software responds by displaying the message or changing the CLI level.

• The software retains the running-config that is currently on the device, and changes the running-config only by adding new commands from the configuration file. If the running config already contains a command that is also in the configuration file you are loading, the CLI rejects the new command as a duplicate and displays an error message. For example, if the running-config already contains a a command that configures ACL 1, the software rejects ACL 1 in the configuration file, and displays a message that ACL 1 is already configured.

• The file can contain global CONFIG commands or configuration commands for interfaces, routing protocols, and so on. You cannot enter User EXEC or Privileged EXEC commands.
The default CLI configuration level in a configuration file is the global CONFIG level. Thus, the first command in the file must be a global CONFIG command or "!". The ! (exclamation point) character means "return to the global CONFIG level".

**NOTE**
You can enter text following "!" as a comment. However, the "!" is not a comment marker. It returns the CLI to the global configuration level.

**NOTE**
If you copy-and-paste a configuration into a management session, the CLI ignores the "!" instead of changing the CLI to the global CONFIG level. As a result, you might get different results if you copy-and-paste a configuration instead of loading the configuration using TFTP.

Make sure you enter each command at the correct CLI level. Since some commands have identical forms at both the global CONFIG level and individual configuration levels, if the CLI response to the configuration file results in the CLI entering a configuration level you did not intend, then you can get unexpected results.

For example, if a trunk group is active on the device, and the configuration file contains a command to disable STP on one of the secondary ports in the trunk group, the CLI rejects the commands to enter the interface configuration level for the port and moves on to the next command in the file you are loading. If the next command is a spanning-tree command whose syntax is valid at the global CONFIG level as well as the interface configuration level, then the software applies the command globally. Here is an example.

The configuration file contains these commands.

```
interface ethernet 2
no spanning-tree
```

The CLI responds like this.

```
FastIron(config)# interface ethernet 2
Error - cannot configure secondary ports of a trunk
FastIron(config)# no spanning-tree
FastIron(config)#
```

If the file contains commands that must be entered in a specific order, the commands must appear in the file in the required order. For example, if you want to use the file to replace an IP address on an interface, you must first remove the old address using "no" in front of the ip address command, then add the new address. Otherwise, the CLI displays an error message and does not implement the command. Here is an example.

The configuration file contains these commands.

```
interface ethernet 11
ip address 10.10.10.69/24
```

The running-config already has a command to add an address to port 11, so the CLI responds like this.

```
FastIron(config)# interface ethernet 11
FastIron(config-if-e1000-11)# ip add 10.10.10.69/24
Error: can only assign one primary ip address per subnet
FastIron(config-if-e1000-11)#
```

To successfully replace the address, enter commands into the file as follows.
Loading and saving configuration files

interface ethernet 11
no ip address 20.20.20.69/24
ip address 10.10.10.69/24

This time, the CLI accepts the command, and no error message is displayed.

FastIron(config)# interface ethernet 11
FastIron(config-if-e1000-11)# no ip add 20.20.20.69/24
FastIron(config-if-e1000-11)# ip add 10.10.10.69/24

• Always use the end command at the end of the file. The end command must appear on the last line of the file, by itself.

Loading the configuration information into the running-config

To load the file from a TFTP server, use either of the following commands:

• copy tftp running-config ip-addr filename
• ncopy tftp ip-addr filename running-config

NOTE
If you are loading a configuration file that uses a truncated form of the CLI command access-list, the software will not go into batch mode.

For example, the following command line will initiate batch mode.

access-list 131 permit host pc1 host pc2

The following command line will not initiate batch mode.

acc 131 permit host pc1 host pc2

Maximum file sizes for startup-config file and running-config

Each Brocade device has a maximum allowable size for the running-config and the startup-config file. If you use TFTP to load additional information into a device running-config or startup-config file, it is possible to exceed the maximum allowable size. If this occurs, you will not be able to save the configuration changes.

The maximum size for the running-config and the startup-config file is 64K each.

To determine the size of a running-config or startup-config file, copy it to a TFTP server, then use the directory services on the server to list the size of the copied file. To copy the running-config or startup-config file to a TFTP server, use one of the following commands:

• Commands to copy the running-config to a TFTP server:
  • copy running-config tftp ip-addr filename
  • ncopy running-config tftp ip-addr from-name
• Commands to copy the startup-config file to a TFTP server:
  • copy startup-config tftp ip-addr filename
  • ncopy startup-config tftp ip-addr from-name
Loading and saving configuration files with IPv6

Platform Support:
- FastIron X Series devices running software release 02.4.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later

The `copy` command for IPv6 allows you to do the following:
- Copy a file from a specified source to an IPv6 TFTP server
- Copy a file from an IPv6 TFTP server to a specified destination

Copying a file to an IPv6 TFTP server

You can copy a file from the following sources to an IPv6 TFTP server:
- Flash memory
- Running configuration
- Startup configuration

**Copying a file from flash memory**

For example, to copy the primary or secondary boot image from the device flash memory to an IPv6 TFTP server, enter a command such as the following.

`FESX Router# copy flash tftp 2001:7382:e0ff:7837::3 test.img secondary`

This command copies the secondary boot image named `test.img` from flash memory to a TFTP server with the IPv6 address of `2001:7382:e0ff:7837::3`.

**Syntax:** `copy flash tftp ipv6-address source-file-name primary | secondary`

The `ipv6-address` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The `source-file-name` parameter specifies the name of the file you want to copy to the IPv6 TFTP server.

The `primary` keyword specifies the primary boot image, while the `secondary` keyword specifies the secondary boot image.

**Copying a file from the running or startup configuration**

For example, to copy the running configuration to an IPv6 TFTP server, enter a command such as the following.

`FESX Router# copy running-config tftp 2001:7382:e0ff:7837::3 newrun.cfg`

This command copies the running configuration to a TFTP server with the IPv6 address of `2001:7382:e0ff:7837::3` and names the file on the TFTP server `newrun.cfg`.

**Syntax:** `copy running-config | startup-config tftp ipv6-address destination-file-name`
Loading and saving configuration files with IPv6

Specify the **running-config** keyword to copy the running configuration file to the specified IPv6 TFTP server.

Specify the **startup-config** keyword to copy the startup configuration file to the specified IPv6 TFTP server.

The tftp **ipv6-address** parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **destination-file-name** parameter specifies the name of the file that is copied to the IPv6 TFTP server.

### Copying a file from an IPv6 TFTP server

You can copy a file from an IPv6 TFTP server to the following destinations:

- Flash memory
- Running configuration
- Startup configuration

#### Copying a file to flash memory

For example, to copy a boot image from an IPv6 TFTP server to the primary or secondary storage location in the device flash memory, enter a command such as the following.

```bash
FESX Router# copy tftp flash 2001:7382:e0ff:7837::3 test.img secondary
```

This command copies a boot image named test.img from an IPv6 TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the secondary storage location in the device flash memory.

**Syntax:** `copy tftp flash ipv6-address source-file-name primary | secondary`

The **ipv6-address** parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **source-file-name** parameter specifies the name of the file you want to copy from the IPv6 TFTP server.

The **primary** keyword specifies the primary storage location in the device flash memory, while the **secondary** keyword specifies the secondary storage location in the device flash memory.

#### Copying a file to the running or startup configuration

For example, to copy a configuration file from an IPv6 TFTP server to the running or startup configuration, enter a command such as the following.

```bash
FESX Router# copy tftp running-config 2001:7382:e0ff:7837::3 newrun.cfg overwrite
```

This command copies the newrun.cfg file from the IPv6 TFTP server and overwrites the running configuration file with the contents of newrun.cfg.

**NOTE**

To activate this configuration, you must reload (reset) the device.

**Syntax:** `copy tftp running-config | startup-config ipv6-address source-file-name [overwrite]`
Specify the **running-config** keyword to copy the running configuration from the specified IPv6 TFTP server.

The **ipv6-address** parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **source-file-name** parameter specifies the name of the file that is copied from the IPv6 TFTP server.

The **overwrite** keyword specifies that the device should overwrite the current configuration file with the copied file. If you do not specify this parameter, the device copies the file into the current running or startup configuration but does not overwrite the current configuration.

**Using the IPv6 ncopy command**

**Platform Support:**

- FastIron X Series devices running software release 02.4.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later

The **ncopy** command for IPv6 allows you to do the following:

- Copy a primary or secondary boot image from flash memory to an IPv6 TFTP server.
- Copy the running configuration to an IPv6 TFTP server.
- Copy the startup configuration to an IPv6 TFTP server
- Upload various files from an IPv6 TFTP server.

**Copying a primary or secondary boot Image from flash memory to an IPv6 TFTP server**

For example, to copy the primary or secondary boot image from the device flash memory to an IPv6 TFTP server, enter a command such as the following.

```
FESX Router# ncopy flash primary tftp 2001:7382:e0ff:7837::3 primary.img
```

This command copies the primary boot image named primary.img from flash memory to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3.

**Syntax:** `ncopy flash primary | secondary tftp ipv6-address source-file-name`

The **primary** keyword specifies the primary boot image, while the **secondary** keyword specifies the secondary boot image.

The **tftp ipv6-address** parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **source-file-name** parameter specifies the name of the file you want to copy from flash memory.

**Copying the running or startup configuration to an IPv6 TFTP server**

For example, to copy a device running or startup configuration to an IPv6 TFTP server, enter a command such as the following.

```
FESX Router# ncopy running-config tftp 2001:7382:e0ff:7837::3 bakrun.cfg
```
This command copies a device running configuration to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 and names the destination file bakrun.cfg.

**Syntax:** `ncopy running-config | startup-config tftp ipv6-address destination-file-name`

Specify the `running-config` keyword to copy the device running configuration or the `startup-config` keyword to copy the device startup configuration.

The `tftp ipv6-address` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The `destination-file-name` parameter specifies the name of the running configuration that is copied to the IPv6 TFTP server.

### Uploading files from an IPv6 TFTP server

You can upload the following files from an IPv6 TFTP server:

- Primary boot image
- Secondary boot image
- Running configuration
- Startup configuration

#### Uploading a primary or secondary boot image from an IPv6 TFTP server

For example, to upload a primary or secondary boot image from an IPv6 TFTP server to a device flash memory, enter a command such as the following.

```
FESX Router# ncopy tftp 2001:7382:e0ff:7837::3 primary.img flash primary
```

This command uploads the primary boot image named primary.img from a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the device primary storage location in flash memory.

**Syntax:** `ncopy tftp ipv6-address source-file-name flash primary | secondary`

The `tftp ipv6-address` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The `source-file-name` parameter specifies the name of the file you want to copy from the TFTP server.

The `primary` keyword specifies the primary location in flash memory, while the `secondary` keyword specifies the secondary location in flash memory.

#### Uploading a running or startup configuration from an IPv6 TFTP server

For example, to upload a running or startup configuration from an IPv6 TFTP server to a device, enter a command such as the following.

```
FESX Router# ncopy tftp 2001:7382:e0ff:7837::3 newrun.cfg running-config
```

This command uploads a file named newrun.cfg from a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the device.

**Syntax:** `ncopy tftp ipv6-address source-file-name running-config | startup-config`
The `tftp ipv6-address` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The `source-file-name` parameter specifies the name of the file you want to copy from the TFTP server.

Specify the `running-config` keyword to upload the specified file from the IPv6 TFTP server to the device. The device copies the specified file into the current running configuration but does not overwrite the current configuration.

Specify the `startup-config` keyword to upload the specified file from the IPv6 TFTP server to the device. The device copies the specified file into the current startup configuration but does not overwrite the current configuration.

**Using SNMP to save and load configuration information**

You can use a third-party SNMP management application such as HP OpenView to save and load a configuration on a Brocade device. To save and load configuration information using HP OpenView, use the following procedure.

**NOTE**
The syntax shown in this section assumes that you have installed HP OpenView in the “/usr” directory.

1. Configure a read-write community string on the Brocade device, if one is not already configured. To configure a read-write community string, enter the following command from the global CONFIG level of the CLI.

   ```
   snmp-server community string ro | rw
   ```

   where `string` is the community string and can be up to 32 characters long.

2. On the Brocade device, enter the following command from the global CONFIG level of the CLI.

   ```
   no snmp-server pw-check
   ```

   This command disables password checking for SNMP set requests. If a third-party SNMP management application does not add a password to the password field when it sends SNMP set requests to a Brocade device, by default the Brocade device rejects the request.

3. From the command prompt in the UNIX shell, enter the following command.

   ```
   /usr/OV/bin/snmpset -c rw-community-string fdry-ip-addr 1.3.6.1.4.1.1991.1.1.2.1.5.0 ipaddress tftp-ip-addr 1.3.6.1.4.1.1991.1.1.2.1.8.0 octetstringascii 1.3.6.1.4.1.1991.1.1.2.1.9.0 integer command-integer
   ```

   where

   - `rw-community-string` is a read-write community string configured on the Brocade device.
   - `fdry-ip-addr` is the IP address of the Brocade device.
   - `tftp-ip-addr` is the TFTP server IP address.
   - `config-file-name` is the configuration file name.
   - `command-integer` is one of the following:
Scheduling a system reload

20 – Upload the startup-config file from the flash memory of the Brocade device to the TFTP server.

21 – Download a startup-config file from a TFTP server to the flash memory of the Brocade device.

22 – Upload the running-config from the flash memory of the Brocade device to the TFTP server.

23 – Download a configuration file from a TFTP server into the running-config of the Brocade device.

NOTE
Option 23 adds configuration information to the running-config on the device, and does not replace commands. If you want to replace configuration information in the device, use “no” forms of the configuration commands to remove the configuration information, then use configuration commands to create the configuration information you want. Follow the guidelines in “Dynamic configuration loading” on page 97.

Erasing image and configuration files

To erase software images or configuration files, use the commands described below. These commands are valid at the Privileged EXEC level of the CLI:

- `erase flash primary` erases the image stored in primary flash of the system.
- `erase flash secondary` erases the image stored in secondary flash of the system.
- `erase startup-config` erases the configuration stored in the startup configuration file; however, the running configuration remains intact until system reboot.

Scheduling a system reload

In addition to reloading the system manually, you can configure the Brocade device to reload itself at a specific time or after a specific amount of time has passed.

NOTE
The scheduled reload feature requires the system clock. You can use a Simple Network Time Protocol (SNTP) server to set the clock or you can set the device clock manually. Refer to “Specifying a Simple Network Time Protocol (SNTP) server” on page 44 or “Setting the system clock” on page 46.

Reloading at a specific time

To schedule a system reload for a specific time, use the `reload at` command. For example, to schedule a system reload from the primary flash module for 6:00:00 AM, April 1, 2003, enter the following command at the global CONFIG level of the CLI.

`FastIron# reload at 06:00:00 04-01-03`

Syntax: `reload at hh:mm:ss mm-dd-yy [primary | secondary]`

- `hh:mm:ss` is hours, minutes, and seconds.
Diagnostic error codes and remedies for TFTP transfers

If an error occurs with a TFTP transfer to or from a Brocade Layer 2 Switch or Layer 3 Switch, one of the following error codes is displayed on the console.

<table>
<thead>
<tr>
<th>Error code</th>
<th>Message</th>
<th>Explanation and action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Flash read preparation failed.</td>
<td>A flash error occurred during the download.</td>
</tr>
<tr>
<td>2</td>
<td>Flash read failed.</td>
<td>Retry the download. If it fails again, contact customer support.</td>
</tr>
<tr>
<td>3</td>
<td>Flash write preparation failed.</td>

1. FGS and FLS models can be upgraded in the field to support stacking using the Upgrade Kit. For information about how to order and install the Upgrade Kit, refer to the Foundry FastIron GS Compact Layer 2 Switch Hardware Installation Guide and the Foundry FastIron LS Hardware Installation Guide.

Brocade IronStack overview

This section gives a brief overview of IronStack technology, including IronStack terminology. This section also lists the FastIron models that support stacking.

IronStack technology features

A stack is a group of devices that are connected so that they operate as a single chassis. Brocade IronStack technology features include:

- Management by a single IP address
- Support for up to eight units per stack
- Flexible stacking ports
- Linear and ring stack topology support
- Secure-setup utility to make stack setup easy and secure
Brocade IronStack overview

- Active Controller, Standby Controller, and member units in a stack
- Active Controller management of entire stack
- Active Controller download of software images to all stack units
- Standby Controller for stack redundancy
- Active Controller maintenance of information database for all stack units
- Packet switching in hardware between ports on stack units
- All protocols operate on an IronStack in the same way as on a chassis system.

Brocade stackable models

Platform Support:
- FCX-S devices running software release 06.0.00 and later
- FastIron GS-STK and FastIron LS-STK devices running software version 05.0.00 and later

FastIron GS-STK and FastIron LS-STK devices

All FastIron GS-STK and FastIron LS-STK devices running software release 05.0.00 or later can be active members of a Brocade IronStack. Existing FGS and FLS models can be upgraded in the field to support stacking using the Upgrade Kit. For information about how to order and install the Upgrade Kit, refer to the Foundry FastIron GS Compact Layer 2 Switch Hardware Installation Guide and the Foundry FastIron LS Hardware Installation Guide.

The FGS-STK and FLS-STK models, and the upgrade kits are listed below:

FGS-STK models:
- FGS624P-STK
- FGS648P-STK
- FGS624P-DC-STK
- FGS648P-DC-STK
- FGS624P-POE-STK
- FGS648P-POE-STK
- FGS624P-POE-DC-STK
- FGS648P-POE-DC-STK
- FGS624XGP-STK
- FGS648P-POE-DC-STK
- FGS624XGP-DC-STK
- FGS624XGP-POE-STK
- FGS624XGP-POE-DC-STK

FLS-STK Models:
- FLS624-STK
- FLS648-STK
- FLS624-STK-CXU
- FLS648-STK-CXU
- FLS624-STK-U
Upgrade Kits:

- FGS624-STK-CXU
- FGS648-STK-CXU
- FGS624-STK-U
- FGS648-STK-U
- FLS624-STK-CXU
- FLS648-STK-CXU
- FLS624-STK-U
- FLS648-STK-U

**FastIron CX-S devices**

All FastIron CX-S devices running software release 06.0.00 or later can be active members of a Brocade IronStack. For information about how to install FCX devices, see the Brocade FastIron CX Hardware Installation Guide.

**FCX-S Models:**

- FCX648S
- FCX624S-HPOE
- FCX648S-HPOE
- FCX624S-ADV
- FCX648S-ADV
- FCX624S-HPOE-ADV
- FCX648S-HPOE-ADV

**FCX-S Field Replaceable Units**

- 2-port 10 Gbps E XFP pluggable module
- 210 Watt removable Power Supply Unit (non-POE models)
- 620 Watt removable Power Supply Unit (POE models)
- Removable blower for non-POE models
- Removable blower for POE models

**Brocade IronStack terminology**

**Stack unit roles:**

- **Active Controller** - Handles stack management and configures all system- and interface-level features.
- **Future Active Controller** - The unit that will take over as Active Controller after the next reload, if its priority has been changed to the highest priority. When a priority for a stack unit is changed to be higher than the existing Active Controller, the takeover does not happen immediately to prevent disruptions in the stack operation.
• **Standby Controller** - The stack member with the highest priority after the Active Controller. The Standby Controller takes over if the current Active Controller fails.

• **Stack Member** - A unit functioning in the stack in a capacity other than Active or Standby Controller.

• **Stack Unit** - Any device functioning within the stack, including the Active Controller and Standby Controller.

  • **Upstream Stack Unit** - An upstream unit is connected to the first stacking port on the Active Controller. (The left-hand port as you face the stacking ports.) Refer to Figure 10 and Figure 11.
  
  • **Downstream Stack Unit** - A downstream unit is connected to the second stacking port on the Active Controller. (The right-hand port as you face the stacking ports.) Refer to Figure 10 and Figure 11.

**General terminology**

• **Bootup Role** - the role a unit takes during the boot sequence. This role can be standalone, Active Controller, Standby Controller, or stack member. The Active Controller or a standalone unit can access the full range of the CLI. Until a stack is formed, the local consoles on the Standby Controller and stack members provide access to a limited form of the CLI, such as the show, stack, and a few debug commands. When the stack is formed, all local consoles are directed to the Active Controller, which can access the entire CLI. The last line of output from the `show version` command indicates the role of a unit, unless it is a standalone unit, in which case it is not shown. For example:

  My stack unit ID = 1, bootup role = active

• **Clean Unit** - A unit that contains no startup flash configuration or run time configuration. To erase old configuration information, enter the `erase startup-config` command and reset the unit. For FCX devices, the run-time configuration on a clean unit may also contain default-port information.

• **Control Path** - A path across stacking links dedicated to carrying control traffic such as commands to program hardware or software image data for upgrades. A stack unit must join the control path to operate fully in the stack.

• **Default Port** - FastIron CX devices use the `default-port` command to define stacking port candidates.

• **Interprocessor Communications (IPC)** - The process by which proprietary packets are exchanged between stack unit CPUs.

• **IronStack** - A set of Brocade stackable units (maximum of eight) and their connected stacking links so that: all units can be accessed through their common connections, a single unit can manage the entire stack, and configurable entities, such as VLANs and trunk groups, can have members on multiple stack units.

• **Non-Functioning Stack Unit** - A stack unit that is recognized as a stack member, and is communicating with the Active Controller over the Control Path, but is in a non-functioning state. Because of this state, traffic from the non-stack ports will not be forwarded into the stack - they will be dropped or discarded. This may be caused by an image or configuration mismatch.

• **Sequential Connection** - Stack unit IDs, beginning with the Active Controller, are sequential. For example, 1, 3, 4, 6, 7 is sequential if Active Controller is 1 (gaps are allowed). 1, 7, 6, 4, 3 are non-sequential in a linear topology, but become sequential in a ring topology when counted from the other direction as: 1, 3, 4, 6, 7.
Building an IronStack

This section describes how to build an IronStack. Before you begin, you should be familiar with the supported stack topologies and the software requirements. When you are ready to build your stack, you can go directly to the instructions.

Brocade IronStack topologies

Brocade IronStack technology supports linear and ring stack topologies. Although Brocade stackable units may be connected in a simple linear topology, Brocade recommends a ring topology because it offers the best redundancy and the most resilient operation.

Figure 10 shows a linear stack topology. Figure 11 shows a ring stack topology. These illustrations depict one cabling configuration, but cabling methods may differ depending on requirements. For information about how to physically connect your stacking units, see the Foundry FastIron GS Compact Layer 2 Switch Hardware Installation Guide, the Foundry FastIron LS Hardware Installation Guide, or the Foundry FastIron CX Hardware Installation Guide.
**Mixed unit topologies**

A Brocade IronStack can contain all FGS-STK devices, all FLS-STK devices, or any combination of the two. FastIron CX-S devices cannot be combined in a stack with FGS-STK or FLS-STK devices. In mixed stacks, the stack ports are located on the front panel of FGS-STK devices, and on the rear panel of FLS-STK devices. Building a mixed-environment stack requires longer cables than an unmixed stack. Plan your installation accordingly.

For more information about connecting mixed stacks, see the *Foundry FastIron GS Compact Layer 2 Switch Hardware Installation Guide* and the *Foundry FastIron LS Hardware Installation Guide*.

For more information about connecting FastIron CX-S devices in stack topologies, see the *Brocade FastIron CX Hardware Installation Guide*.

*Figure 10* shows a linear stack topology. *Figure 11* shows a ring stack topology. These illustrations depict only one cabling configuration, but cabling methods may differ depending on requirements. For information about how to physically connect your stacking units, refer to the *Foundry FastIron GS Compact Layer 2 Switch Hardware Installation Guide* and the *Foundry FastIron LS Hardware Installation Guide*.

---

**NOTE**

FCX devices cannot be connected in a stack with non-FCX devices.

---

**FIGURE 10**  Linear stack topology (FGS-STK and FLS-STK devices)

---

**NOTE**

In FGS-STK and FLS-STK linear topologies, stack units at either end of the stack use only one stacking port. The unused stacking port may be used as a data port.

---

**FIGURE 11**  Ring stack topology (FGS-STK and FLS-STK devices)
In FGS-STK and FLS-STK ring topologies, stack units are considered both upstream and downstream because every unit can be accessed from either direction.

**FastIron CX stack topologies**

FastIron CX devices cannot be mixed in a stack with other devices. However, you can mix 24-port and 48-port FCX devices in a single stack, to a maximum of eight units per stack.

**FIGURE 12** FastIron CX linear and ring stack topologies
Software requirements

All units in an IronStack must be running the same software version. See “Troubleshooting an IronStack” on page 177 for more information about troubleshooting software and other mismatches on an IronStack.

IronStack construction methods

There are three ways to build an IronStack.

1. Use the secure-setup utility to form your stack. Secure-setup gives you control over the design of your stack topology and provides security through password verification. For the secure-setup procedure, refer to “Scenario 1 - Configuring a three-member IronStack in a ring topology using secure-setup” on page 117.

2. Automatic stack configuration. With this method, you enter all configuration information, including the module type and the priorities of all members into the unit you decide will be the Active Controller and set its priority to be the highest. When you enable stacking on the Active Controller the stack then forms automatically. This method requires that you start with clean units (except for the Active Controller) that do not contain startup or run time configurations. Refer to “Scenario 2 - Configuring a three-member IronStack in a ring topology using the automatic setup process” on page 121.

3. Manual stack configuration. With this method, you configure every unit individually, and enable stacking on each unit. Once the units are connected together, they will automatically operate as an IronStack. With this method the unit with the highest priority becomes the Active Controller, and ID assignment is determined by the sequence in which you physically connect the units. Refer to “Scenario 3 - Configuring a three-member IronStack in a ring topology using the manual configuration process” on page 124.

Configuration notes

Before you configure your IronStack, consider the following guidelines:

- Consider the number of units, and the mix of units your stack will contain, and how the stacking ports on the units will be connected. For more information refer to the Foundry FastIron GS Compact Layer 2 Switch Hardware Installation Guide, or the Foundry FastIron LS Hardware Installation Guide. For FCX devices, refer to the Brocade FastIron CX Hardware Installation Guide.

- The stack should be physically cabled in a linear or ring topology. Connect only those units that will be active in the stack.

- Make sure all units intended for the stack are running the same software version (release 05.0.00 and later). Refer to “Confirming software versions” on page 148.

- When you have a full stack of 8 units, you may need to increase the trap hold time from the default, which is 60 seconds, to three minutes (180 seconds). This will prevent the loss of initial boot traps. To increase the trap hold time, use the following command.

  FCX Switch# snmp-server enable traps hold 180
  Syntax: snmp-server enable traps hold <seconds>

  **NOTE**
  The router image takes longer to boot than the switch image.
Scenario 1 - Configuring a three-member IronStack in a ring topology using secure-setup

NOTE
This example uses FGS-STK and FLS-STK devices, however this process also works for FCX devices. For more detailed information about configuring an FCX IronStack, see “Configuring an FCX IronStack” on page 125.

This scenario describes how to build an IronStack using the secure-setup utility. Secure-setup lets you easily configure your entire stack through the Active Controller, which propagates the configuration to all stack members. Secure-setup is the most secure way to build an IronStack, and gives you the most control over how your stack is built. For example, secure-setup offers three security features that prevent unauthorized devices from accessing or joining an IronStack:

- Authentication of secure-setup packets provides verification that these packets are from genuine Brocade stack unit. MD5-based port verification confirms stacking ports.
- Superuser password is required to allow password-protected devices to become members of an IronStack.
- The stack disable command. When this command is issued, a unit does not listen for or send stacking packets, which means that no other device in the network can force the stacking-disabled unit to join an IronStack.

Secure-setup can also be used to add units to an existing IronStack (refer to “Adding, removing, or replacing units in an IronStack” on page 172) and to change the stack IDs of stack members (refer to “IronStack unit identification” on page 143).

When secure-setup is issued on a unit that is not already the Active Controller, this unit becomes the Active Controller, and, if it does not have an assigned priority, secure-setup assigns it a priority of 128. Any unit that then tries to join the stack must have an assigned priority less than 128. If secure-setup discovers a unit with a priority of 128 or higher, it changes the priority to 118.

When secure-setup is issued on a unit that is not already the Active Controller, this unit becomes the Active Controller. If this unit does not already have an assigned priority, secure-setup will assign this unit a priority of 128 by default, if no other units in the stack have a priority higher than 128. If another unit in the stack has a priority of 128 or higher, secure-setup will give the Active Controller a priority equal to the highest priority unit in the stack (which is by default the Standby Controller). When the Active Controller and the Standby Controller have identical priorities, during a reset, the old Active Controller cannot reassume its role from the Standby Controller (which has become the Active Controller at the reset).

If the previous Active Controller again becomes active, and you want it to resume the role of Active Controller, you should set the priority for the Standby Controller to a priority lower than 128. If you do not want the previous Active Controller to remain Active Controller, you can set the same priority for both Active and Standby controllers, (higher than, or equal to 128).

NOTE
Secure-setup works for units within a single stack. It does not work across stacks.

Figure 11 on page 114 shows an IronStack with three units in a ring topology. Refer to this figure as you follow the procedure steps for this scenario.

Follow the steps given below to configure a three-member stack in a ring topology using secure-setup.
1. Connect the devices using the stacking ports and stack cabling. For more information refer to the appropriate hardware installation guides.

2. Power on the units.

3. Connect your console to the intended Active Controller. The unit through which you run secure-setup becomes the Active Controller by default.

4. Issue the `stack enable` command on the intended Active Controller.

```
FGS648-STK Switch# config t
FGS648-STK Switch(config)# stack enable
FGS648-STK Switch(config)# exit
FGS648-STK Switch#
```

5. Enter the `stack secure-setup` command. As shown in the following example, this command triggers a Brocade proprietary discovery protocol that begins the discovery process in both upstream and downstream directions. The discovery process produces a list of upstream and downstream devices that are available to join the stack. Secure-setup can detect up to 7 units in each direction (14 total), but since the maximum number of units in a stack is 8, you must select a maximum of 7 units from both directions.

**NOTE**
To exit the secure-setup, enter `^C` at any time.

You should see output similar to the following.

```
FLS648-STK Switch# stack secure-setup
FLS648-STK Switch# Discovering the stack topology...

Current Discovered Topology - RING

Available UPSTREAM units
Hop(s)  Type    Mac Address
1       FLS624  0012.f239.2d40
2       FLS624  0012.f2d5.2100

Available DOWNSTREAM units
Hop(s)  Type    Mac Address
1       FLS624  0012.f2d5.2100
2       FGS624  0012.f239.2d40

Do you accept the topology (RING) (y/n)?: y

If you accept the topology, you will see output similar to the following.

Selected Topology:
Active  Id   Type    Mac Address
1    FLS648  00e0.52ab.cd00

Selected UPSTREAM units
Hop(s)  Id   Type    Mac Address
1       3    FLS624  0012.f239.2d40
2       2    FGS624  0012.f2d5.2100

Selected DOWNSTREAM units
Hop(s)  Id   Type    Mac Address
1  2  FGS624  0012.f2d5.2100
2  3  FLS624  0012.f239.2d40

Do you accept the unit ids (y/n)?: y

To accept the unit ID assignments, type y. If you do not want to accept the ID assignments, type n. You can use secure-setup to renumber the units in your stack. Refer to “Renumbering stack units” on page 174.

If you accept the unit IDs, the stack is formed, and you can see the stack topology using the show stack command.

FLS624-STK Switch# show stack
alone: standalone, D: dynamic config, S: static config
ID   Type   Role    Mac Address    Pri State    Comment
1  S FLS648 active 00e0.52ab.cd00 128 local    Ready
2  D FLS624 standby 0012.f2d5.2100  60 remote   Ready
3  D FGS624 member 0012.f239.2d40   0 remote   Ready

active        standby
+---+        +---+        +---+
-2/1| 1 |3/1--2/1| 2 |3/1--2/2| 3 |2/1-
+---+        +---+        +---+

Current stack management MAC is 00e0.52ab.cd00

NOTE
For field descriptions for the show stack command, refer to “Displaying stack resource information” on page 160.

NOTE
In this output, D indicates a dynamic configuration. After you perform a write memory, this display will change to S, for static configuration.

6. The Active Controller automatically checks all prospective stack members to see if they are password protected. If a unit is password protected, you will be asked to enter the password before you can add the unit. If you do not know the password, take one of the following actions:

- Discontinue secure-setup by entering ^C
- Obtain the device password from the administrator
- Continue secure-setup for your stack. The password-protected device and all devices connected behind it will not be included in the setup process.

In the following example, the second unit is password protected, so you are asked for the password.

FGS624-STK Switch# stack secure-setup
FGS624-STK Switch# Discovering the stack topology...

Verifying password for the password protected units...

Found UPSTREAM units
Hop(s)   Type    Mac Address
1  2  FLS648  001b.ed5e.c480
2  3  FGS648  00e0.5205.0000

Enter password for FGS648 located at 2 hop(s): ****

Enter the number of the desired UPSTREAM units (1-2)[1]: 2
5 Building an IronStack

Selected Topology:
Active  Id   Type    Mac Address
 1  FGS624  00e0.5201.4000

Selected UPSTREAM units
Hop(s)  Id   Type    Mac Address
 1     2    FLS648  001b.ed5e.c480
 2     3    FGS648  00e0.5205.0000

Do you accept the unit id's (y/n)?: y

7. When the Active Controller has finished the authentication process, you will see output that shows the suggested assigned stack IDs for each member. You can accept these recommendations, or you can manually configure stack IDs. Enter the show stack command to verify that all units are in the ready state.

FGS624-STK Switch# show stack
alone: standalone, D: dynamic config, S: static config
ID Type Role    Mac Address    Pri State    Comment
 1 S FGS624 active  00e0.5201.4000 128 local    Ready
 2 S FLS648 standby 001b.ed5e.c480   0 remote   Ready
 3 S FGS648 member  00e0.5205.0000   0 remote   Ready

---+        +---+        +---+
-2/1| 1 |3/1--2/1| 2 |3/1--2/2| 3 |2/1--
    +---+        +---+        +---+   |
    |                                     |
---+-------------------------------------|
Current stack management MAC is 00e0.5201.4000
FLS624-STK Switch#

NOTE
For field descriptions for the show stack command, refer to “Displaying stack resource information” on page 160.

8. Enter the write memory command on the Active Controller once all of the stack units are active. This command initiates configuration synchronization, which copies the configuration file of the Active Controller to the rest of the stack units.

NOTE
The secure-setup process may modify your configuration with information about new units, stacking ports, etc. For this reason, it is very important to save this information by issuing the write memory command. If you do not do this, you may lose your configuration information the next time the stack reboots.

The secure-setup process for your stack is now complete.

NOTE
During the secure-setup process, after 1 minute of inactivity, authentication for stack members will expire and you will need to restart the process.
Scenario 2 - Configuring a three-member IronStack in a ring topology using the automatic setup process

This example uses FGS-STK and FLS-STK devices, however this process also works for FCX devices. FCX devices determine stacking port candidates through the default-port setting. An FCX device with the default port configuration is still considered a clean unit. To ensure that the device remains a clean unit, do not do a write memory on the device.

For more detailed information about configuring an FCX IronStack, see “Configuring an FCX IronStack” on page 125.

Follow the steps given below to configure a three-member IronStack in a ring topology using automatic setup process.

1. Power on the devices.
2. This process requires clean devices (except for the Active Controller) that do not contain any configuration information. To change a device to a clean device, enter the `erase startup-config` command and reset the device. When all of the devices are clean, continue with the next step.

   **NOTE**
   The physical connections must be sequential, and must match the stack configuration.

3. Log in to the device that you want to be the Active Controller.
4. Configure the rest of the units by assigning ID numbers and module information on each unit. The stack ID can be any number from 1 through 8.

   ```
   FLS624-STK Switch# config t
   FLS624-STK Switch(config)# stack unit 2
   FLS624-STK Switch(config-unit-2)# module 1 fls-24-port-copper-base-module
   FLS624-STK Switch(config-unit-2)# module 2 fls-xfp-1-port-10g-module
   FLS624-STK Switch(config-unit-2)# module 3 fls-xfp-1-port-10g-module
   FLS624-STK Switch(config-unit-2)# stack unit 3
   FLS624-STK Switch(config-unit-3)# module 1 fls-24-port-copper-base-module
   FLS624-STK Switch(config-unit-3)# module 2 fls-xfp-1-port-10g-module
   FLS624-STK Switch(config-unit-3)# module 3 fls-xfp-1-port-10g-module
   ```

   **NOTE**
   Each stack unit must have a unique ID number.

5. Assign a priority to the Active Controller using the `priority` command, as shown.

   ```
   FLS624-STK Switch(config)# stack unit 1
   FLS624-STK Switch(config-stack-1)# priority 255
   ```

   **Syntax:** priority <num from 0-255> (255 is the highest priority)

6. Assign a priority to the unit that will act as Standby Controller.

   ```
   FLS624-STK Switch(config)# stack unit 2
   FLS624-STK Switch(config-unit-2)# priority 240
   ```

7. Do a `write memory` command to save your settings.

8. Enter the `stack enable` command.
9. Physically connect the devices in a stack topology, which triggers an election during which the stack is automatically configured. For more information about cabling the devices, refer to the appropriate hardware installation guides.

**NOTE**
When you are configuring individual stack units, you can skip ID numbers. However, the sequence in which the units are connected must match the order in which you configure them. For example, you could configure unit 1 as FGS624, unit 3 as FGS648, unit 4 as FGS624, unit 6 as FLS624 and unit 7 as FLS648. The physical connection order must be: Active (FGS624), FGS648 (3), FGS624 (4), FLS624 (6) and FLS648 (7). The Active Controller is stack unit 1.

10. Verify your stack configuration by entering the `show running config` command.

```
FLS624-STK Switch# show running config
Current configuration:
! ver 05.0.02
! stack unit 1
  module 1 fls-24-port-copper-base-module
  module 2 fls-xfp-1-port-10g-module
  module 3 fls-xfp-1-port-10g-module
  priority 255
stack unit 2
  module 1 fls-24-port-copper-base-module
  module 2 fls-xfp-1-port-10g-module
  module 3 fls-xfp-1-port-10g-module
  priority 240
stack unit 3
  module 1 fls-24-port-copper-base-module
  module 2 fls-xfp-1-port-10g-module
  module 3 fls-xfp-1-port-10g-module
stack enable
!
```

**NOTE**
For field descriptions for the `show running config` command, refer to “Displaying running configuration information” on page 168.

11. To see information about your stack, enter the `show stack` command.

```
FLS624-STK Switch# show stack
alone: standalone, D: dynamic config, S: static config
ID   Type   Role    Mac Address    Pri State    Comment
-----+--------+---------+----------------+------------+-------------
1 S   FLS624 active 00e0.5200.0100 255 local Ready
2 S   FLS624 standby 0012.f2eb.afc0 240 remote Ready
3 S   FGS624 member 001b.ed5d.a1c0 0 remote Ready

active  standby
+-++-+-++-+-++-
-2/1| 1 |3/1--2/1| 2 |3/1--2/2| 3 |2/1-
|+-++-+-++-+-++
|
|-----------------------------|

Current stack management MAC is 00e0.5200.0100
FLS624-STK Switch#
```
NOTE
For field descriptions for the `show stack` command, refer to “Displaying stack resource information” on page 160.

Configuration notes for scenario 2

Consider the following items when building a stack using the automatic setup process:

- If a new unit configuration matches other unit configurations, the Active Controller gives this unit the lowest sequential ID. For example, in a stack configuration that contains eight FGS624 configurations, but only units 1, 4 and 8 are currently active, if you place a new FGS624 unit between units 4 and 8, the new unit will be assigned ID 5, even though it might match unused IDs 2, 3, 5, 6, and 7, because 5 is the lowest sequential ID.

- In a ring topology, the same new unit might assume either ID if either direction produces sequential IDs. For example, in a four-member stack where IDs 2 and 4 are reserved, a new unit could assume either ID 2 or ID 4 because either ID 1, 2, 3 or 1, 3, 4 is sequential.
Building an IronStack

Scenario 3 - Configuring a three-member IronStack in a ring topology using the manual configuration process

NOTE
This example uses FGS-STK and FLS-STK devices, however this process also works for FCX devices. For more detailed information about configuring an FCX IronStack, see “Configuring an FCX IronStack” on page 125

Follow the steps given below to configure a three-member IronStack in a ring topology using the manual configuration process.

1. Power on the devices. Do not connect the stacking cables at this point.

2. Assign a priority of 255 to unit 1, and a priority of 240 to unit 3 using the priority command. You do not have to assign a priority to the third device. Enter the stack enable command on each device. In this example, device 1 will be the Active Controller and device 2 will be the Standby Controller.

   **Unit 1**
   
   FLS624-STK Switch# config t
   FLS624-STK Switch(config)# stack unit 1
   FLS624-STK Switch(config-unit-1)# priority 255
   FLS624-STK Switch(config-unit-1)# stack enable

   Enable stacking. This unit actively participates in stacking
   Write startup-config done.
   FLS624-STK Switch(config-unit-1)# Flash Memory Write (8192 bytes per dot)
   .Flash to Flash Done.
   FLS624-STK Switch(config-unit-1)# end

   **Unit 2**
   
   FLS624-STK Switch# config t
   FLS624-STK Switch(config)# stack enable

   Enable stacking. This unit actively participates in stacking
   FLS624-STK Switch(config)# Handle election, was standalone --> member, assigned-ID=2, T=261285 ms.
   Write startup-config done.
   FLS624-STK Switch(config-unit-1)# Flash Memory Write (8192 bytes per dot)
   .Flash to Flash Done.
   FLS624-STK Switch(config-unit-1)# end
   FLS624-STK Switch# config t

   **Unit 3**
   
   FLS624-STK Switch# config t
   FLS624-STK Switch(config)# stack unit 1
   FLS624-STK Switch(config-unit-1)# priority 240
   FLS624-STK Switch(config-unit-1)# stack enable

   Enable stacking. This unit actively participates in stacking
   FLS624-STK Switch(config-unit-1)# end

3. Connect the devices in a stack topology. The Active Controller will retain its ID. The rest of the units are assigned unique ID numbers depending on the sequence in which you connected them.
For more information about cabling the devices, refer to the appropriate hardware installation guides.

**NOTE**
This method does not guarantee sequential stack IDs. If you want to change stack IDs to make them sequential, you can use secure-setup. Refer to “Renumbering stack units” on page 174.

### Configuring an FCX IronStack

The process for building a stack of FCX devices is similar to that for mixed stacks of FGS-STK and FLS-STK devices, except that FCX devices cannot be intermixed with non-FCX devices, and FCX devices have more possible stacking ports.

Every FCX device contains two default 16 Gbps stacking ports on the rear panel and two 10 Gbps ports on the front panel that can also be used as stacking ports. An FCX IronStack may contain up to 8 24-port and 48-port devices, using any combination of the rear panel stacking ports and the front panel optional stacking ports. To use ports other than the factory-default 16 Gbps ports, you must define the ports for each device in the run time configuration. You can also configure the 16 Gbps ports to operate as 10 Gbps ports. See “Configuring FCX stacking ports” on page 125.

An FCX “clean unit” may contain a default port configuration, but it is still considered a clean unit. To preserve this state, do not do a write memory on the unit before you build the stack. An FCX device with the default port configuration is still considered a clean unit. To ensure that the device remains a clean unit, do not do a write memory on the device. (Write memory adds a startup-config, and the device is no longer a clean unit.)

**NOTE**
The automatic setup process will not work for FCX devices that do not contain the default port information in their clean unit configurations.

### Configuring FCX stacking ports

FastIron CX devices have two 10 Gbps ports on the front panel and two 16 Gbps ports on the rear panel. All of these ports may be used as stacking ports, however there are some rules for configuring the ports when setting up an FCX IronStack.

**Configuring CX4 ports from 16 Gbps to 10 Gbps**

You can configure the 16 Gbps CX4 ports to operate as 10 Gbps ports, as shown in the following example.

**NOTE**
Both ends of a link must be configured for 10 Gbps for the link to operate as 10 Gbps. If you want the link to operate as a 16 Gbps link, both ends of the link must be configured for 16 Gbps.

```
FCX624S-F Router# config t
FCX624S-F Router(config)# interface e 1/2/1
FCX624S-F Router(config-if-e10000-cx4-1/2/1)# speed-duplex

FCX624S-F Router(config-if-e10000-cx4-1/2/1)#

**Configuring default ports on FCX devices**

FCX devices ship with two default stacking ports configured. Use the `stack-port` command to select only one of these factory default ports as the stacking port. If you do not configure `stack-port`, both default ports will operate as stacking ports.

Use the `default-port` command to use ports other than the factory default ports as stacking ports. You must configure default-port on each unit before building a stack. Once you have configured default-port on all units, you can then use any of the three stack construction methods to build a stack. The Active Controller then learns the port configuration for each unit.

**NOTE**
You cannot change the setting for a default port if the port is in use.

**Configuring stacking ports**

When stacking is enabled on FGS-STK and FLS-STK devices, the first two ports can act as stacking ports. The stacking ports for FGS-STK devices are ports X/2/1 and X/2/2. The stacking ports for FLS-STK devices are ports X/2/1 and X/3/1.

You have the option to configure only one of these ports as a stacking port, in which case the other port functions as a regular port. **Table 33** identifies these ports for each model.

<table>
<thead>
<tr>
<th>Device</th>
<th>Slot 1</th>
<th>Slot 2</th>
<th>Slot 3</th>
<th>Slot 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLS624-STK</td>
<td>24 10/100/1000 ports on front panel</td>

<td>N/A</td>
</tr>
</tbody>
</table>
FIGS624XGP-STK Switch(config)# stack unit 3
FIGS624XGP-STK Switch(config-unit-3)# stack-port 3/2/1
Syntax: [no] stack-port stack-unit/slotnum/portnum
If you enter an incorrect stack port number, you will get an error similar to the following.

FGS624XGP-STK Switch(config-unit-3)# stack-port 3/4/1
Error! port 3/4/1 is invalid
FGS624XGP-STK Switch(config-unit-3)# stack-port 3/2/1

To return both ports to stacking status, enter the no stack-port command on the single stacking port. This converts both ports to stacking ports. By default, if both ports are stacking ports, they are displayed by the system only when stacking is enabled. If only one port is configured as a stacking port, the system always displays this port.

**Build a stack using the default 16 Gbps stacking ports**

On all FCX devices, the 16 Gbps ports are the default stacking ports. If you are building a stack of FCX devices, and you want to use only the 16 Gbps ports, simply connect the units and use secure-setup on stack unit 1. secure-setup will build the stack automatically, as shown in the following example.

1. To build a stack of three FCX devices using the default stacking ports, first connect all three devices using the stacking ports. If you issue a show stack and show running config commands at this point on each stack unit 1, you should see results similar to the following.

FCX624S-ADV Router# show stack
***** Warning! stack is not enabled. *****

stack enable
**Build a stack using the 10 Gbps stacking ports**

If you are building a stack of FCX devices, and you want to use only the 10 Gbps ports, you must change the default port setting on all units before you connect the stack. Once this is done, you can enable stacking and secure-setup on stack unit 1 and the stack will build automatically, as shown in the following example.

---

**NOTE**

For this scenario, all units must be clean units (unit ID 1) before you add them to the stack. FCX devices determine stacking port candidates through the default-port setting. An FCX clean unit with the default-port configuration is still considered a clean unit. To make sure the device remains a clean unit, do not do a write memory on the device (which adds a startup-config, and the device is no longer a clean unit).

1. Change default-port from the 16 Gbps rear panel port to the 10 Gbps front panel port for all 3 units, as shown.

   **For stack unit 1:**
   
   FC624S-ADV Router# config t
   FC624S-ADV Router(config)# stack unit 1
   FC624S-ADV Router(config-unit-1)# default-port 1/3/1 1/3/2
   FC624S-ADV Router(config-unit-1)# write mem
   Write startup-config done.
   FC624S-ADV Router(config-unit-1)# Flash Memory Write (8192 bytes per dot)
   Flash to Flash Done.
   FC624S-ADV Router(config-unit-1)# end

   **For stack unit 2:**
   
   FC624S-ADV Router# config t
   FC624S-ADV Router(config)# stack unit 1
   FC624S-ADV Router(config-unit-1)# default-port 1/3/1 1/3/2
   FC624S-ADV Router(config-unit-1)# write mem
   Write startup-config done.
   FC624S-ADV Router(config-unit-1)# Flash Memory Write (8192 bytes per dot)
   Flash to Flash Done.
   FC624S-ADV Router(config-unit-1)# end

   **For stack unit 3:**
   
   FC624S-ADV Router# config t
   FC624S-ADV Router(config)# stack unit 1
   FC624S-ADV Router(config-unit-1)# default-port 1/3/1 1/3/2
   FC624S-ADV Router(config-unit-1)# write mem
   Write startup-config done.
   FC624S-ADV Router(config-unit-1)# Flash Memory Write (8192 bytes per dot)
   Flash to Flash Done.
   FC624S-ADV Router(config-unit-1)# end

   Enter the show stack command and the show running config command on each unit to confirm the settings. The following example shows settings for stack unit 1.
Building an IronStack

2. Connect the devices using the front panel 10 Gbps ports.

3. Log in to the unit that is functioning as the Active Controller (in this example, stack unit 1) and enable stacking and start stack secure-setup, as shown:

   On stack unit 1:

   FCX624S-ADV Router# config t
   FCX624S-ADV Router(config)# stack enable
   Enable stacking. This unit actively participates in stacking
   FCX624S-ADV Router(config)# end
   FCX624S-ADV Router# stack secure-setup
   FCX624S-ADV Router# Discovering the stack topology...
   Available DOWNSTREAM units

   !
Building an IronStack

Building an FCX IronStack using default 16 Gbps stacking ports and front panel 10 Gbps ports.

Perform the following steps to configure an FCX IronStack using the default 16 Gbps ports on stack unit 1, a 16 Gbps and a 10 Gbps port on stack unit 2, and a 10 Gbps port on stack unit 3.

**NOTE**
When more than three units in an FCX IronStack are using a mix of 10 Gbps and 16 Gbps ports, and you want to change the port settings from 10 Gbps back to 16 Gbps, the unit where you are making the changes may be disconnected from the Active Controller.

1. Since stack unit 1 will be using the default 16 Gbps ports, you do not need to define the default port for this unit.
2. On the device that will become stack unit 2, configure both the 16 Gbps port and the 10 Gbps port as the default ports.

**NOTE**
Until the stack is built, all units will display as stack unit 1.

```
FCX648SHPOE Router# config t
FCX648SHPOE Router(config)# stack unit 1
FCX648SHPOE Router(config-unit-1)# default-port 1/2/1 1/3/1
FCX648SHPOE Router(config-unit-1)# write memory
Write startup-config done.
FCX648SHPOE Router(config-unit-1)# Flash Memory Write (8192 bytes per dot)
Flash to Flash Done.
FCX648SHPOE Router(config-unit-1)# end
```

3. On the device that will become stack unit 3, configure the 10 Gbps port as the default port.

```
FCX648SHPOE Router# config t
FCX648SHPOE Router(config)# stack unit 1
FCX648SHPOE Router(config-unit-1)# default-port 1/3/1 1/3/2
FCX648SHPOE Router(config-unit-1)# write memory
```
Write startup-config done.
FCX648SHPOE Router(config-unit-1)# Flash Memory Write (8192 bytes per dot)
. Flash to Flash Done.
FCX648SHPOE Router(config-unit-1)# end

4. Connect the 16 Gbps port between stack unit 1 (1/2/1) and stack unit 2 (2/2/1) then connect the 10 Gbps port between stack unit 2 (2/3/1) and stack unit 3 (3/3/1).

On stack unit 1:
FCX624SHPOE Router# show interface brief | in /2/
1/2/1 Up Forward Full 16G None No 0 001b.f2e5.0119
1/2/2 Down None None None None No 0 001b.f2e5.011a
FCX624SHPOE Router#

On stack unit 2:
FCX648SHPOE Router# show interface brief | in /2/
2/2/1 Up Forward Full 16G None No 0 0012.f2d6.0542
2/2/2 Down None None None None No 0 0012.f2d6.0543
FCX648SHPOE Router#

On stack unit 3:
FCX-648SHPOE Router# show interface brief | in /3/
1/3/1 Up Forward Full 10G None No 0 0012.f2d6.0544
1/3/2 Down None None None None No 0 0012.f2d6.0545

You are now ready to activate your stack using stack enable and secure-setup. Proceed to the next section.

**Using secure-setup to build an FCX stack**

You can use the secure-setup utility to build an FCX IronStack by performing the following steps.

1. When you have designated the desired stacking ports and connected your FCX units together, on stack unit 1, enter stack enable and stack secure-setup, as shown.

    FCX624SHPOE Router# stack enable
    FCX624SHPOE Router# stack secure-setup
    FCX624SHPOE Router# Discovering the stack topology...

    Available UPSTREAM units

Verifying an IronStack configuration

Follow the steps given below to verify your IronStack configuration.

1. Log in to the Active Controller and verify the stack information by entering the `show running-config` and `show stack` or `show stack detail` commands. If your stack is configured properly, you should see the following:
   - One Active Controller, one Standby Controller, and stack members.
   - All stack members show a status of Ready.

The following output shows a stack of mixed FGS and FLS devices. For output from an FCX stack, see “Verifying an FCX IronStack configuration” on page 136.

```
FLS624-STK Switch(config)# show running-configuration

My stack unit ID = 8, bootup role = active
*** NOT FOR PRODUCTION ***

**NOTE**
For field descriptions for the `show running config` command, refer to “Displaying running configuration information” on page 168.

**NOTE**
For field descriptions for the `show stack` and `show stack detail` commands, refer to “Displaying stack resource information” on page 160.

The output from the `show stack` command contains a visual diagram of the stack. The dashed line between ports 1/2/1 and 3/2/1 indicates that this stack is configured in a ring topology. If the link between ports 1/2/1 and 3/2/1 is lost, the stack topology changes to linear, and the diagram changes to resemble the following.

```
 active               standby
+-----+      +-----+      +-----+
-2/1 | 1 |3/1--2/1| 2 |3/1--2/2| 3 |2/1-
      +-----+      +-----+      +-----+
```

The interfaces at either of a stack member are stacking ports. If no interface is displayed, it indicates that there is no stacking port configured. For example, the following diagram shows that stack units 1 and 3 each have only one stacking port configured.

```
 active               standby
+-----+      +-----+      +-----+
| 1 |3/1--2/1| 2 |3/1--2/2| 3 |
      +-----+      +-----+      +-----+
```

For more detailed information, you can enter the `show stack detail` command.

**IronStack management**

This section describes how to manage your IronStack:
Managing your Brocade IronStack

Your Brocade IronStack can be managed through a single IP address. You can manage the stack using this IP address even if you remove the Active Controller or any member from the stack. You can also connect to the Active Controller through Telnet or SSH using this address. All management functions, such as SNMP, use this IP address to acquire MIB information and other management data.

A Brocade IronStack can be configured and managed using the command line interface (CLI) over a serial connection to a console port, or using IronView Network Manager. To determine what version of IronView Network Manager supports IronStack refer to the IronView Network Manager User Guide.

Logging in through the CLI

You can access the IronStack and the CLI in two ways:

- Through a direct serial connection to the console port
- Through a local or remote Telnet session using the stack IP address

You can initiate a local Telnet or SNMP connection by attaching a cable to a port and specifying the assigned management station IP address.

The stacking commands in the CLI are organized into the following levels:

- **Global** – Commands issued in the global mode are applied to the entire stack.
- **Stack Member Configuration Mode** – Commands issued in this mode apply to the specified stack member. Configuration information resides in the Active Controller.
- **Configuration Mode** – This is where you make configuration changes to the unit. To save changes across reloads, you need to save them to the Active Controller startup-config file. The configuration mode contains sub-levels for individual ports, for VLANs, for routing protocols, and other configuration areas.

**NOTE**

By default, any user who can open a serial or Telnet connection to the IronStack can access all of these CLI levels. To secure access, you can configure Enable passwords or local user accounts, or you can configure the Active Controller to use a RADIUS or TACACS/TACACS+ server for authentication. Refer to Chapter 39, “Securing Access to Management Functions”.

Logging in through IronView Network Manager

IronView Network Manager supports stack technology. To determine what version of IronView Network Manager supports stack technology and to find information on IronView Network Manager, refer to the IronView Network Manager User Guide.

Logging in through the console port

When a device becomes a stack member in the IronStack, it establishes a remote connection to a virtual console port on the Active Controller. Input and output are relayed between the physical console port on the stack member and the virtual console port on the Active Controller. Since each stack member connects to an independent virtual console port on the Active Controller, the console ports on multiple stack units may be used simultaneously. However, messages displayed on the Active Controller physical console port during a reload will not be visible on the console ports.
of the stack members because the remote connections are not established until the software loading process is complete. It is preferable to connect a cable to the console port on the stack unit that will normally be the Active Controller, rather than to the console port of one of the other stack units.

When a stack unit establishes communication with the Active Controller, it also establishes a remote console session to the Active Controller. In a normally functioning IronStack, a console cable may be connected to any of the stack units and provide access to the same commands on the Active Controller.

You can terminate a session by entering Ctrl+O followed by 'x' or 'X', or by entering the 'exit' command from the User EXEC level, or by entering the 'logout' command at any level.

**NOTE**
For the rconsole connections from the stack units to the Active Controller, the escape sequence and other methods of terminating the session are not available.

**NOTE**
Error messages that are generated during a reload of the Active Controller will not appear on rconsole connections from the stack units to the Active Controller. To see these error messages, you must connect a console cable to the Active Controller itself.

To establish an rconsole session, enter the rconsole command as shown:

```
FGS648P-STK Switch# rconsole 1
```

**Syntax:** rconsole stack-unit

The following example shows how to establish rconsole sessions to stack members. Notice that the show stack command on the stack members displays different information than what is shown when the show stack command is entered on the Active Controller.

To see the status of your stack units, enter the show stack command on the Active Controller.

```
FGS648P-STK Switch# show stack
alone: standalone, D: dynamic config, S: static config
ID Type Role       Mac Address Pri  State    Comment
1 S FGS648P active 0012.f2de.8100 128  local    Ready
2 S FGS624P standby 0012.f2e2.ba40 0    remote   Ready
3 S FGS624P member 001b.ed7a.22c0 0    remote   Ready
```

To see the status of your stack units, enter the show stack command on the Active Controller.

```
Current stack management MAC is 0012.f2de.8100
```

**NOTE**
For field descriptions for the show stack command, refer to “Displaying stack resource information” on page 160.

Establish a remote console session with stack unit 2.
Establish a remote console session with stack unit 3.

3 S FGS624P member 001b.ed7a.22c0 0 local Ready
rconsole-3@FLS624P Switch# logout
Disconnected. Returning to local session...

IronStack management MAC address

The IronStack is identified in the network by a single MAC address, usually the MAC address of the Active Controller (the default). If a new Active Controller is elected, the MAC address of the new Active Controller (by default) becomes the MAC address for the entire stack. However, you can manually configure your stack to use a specified MAC address. Refer to “Manual allocation of the IronStack MAC address” on page 141.

In an IronStack, the management MAC address is generated by the software, and is always the MAC address of the first port of the Active Controller. This ensures that the management MAC address remains consistent across stack reboots, and helps prevent frequent topology changes as a result of protocol enable, disable, and configuration changes.

When you are configuring Layer 2 protocols on stack units, such as STP, RSTP, and MSTP, the management MAC address of the Active Controller acts as the Bridge ID.

You can also configure the IronStack to retain its original MAC address, or wait for a specified amount of time before assuming the address of a new Active Controller, using the Persistent MAC Address feature (refer to “Persistent MAC address” on page 153).

NOTE
All physical IP interfaces on IronStack devices share the same MAC address. For this reason, if more than one connection is made between two devices, one of which is an FGS-STK or FLS-STK device, Brocade recommends the use of virtual interfaces. It is not recommended to connect two or more physical IP interfaces between two routers.

Manual allocation of the IronStack MAC address

You can manually configure your IronStack to use a specific MAC address. This overrides the default condition where the stack uses the MAC address of whatever unit is currently serving as Active Controller.
NOTE
This command is useful for administration purposes, however it should be used with caution to prevent duplication of MAC addresses.

To configure a stack MAC address manually, enter the following command.

FGS648P-STK Switch(config)# stack mac 0000.0000.0011

Syntax:  [no] stack mac mac-address

mac-address - a hexadecimal MAC address in the xxxx.xxxx.xxxx format

Enter the no form of this command to return the MAC address to that of the Active Controller.

Output for this command resembles the following.

FLS648-STK Switch(config)# stack mac 0000.0000.0011
FPLS648-STK Switch(config)# show running-config
Current configuration:
!
ver 05.0.01 100T7e1

Boot Prom MAC: 0012.f2de.9440
Management MAC: 0000.0000.0011

The stack unit 2 chassis info:

Power supply 1 (NA - AC - Regular) present, status ok
Power supply 2 not present
NOTE
For field descriptions for the show chassis command, refer to “Displaying chassis information” on page 158.

Removing MAC address entries

You can remove the following types of learned MAC address entries from the Brocade system MAC address table:

- All MAC address entries
- All MAC address entries for a specified Ethernet port
- All MAC address entries for a specified VLAN
- A specified MAC address entry in all VLANs

For example, to remove entries for the MAC address 000d.cb80.00d0 in all VLANs, enter the following command at the Privileged EXEC level of the CLI.

```
FCX648SHPOE Switch# clear mac-address 000d.cb80.00d0
```

Syntax: clear mac-address mac-address | ethernet port-num | vlan number

If you enter the clear mac-address command without any parameters, the software removes all MAC entries.

Use the <mac-address> parameter to remove a specified MAC address from all VLANs. Specify the MAC address in the following format: HHHH.HHHH.HHHH.

Use the ethernet port-num parameter to remove all MAC addresses for a specified Ethernet port.

Use the vlan number parameter to remove all MAC addresses for a specified VLAN.

IronStack unit identification

Stack units are identified by numbers 1 though 8. You can display stack unit IDs by entering the show stack command (refer to “Displaying IronStack information” on page 156).

A new device (one that has not been connected in an IronStack or has not been manually assigned a stack unit number) ships with a default number of 1. Once you enable stacking and the unit becomes part of an IronStack, its default stack unit number changes to the lowest available number in the stack.

Stack units must each have a unique identification number. Every stack member, including any standalone units, retains its stack unit number unless that number is already being used in the stack, or until you manually renumber the unit using secure-setup. For more information about how to renumber stack IDs using secure-setup, refer to “Renumbering stack units” on page 174.

IronStack unit priority

A unit with a higher priority is more likely to be elected Active Controller. The priority value can be 0 to 255 with a priority of 255 being the highest. The default priority value assigned to the Active Controller and Standby is 128.
You can assign the highest priority value to the stack unit you want to function as the Active Controller. When you enter a new priority value for a stack unit, that value takes effect immediately, but does not affect the current Active Controller until the next reset. Refer to “Changing the priority of a stack unit” on page 144.

You can give your Active and Standby Controllers the same priority, or different priorities (Active highest, Standby second-highest). When Active and Standby Controllers have the same priority, if the Active fails and the Standby takes over, then the original Active becomes operational again, it will not be able to resume its original role. In the same situation, when the priorities of the Active and Standby Controllers are different, the old Active Controller will regain its role and will reset the other units.

If you want to assign the same priority to the Active and Standby Controllers, you must do so after the stack is formed. This prevents the intended Standby Controller from becoming the Active Controller during stack construction.

Changing the priority of a stack member will trigger an election that takes effect immediately unless the Active Controller role changes. If this is the case, the changes will not take effect until after the next stack reload.

To display stack member priority values, enter the show stack command.

```
FLS624-STK Switch(config-unit-3)# show stack
alone: standalone, D: dynamic config, S: static config
ID Type Role      Mac Address      Pri State    Comment
1 S   FLS624 active    0012.f2eb.a900   128  local    Ready
2 S   FLS624 standby   00f0.424f.4243   0    remote   Ready, member after reload
3 S   FLS624 member    001b.ed5d.a100   200  remote   Ready, active after reload
FLS624-STK Switch(config-unit-3)#
```

Changing the priority of a stack unit

To change the priority value for a stack unit, enter the priority command.

```
FLS624-STK Switch(Config)# stack unit 1
FLS624-STK Switch(Config-unit-1)# priority 128
```

Syntax: `priority num from 0-255` (255 is the highest priority)

CLI command syntax

CLI syntax that refers to stack units must contain all of the following parameters:

Syntax: `command [stack-unit | slotnum | portnum]`

- `stack-unit` - required on stackable FastIron devices running software release 0.5.00 or later. If the FastIron GS or LS device is operating as a standalone, the stack-unit will always be 1. Stack IDs can be any number from 1 through 8.
- `slotnum` - required on chassis devices and on FastIron GS devices running software release 02.5.00 or later. For stackable devices, slotnum refers to specific groups of ports on each device.
- `portnum` - a valid port number.
- `port-list` - you can list all of the ports individually, use the keyword to to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually.
**IronStack CLI commands**

CLI commands specific to stacking are listed in Table 34, with a link to the description for each command. For more information about CLI commands and syntax conventions, refer to Chapter 2, “Getting Familiar with Management Applications”.

Stacking mode

When a unit is stack-enabled or joins a stack either actively or passively, it reserves Priority Queue 7 for stacking traffic control, assigns buffers for the stacking ports, and configures the first two 10 Gbps ports as stacking ports.

NOTE
Designated stacking ports cannot contain any configuration information, such as vlan membership, etc. If configuration information exists, stack enable will fail. You must remove all configuration information from the port and re-issue the stack enable command.

To enable stacking mode on a new unit before you add it to the stack, enter the following command.

```
FLS648-STK Switch(config)# stack enable
```

Enable stacking. This unit actively participates in stacking

Syntax:  [no] stack enable

To see the configuration of the stack at any time, enter the show stacking configuration command.

To remove stacking capability, enter the no stack enable command. This prevents the unit from actively sending out probe messages, however the unit could still be called to join a stack by an Active Controller. To prevent this, enter the stack disable command.

The stack disable command prevents a unit from sending or listening for any stacking probe messages. In this mode, the unit cannot be forced to join a stack.

```
FLS648 Switch(config)# stack disable
```

Syntax:  [no] stack disable

To remove this restriction, enter the no stack disable command.

Upgrading software

This section describes how to upgrade FGS and FLS devices currently running release 04.2.00 or earlier to release 04.1.00. This section does not apply to FCX devices.

NOTE
If you are running software versions earlier than 04.2.00 (for example, 04.1.00, 04.1.01...), you must first upgrade to release 04.2.00 or later (e.g., 04.3.01) non-stacking software before upgrading to 05.0.01. Software releases that are numbered 04.x.xx and lower are non-stacking releases. Software release that are numbered 05.x.xx and higher are stacking releases.

Perform the following steps to upgrade software version 04.2.00 to version 04.1.00.
1. Perform the memory and EEPROM upgrade on the device. For more information, see the instructions that shipped with your upgrade kit.

**NOTE**
Software version 04.1.00 will not work on standalone devices that have not been upgraded to support IronStack stacking technology.

2. Copy new boot code using the following command.

   FGS624P-STK Switch# copy tftp flash X.X.X.X FGZ05000.bin bootrom

   You should see output similar to the following.

   FGS624P-STK Switch# Flash Memory Write (8192 bytes per dot).........................
   (Boot Flash Update)Erase........Write..........
   TFTP to Flash Done

3. Copy the 04.1.00 software image using the following command.

   FGS624P-STK Switch# copy tftp flash X.X.X.X FGS05001.bin primary
   FGS624P-STK Switch# Flash Memory Write (8192 bytes per dot)
   ..................................................
   ...........................................
   ...........................................
   TFTP to Flash Done
   FGS624P-STK Switch# show flash
   Compressed Pri Code size = 3096603, Version 05.0.01 (FGS05001.bin)
   Compressed Sec Code size = 2873963, Version 04.2.00 (fgs04200.bin)
   Compressed BootROM Code size = 416315, Version 05.0.01T7e5
   Code Flash Free Space = 196608
   FGS624P-STK Switch#

4. Restart the device with the upgraded software and proceed to step 5. If you encounter a problem at this step, make sure the memory DIMM and stacking EEPROM are installed correctly. If the stacking EEPROM is missing or not installed correctly or if you have installed the wrong EEPROM, you may see output similar to the following.

   FGS MEM size: 0x10000000
   FGS Flash config....
   FGS Boot Code Version 05.0.01
   Enter 'b' to stop at boot....
   BOOT INFO: load monitor from primary, size=103408
   BOOT INFO: load image from primary........
   BOOT INFO: bootparam at 000543e8, mp_flash_size=002ee6c5
   BOOT INFO: code decompression completed
   BOOT INFO: branch to 00400100
   Starting Main Task....... 
   ############################################################################### 
   ERR: This software needs License PROM to be installed in the system
   ############################################################################### 
   System Reset!

   If your memory DIMM is not installed correctly, you will see output similar to the following.

   FGS Mem size: 0x8000000
   Flash Config...
   FGS Boot Code Version 05.0.01
   Enter 'b' to stop at boot.....
   BOOT INFO: load monitor from primary, size = 103380
   BOOT INFO: debug enabled!!
Upgrading software

BOOT INFO: load image from primary...
BOOT INFO: bootparam at 00054338 mp_flash_size = 002f1aeb
BOOT INFO: code decompression completed
BOOT INFO: branch to 00400100
Starting Main Task...

*****************************************************************************
ERR: This software requires 256M memory to be installed in the system.
*****************************************************************************
System Reset!

NOTE
You will also see this message if your memory is installed correctly, but your boot code is not 05.0.00a or later.

NOTE
If you do not have the correct EEPROM for the upgrade, you will need to recover your 4.2 image. For information about how to do this refer to “Recovering an earlier version of a startup configuration” on page 156.

5. When you have confirmed that your hardware upgrade is installed correctly, restart to system and check the software version using the show version command.

Confirming software versions

All units in an IronStack must be running the same software image. To confirm this, check the software version on all devices that you want to add to your IronStack. Upgrade any units that are running older versions of the software before you build your stack.

1. Attach a console to the console port of the stack unit.

2. Enter the show version command. Output similar to the following is displayed.
If any unit is running an incorrect version of the software, it will appear as non-operational. You must install the correct version on this unit for it to operate properly in the stack.

**NOTE**
A stack unit in a non-operational state can still receive an image file from the Active Controller.

**Running 5.X software images on devices with 4.X or 3.X startup configuration files**

Release 05.0.00 can read startup-config.txt files generated by earlier software images but a 05.0.00 startup-config.txt file cannot be read by earlier software images. In addition, some features that are supported in release 04.2.00, such as DHCP-client, are not supported in 05.0.00.

To recover a pre-05-0.00 startup-config.txt file, use the `stack unconfigure rollback` command (refer to “Recovering an earlier version of a startup configuration” on page 156 for more information.)

When you boot a 5.x image on a device with a 4.x or 3.x startup-config.txt file, the operation should be transparent. The system automatically performs interface format conversion from 0/X/X to 1/X/X. The pre-5.0 startup-config.txt is renamed to start-config.v4 when a `write memory` command is issued, or when the Active Controller tries to synchronize all startup configurations.

**NOTE**
If you enter the `erase startup-config` or `stack unconfigure clean` commands, all startup-config txt-related files, such as startup-config.v4 and startup-config.old are erased. You will no longer be able to recover pre 5.x startup-config.txt files.

**Running 4.X software images on devices with 5.X startup configuration files**

Devices running 4.2 or later non-stacking software (i.e., 4.X) cannot read 5.X startup-config.txt files. You should recover the 4.X startup-config.txt file before running a 4.X software image. Use the `stack unconfigure rollback` command on devices running the 5.X image.(refer to “Recovering an earlier version of a startup configuration” on page 156 for more information.)

**Copying the flash image to a stack unit from the Active Controller**

**Syntax:** `copy flash flash`

To copy the flash image to a stack unit from the Active Controller primary or secondary flash, enter the following command.

**Syntax:** `copy flash flash [primary | secondary | unit-id-pri | unit-id-sec]`

- **primary** - Copy secondary to primary
- **secondary** - Copy primary to secondary
- **unit-id-pri** - Copy active primary image to unit-id
Upgrading software

- **unit-id-sec** - Copy active secondary image to unit-id

The **unit-id-pri** or **unit-id-sec** keywords are used to copy the images to a stack member from the Active Controller primary and secondary flash, respectively. An example is given below.

```
FLS624-STK Switch# copy flash flash unit-id-pri ?
ASCII string  unit-id (1-8) list or all
FLS624-STK Switch# copy flash flash unit-id-pri 2
```

**Reloading a stack unit**

To reload a stack unit, enter the following command.

```
FLS624-STK Switch# reload
```

Syntax: `reload [after | at | cancel | unit-id]`

- **after** - schedule reloading after certain time period
- **at** - schedule reloading at an exact later time
- **cancel** - cancel scheduled reload
- **unit-id** - stack members to reload

```
FLS624-STK Switch# reload unit-id ?
ASCII string  unit-id list: 2,3,5-7,8 (no space)
```

```
FLS624-STK Switch# reload unit-id 2,4-6,8
```

Reload request sent to specified stack member(s)...

**NOTE**
The unit-id list can be a combination, such as 2,4-6,8 (tokens must be separated by comma and there is no space).

**Configuring default ports on FCX devices**

On FCX devices, the **default-port** command is used to define stacking port candidates. A stacking port is always a default port, but a default port may not necessarily be a stacking port. Default ports can become stacking ports using the secure-setup utility, or through automatic stack building.

Secure-setup probe packets can be received by a default port whether or not it is a stacking port. Stacking packets can be only received by a stacking port (which is also always a default port). In order to use stacking ports that are not defined in the default configuration, you must define the port settings for each unit using the **default-port** command, so that secure-setup can discover the topology of the stack.

Every FCX device contains two default 16 Gbps stacking ports on the rear panel and two 10 Gbps ports on the front panel that can also be used as stacking ports. An FCX IronStack may contain up to 8 24-port and 48-port devices, using any combination of the rear panel stacking ports and the front panel optional stacking ports. To use the front panel ports as stacking ports, you must define the ports for each device in the run time configuration.

The 4-byte Ethernet preamble for the Ethernet frame is used when a port is configured as a default port. For non-default ports, the standard 8-byte Ethernet preamble is used. Frames that travel from a default port on one device must go to a peer default port, otherwise the preambles will not match and the packet will not be forwarded.
Controlling stack topology

Because FGS-STK and FLS-STK devices allow you to use one of the two ports intended for stacking as a regular data port, you can control the size of your stack. The following example shows a stack where the existing ring topology is changed so that only one unit in the upstream direction is connected through a stacking port, which limits the size of the stack to two units.

```
FLS624-STK Switch# stack secure-setup
FLS624-STK Switch# Discovering the stack topology...

Current Discovered Topology - RING

Available UPSTREAM units

```
Managing IronStack partitioning

When a unit in an IronStack with a linear topology fails, the IronStack divides (partitions) into two or more separate stacks that all have the same configuration. This may cause an IP address conflict in the network. If you want to keep the stacks separate, you will need to change the IP address of each new stack.

When a stack breaks into partitions, the partition with the Active Controller remains operational. If a partition contains the Standby Controller, this partition will become operational because the Standby Controller will assume the Active role and will reload the partition units. A partition without an Active or Standby Controller will not function. To reconfigure these units to act in standalone mode, you must first do a `stack unconfigure me` command on each unit. Refer to "Unconfiguring an IronStack" on page 154.

To reverse the partitioning, reconnect all of the units into the original stack topology using the stacking ports. This is the same as merging stacks. If the original Active Controller again has the highest priority, it will regain its role. If two partition Active Controllers have the same priority, the Active Controller with the most stack members will win the election. This process helps minimize traffic interruption.

Ring topology stacks do not partition in the event of a member failure. Operation is interrupted briefly while the stack recalculates a new path. Ring topologies are more stable than linear topologies because they provide redundant pathways in case of accidental failure.

Merging IronStacks

IronStacks may be merged, but the total number of stack units must not exceed 8. For example, you could combine two stacks with 4 units each into a single stack of 8 units.

You can merge stacks by connecting them together using the stacking ports. Before doing this, make sure that none of the stacking ports have been reconfigured as data ports (for example, ports on an end unit in a linear stack topology). You cannot use secure-setup to merge stacks because secure-setup does not work across stack boundaries.

When stacks are merged, an election is held among the Active Controllers. The winner retains its configuration and the IDs of all of its original stack members. The remaining stack units lose their configuration and are reset. If the IDs of the losing stack units conflict with the IDs of the winning units they may change, and the IDs will no longer be sequential. You can use secure-setup to renumber the members in the newly merged stack. The following examples show how stack merging works:

- If a stack partitions into multiple stacks because of a connection failure, and you fix the connection, the stack partitions will merge back into the original stack with no change to stack IDs, because in this case all stack IDs are distinct.
- In a linear stack topology, the end units of the stack will have only one stacking port configured. Before you can merge two linear stacks, you must reconfigure the end units so that both ports are stacking ports.

MIB support for the IronStack

All statistics about packets received and sent, RMON, jumbo frames, runts, giants, and other instances are gathered through the stack interfaces and are accessible through SNMP. The functionality for an IronStack is the same as that for a standard 10 Gbps interface. Information includes types of modules, including optics modules.
NOTE
A type counter has been added to count the number of packets greater than 1518 bytes (jumbo frames).

For detailed information about stacking MIBs, refer to the *MIB Reference Guide*.

**Persistent MAC address**

The MAC address for the entire IronStack is determined by the MAC address of the Active Controller. When an Active Controller is removed from the stack, and a new Active Controller is elected, by default the MAC address of the new Active Controller becomes the MAC address for the IronStack. When you enable the Persistent MAC Address feature, you configure a time delay before the stack MAC address changes. During this configured interval, if the previous Active Controller is reinstalled in the stack, the stack continues to use the MAC address of this unit, even though it may no longer be the Active Controller. If the previous Active Controller does not rejoin the stack during the specified time interval, the stack assumes the address of the new Active Controller as the stack MAC address.

The Persistent MAC Address feature allows you to configure a period of time during which the original base MAC address will not change if Active Controller fails, or is removed for maintenance. This timer is triggered when the Standby Controller becomes the Active Controller. When the timer expires, the new Active Controller will change the previous MAC address to its base MAC address and advertise this MAC address to management VLANs to update the ARP peer table. If you want to use the new address, you will have to re-enter the `stack-persistent-mac-timer` command again to reactivate the persistent MAC address,

```plaintext
stack persistent-mac-timer
```

**Syntax:** `[no] stack persistent-mac-timer number`

- `number` - the number of minutes during which the IronStack will retain the original MAC Address if the Active Controller fails or is removed for service. The valid value range is from 5 - 6000 minutes. If you enter a 0, it means “keep this address forever”. The default is 60 minutes.

To enable Persistent MAC Address, enter the following command.

```plaintext
FGS624P-STK Switch(config)# stack persistent-mac-timer <number>
```

To disable Persistent MAC Address, enter the following command.

```plaintext
FGS624P-STK Switch# no stack persistent-mac-timer
```

**NOTE**
If you enter the `[no]` version of this command while the persistent MAC address timer is active, the stack will disregard the persistent MAC address and will assume the MAC address of the new Active Controller.

In the following example, the persistent MAC timer has been set to the default of 60 minutes.

**NOTE**
Persistent MAC and stack MAC cannot be used together.
Upgrading software

FLS648-STK Switch(config)# stack persistent-mac 60

  module 1 fgs-48-port-management-module
  module 2 fgs-cx4-2-port-10g-module
  priority 40
stack enable
stack persistent-mac 60
stack mac 0012.f2d5.9380

To display the stack MAC addresses, enter the `show stack` command.

FGS648P-STK Switch(config)# show stack
alone: standalone, D: dynamic config, S: static config
ID     Type      Role       Mac Address      Prio State    Comment
1 S  FGS648p   active     0012.f2d5.9380   80   reserved    Ready
2 S  FGS648    standby    00e0.6666.8880   0    remote   Ready
3 S  FGS624     master     0012.f2dc.0ec0   40   local    Ready
Current persistent MAC is 0012.f2d5.9380

FGS648P-STK Switch(config)# stack mac 111.111.111
Error: persistent stacking MAC address timer is configured

FLS648 Switch(config)#

The following example shows what the Persistent MAC information looks like in the output of the `show stack` command when the Standby Controller becomes the Active Controller.

FGS648P-STK Switch(config)# show stack
alone: standalone, D: dynamic config, S: static config
ID     Type      Role       Mac Address      Prio State    Comment
1 S  FGS648P   active     0000.0000.0000   80   reserved    Ready
2 S  FGS648    standby    00e0.6666.8880   0    remote   Ready
3 S  FGS624     master     0012.f2dc.0ec0   40   local    Ready
FGS648P-STK Switch# Persistent MAC timer expires in 59 minutes 52 seconds.

Current persistent MAC is 0012.f2d5.9380

Unconfiguring an IronStack

The `stack unconfigure` command is a run time command that returns stack units to their pre-stacking state. When a stack unit is unconfigured, its stacking flash is removed, and its startup-config.txt flash file is recovered. These actions apply to all units to which this command is applied, regardless of the role of the unit in the stack.
When the `stack unconfigure` command is applied to the Active Controller, it removes `stack enable` from the run time configuration but not from the startup configuration. If you want to remove `stack enable` from the Active Controller permanently, you must enter the `write memory` command.

When the `stack unconfigure` command is applied to the Standby Controller or a stack member (besides the Active Controller) it removes `stack enable` from the recovered startup-config.txt and resets the unit.

When a stack unit that did not have an original startup-config file is unconfigured, it becomes a clean unit. It is possible that this unit could automatically rejoin the stack if its module configuration matches that of the Active Controller. To prevent this from happening accidentally, it is best to first disconnect the unit, and then issue the `stack unconfigure` command on it.

To remove the configuration from a specific IronStack unit, or from the entire stack, enter a command similar to the following.

```plaintext
FGS648P-STK Switch# stack unconfigure 3
```

**Syntax:** `stack unconfigure stack-unit | all | me | clean | rollback`

- `stack unit` - unconfigure the stack member with this ID
- `all` - unconfigure every unit including this unit
- `me` - unconfigure this unit only
- `clean` - removes all startup configuration files including v4 and v5 and makes this a clean unit
- `rollback` - recovers the earlier version (4 or 3) of a startup configuration (refer to “Recovering an earlier version of a startup configuration” on page 156.)

**NOTE**
The `stack unconfigure me` command is available to all units, while `stack unconfigure all` and `stack unconfigure stack-unit` are available on the Active Controller only.

The following example shows a session where stack unit 2 is unconfigured.

```plaintext
FLS624-STK Switch# show stack
alone: standalone, D: dynamic config, S: static config
ID   Type   Role    Mac Address    Pri State    Comment
1 S  FLS624 active  0012.f2eb.a900 128 local    Ready
2 S  FLS648 standby 00f0.424f.4243   0 remote   Ready
3 S  FGS624 member  00e0.5201.0100   0 remote   Ready

FLS624-STK Switch# stack unconfigure 2
Will recover pre-stacking startup config of this unit, and reset it. Are you sure? (enter 'y' or 'n'): y
Stack 2 deletes stack bootup flash and recover startup-config.txt from .old

FLS624-STK Switch# show stack
alone: standalone, D: dynamic config, S: static config
ID   Type   Role    Mac Address    Pri State    Comment
1 S  FLS624 active  0012.f2eb.a900 128 local    Ready
2 S  FLS648 member  0000.0000.0000   0 reserved
3 S  FGS624 standby 00e0.5201.0100   0 remote   Ready
```

When the `stack unconfigure 2` command is issued, stack unit 2 recovers the startup-config.txt from the startup-config.old configuration file that was saved when this unit downloaded its configuration from the Active Controller. As the output shows, stack member 2 has been removed from the stack, and ID 2 is now is reserved for a replacement unit. Stack member 3 is now the Standby Controller.
Recovering an earlier version of a startup configuration

The **stack unconfigure rollback** command recovers the earlier version (4 or 3) of a startup configuration. When a system that is running stacking (05.0.00 and later) discovers that its startup configuration is an earlier version, it saves this configuration to a startup-config.v4 when a **write memory** command is issued, or when the Active Controller tries to synchronize all startup configurations. The **stack unconfigure rollback** command is similar to the **stack unconfigure** command except that it does not remove “stack enable” from the run time or startup configuration.

**stack unconfigure** and **stack unconfigure rollback** are unrelated commands that recover different startup-config.txt files. Both commands permanently delete the current startup-config.txt and replace it with a pre-stacking (pre-05.0.00) startup-config.txt file.

**NOTE**
When you issue the **stack unconfigure rollback** command to recover the previous startup-config.v4 file, DO NOT issue a **write memory** command, as **write memory** will overwrite the recovered file. You should reboot from a pre-5.x image without doing a **write memory**.

If you enter the **erase startup-config** or **stack unconfigure clean** commands, all startup-config text-related files, such as startup-config.v4 and startup-config.old are erased. You will no longer be able to recover pre 5.x startup-config.txt files.

**Syntax:** `stack unconfigure rollback [<stack-unit> | all | me]`
- `<stack-unit>` - recover the version 4 startup config for the stack member with this ID
- `all` - recover the version 4 startup config for every unit including this unit
- `me` - recover the version 4 startup config for this unit only

Displaying IronStack information

This section describes the **show** commands for an IronStack, including output examples and field descriptions.

Displaying flash information

Use the **show flash** command to display flash memory information for all members of a stack, or for a specified stack member.

**Syntax:** `show flash stack-id`

Output from the **show flash** command for a stack resembles the following (for a stack with three members).

From the Active Controller for the entire stack:

```
FGS624P-STK Switch# show flash
Stack unit 1:
Compressed Pri Code size = 3034232, Version 05.0.00T7e1 (fgs05000.bin)
Compressed Sec Code size = 2873568, Version 04.2.00T7e1 (fgs04200.bin)
Compressed BootROM Code size = 405217, Version 04.0.00T7e5
Code Flash Free Space = 2146304
Stack unit 2:
Compressed Pri Code size = 3034232, Version 05.0.00T7e1 (fgs05000.bin)
Compressed Sec Code size = 2873523, Version 04.2.00aT7e1 (fgs04200a.bin)
Compressed BootROM Code size = 403073, Version 03.0.00T7e5
```
Code Flash Free Space = 24117248
Stack unit 3:
Compressed Pri Code size = 3034232, Version 05.0.00T7e1 (fgs05000.bin)
Compressed Sec Code size = 2873568, Version 04.2.00T7e1 (fgs04200.bin)
Compressed BootROM Code size = 405217, Version 04.0.00T7e5
Code Flash Free Space = 2252800
FGS624P-STK Switch#

For stack member 3 only:

FGS624P-STK Switch# show flash stack 3
Stack unit 3:
Compressed Pri Code size = 3034232, Version 05.0.00T7e1 (fgs05000.bin)
Compressed Sec Code size = 2873568, Version 04.2.00T7e1 (fgs04200.bin)
Compressed BootROM Code size = 405217, Version 04.0.00T7e5
Code Flash Free Space = 2252800
FGS624P-STK Switch#

Table 35 describes the fields displayed in this example.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compressed Pri Code size</td>
<td>The compressed size, version, and image name for the Primary Code</td>
</tr>
<tr>
<td>Compressed Sec Code size</td>
<td>The compressed size, version, and image name for the Secondary Code</td>
</tr>
<tr>
<td>Compressed BootROM Code size</td>
<td>The compressed size and version for the BootROM Code</td>
</tr>
<tr>
<td>Code Flash Free Space</td>
<td>The amount of available free space on the Flash memory</td>
</tr>
</tbody>
</table>

**Displaying memory information**

The `show memory` command displays information about stack units. The following example shows output from this command for a stack with eight units.

**Syntax: show memory**

FGS648P-STK Switch# show memory
Stack unit 1:
  Total DRAM: 268435456 bytes
  Dynamic memory: 238026752 bytes total, 182820476 bytes free, 23% used
Stack unit 2:
  Total DRAM: 268435456 bytes
  Dynamic memory: 238026752 bytes total, 172751776 bytes free, 27% used
Stack unit 3:
  Total DRAM: 268435456 bytes
  Dynamic memory: 238026752 bytes total, 172751776 bytes free, 27% used
Stack unit 4:
  Total DRAM: 268435456 bytes
  Dynamic memory: 238026752 bytes total, 172751776 bytes free, 27% used
Stack unit 5:
  Total DRAM: 268435456 bytes
  Dynamic memory: 238026752 bytes total, 107140664 bytes free, 54% used
Stack unit 6:
  Total DRAM: 268435456 bytes
  Dynamic memory: 238026752 bytes total, 172751740 bytes free, 27% used
Stack unit 7:
  Total DRAM: 268435456 bytes
  Dynamic memory: 238026752 bytes total, 182820504 bytes free, 23% used
Stack unit 8:
  Total DRAM: 268435456 bytes
  Dynamic memory: 238026752 bytes total, 182811440 bytes free, 23% used
BR-FGS648P Router#

Table 36 describes the fields displayed in this output example.

<table>
<thead>
<tr>
<th>This field</th>
<th>Describes...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total DRAM</td>
<td>The size (in bytes) of DRAM</td>
</tr>
<tr>
<td>Dynamic memory</td>
<td>The total number of bytes in dynamic memory, including the number of bytes</td>
</tr>
<tr>
<td></td>
<td>that are available (free, or unused), and the percentage of memory used.</td>
</tr>
</tbody>
</table>

**Displaying chassis information**

The `show chassis` command displays chassis information for each stack unit. Output resembles the following (in this example, a three member stack).

**Syntax: show chassis**

FGS648P-STK Switch# show chassis
The stack unit 1 chassis info:

  Power supply 1 (NA - AC - Regular) present, status ok
  Power supply 2 not present
  
  Fan 1 ok
  Fan 2 ok
  
  Exhaust Side Temperature Readings:
  Current temperature : 33.0 deg-C
  Warning level.......: 85.0 deg-C
  Shutdown level......: 90.0 deg-C
  
  Intake Side Temperature Readings:
  Current temperature : 31.0 deg-C

  Boot Prom MAC: 0012.f2e4.6e00
  Management MAC: 0012.f2e4.6e00

The stack unit 2 chassis info:

  Power supply 1 (NA - AC - Regular) present, status ok
  Power supply 2 not present
  
  Fan 1 ok
  Fan 2 ok
  
  Exhaust Side Temperature Readings:
  Current temperature : 32.5 deg-C
  Warning level.......: 85.0 deg-C
  Shutdown level......: 90.0 deg-C
  
  Intake Side Temperature Readings:
  Current temperature : 31.0 deg-C

  Boot Prom MAC: 0012.f2e3.11c0

The stack unit 3 chassis info:

  Power supply 1 (NA - AC - Regular) present, status ok
  Power supply 2 not present
  
  Fan 1 ok
Fan 2 ok

Exhaust Side Temperature Readings:
Current temperature : 31.5 deg-C
Warning level.......: 85.0 deg-C
Shutdown level......: 90.0 deg-C

Intake Side Temperature Readings:
Current temperature : 32.0 deg-C

Boot Prom MAC: 0012.f2db.e500

Table 37 describes the fields displayed in this output example.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Describes...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power Supply 1</td>
<td>The status of the primary power supply.</td>
</tr>
<tr>
<td>Power Supply 2</td>
<td>The status of the secondary power supply, if present.</td>
</tr>
<tr>
<td>Fan 1 and Fan 2</td>
<td>The status of the cooling fans</td>
</tr>
<tr>
<td>Exhaust Side Temperature Readings</td>
<td>From the air exhaust side of the chassis, the current temperature reading, the warning level temperature setting, and the shutdown level temperature setting.</td>
</tr>
<tr>
<td>Intake Side Temperature Reading</td>
<td>The current temperature reading from the air intake side of the chassis.</td>
</tr>
<tr>
<td>Boot Prom MAC</td>
<td>The MAC address of the boot prom</td>
</tr>
<tr>
<td>Management MAC</td>
<td>For the Active Controller only, the management MAC address</td>
</tr>
</tbody>
</table>

Displaying stack module information

The show module command displays information about the stack unit modules. Output resembles the following.

Syntax: show module

```text
FLS648P-STK Switch(config)# show module

Module                Status  Ports    Starting MAC
S1:M1 FGS-24G 24-port Management Module + PoE OK  24    00e0.5201.4000
S1:M2 FGS-2XGC 2-port 10G Module (2-CX4) OK  2    00e0.5201.4018
S1:M3 FGS-1XG 1-port 10G Module (1-XFP) OK  1    00e0.5201.401a
S3:M1 FLS-48G 48-port Management Module OK  48    001b.ed5e.c480
S3:M2 FLS-1XG 1-port 10G Module (1-XFP) OK  1    001b.ed5e.c4b0
S3:M3 FLS-1XGC 1-port 10G Module (1-CX4) OK  1    001b.ed5e.c4b1
S4:M1 FLS-48G 48-port Management Module OK  48    001b.ed5e.ac00
S4:M2 FLS-1XGC 1-port 10G Module (1-CX4) OK  1    001b.ed5e.ac30
S4:M3 FLS-1XG 1-port 10G Module (1-XFP) OK  1    001b.ed5e.ac31
S5:M1 FLS-24G 24-port Management Module OK  24    001b.ed5d.a180
S5:M2 FLS-1XG 1-port 10G Module (1-XFP) OK  1    001b.ed5d.a198
S5:M3 FLS-1XG 1-port 10G Module (1-XFP) OK  1    001b.ed5d.a199
S5:M4 FLS-1XG 1-port 10G Module (1-XFP) OK  1    001b.ed5d.a19a
S6:M1 FLS-24G 24-port Management Module OK  24    00e0.5200.3000
S6:M2 FLS-1XGC 1-port 10G Module (1-CX4) OK  1    00e0.5200.3018
S6:M3 FLS-1XGC 1-port 10G Module (1-CX4) OK  1    00e0.5200.3019
S7:M1 FLS-48G 48-port Management Module OK  48    00e0.4444.0000
S7:M2 FLS-1XGC 1-port 10G Module (1-CX4) OK  1    00e0.4444.0030
S7:M3 FLS-1XGC 1-port 10G Module (1-CX4) OK  1    00e0.4444.0031
S8:M1 FLS-48G 48-port Management Module OK  48    0012.f2eb.d540
```
Displaying stack resource information

Use the show stack resource command to display stack resource information, as shown in this example.

Syntax: show stack resource

```
FCX648SHPOE Switch# show stack resource

<table>
<thead>
<tr>
<th>alloc</th>
<th>in-use</th>
<th>avail</th>
<th>get-fail</th>
<th>limit</th>
<th>get-mem</th>
<th>size</th>
<th>init</th>
</tr>
</thead>
<tbody>
<tr>
<td>register attribute</td>
<td>2400</td>
<td>2347</td>
<td>53</td>
<td>0</td>
<td>556800</td>
<td>3089</td>
<td>142</td>
</tr>
<tr>
<td>general 12B data</td>
<td>32</td>
<td>8</td>
<td>24</td>
<td>0</td>
<td>7424</td>
<td>8</td>
<td>12</td>
</tr>
<tr>
<td>RB-tree node</td>
<td>4096</td>
<td>2347</td>
<td>1749</td>
<td>0</td>
<td>237568</td>
<td>2702</td>
<td>18</td>
</tr>
</tbody>
</table>
```

Displaying stack information

You can display information about any and all of the members in an IronStack by entering `show` commands from the Active Controller console port. If you enter show commands from a member unit that is not the Active Controller, the information may not be displayed correctly.

The `show stack` command displays general information about an IronStack, for all members, for a specified member, and with additional detail if required.
Syntax: `show stack stack-unit | detail`

The following output covers the entire stack.

```text
FLS648-STK Switch(config)# show stack
alone: standalone, D: dynamic config, S: static config
ID  Type    Role    Mac Address    Pri State    Comment
1  S  FLS648 active  00:12.f2eb.a900 130  local    Ready
2  S  FLS648 standby 00f0.424f.4243 0  remote   Ready
3  S  FGS624 member  00e0.5201.0100 0  remote   Ready
4  S  FGS624 member  0000.0000.0000 0 reserved
```

If you add a stack member ID, output is displayed for that member only.

```text
FGS648-STK Switch# show stack 1
ID  Type    Role       Mac Address      Prio State    Comment
1  S  FGS648 active     0012.f2eb.a900   130  local    Ready
```

```text
FGS648-STK Switch# show stack 2
ID  Type    Role       Mac Address      Prio State    Comment
2  S  FGS648 standby    00f0.424f.4243   0    remote   Ready, member after reload
```

```text
FGS648-STK Switch# show stack 3
ID  Type    Role       Mac Address      Prio State    Comment
3  S  FGS624 member     00f0.424f.4243   0    remote   Ready
```

If you add `detail` to the `show stack` command, output resembles the following.

```text
FLS648P-STK Switch(config)# show stack detail
ID  Type    Role       Mac Address      Prio State    Comment
1  S  FGS624 member     00e0.5201.4000   0    remote   Ready
2  S  FGS624 member     00e0.5205.0000   0    remote   Ready
3  S  FGS624 member     001b.ed5e.c480   0    remote   Ready
4  S  FGS624 active     001b.ed5e.ac00   128  local    Ready
5  S  FGS624 standby    001b.ed5d.a180   0    remote   Ready
6  S  FGS624 member     00e0.5200.3000   0    remote   Ready
7  S  FGS624 member     00e0.4444.0000   0    remote   Ready
8  S  FGS624 member     0012.f2eb.d540   0    remote   Ready
```

```text

Upgrading software

### Displaying stack flash information

Use the `show stack flash` command to display information about flash memory for stack members, as shown in this example.

**Syntax:** `show stack flash`

FCX624S-F Switch# show stack flash
There is no startup-config.old
There was no stack flash read during bootup

Current written stack flash:
FCX624SF, ID =1, role= active, priority=128, config=1, jumbo=X PPVLAN=X S2M= stack p: [0]=1/2/1 [1]=1/2/2 , , hash-chain=X vlan#=X active-chg=0

**Syntax:** `show stack flash`

### Table 40

<table>
<thead>
<tr>
<th>This field</th>
<th>Indicates...</th>
</tr>
</thead>
<tbody>
<tr>
<td>D: dynamic configuration</td>
<td>The configuration for this unit is dynamic and may be overwritten by a new stack unit. To change to a static configuration, enter the <code>write memory</code> command.</td>
</tr>
<tr>

Displaying stack neighbors

The show stack neighbors command displays information about stack member neighbors.

Syntax: show stack neighbors

FGS648P-STK Switch# show stack neighbors
ID Stack-port1 Stack-port2
1  3   2
2  1   3
3  2   1

The topology of stack system is ring, and has 3 stack unit(s)
From left to right (starting with active unit): 1 2 3

Table 43 describes the output from the show stack neighbors command.
Displaying stack port information

The `show stack stack-ports` command displays information about stack port status.

Syntax: `show stack stack-ports`

```
FLS648-STK Switch(config)# show stack stack-ports
ID     Stack-port1      Stack-port2
1      up  (1/2/1)      up  (1/2/2)
2      up  (2/2/1)      up  (2/2/2)
3      up  (3/2/1)      up  (3/3/1)
4      up  (4/2/1)      up  (4/3/1)
5      up  (5/2/1)      up  (5/3/1)
```

**Table 44** describes the output from the `show stack stack-ports` command.

Displaying running configuration information

The `show running-config` command displays information about the current stack configuration.

Syntax: `show running-config`

```
FLS648P-STK Switch(config)# show running-config
Current configuration:
!
ver 05.0.00T7e1
!
stack unit 1
  module 1 fgs-24-port-management-module
  module 2 fgs-cx4-2-port-10g-module
  module 3 fgs-xfp-1-port-10g-module
  stack-port 1/2/1 1/3/1
stack unit 2
  module 1 fgs-48-port-management-module
  module 2 fgs-xfp-2-port-10g-module
stack unit 3
  module 1 fls-48-port-copper-base-module
  module 2 fls-xfp-1-port-10g-module
  module 3 fls-cx4-1-port-10g-module
stack unit 4
  module 1 fls-48-port-copper-base-module
  module 2 fls-cx4-1-port-10g-module
```
module 3 fgs-xfp-1-port-10g-module
priority 128
stack enable
!

Table 45 describes the output from the show running-config command.

<table>
<thead>
<tr>
<th>Field</th>
<th>Indicates...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stack unit &lt;#&gt;</td>
<td>The stack identification number for this unit.</td>
</tr>
<tr>
<td>Module &lt;#&gt;</td>
<td>Identifies the configuration for modules on this unit.</td>
</tr>
<tr>
<td>Pri</td>
<td>Indicates that a priority has been assigned to this stack unit</td>
</tr>
</tbody>
</table>

**Displaying configured stacking ports**

The stacking ports may display in the output from the show running-config command in three different ways.

1. When stacking is enabled, the output shows both stacking ports.

```
stack unit 1
 module 1 fgs-24-port-management-module
 module 2 fgs-cx4-2-port-10g-module
 module 3 fgs-xfp-1-port-10g-module
 stack-port 1/2/1 1/3/1
```

2. When stacking is not enabled, neither stacking port is displayed.

```
stack unit 1
 module 1 fgs-24-port-management-module
 module 2 fgs-cx4-2-port-10g-module
 module 3 fgs-xfp-1-port-10g-module
```

3. If one stacking port is configured, that port will be displayed regardless of whether or not stacking is enabled.

```
stack unit 1
 module 1 fgs-24-port-management-module
 module 2 fgs-cx4-2-port-10g-module
 module 3 fgs-xfp-1-port-10g-module
 stack-port 1/3/1
```

**Displaying software version information**

The show version command shows the software version that the stack is running. Note that the last line of this output shows the bootup ID and role for this unit. Output resembles the following.

**Syntax: show version**

```
FLS648P-STK Switch(config)# show version
SW: Version 05.0.02T7el Copyright (c) 2009 Brocade Communications Systems, Inc.

Displaying stacking port statistics

The show statistics stack-ports command displays information about all stacking ports in an IronStack topology.

Syntax: show statistics stack-ports
Adding, removing, or replacing units in an IronStack

The following sections describe how to add, remove, or replace units in an IronStack. The recommended method is to connect units to the stack before you supply power to the units, however, you can also connect powered units.

**Installing a new unit in an IronStack using secure-setup**

This method can be applied to clean units, or units that have existing configurations.

1. Connect the new unit to the stack by connecting the 10 Gbps stacking ports.
2. Run secure-setup on the Active Controller and assign an ID to the new unit. The Active Controller will reset the new unit.
3. Once the new unit boots and joins the stack, do a write memory on the Active Controller.

**Installing a new unit using static configuration**

If the new unit is a clean unit and the connection is sequential you can add it using the static setup process.

---

</table>
1. Enter the module configuration of the new unit into the Active Controller's configuration.

2. Connect the new unit to the stack using the 10 Gbps stacking ports. The sequence in which you connect the unit must match that of the Active Controller configuration. The Active Controller automatically resets the unit.

3. Once the new unit boots and joins the stack, do a write memory on the Active Controller. You should see the following message.

   Done hot swap: Set stack unit 3 to Fully-Operational:16

### Configuration notes

Configuration on a new unit can be accomplished in three ways:

- If the Active Controller has no configuration information for the new unit, it learns the new unit configuration. This is a dynamic configuration and will disappear if the new unit leaves the stack. In order for the configuration to stay on the Active Controller (to make it a static configuration), you must do a write memory on the Active Controller.

- If the Active Controller has configuration information for a new unit, and it matches the base module (module 1) of the new unit, no action is necessary. If configuration information for non-base modules on the new unit does not match the information on the Active Controller, the Active Controller learns the configuration for the new unit module types and merges it with the information it has for the base module. This merged configuration remains static and will stay on the Active Controller even if the new unit leaves the stack.

- If the Active Controller has configuration information for the new unit, but it does not match the base module of the new unit, a configuration mismatch can occur where the configuration related to this unit is removed even after the mismatch is resolved. Refer to “Recovering from a mismatch” on page 182 for more information.

### Removing a unit from an IronStack

To remove a unit from the stack, disconnect the cables from the stacking ports. This can be done whether the units are powered-on or powered-off. When you remove a unit that is powered-on, it is still in stacking enabled mode. To remove the stacking files, enter the `stack unconfigure me` or `stack unconfigure clean` command. When the unit reboots, it will operate as a standalone unit. Refer to “Unconfiguring an IronStack” on page 154.

When a unit is removed from a stack, the Active Controller deletes this unit configuration if it is dynamically learned. Refer to “Brocade IronStack terminology” on page 111 for definitions of static and dynamic configurations.

### Replacing an IronStack unit

**Replacing with a clean unit**

If the stack unit ID numbering is sequential, you can easily swap a failed unit with an identical clean unit using this procedure.

1. Remove the old unit from the stack.

2. Make sure that the hardware (module) configuration of the replacement unit is identical to that of the failed unit.

3. Connect the new unit to the stack using the same stacking ports used by the old unit.
4. If the configuration of the replacement unit matches the configuration on the Active Controller, the Active Controller resets the new unit, which automatically becomes active in the stack, and the stack retains its original topology.

**Replacing with multiple clean units**

If you are replacing multiple old units with clean units, the Active Controller replaces the unit with the lowest ID first. For example, if you remove units 5 and 6 (which are FGS624P-STK devices), the Active Controller assigns ID 5 to the first new FGS624P-STK device you install. If you wanted this particular unit to replace unit 6, instead of unit 5, you must use secure-setup.

You must use secure-setup if the replacement is not a clean unit, the connection is not sequential, or you do not want the Active Controller to trigger an automatic replacement. Use the following steps.

1. Remove the old stack unit from the stack
2. Connect the new unit to the existing stack using the same stacking ports used by the old unit.
3. Run secure-setup to select the ID of the old unit for the new unit. The Active Controller resets the unit, and it joins the stack.

**NOTE**

Adding, removing or replacing a stack unit which is not at the end of linear topology may cause the other units in the stack to reset if these units lose their path to the Active controller during the process. Adding or removing a unit in a ring topology should not cause the other units to reset because each unit can still find a path to the Active Controller.

**Moving a unit to another stack**

Moving a member from a stack and to another stack can result in non-sequential ID assignment. The Active Controller will honor the new unit original ID if that ID is not being used in the new stack. The Active Controller will assign a new ID if the original ID is already being used. To prevent non-sequential stack ID assignments, configure the unit that is moving as a clean unit before adding it to the new stack.

**Removing an Active Controller from a powered stack**

To remove an Active Controller from a powered stack, disconnect the Active Controller. The Standby Controller waits for 30 seconds and then assumes the role of Active Controller. A single Active Controller device functions as a standalone unit even it is still stacking-enabled. You do not have to issue a `stack unconfigure me` command for an Active Controller.

**Renumbering stack units**

You can use secure-setup to renumber stack units in a previously constructed stack. In the following example, three units make up a stack, yet two of the units are numbered 5 and 6 (the Active Controller is numbered 1). Since this stack is only going to contain 3 units, you can renumber the other units so that they are unit 2 and unit 3.

The most effective way to number your stack members is sequentially. You can skip numbers, but they should still be sequential, from 1 to 8. Sequential numbering makes it easy to replace stack units, and easier to troubleshoot issues.
NOTE
In a ring topology, 1, 2, 4, 5, and 1, 5, 4, 2 are both sequential.

Example

FGS624-STK Switch# stack secure-setup
FLS624-STK Switch# Discovering the stack topology...

Available UPSTREAM units
Hop(s)  Type       Mac Address
1       FLS624  0012.f2d5.2100
2       FLS624  001b.ed5d.9940

Enter the number of the desired UPSTREAM units (1-2) [1]: 2

Selected topology:
Active id  Type       Mac Address
  1   FLS624  0012.f239.2d40

Selected UPSTREAM units
Hop(s)   id  Type       Mac Address
 1   5   FLS624  0012.f2d5.2100
 2   6   FLS624  001b.ed5d.9940

Do you accept the unit ids? (y/n)?: n

Enter an unused id for the UPSTREAM FLS623 unit at 1 hop(s) (1-8) [5]: 2
Enter an unused id for the UPSTREAM FLS624 unit at 2 hop(s) (1-8) [6]: 3

FLS624-STK Switch# Election, was active, no role change, assigned-ID=1
reset unit 2: diff bootup id=5
reset unit 3: diff bootup id=6
Election, was active, no role change, assigned-ID=1

FLS624-STK Switch# show stack
ID  Type   Role  Mac Address  Pri  State    Comment
 1  S  FLS624 active  0012.f239.2d40 128  local    Ready
 2  S  FLS624 standby 0012.f2d5.2100  0  remote   Ready
 3  S  FLS624 member  001b.ed5d.9940  0  remote   Ready

Configuration Notes:

- Renumbering may result in the removal of a unit configuration if the stack unit base module
does not match the configuration on the Active Controller. However, secure-setup renumbering
never changes the interface configuration. For example, if you switch the IDs of identical units
2 and 3, the Active Controller does not change 2/1/5 to 3/1/5 and vice versa.

- If the configuration for the ID you select for a specific unit does not match the configuration on
that unit, secure-setup will change the static configuration into a dynamic configuration so it
can be overwritten by the learned configuration.

- When swapping IDs for two or more identical units - for example, if units 2, 3, and 4 are
identical, changing 2 to 3, 3 to 4, and 4 to 2 will not affect the configurations of the units
except that the units will reset and assume the new IDs.

- If you swap IDs for two units that are not identical - for example, unit 2 is an FGS624 and unit 3
is an FLS624, you may cause a configuration mismatch. If this happens, the Active Controller
removes the configurations and resets both units. When both units boot with new IDs, the
Active Controller learns their module types and creates new unit configurations for both.
However, all interface configuration information related to units 2 and 3 is gone.
- When you renumber identical units using secure-setup, the configurations are not mapped to the new units (since the configurations match exactly). However, if you switch the IDs of units that are not identical, a configuration mismatch occurs. Refer to “Recovering from a mismatch” on page 182.
- When you assign an unused ID to a stack unit, the unit is reset with the new ID. All unit and interface configuration information related to the old stack ID is deleted. The Active Controller learns the configuration for the new unit (instead of creating interface configuration for the new unit).
- Release 5.0 does not support user changes to the Active Controller ID.
- Secure-setup does not swap configuration information for units that have had their IDs changed. For example, it does not change the 2/1/3 interface configuration or VLAN membership information into 3/1/3 information if the unit ID changes from 2 to 3.
- If the configuration for a unit being replaced does not match the new unit type, the Active Controller removes the unit configuration and associated interface configuration.
- All learned configurations due to mismatches or the addition of new units are dynamic configurations. To convert them into static configurations, do a write memory to preserve the configurations if a unit is removed from the stack.

Syslog, SNMP, and traps

Syslog messages from stack units are forwarded to, and can be viewed from, the Active Controller. All stack units support SNMP gets, sets, and traps, which are managed by the Active Controller. An SNMP trap is sent from a stack unit to the stack Active Controller, and forwarded from the Active Controller to an SNMP-configured server. An external network management station can execute SNMP gets and sets for MIBs and collect information about any port on the stack.

SNMP traps can be configured for the insertion or removal of a stack unit or uplink module, and for optic identification.

For more information about Syslog messages, refer to Chapter 50, “Using Syslog”.

Configuring SNMP for an IronStack

SNMP server and feature configuration is the same for an IronStack as it is for standalone units. In an IronStack, SNMP gets and sets are processed by the Active Controller for the Standby Controller and all stack members. SNMP traps generated by the Standby Controller and stack members are propagated to the configured SNMP server through the Active Controller. For more information about how to configure an SNMP server for FastIron devices, refer to Chapter 48, “Securing SNMP Access”.

SNMP engine IDs for stackable devices

For Brocade stacking devices, if an engine ID is not manually created or a stack MAC address is not specified and saved, the stack will lose its engine ID if the Active Controller fails and the Standby Controller takes over, because the Standby Controller creates a new engine ID at bootup. To prevent this from happening, you will need to either create a new engine ID or create a new stack MAC address to ensure that the engine ID is saved to the startup configuration. This should be done before the SNMPv3 user is created.

If a new Active Controller is elected (for example, the Standby Controller becomes the Active Controller) you will see the following results:
Troubleshooting an IronStack

The most common reason for an unsuccessful stack build is either a software configuration mismatch, a hardware configuration mismatch, or a combination of both.

The following sections describe common troubleshooting procedures for an IronStack:

- “Troubleshooting an unsuccessful stack build” on page 177
- “Troubleshooting a stacking upgrade” on page 179
- “Troubleshooting image copy issues” on page 180
- “Configuration mismatch” on page 182
- “Recovering from a mismatch” on page 182
- “Troubleshooting secure-setup” on page 184
- “Troubleshooting unit replacement issues” on page 184

Troubleshooting an unsuccessful stack build

If you are unable to build a stack, (for example, the `show stack` command does not display any stack units), perform the following steps.

1. Enter the `show run` command on each unit to make sure the configuration contains “stack enable”. If it does not, enter the `stack enable` command on the unit. Before a stack is formed, you can still access the console port on each device. Once a stack is successfully formed, you are redirected to the Active Controller.

   NOTE
   If you are building a stack using secure-setup, you do not have to enter stack enable on each unit.

2. Check that all of your stacking port connections are secure and working properly. Enter the `show interface stack` on each device to confirm that the stacking port links are up and the ports are in the forward state.

   FLS624-STK Switch# show interfaces stack
   Port Link State Dupl Speed Trunk Tag P MAC Name
   1/2/1 Up Forward Full 10G None No 1 0012.f2eb.a902
   1/2/2 Up Forward Full 10G None No 1 0012.f2eb.a904

3. Confirm that all of the devices are running the same software image
4. Use the `show log` command to display any IPC version mismatch messages. These messages appear in one minute when receiving mismatched probe packets, and then once every 10 minutes.

5. Type `show stack ipc` to see if any traffic has been sent or received. Enter `clear stack ipc` to clear the traffic statistics and then enter `show stack ipc` again so you can easily see differences in traffic flow.

```
FLS648-STK Switch# show stack ipc
Recv IPC 330 packets
Message types have callbacks:
   1 : Reliable IPC message           2 : Reliable IPC atomic batch
   .... more message types removed.
Send message types:
   [14]=126,
Recv message types:
   [20]=1,    [27]=9,
Statistics:
   send pkt num      :       964,    recv pkt num      :       330,
   send msg num      :       964,    recv msg num      :       330,
   send frag pkt num :         0,    recv frag pkt num :         0,
   pkt buf alloc     :       964,
   Reliable-mail send success receive time us
   target ID          0        0        0        0
   target MAC         0        0        2        0
There is 0 current jumbo IPC session
Possible errors:
   *** state not ready :      1,
```

If the send message types: field is empty, it means that stack enable has not been configured. If the number of Recv IPC packets increases, but there are no Recv message types, then the packets are being dropped for various reasons, including the wrong IPC version, or a checksum error. The Possible errors field will list reasons for packet loss.

**NOTE**
A small ***state not ready" count is normal, but if it continues to increase a problem is indicated.

6. If the results of a `show stack` command show other stack members, but lists them as non-operational, this could be due to an image mismatch, or a configuration mismatch. In the event of an image mismatch, you can download the correct images to the entire stack from the Active Controller. Refer to “Configuration mismatch” on page 182 for more information about configuration mismatches.

**NOTE**
If your intended stacking ports are connected in a ring topology, they will not all appear to be in the forwarding state because of spanning tree, but secure-setup can still build the stack.
7. If you run out of flash memory while doing a **write memory**, your stack devices may contain very large startup-config.v4 or startup-config.old files, which are preserved for recovery purposes (refer to “**Unconfiguring an IronStack**” on page 154 for more information). If you do not need these files, you can delete them using the **flash delete** command. Enter the **show dir** command to see all flash files.

8. Check to be sure you do not have any stacking to non-stacking connections. You may see a message similar to the following.

   Warning! Proc ????? packet in 2m from 0012.f2222.8300, Wrong dev/port: dev=4, port=18, DSA=4971100 497--E
   You might have stacking to non-stacking port connections

   This indicates that you may have a connection between a stacking port and a non-stacking port. This message will appear every 10 minutes after the first display. If you see this message once only, and your connections are correct, your stack should be operating properly. Only repeat displays of this message indicate a problem.

**Troubleshooting a stacking upgrade**

After you upgrade your FGS or FLS to support stacking, (refer to the **FastIron GS Compact Switch Hardware Installation Guide** for more information about hardware upgrades for stacking), restart the device with the upgraded 05.0.00 software. If you encounter a problem at this step, make sure the memory DIMM and stacking EEPROM are installed correctly. If they are not installed correctly, you may see output similar to the following.

   FGS MEM size: 0x10000000
   FGS Flash config....
   FGS Boot Code Version 05.0.00
   Enter 'b' to stop at boot....
   BOOT INFO: load monitor from primary, size=103408
   BOOT INFO: load image from primary.........
   BOOT INFO: bootparam at 000543e8, mp_flash_size=002ee6c5
   BOOT INFO: code decompression completed
   BOOT INFO: branch to 00400100
   Starting Main Task....
   *****************************************************************************
   ERR: This software needs License PROM to be installed in the system
   *****************************************************************************
   System Reset!

   If your memory DIMM is not installed correctly, you will see output similar to the following.

   FGS Mem size: 0x8000000
   Flash Config...
   FGS Boot Code Version 05.0.00
   Enter 'b' to stop at boot.....
   BOOT INFO: load monitor from primary, size = 103380
   BOOT INFO: debug enabled!!
   BOOT INFO: load image from primary...
   BOOT INFO: bootparam at 00054338 mp_flash_size = 002f1aeb
   BOOT INFO: code decompression completed
   BOOT INFO: branch to 00400100
   Starting Main Task ...
   *****************************************************************************
   ERR: This software requires 256M memory to be installed in the system.
   *****************************************************************************
   System Reset!
Check your upgraded hardware for the following situations:

- EEPROM is installed incorrectly in the socket. Make sure Pin 1 on the EEPROM matches the Pin 1 hole in the socket.
- Make sure your memory DIMM is securely installed in the memory DIMM socket. Refer to the hardware installation guide or the instructions that came with your upgrade kit for more information.

Troubleshooting image copy issues

The `copy tftp flash` command copies the image to all stack units including the Active Controller. The `copy flash flash` command copies the image from the primary or secondary flash on the Active Controller to the primary or secondary flash image of a stack member, respectively. If you are unable to copy an image to one or more stack units, check the following:

- Make sure the unit is actually part of the stack. Use the `show stack` command.
- If a unit joins a stack after the `image copy` command was issued, you will need to copy the image to this unit separately.

Stack mismatches

When a stack mismatch occurs, the Active Controller can put any stack member into a non-operational state, which disables all of the ports except the stacking ports. Stack mismatches can occur for a variety of reasons, which are discussed in this section.

**NOTE**
The Active Controller can still download an image to the non-operational unit.

The Active Controller generates a log message whenever it puts a stack unit into a non-operational state. The following examples describe the types of mismatches and the related log message:

- **Advanced feature mismatch** - The Active Controller is enabled for advanced features (such as BGP) and the stack unit is not enabled.
  
  Stack: Unit 2 00e0.1020.0100 doesn't have the matching advanced feature privileges

- **Image mismatch** - A stack unit is running a different software image than that of the Active Controller.
  
  Stack: Unit 2 00c0.1020.0100 image mismatch

- **Configuration mismatch** - The module configuration for a stack unit does not match the reserved configuration on the Active Controller.
  
  Stack: Unit 2 00e0.1020.0100 config mismatch

- **Memory allocation mismatch** - The Active Controller does not have enough memory to accommodate the stack unit.
  
  Stack: Malloc failure for unit 2.00e0.1020.0100

These mismatches are described in the following sections.
Advanced feature mismatch

FCX stack unit advanced feature privileges must be enabled to run advanced features such as BGP. Both Active and Standby units must be enabled for advanced features for these features to operate across the stack. A unit that is not enabled for these features is put into a non-operational state.

If the Active Controller is not enabled for advanced features, these features will not operate on the stack.

Image mismatch

IronStack technology requires that all stack units run the same version of the software image. In cases where the software version differs, there are two levels of mismatch, major and minor.

Major mismatch

A major mismatch indicates an Interprocessor Communications (IPC)-related data structure change, or an election algorithm change, or that a version of the software that does not support stacking is installed on a unit. This can happen when the software undergoes a major change (such as a change from 05.0.00 to 05.1.00). When a major mismatch occurs, the system logs and prints a message similar to the following.

Warning! Recv 424 IPC in 1m from 0012.f2eb.a900 e1/1/25: wrong version 5 !=6. Please make sure all units run the same image.

In a major mismatch, the stack cannot be built and will not operate. You must download the correct version of the software to the mismatched units individually.

Minor mismatch

With a minor mismatch, an operating stack can still exist, but traffic is dropped from all ports except for the stacking ports for units with the mismatched software. You can download the correct image to the mismatched devices from the Active Controller. A minor software mismatch means that there is no IPC or election algorithm change, but there is a release version disparity. Minor software mismatches can happen with patch release upgrades. The system logs and prints a message similar to the following.

Warning! put stack unit 2 to non-operational reason=image mismatch

The show stack command displays output similar to the following.

```
FLS624-STK Switch# show stack
alone: standalone, D: dynamic config, S: static config
ID Type  Role   Mac Address       Pri   State  Comment
1 S FLS624 active 0012.f2eb.a900 128 local Ready
2 S FLS648 standby 00f0.424f.4243  0 remote NON-OP: image mismatch
3 S FGS624 member 00e0.5201.0100  0 remote Ready
```

If the configuration of a stack unit does not match the configuration of the Active Controller, the stack unit will not function. You must manually correct the configuration error for the unit to become operational within the stack. In this example, unit 2 is non-operational due to an image mismatch. To correct this situation, use the copy flash flash command (refer to “Copying the flash image to a stack unit from the Active Controller” on page 149).
Stack mismatches

Configuration mismatch

Generally, when a stack unit is added to or removed from the stack, its static configuration is not overwritten by the Active Controller. However, secure-setup allows you to overwrite a static configuration on a unit, in which case the Active Controller deletes the configuration for the old unit, and adds the configuration of the new unit.

A configuration mismatch occurs when the base module configuration for a replacement stack unit does not match the run time configuration on the Active Controller (for example, if you remove an FGS624P-STK unit and try to replace it with an FLS624-STK unit). If the configuration on the Active Controller is static, it cannot be overwritten by the new configuration, and a configuration mismatch occurs.

Configuration mismatches can happen during manual setups, or when moving a unit from one stack to another stack. secure-setup will try to overwrite a configuration mismatch even if the configuration is static. The overwrite attempt may fail if there are multi-slot trunk or LACP configurations on the ports of the unit to be overwritten. If this is the case, secure-setup will be unable to resolve the mismatch.

When you renumber identical units using secure-setup, the configurations are not mapped to the new units (since they match exactly). However, if you switch the IDs of units that are not identical, a configuration mismatch occurs.

Configuration mismatches can also occur when LACP or multi-slot trunking configurations exist on the modules of replacement units. In these cases, you will need to manually remove the LACP or multi-slot trunking configuration on the replacement unit before you try to add it to the stack.

When a configuration mismatch occurs, port-related functions on all ports are disabled on the mismatched unit (except for the stacking ports). All other functions are unaffected. For example, the Active Controller can still copy the unit’s image or reset the unit. Please refer to “Recovering from a mismatch” on page 182.

Memory allocation failure

A memory allocation (malloc) failure occurs when the Active Controller does not have enough memory to run a stack unit. This failure may occur if you configure large numbers (for example, 4 K of VLANs, or STP instances (for example, 255) in the router image. This message means that the Active Controller is low on memory after allocating these resources and does not have enough remaining memory to control a stack member. You can correct this by reducing the number of VLANs or STP instances.

**NOTE**

After you make configuration changes such as number of VLANs or STP instances, you must reset the stack.

Recovering from a mismatch

When a configuration mismatch occurs, the Active Controller logs and displays a configuration mismatch message, and puts the mismatched unit into a non-operational state. In the following example, the original stack unit 3 has failed, and a replacement unit has been installed that does not match the configuration of the original unit. You should see the following message.

Warning! put stack unit 3 to non-operational reason= config mismatch
Follow the steps given below to recover from a configuration or image mismatch.

1. Enter the `stack secure-setup` command.

2. Enter the `show stack` command to see the status of the stack, and a `show running-config` command to see the configurations of the stack units. If secure-setup does not resolve the configuration mismatch, proceed to step 3.

```
FLS624-STK Switch# show stack
alone: standalone, D: dynamic config, S: static config
ID     Type     Role       Mac Address      Pri State          Comment
1      FLS624   active    0012.f2eb.a900 128 local    Ready
2      FLS648   member   00f0.424f.4243 0 remote    Ready
3      FGS624   standby  00e0.5201.0100 0 remote   NON-OP: config mismatch
```

```
FLS624-STK Switch# show running config
stack unit 1
  module 1 fls-24-port-copper-base-module
  module 3 fls-cx4-1-port-10g-module
  module 4 fls-xfp-1-port-10g-module
  priority 128

stack unit 2
  module 1 fgs-24-port-management-module
  module 3 fgs-xfp-1-port-10g-module

stack unit 3
  module 1 fls-48-port-copper-base-module
  module 2 fls-cx4-1-port-10g-module
  module 3 fls-cx4-1-port-10g-module
  stack enable
```

3. To resolve the mismatch, you must remove the configuration for stack unit 3. Use the following command.

```
FLS624-STK Switch# no stack unit 3
```

If you are unable to remove the configuration because of a multi-slot trunk configuration, it means secure-setup cannot overwrite the Active Controller's configuration due to multi-slot trunking configurations on the ports of the unit to be overwritten. You must first manually remove the multi-slot trunk configuration.

4. When you have successfully deleted the mismatched stack unit, a re-election is triggered, and the Active Controller learns the correct module configuration from the Standby Controller or from other stack members.

Follow the steps given below to recover from an image mismatch.

1. Use the `copy flash flash` command to replace a mis-matched image with the correct image. Refer to “Copying the flash image to a stack unit from the Active Controller” on page 149.

2. Reset the unit. After the reset, the unit will contain the new image and the mis-match condition will not exist. To verify, use the `show stack` command.
Troubleshooting secure-setup

Secure-setup can be used to form linear and ring stack topologies. For information about the procedure, refer to “Scenario 1 - Configuring a three-member IronStack in a ring topology using secure-setup” on page 117. During this procedure, if secure-setup does not detect all the units that should be detected, perform the following checks:

- Make sure that all the cables are properly connected
- Make sure that all the relevant ports are in UP state
- Make sure that all the units are running the same image
- Make sure that you issue the stack enable command only on the unit that will serve as the Active Controller
- Make sure that stack disable is not configured on any prospective members
- Make sure that the connection is sequential (refer to “Brocade IronStack terminology” on page 111, Sequential Connection.)

If secure-setup times out (this may happen due to inactivity), you will not be able to make any changes in your configuration or stack topology until you restart the session by entering the stack secure-setup command.

The unit discovery process is triggered when secure-setup is initiated. However, if the stack unit is placed in a topology where another unit in the stack is already running the discovery process, the current discovery process is terminated. If this is the case, you will see a message similar to the following.

"Topology discovery is already in progress originated from <mac-address>. Please try later."

This means a discovery process is already active and was initiated from the unit with the <mac-address> mentioned in the message. You will need to re-issue secure-setup.

If there is already an active discovery process, secure-setup may not discover all the intended units. If this is the case, you will need to restart the secure-setup process.

Troubleshooting unit replacement issues

If you are unsuccessful in building a stack using the automatic setup process (refer to “Scenario 2 - Configuring a three-member IronStack in a ring topology using the automatic setup process” on page 121), or adding or replacing a unit in a stack, consider the following issues:

- Make sure that the number of units in your stack does not exceed the maximum of 8
- Make sure that the replacement unit is a clean unit (does not contain a startup-config.txt file)
- Make sure that the replacement unit running configuration does not contain “stack enable”
- Make sure that the replacement unit running configuration does not contain “stack disable”
- Make sure that the configurations of the stack ports on the Active Controller match the physical connections to the unit
More about IronStack technology

This section discusses stacking technology in greater detail than the information presented in Section 1.

Configuration, startup configuration files and stacking flash

Stacking system behavior is defined by the run time configuration, which can be displayed using the `show run` command. The `write memory` command stores the run time configuration in a flash file called `startup-config.txt`. During bootup, the system reads and applies the `startup-config.txt` file to the run time configuration. The `startup-config.txt` file can be shown using the `show config` command.

The stacking system installs a `stacking.boot` file on each unit that tells the unit what its role is during the boot process. The `stacking.boot` file is generated whenever there is an election that defines the roles for all units.

When an Active Controller is booted, or a `write memory` command is issued, the Active Controller synchronizes its `startup-config.txt` file to every stack unit. The original `startup-config.txt` files in the Standby Controller and other stack members are renamed to `startup-config.old`. If you issue the “stack unconfigure me” command on the Standby Controller or stack member directly, these units will recover their original `startup-config.txt` files and reboot as standalone devices. If you enter the `stack unconfigure all` command from the Active Controller all devices will recover their old `startup-config.txt` files and become standalone devices. When this happens, the `startup-config.old` file is renamed to `startup-config.txt`, and the `stacking.boot` file is removed. For more information, refer to “Unconfiguring an IronStack” on page 154.

Whenever a change is made to a stack unit’s configuration, such as priority, (which could affect stack elections) an election is held, and the result is written into the `stacking.boot` file. A prompt message appears on the console that suggests you do a `write memory`. For an Active Controller role change to take effect, you will need to reset the entire stack.

If you do not do a `write memory`, and reset the stack, the stack units will continue to operate in their roles as defined by the `stacking.boot` file. After the reset, each unit readjusts based on the current run time configuration. However, you may get different results depending on what has not been saved. If you have renumbered the stack unit IDs, you may see a configuration mismatch, because your changes no longer match the Active Controller configuration.

If you change priorities to elect an Active Controller, the new Active Controller will assume its role after a reboot whether you have done a `write memory` or not. If you do not save your priority change before the next reboot, the reboot will trigger an election that may result in a different winner based on the priority in the unsaved configuration. The new winner assumes its role after the next reboot.

If you change the stacking port configuration and do not save your changes, you may encounter connectivity errors. To recover from a configuration error, run Secure Startup to define the correct stacking port.

**NOTE**

You should always do a `write memory` after making stacking-related configuration changes such as priority and stacking ports. If you do not want to keep the changes, change the configuration back to the previous version, and do a `write memory`. Do not discard configuration changes by using the reset without a `write memory`. 
Flexible stacking ports

Because FGS-STK and FLS-STK devices do not have dedicated stacking ports, they offer the flexibility to use each 10 Gbps port as a stacking port or a regular data port. Each stack member contains two full-duplex 10 Gbps possible stack ports, and can operate in a stack with up to 40 Gbps throughput. When stacking is enabled, the first two 10 Gbps ports become stacking ports by default. You have the option, however, to configure only one of the 10 Gbps ports as a stacking port and use the other 10 Gbps port as a regular data port.

For the locations of these ports on FGS-STK and FLS-STK devices, refer to Table 33 on page 127.

IronStack topologies

Brocade IronStack technology supports both linear and ring stack topologies. Because the unicast switching follows the shortest path in a ring topology, this topology offers the strongest redundancy. When the ring is broken, the stack recalculates the forwarding path the resumes the flow of traffic within a few seconds. In a ring topology, all stack members must have two stacking ports, however, in a linear topology, both end units use only one stacking port, leaving the other port available as a data port. To see an illustrated example of each topology, refer to “Brocade IronStack topologies” on page 113.

Port down and aging

If a unit is powered down, or the stacking link is removed, the system immediately detects the port down and knows that its neighbor is gone. That unit is immediately removed from the Active Controller. If a unit is gone or no longer stack-enabled, but its stacking link is still on, it will take 20 seconds to age the neighbor out. The following message will be logged and displayed.

Warning! my mac=00f0.424f.4243, age out up-stream

Device roles and elections

There are three distinct roles played by units that are part of an IronStack:

- Active Controller
- Standby Controller
- Stack member

Active Controller

The Active Controller contains the saved and running configuration files for each stack member. The configuration files include the system-level settings for the stack, and the interface-level settings for each stack member, as well as MIB counters and port status. The Standby Controller also has a synchronized copy of the Active Controller startup config file for use in the event the Active Controller fails.

When a stack is formed, the console function for each stack member is automatically redirected to the Active Controller console. The Active Controller console port handles all stack management functions, as well as ping, Telnet sessions, and tftp image downloads for every stack member. If you connect to the console port on a stack member that is not the Active Controller, you are automatically directed through the console of the Active Controller.
The Active Controller synchronizes its start-up configuration with the Standby Controller and the rest of the stack members. You can recover the previous flash configuration of the Standby Controller and the stack members by issuing the `stack unconfigure` command. For an example of this command and the output generated, refer to “Unconfiguring an IronStack” on page 154.

The Active Controller may reset the rest of the stack members, if necessary. However, if the Active Controller itself must be reset because of a role or ID change, you must issue the `reset` command.

If the Active Controller fails, the Standby controller waits 30 seconds, and then takes over as Active Controller, resetting itself and all other stack members. If the old Active Controller becomes operational, it may or may not resume its role as Active, depending on the configured priorities.

**Standby Controller**

In addition to the Active Controller, another stack member is elected as the Standby Controller. After a default interval of 30 seconds, the Standby Controller takes over if the Active Controller fails.

**NOTE**

Because it can take as long as 20 seconds to age out a neighbor, the Standby takeover period may last up to 50 seconds. Refer to “Port down and aging” on page 186.)

The Standby Controller synchronizes its configuration with the Active Controller at each reset.

**Bootup role**

When a stack unit boots, it boots in a particular role, such as standalone, Active Controller, Standby Controller, or stack member. When the bootup role is Standby Controller or stack member, the CLI available to the unit is limited to `show` and `stack` commands. A unit in the role of Standby or stack member will not act without instructions from the Active Controller. To convert a Standby Controller or stack member into a standalone device, use the `stack unconfigure me` command, (refer to “Unconfiguring an IronStack” on page 154).

The last line of the `show version` output identifies the unit role unless if the unit is a standalone.

```
My stack unit ID = 1, bootup role = active
My stack unit ID = 3, bootup role = standby
```

**Active Controller and Standby Controller elections**

Whenever there is a topology change in the stack (a reset, unit failure, or the addition or removal of members), elections are held to determine the status of the Active Controller and Standby Controller. The results of an election take effect after the next stack reset.

The following conditions, in the order shown, determine which units will serve as Active Controller and Standby Controller after an election:

- **Boot as active controller** - Indicates that a unit was previously Active Controller before the current boot sequence and will again assume the role of Active Controller when two standalone units are combined into a stack. When a third standalone unit joins the stack, a current Active Controller becomes subject to the other factors in this list. The reason for this hierarchy of factors is to achieve a predictable winner regardless of the boot up sequence for a unit. You can upgrade your current Active Controller to “boot as active controller” status by performing a `write memory`. The system interprets the write memory action as a directive to maintain the current Active Controller role regardless of resets or a new unit joining the stack.
More about IronStack technology

- **Priority** - The unit with the highest priority value.
- **Greater number of members** - The unit that has control over the greater number of stack members.
- **Lowest boot stack ID** - The unit that has the lowest boot stack ID (1-8, 1 is the lowest).
- **MAC address** - The member with the lowest MAC address.

**Active Controller and Standby Controller resets**

If the Active Controller is reset or removed from the stack, the entire stack reloads and Active Controller and Standby Controller elections are initiated. If the unit functioning as the previous Active Controller is no longer part of the stack, the Standby Controller unit becomes the new Active Controller. After a reset, if no stack member qualifies as Active Controller, the existing Standby Controller waits 30 seconds and then assumes the role of Active Controller.

If both Active and Standby Controllers are removed the rest of the stack will continue to function because they are operating on whatever is programmed in the hardware. The stack members will not be able to learn any new addresses. You will see the following message every few minutes.

*Stack member is non-operational because of no Active or Standby Controller*

You can recover to standalone mode by "stack unconfigure me"

Use `stack unconfigure me` to restore the units into standalone devices with a pre-stacking configuration.

**Selecting a standby unit**

You can choose a Standby Controller by configuring a stack unit priority to be the second highest, or the same as the Active Controller. If the priorities are configured the same for both, when the original Active Controller fails, the Standby Controller takes over. If the original Active Controller becomes active again, it will not win back its active role, which helps to minimize interruption of the stack. However, if the original Active Controller has the higher priority, it will win back its role and reset all of the stack units.

**Standby controller election criteria**

The Standby Controller election is based on the following criteria.

1. The highest priority
2. Bootup as Active Controller
3. Bootup as Standby Controller
4. The lowest boot ID
5. The lowest MAC address

Since Standby election candidates must have startup configurations that have been synchronized with the Active Controller, if the Active Controller does not have a startup-config.txt file, there will not be a Standby controller. Once a `write memory` is performed on the Active Controller, the startup-config.txt file is written and synchronized to all stack members, and a Standby Controller can be elected.
IPv6 management overview

This chapter describes the IPv6 management features available for FGS, FLS, FWS, FGS-STK, FLS-STK, FCX, and TIX devices, including command syntax and management examples.

NOTE
For details about IPv6 management on FastIron X Series devices, refer to “IPv6 management (IPv6 host support)” on page 218.

IPv6 was designed to replace IPv4, the Internet protocol that is most commonly used currently throughout the world. IPv6 increases the number of network address bits from 32 (IPv4) to 128, which provides more than enough unique IP addresses to support all of the network devices on the planet into the future. IPv6 is expected to quickly become the network standard.

Brocade FastIron devices that support IPv6 may be used as management hosts. Interfaces on these devices are configured with IPv6 addresses, but do not have full IPv6 routing enabled. IPv6 is available on all FastIron devices that are running Layer 2, Base Layer 3, or Full Layer 3 software images.

NOTE
Brocade FastIron devices can serve as management hosts on an IPv6 network. However, IPv6 routing functionality is not supported for these devices.

IPv6 addressing

IPv4 is limited because of the 32-bit addressing format, which cannot satisfy potential increases in the number of users, geographical needs, and emerging applications. To address this limitation, IPv6 introduces a new 128-bit addressing format.

An IPv6 address is composed of 8 fields of 16-bit hexadecimal values separated by colons (:). Figure 13 shows the IPv6 address format.

FIGURE 13 IPv6 address format

<table>
<thead>
<tr>
<th>Network Prefix</th>
<th>Interface ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>HHHH HHHH HHHH</td>
<td>HHHH HHHH</td>
</tr>
</tbody>
</table>

As shown in Figure 13, HHHH is a 16-bit hexadecimal value, while H is a 4-bit hexadecimal value. The following is an example of an IPv6 address.

Note that this IPv6 address includes hexadecimal fields of zeros. To make the address less cumbersome, you can do the following:

- Omit the leading zeros; for example, 2001:0:0:200:DOFF:FE48:4672.
- Compress the successive groups of zeros at the beginning, middle, or end of an IPv6 address to two colons (::) once per address; for example, 2001::200:DOFF:FE48:4672.

When specifying an IPv6 address in a command syntax, keep the following in mind:

- You can use the two colons (::) only once in the address to represent the longest successive hexadecimal fields of zeros
- The hexadecimal letters in IPv6 addresses are not case-sensitive

As shown in Figure 13, the IPv6 network prefix is composed of the left-most bits of the address. As with an IPv4 address, you can specify the IPv6 prefix using the `<prefix>/<prefix-length>` format, where the following applies.

The `<prefix>` parameter is specified as 16-bit hexadecimal values separated by a colon.

The `<prefix-length>` parameter is specified as a decimal value that indicates the left-most bits of the IPv6 address.

The following is an example of an IPv6 prefix.

2001:FF08:49EA:D088::/64

### Enabling and disabling IPv6 on FastIron devices

IPv6 is enabled by default for Brocade devices that support it. If desired, you can disable IPv6 on a global basis on an device by entering the following command at the Global CONFIG level of the CLI.

```
FastIron(config)# no ipv6 enable
```

**Syntax:** no ipv6 enable

To re-enable IPv6 after it has been disabled, enter the `ipv6 enable` command.

### IPv6 management features

**Platform Support:**

- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later (except where noted)
- TurboIron devices running software release 04.2.00 and later

This section describes the CLI management commands that are available to FastIron devices that support IPv6.

### IPv6 access list

**Platform Support:**

- Not supported on FCX devices
IPv6 management features

- Not supported on TurboIron devices

When you enter the `ipv6 access-list` command, the Brocade device enters the IPv6 Access List configuration level, where you can access several commands for configuring IPv6 ACL entries.

**NOTE**
Unlike IPv4, there is no distinction between standard and extended ACLs in IPv6.

**Example**
```
FastIron(config)# ipv6 access-list netw
FastIron(config-ipv6-access-list-netw)#
```

**Syntax:** `ipv6 access-list` *ACL name*

The `ACL name` parameter specifies a name for the IPv6 ACL. An IPv6 ACL name cannot start with a numeral, for example, `1access`. Also, an IPv4 ACL and an IPv6 ACL cannot share the same name.

**IPv6 debug**

**Platform Support:**
- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later
- Not supported for FCX devices

The `debug ipv6` commands enable the collection of information about IPv6 configurations for troubleshooting.

**Syntax:** `debug ipv6 address cache icmp mld nd packet ra`

- `address` - IPv6 address
- `cache` - IPv6 cache entry
- `icmp` - ICMPv6
- `mld` - MLD protocol activity
  - `add-del-oif [ all clear ] clear detail down-port error group level mcache-group mcache-source packet phy-port prime-port show source timer vlan`
- `nd` - neighbor discovery
- `packet` - IPv6 packet
- `ra` - router add

**IPv6 Web management using HTTP and HTTPS**

**Platform Support:**
- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later
- Not supported on FCX devices
- Not supported on TurboIron devices
When you have an IPv6 management station connected to a switch with an IPv6 address applied to the management port, you can manage the switch from a Web browser by entering `http://[ipv6 address]` or `https://[ipv6 address]` in the browser address field.

**NOTE**
You must enclose the IPv6 address with square brackets `[ ]` in order for the Web browser to work.

### Restricting web access

**Platform Support:**
- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later
- Not supported on TurboIron devices

You can restrict Web management access to include only management functions on a Brocade device that is acting as an IPv6 host, or restrict access so that the Brocade host can be reached by a specified IPv6 device.

**Restricting Web management access by specifying an IPv6 ACL**
You can specify an IPv6 ACL that restricts Web management access to management functions on the device that is acting as the IPv6 host.

**Example**

```
FastIron(config)# access-list 12 deny host 2000:2383:e0bb::2/128 log
FastIron(config)# access-list 12 deny 30ff:3782::ff89/128 log
FastIron(config)# access-list 12 deny 3000:4828::fe19/128 log
FastIron(config)# access-list 12 permit any
FastIron(config)# web access-group ipv6 12
```

**Syntax:** `web access-group ipv6 ipv6 ACL name`
where `ipv6 ACL name` is a valid IPv6 ACL.

**Restricting Web management access to an IPv6 host**
You can specify a single device with an IPv6 address to have Web management access to the host device. No other device except the one with the specified IPv6 address can access the Web Management Interface.

**Example**

```
FastIron(config)# web client ipv6 3000:2383:e0bb::2/128
```

**Syntax:** `web client ipv6 ipv6-address`

The `ipv6-address` you specify must be in hexadecimal format using 16-bit values between colons as documented in RFC 2373.

### IPv6 logging

**Platform Support:**
- FGS and FLS devices running software release 04.0.00 and later
IPv6 management features

- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later

This feature allows you to specify an IPv6 server as the Syslog server.

**Specifying an IPv6 Syslog server**

To specify an IPv6 Syslog server, enter the `log host ipv6` command as shown below.

```plaintext
FastIron(config)# log host ipv6 2000:2383:e0bb::4/128
```

**Syntax:**

```plaintext
[no] log host ipv6 ipv6-address [ udp-port-num ]
```

- The `ipv6-address` must be in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The `udp-port-num` optional parameter specifies the UDP application port used for the Syslog facility.

**Name-to-IPv6 address resolution using IPv6 DNS server**

The Domain Name Server (DNS) resolver feature lets you use a host name to perform Telnet, ping, and traceroute commands. You can also define a DNS domain on a Brocade device and thereby recognize all hosts within that domain. After you define a domain name, the Brocade device automatically appends the appropriate domain to the host and forwards it to the domain name server.

For example, if the domain “newyork.com” is defined on a Brocade device, and you want to initiate a ping to host “NYC01” on that domain, you need to reference only the host name in the command instead of the host name and its domain name. For example, you could enter either of the following commands to initiate the ping.

```plaintext
FastIron# ping nyc01
FastIron# ping nyc01.newyork.com
```

**NOTE**

FCX devices do not support IPv6 DNS server name resolution.

**Defining an IPv6 DNS entry**

IPv6 defines new DNS record types to resolve queries for domain names to IPv6 addresses, as well as IPv6 addresses to domain names. Brocade devices running IPv6 software support AAAA DNS records, which are defined in RFC 1886.

AAAA DNS records are analogous to the A DNS records used with IPv4. They store a complete IPv6 address in each record. AAAA records have a type value of 28.

To establish an IPv6 DNS entry for the device, enter the following command.

```plaintext
FastIron(config)# ipv6 dns domain-name companynet.com
```

**Syntax:**

```plaintext
[no] ipv6 dns domain-name domain name
```

To define an IPv6 DNS server address, enter the following command.

```plaintext
FastIron(config)# ipv6 dns server-address 200::1
```

**Syntax:**

```plaintext
[no] ipv6 dns server-address ipv6-addr [ ipv6-addr ] [ ipv6-addr ] [ ipv6-addr ]
```
As an example, in a configuration where ftp6.companynet.com is a server with an IPv6 protocol stack, when a user pings ftp6.companynet.com, the Brocade device attempts to resolve the AAAA DNS record. In addition, if the DNS server does not have an IPv6 address, as long as it is able to resolve AAAA records, it can still respond to DNS queries.

**IPv6 ping**

The ping command allows you to verify the connectivity from a Brocade device to an IPv6 device by performing an ICMP for IPv6 echo test.

For example, to ping a device with the IPv6 address of 2001:3424:847f:a385:34dd::45 from the Brocade device, enter the following command:

```
FastIron# ping ipv6 2001:3424:847f:a385:34dd::45
```

**Syntax:**
```
ping ipv6 ipv6-address [outgoing-interface [port | ve number]] [source ipv6-address] [count number] [timeout milliseconds] [ttl number] [size bytes] [quiet] [numeric] [no-fragment] [verify] [data 1-to-4 byte hex] [brief]
```

- The `ipv6-address` parameter specifies the address of the router. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The `outgoing-interface` keyword specifies a physical interface over which you can verify connectivity. If you specify a physical interface, such as an Ethernet interface, you must also specify the port number of the interface. If you specify a virtual interface, such as a VE, you must specify the number associated with the VE.
- The `source` `ipv6-address` parameter specifies an IPv6 address to be used as the origin of the ping packets.

**NOTE**
The `outgoing-interface` and `source` options are available only on router code and not on switch code.

- The `count number` parameter specifies how many ping packets the router sends. You can specify from 1 - 4294967296. The default is 1.
- The `timeout milliseconds` parameter specifies how many milliseconds the router waits for a reply from the pinged device. You can specify a timeout from 1 - 4294967294 milliseconds. The default is 5000 (5 seconds).
- The `ttl number` parameter specifies the maximum number of hops. You can specify a TTL from 1 - 255. The default is 64.
- The `size bytes` parameter specifies the size of the ICMP data portion of the packet. This is the payload and does not include the header. You can specify from 0 - 10173. The default is 16.
- The `no-fragment` keyword turns on the "do not fragment" bit in the IPv6 header of the ping packet. This option is disabled by default.

**NOTE**
The `no-fragment` option is not supported on TurboIron devices.

- The `quiet` keyword hides informational messages such as a summary of the ping parameters sent to the device, and instead only displays messages indicating the success or failure of the ping. This option is disabled by default.
- The `verify` keyword verifies that the data in the echo packet (the reply packet) is the same as the data in the echo request (the ping). By default the device does not verify the data.
• The **data 1 - 4 byte hex** parameter lets you specify a specific data pattern for the payload instead of the default data pattern, "abcd", in the packet's data payload. The pattern repeats itself throughout the ICMP message (payload) portion of the packet.

**NOTE**
For parameters that require a numeric value, the CLI does not check whether the value you enter is within the allowed range. Instead, if you do exceed the range for a numeric value, the software rounds the value to the nearest valid value.

• The **brief** keyword causes ping test characters to be displayed. The following ping test characters are supported.

  I Indicates that a reply was received.
  . Indicates that the network server timed out while waiting for a reply.
  U Indicates that a destination unreachable error PDU was received.
  I Indicates that the user interrupted ping.

**SNMP3 over IPv6**

Brocade FastIron devices (with the exception of FCX devices) support IPv6 for SNMP version 3. For more information about how to configure SNMP, refer to Chapter 48, "Securing SNMP Access".

**Secure Shell and IPv6**

Secure Shell (SSH) is a mechanism that allows secure remote access to management functions on the Brocade device. SSH provides a function similar to Telnet. You can log in to and configure the Brocade device using a publicly or commercially available SSH client program, just as you can with Telnet. However, unlike Telnet, which provides no security, SSH provides a secure, encrypted connection to the Brocade device.

To open an SSH session between an IPv6 host running an SSH client program and the Brocade device, open the SSH client program and specify the IPv6 address of the device. For more information about configuring SSH on the Brocade device, refer to “SSH version 2 support” on page 1495.

**IPv6 Telnet**

Telnet sessions can be established between a Brocade device to a remote IPv6 host, and from a remote IPv6 host to the Brocade device using IPv6 addresses.

The **telnet** command establishes a Telnet connection from a Brocade device to a remote IPv6 host using the console. Up to five **read-access** Telnet sessions are supported on the router at one time. **Write-access** through Telnet is limited to one session, and only one outgoing Telnet session is supported on the router at one time. To see the number of open Telnet sessions at any time, enter the **show telnet** command.

**Example**

To establish a Telnet connection to a remote host with the IPv6 address of 3001:2837:3de2:c37::6, enter the following command.

```
FastIron# telnet 3001:2837:3de2:c37::6
```
IPv6 management commands

Syntax: telnet ipv6-address [port-number | outgoing-interface ethernet port | ve number]

• The ipv6-address parameter specifies the address of a remote host. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
• The port-number parameter specifies the port number on which the Brocade device establishes the Telnet connection. You can specify a value between 1 - 65535. If you do not specify a port number, the Brocade device establishes the Telnet connection on port 23.
• If the IPv6 address you specify is a link-local address, you must specify the outgoing-interface ethernet port | ve number parameter. This parameter identifies the interface that must be used to reach the remote host. If you specify an Ethernet interface, you must also specify the port number associated with the interface. If you specify a VE interface, also specify the VE number.

Establishing a Telnet session from an IPv6 host

To establish a Telnet session from an IPv6 host to the Brocade device, open your Telnet application and specify the IPv6 address of the Layer 3 Switch.

IPv6 traceroute

The traceroute command allows you to trace a path from the Brocade device to an IPv6 host.

NOTE
IPv6 traceroute is not supported on FCX devices.

The CLI displays trace route information for each hop as soon as the information is received. Traceroute requests display all responses to a minimum TTL of 1 second and a maximum TTL of 30 seconds. In addition, if there are multiple equal-cost routes to the destination, the Brocade device displays up to three responses.

For example, to trace the path from the Brocade device to a host with an IPv6 address of 3301:23dd:349e:a384::34, enter the following command.

FastIron# traceroute ipv6 3301:23dd:349e:a384::34

Syntax: traceroute ipv6 ipv6-address

The ipv6-address parameter specifies the address of a host. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

IPv6 management commands

The following management CLI commands are available in FastIron devices that support IPv6:

• show ipv6 traffic
• clear ipv6 traffic
• show ipv6 TCP
• show ipv6 access-list
• show ipv6 neighbor
• clear ipv6 neighbor
Chapter 7

Monitoring Hardware Components

Hardware support

The procedures in this chapter describe how to configure the software to monitor hardware components. You can configure the software to do the following:

- Detect and report statistics about a cable connected to a copper port
- Monitor temperature and signal power levels for optical transceivers

Table 48 lists which Brocade devices support the features discussed in this chapter.

<table>
<thead>
<tr>
<th>Feature</th>
<th>FastIron X Series</th>

<tr>
<td>Digital optical monitoring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Virtual cable testing

FastIron devices support Virtual Cable Test (VCT) technology. VCT technology enables the diagnosis of a conductor (wire or cable) by sending a pulsed signal into the conductor, then examining the reflection of that pulse. This method of cable analysis is referred to as Time Domain Reflectometry (TDR). By examining the reflection, the Brocade device can detect and report cable statistics such as local and remote link pair, cable length, and link status.

Configuration notes

- This feature is supported on copper ports only. It is not supported on fiber ports.
- This feature is not supported on TurboIron X Series devices.
- The port to which the cable is connected must be enabled when you issue the command to diagnose the cable. If the port is disabled, the command is rejected.
- If the port is operating at 100 Mbps half-duplex, the TDR test on one pair will fail.
- If the remote pair is set to forced 100 Mbps, any change in MDI/MDIX may cause the device to interpret the Multilevel Threshold-3 (MLT-3) as a reflected pulse, in which case, the device will report a faulty condition. In this scenario, it is recommended that you run the TDR test a few times for accurate results.

Command syntax

To diagnose a cable using TDR, enter commands such as the following at the Privileged EXEC level of the CLI.
Virtual cable testing

FastIron# phy cable-diag tdr 1

The above command diagnoses the cable attached to port 1.

When you issue the `phy-cable-diag` command, the command brings the port down for a second or two, then immediately brings the port back up.

Syntax: `phy cable-diag tdr port-num`

For `portnum`, specify the port in one of the following formats:

- FastIron GS and LS compact switches – `stack-unit/slotnum/portnum`
- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`

**Viewing the results of the cable analysis**

To display the results of the cable analysis, enter a command such as the following at the Privileged EXEC level of the CLI.

```
FastIron> show cable-diag tdr 1
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Speed</th>
<th>Local pair</th>
<th>Pair Length</th>
<th>Remote pair</th>
<th>Pair status</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>1000M</td>
<td>Pair A</td>
<td>&lt;50M</td>
<td>Pair B</td>
<td>Terminated</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Pair B</td>
<td>&lt;50M</td>
<td>Pair A</td>
<td>Terminated</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Pair C</td>
<td>&lt;50M</td>
<td>Pair D</td>
<td>Terminated</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Pair D</td>
<td>&lt;50M</td>
<td>Pair C</td>
<td>Terminated</td>
</tr>
</tbody>
</table>

In the above output, **Local pair** indicates the assignment of wire pairs from left to right, where Pair A is the left-most pair. **Table 49** shows the **Local pair** mapping to the T568A pin/pair and color assignment from the TIA/EIA-568-B standard.

**TABLE 49** Local pair definition

<table>
<thead>
<tr>
<th>Local pair</th>

</tr>
<tr>
<td>Pair C</td>
<td>Pair 1 (blue)</td>
</tr>
<tr>
<td>Pair D</td>
<td>Pair 4 (brown)</td>
</tr>
</tbody>
</table>

**Figure 14** illustrates the T568A pin/pair assignment.
**Syntax:** show cable-diag tdr *port-num*

For *portnum*, specify the port in one of the following formats:

- FastIron GS and LS compact switches – *stack-unit/slotnum/portnum*
- FastIron chassis devices – *slotnum/portnum*
- FESX, and FWSX compact switches – *portnum*

*Table 50* defines the fields shown in the command output.

**TABLE 50**

</tr>
</tbody>
</table>
Digital optical monitoring

You can configure your Brocade device to monitor optical transceivers in the system, either globally or by specified ports. When this feature is enabled, the system will monitor the temperature and signal power levels for the optical transceivers in the specified ports. Console messages and syslog messages are sent when optical operating conditions fall below or rise above the XFP or SFP manufacturer recommended thresholds.

Supported media

Digital optical monitoring is supported with the following Brocade-qualified media types:

- 1000Base-LHA
- 1000Base-LHB
- 1000Base-LX
- 1000Base-SX
- 100Base-FX-SR (not supported on the TurboIron X Series)
- 100Base-FX-IR (not supported on the TurboIron X Series)
- 100Base-FX-LR (not supported on the TurboIron X Series)
- 10GBase-1310 (not supported on the TurboIron X Series)
- 10GBase-E2R (not supported on the TurboIron X Series)
- 10GBase-LR
- 10GBase-SR
- 10GBase-ZR (not supported on the TurboIron X Series)
- 10GBase-ZRD (not supported on the TurboIron X Series)

Media not supported

Digital optical monitoring is not supported for the following optics:

- 1000Base-SX 2
- 1000Base-BX-D
- 1000Base-BX-U
- E1MG-100BXU
- E1MG-100BXD
- E1MG-BXU
- E1MG-BXD

Supported media

Digital optical monitoring is supported with the following Brocade-qualified media types:

- 1000Base-BX-D
- 1000Base-BX-U
- 1000Base-LHA
• 1000Base-LHB
• 1000Base-LX
• 1000Base-SX
• 1000Base-SX 2

Media not supported
Digital optical monitoring is not supported for the following optics:
• E1MG-100BXU
• E1MG-100BXD
• E1MG-BXU
• E1MG-BXD

Configuration limitations
A Brocade chassis device can monitor a maximum of 24 SFPs and 12 XFPs.

Enabling digital optical monitoring
To enable optical monitoring on all Brocade-qualified optics installed in the device, use the following command.

```
FastIron(config)# optical-monitor
```

To enable optical monitoring on a specific port, use the following command.

```
FastIron(config)# interface ethernet 1/1
FastIron(config-if-e10000-1/1)# optical-monitor
```

To enable optical monitoring on a range of ports, use the following command.

```
FastIron(config)# interface ethernet 1/1 to 1/2
FastIron(config-mif-e10000-1/1-1/2)# optical-monitor
```

Syntax: `[no] optical-monitor`

Use the **no** form of the command to disable digital optical monitoring.

Setting the alarm interval
You can optionally change the interval between which alarms and warning messages are sent. The default interval is three minutes. To change the interval, use the following command.

```
FastIron(config)# interface ethernet 1/1 to 1/2
FastIron(config-mif-e10000-1/1-1/2)# optical-monitor 10
```

Syntax: `[no] optical-monitor [ alarm-interval ]`

For `alarm-interval`, enter a value between 1 and 65535. Enter 0 to disable alarms and warning messages.
NOTE
The commands no optical-monitor and optical-monitor 0 perform the same function. That is, they both disable digital optical monitoring.

Displaying information about installed media

Use the show media, show media slot, and show media ethernet commands to obtain information about the media devices installed per device, per slot, and per port. In release 04.1.00 and later, the results displayed from these commands provide the Type, Vendor, Part number, Version and Serial number of the SFP or XFP optical device installed in the port. 1G M-C indicates 1b Gbps copper media. If no SFP or XFP device is installed in a port, the “Type” field will display “EMPTY”.

The following example outputs are from a FastIron X Series device running software release 04.1.00. The display outputs on your device may differ, depending on the software version running on the device.

Use the show media command to obtain information about the media devices installed in a device.

FastIron# show media
Port   1: Type  : 1G M-SX2(SFP)
        Vendor: Brocade Communications, Inc. Version: 0000
        Part# : TRPAG1XRPBSS-FY    Serial#: 0635000468
Port   2: Type  : EMPTY
Port   3: Type  : EMPTY
Port   4: Type  : 100M M-FX-SR(SFP)
        Vendor: Brocade Communications, Inc. Version: A
        Part# : FTLF1217P2HTL-F1   Serial#: UCQ003A
Port   5: Type  : 1G M-C
Port   6: Type  : 1G M-C
Port   7: Type  : 1G M-C
Port   8: Type  : 1G M-C
Port   9: Type  : 1G M-C
Port  10: Type  : 1G M-C
Port  11: Type  : 1G M-C
Port  12: Type  : 1G M-C
Port  13: Type  : 1G M-C
Port  14: Type  : 1G M-C
Port  15: Type  : 1G M-C

Use the `show media ethernet` command to obtain information about the media device installed in a port.

```
FastIron# show media e 1/17
```

**Syntax:** `show media [slot <slot-num> | ethernet [<slot-num>/]<port-num>]`

### Viewing optical monitoring information

To view temperature and power information for all qualified XFPs and SFPs in a particular slot, use the `show optic` command. The following shows an example output.

```
FastIron> show optic 4
```

<table>
<thead>
<tr>
<th>Port</th>

<tr>
<td>4/4</td>
<td>0.0000 C</td>
<td>0.0000 mA</td>
<td>Normal</td>
<td>Normal</td>
</tr>
</tbody>
</table>

**Syntax:** `show optic slot number`
NOTE
This function takes advantage of information stored and supplied by the manufacturer of the XFP or SFP transceiver. This information is an optional feature of the Multi-Source Agreement standard defining the optical interface. Not all component suppliers have implemented this feature set. In such cases where the XFP or SFP transceiver does not supply the information, a “Not Available” message will be displayed for the specific port on which the module is installed.

The following table describes the information displayed by the show optic command.

TABLE 51  Output from the show optic command

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The Brocade port number.</td>
</tr>
<tr>
<td>Temperature</td>
<td>The operating temperature, in degrees Celsius, of the optical transceiver.</td>
</tr>
<tr>
<td></td>
<td>The alarm status, as described in Table 52.</td>
</tr>
<tr>
<td>Tx Power</td>
<td>The transmit power signal, in decibels (dB), of the measured power referenced to one milliwatt (mW).</td>
</tr>
<tr>
<td></td>
<td>The alarm status, as described in Table 52.</td>
</tr>
<tr>
<td>Rx Power</td>
<td>The receive power signal, in decibels (dB), of the measured power referenced to one milliwatt (mW).</td>
</tr>
<tr>
<td></td>
<td>The alarm status, as described in Table 52.</td>
</tr>
<tr>
<td>Tx Bias Current</td>
<td>The transmit bias power signal, in milliamperes (mA).</td>
</tr>
<tr>
<td></td>
<td>The alarm status, as described in Table 52.</td>
</tr>
</tbody>
</table>

For Temperature, Tx Power, Rx Power, and Tx Bias Current in the show optic command output, values are displayed along with one of the following alarm status values: Low-Alarm, Low-Warn, Normal, High-Warn or High-Alarm. The thresholds that determine these status values are set by the manufacturer of the optical transceivers. Table 52 describes each of these status values.

TABLE 52  Alarm status value description

<table>
<thead>
<tr>
<th>Status value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low-Alarm</td>
<td>Monitored level has dropped below the &quot;low-alarm&quot; threshold set by the manufacturer of the optical transceiver.</td>
</tr>
<tr>
<td>Low-Warn</td>
<td>Monitored level has dropped below the &quot;low-warn&quot; threshold set by the manufacturer of the optical transceiver.</td>
</tr>
<tr>
<td>Normal</td>
<td>Monitored level is within the &quot;normal&quot; range set by the manufacturer of the optical transceiver.</td>
</tr>
<tr>
<td>High-Warn</td>
<td>Monitored level has climbed above the &quot;high-warn&quot; threshold set by the manufacturer of the optical transceiver.</td>
</tr>
<tr>
<td>High-Alarm</td>
<td>Monitored level has climbed above the &quot;high-alarm&quot; threshold set by the manufacturer of the optical transceiver.</td>
</tr>
</tbody>
</table>

Viewing optical transceiver thresholds

The thresholds that determine the alarm status values for an optical transceiver are set by the manufacturer of the XFP or SFP. To view the thresholds for a qualified optical transceiver in a particular port, use the show optic threshold command as shown below.
Digital optical monitoring

FastIron> show optic threshold 2/2
Port 2/2 sfp monitor thresholds:
Temperature High alarm                5a00          90.0000 C
Temperature Low alarm                 d300          -45.0000 C
Temperature High warning              5500          85.0000 C
Temperature Low warning               d800          -40.0000 C
Supply Voltage High alarm             9088
Supply Voltage Low alarm              7148
Supply Voltage High warning            8ca0
Supply Voltage Low warning             7530
TX Bias High alarm                    7530          60.000 mA
TX Bias Low alarm                     01f4          1.000 mA
TX Bias High warning                  61a8          50.000 mA
TX Bias Low warning                   05dc          3.000 mA
TX Power High alarm                   1f07        -001.0001 dBm
TX Power Low alarm                    02c4        -011.4996 dBm
TX Power High warning                 18a6        -001.9997 dBm
TX Power Low warning                  037b        -010.5012 dBm
RX Power High alarm                   2710          000.0000 dBm
RX Power Low alarm                    0028        -023.9794 dBm
RX Power High warning                 1f07        -001.0001 dBm
RX Power Low warning                  0032        -023.0102 dBm

Syntax: show optic threshold port-num

For port-num, specify the port in one of the following formats:

- FastIron GS and LS compact switches – stack-unit/slotnum/portnum
- FastIron chassis devices – slotnum/portnum
- FESX, and FWSX compact switches – portnum

For Temperature, Supply Voltage, TX Bias, TX Power, and RX Power, values are displayed for each of the following four alarm and warning settings: High alarm, Low alarm, High warning, and Low warning. The hexadecimal values are the manufacturer internal calibrations, as defined in the SFF-8472 standard. The other values indicate at what level (above the high setting or below the low setting) the system should send a warning message or an alarm. Note that these values are set by the manufacturer of the optical transceiver, and cannot be configured.

Syslog messages

The system generates Syslog messages for optical transceivers in the following circumstances:

- The temperature, supply voltage, TX Bias, TX power, or TX power value goes above or below the high or low warning or alarm threshold set by the manufacturer.
- The optical transceiver does not support digital optical monitoring.
- The optical transceiver is not qualified, and therefore not supported by Brocade.

For details about the above Syslog messages, refer to Chapter 50, “Using Syslog”.
Digital optical monitoring
IPv6 addressing overview

This chapter explains IPv6 addressing and features and how to configure them on a Brocade FastIron X Series switch.

NOTE
With exception to IPv6 host features, the commands in this chapter are supported on FastIron X Series switches running software release 04.1.00 and later. IPv6 host features, covered in “IPv6 management (IPv6 host support)” on page 218, have been supported on FastIron X Series switches since software release 02.4.00 and TurboIron X Series devices running software release 04.2.00 and later.

NOTE
This chapter does not describe IPv6 routing protocols, which are covered in separate chapters throughout this guide.

IPv6 was designed to replace IPv4, the Internet protocol that is most commonly used currently throughout the world. IPv6 increases the number of network address bits from 32 (IPv4) to 128 bits, which provides more than enough unique IP addresses to support all of the network devices on the planet into the future. IPv6 is expected to quickly become the network standard.

An IPv6 address is composed of 8 fields of 16-bit hexadecimal values separated by colons (::). Figure 15 shows the IPv6 address format.

**Figure 15** IPv6 address format

As shown in Figure 15, HHHH is a 16-bit hexadecimal value, while H is a 4-bit hexadecimal value. The following is an example of an IPv6 address.

Note that this IPv6 address includes hexadecimal fields of zeros. To make the address less cumbersome, you can do the following:

- Omit the leading zeros; for example, 2001:0:0:200:002D:D0FF:FE48:4672.
- Compress the successive groups of zeros at the beginning, middle, or end of an IPv6 address to two colons (::) once per address; for example, 2001::200:2D:D0FF:FE48:4672.

When specifying an IPv6 address in a command syntax, keep the following in mind:
You can use the two colons (::) only once in the address to represent the longest successive hexadecimal fields of zeros.

- The hexadecimal letters in IPv6 addresses are not case-sensitive.

As shown in Figure 15, the IPv6 network prefix is composed of the left-most bits of the address. As with an IPv4 address, you can specify the IPv6 prefix using the `prefix / prefix-length` format, where the following applies.

The `prefix` parameter is specified as 16-bit hexadecimal values separated by a colon.

The `prefix-length` parameter is specified as a decimal value that indicates the left-most bits of the IPv6 address.

The following is an example of an IPv6 prefix.

```
2001:FF08:49EA:D088::/64
```

### IPv6 address types

As with IPv4 addresses, you can assign multiple IPv6 addresses to a switch interface. Table 53 presents the three major types of IPv6 addresses that you can assign to a switch interface.

A major difference between IPv4 and IPv6 addresses is that IPv6 addresses support `scope`, which describes the topology in which the address may be used as a unique identifier for an interface or set of interfaces.

Unicast and multicast addresses support scoping as follows:

- Unicast addresses support two types of scope: global scope and local scope. In turn, local scope supports site-local addresses and link-local addresses. Table 53 describes global, site-local, and link-local addresses and the topologies in which they are used.
- Multicast addresses support a scope field, which Table 53 describes.
IPv6 addressing overview

A switch automatically configures a link-local unicast address for an interface by using the prefix of FE80::/10 (1111 1110 10) and a 64-bit interface ID. The 128-bit IPv6 address is then subjected to duplicate address detection to ensure that the address is unique on the link. If desired, you can override this automatically configured address by explicitly configuring an address.

### IPv6 stateless autoconfiguration

Brocade routers use the IPv6 stateless autoconfiguration feature to enable a host on a local link to automatically configure its interfaces with new and globally unique IPv6 addresses associated with its location. The automatic configuration of a host interface is performed without the use of a server, such as a Dynamic Host Configuration Protocol (DHCP) server, or manual configuration.

### Table 53: IPv6 address types

<table>
<thead>
<tr>
<th>Address type</th>
<th>Description</th>
<th>Address structure</th>
</tr>
</thead>
</table>
| Unicast      | An address for a single interface. A packet sent to a unicast address is delivered to the interface identified by the address. | Depends on the type of the unicast address:  
- Aggregatable global address—An address equivalent to a global or public IPv4 address. The address structure is as follows: a fixed prefix of 2000::/3 (001), a 45-bit global routing prefix, a 16-bit subnet ID, and a 64-bit interface ID.  
- Site-local address—An address used within a site or intranet. (This address is similar to a private IPv4 address.) A site consists of multiple network links. The address structure is as follows: a fixed prefix of FEC0::/10 (1111 1110 11), a 16-bit subnet ID, and a 64-bit interface ID.  
- Link-local address—An address between directly connected nodes on a single network link. The address structure is as follows: a fixed prefix of FE80::/10 (1111 1110 10) and a 64-bit interface ID.  
- IPv4-compatible address—An address used in IPv6 transition mechanisms that tunnel IPv6 packets dynamically over IPv4 infrastructures. The address embeds an IPv4 address in the low-order 32 bits and the high-order 96 bits are zeros. The address structure is as follows: 0:0:0:0:0:0:A.B.C.D.  
- Loopback address—An address (0:0:0:0:0:0:0:1 or ::1) that a switch can use to send an IPv6 packet to itself. You cannot assign a loopback address to a physical interface.  
- Unspecified address—An address (0:0:0:0:0:0:0:0 or ::) that a node can use until you configure an IPv6 address for it. |
| Multicast    | An address for a set of interfaces belonging to different nodes. Sending a packet to a multicast address results in the delivery of the packet to all interfaces in the set. | A multicast address has a fixed prefix of FF00::/8 (1111 1111). The next 4 bits define the address as a permanent or temporary address. The next 4 bits define the scope of the address (node, link, site, organization, global). |
| Anycast      | An address for a set of interfaces belonging to different nodes. Sending a packet to an anycast address results in the delivery of the packet to the closest interface identified by the address. | An anycast address looks similar to a unicast address, because it is allocated from the unicast address space. If you assign a unicast address to multiple interfaces, it is an anycast address. An interface assigned an anycast address must be configured to recognize the address as an anycast address. An anycast address can be assigned to a switch only. An anycast address must not be used as the source address of an IPv6 packet. |
The automatic configuration of a host interface works in the following way: a switch on a local link periodically sends switch advertisement messages containing network-type information, such as the 64-bit prefix of the local link and the default route, to all nodes on the link. When a host on the link receives the message, it takes the local link prefix from the message and appends a 64-bit interface ID, thereby automatically configuring its interface. (The 64-bit interface ID is derived from the MAC address of the host NIC.) The 128-bit IPv6 address is then subjected to duplicate address detection to ensure that the address is unique on the link.

The duplicate address detection feature verifies that a unicast IPv6 address is unique before it is assigned to a host interface by the stateless auto configuration feature. Duplicate address detection uses neighbor solicitation messages to verify that a unicast IPv6 address is unique.

**NOTE**
For the stateless auto configuration feature to work properly, the advertised prefix length in switch advertisement messages must always be 64 bits.

The IPv6 stateless autoconfiguration feature can also automatically reconfigure a host interfaces if you change the ISP for the host network. (The host interfaces must be renumbered with the IPv6 prefix of the new ISP.)

The renumbering occurs in the following way: a switch on a local link periodically sends advertisements updated with the prefix of the new ISP to all nodes on the link. (The advertisements still contain the prefix of the old ISP.) A host can use the addresses created from the new prefix and the existing addresses created from the old prefix on the link. When you are ready for the host to use the new addresses only, you can configure the lifetime parameters appropriately using the `ipv6 nd prefix-advertisement` command. During this transition, the old prefix is removed from the switch advertisements. At this point, only addresses that contain the new prefix are used on the link.

### IPv6 CLI command support

Table 54 lists the IPv6 CLI commands supported.

<table>
<thead>
<tr>
<th>IPv6 command</th>
<th>Description</th>
<th>Switch code</th>
<th>Router code</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear ipv6 cache</td>
<td>Deletes all entries in the dynamic host cache.</td>

</tbody>
</table>
Configuring an IPv6 host address on a Layer 2 switch

In a Layer 3 (router) configuration, each port can be configured separately with an IPv6 address. This is accomplished using the interface configuration process that is described in “Configuring IPv6 on each router interface” on page 214.

In a Layer 2 (switch) configuration, individual ports cannot be configured with an IP address (IPv4 or IPv6). In this situation, the switch has one IP address for the management port and one IP address for the system. This has previously been supported for IPv4 but not for IPv6.

There is support for configuring an IPv6 address on the management port as described in “Configuring the management port for an IPv6 automatic address configuration” on page 213, and for configuring a system-wide IPv6 address on a Layer 2 switch. Configuration of the system-wide IPv6 address is exactly like configuration of an IPv6 address in router mode, except that the IPv6 configuration is at the Global Config level instead of at the Interface Config level.

The process for defining the system-wide interface for IPv6 is described in the following sections:

- “Configuring a global or site-local IPv6 address with a manually configured interface ID” on page 213
- “Configuring a link-local IPv6 address as a system-wide address for a switch” on page 213

NOTE

When configuring an IPv6 host address on a Layer 2 switch that has multiple VLANs, make sure the configuration includes a designated management VLAN that identifies the VLAN to which the global IP address belongs. Refer to “Designated VLAN for Telnet management sessions to a Layer 2 Switch” on page 1421.
Configuring a global or site-local IPv6 address with a manually configured interface ID

To configure a global or site-local IPv6 address with a manually-configured interface ID, such as a system-wide address for a switch, enter a command similar to the following at the Global Config level.

```
```

**Syntax:** `ipv6 address ipv6-prefix / prefix-length`

You must specify the `ipv6-prefix` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the `prefix-length` parameter in decimal value. A slash mark (/) must follow the `ipv6-prefix` parameter and precede the `prefix-length` parameter.

Configuring a link-local IPv6 address as a system-wide address for a switch

To enable IPv6 and automatically configure a global interface enter commands such as the following.

```
FastIron(config)# ipv6 enable
```

This command enables IPv6 on the switch and specifies that the interface is assigned an automatically computed link-local address.

**Syntax:** `[no] ipv6 enable`

To override a link-local address that is automatically computed for the global interface with a manually configured address, enter a command such as the following.

```
FastIron(config)# ipv6 address FE80::240:D0FF:FE48:4672 link-local
```

This command explicitly configures the link-local address `FE80::240:D0FF:FE48:4672` for the global interface.

**Syntax:** `ipv6 address ipv6-address link-local`

You must specify the `ipv6-address` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The `link-local` keyword indicates that the router interface should use the manually configured link-local address instead of the automatically computed link-local address.

Configuring the management port for an IPv6 automatic address configuration

You can have the management port configured to automatically obtain an IPv6 address. This process is the same for any other port and is described in detail in the “Configuring a global IPv6 address with an automatically computed EUI-64 interface ID” on page 216.
Configuring basic IPv6 connectivity on a Layer 3 switch

To configure basic IPv6 connectivity on a Brocade Layer 3 Switch, you must do the following:

- Enable IPv6 routing globally on the switch
- Configure an IPv6 address or explicitly enable IPv6 on each router interface over which you plan to forward IPv6 traffic
- Configure IPv4 and IPv6 protocol stacks. (This step is mandatory only if you want a router interface to send and receive both IPv4 and IPv6 traffic.)

All other configuration tasks in this chapter are optional.

Enabling IPv6 routing

By default, IPv6 routing is disabled. To enable the forwarding of IPv6 traffic globally on the Layer 3 switch, enter the following command.

```
FastIron(config)# ipv6 unicast-routing
```

Syntax: `[no] ipv6 unicast-routing`

To disable the forwarding of IPv6 traffic globally on the Brocade device, enter the `no` form of this command.

**NOTE**

This command is not supported on TurboIron devices because IPv6 unicast routing is not supported on the device.

Configuring IPv6 on each router interface

To forward IPv6 traffic on a router interface, the interface must have an IPv6 address, or IPv6 must be explicitly enabled. By default, an IPv6 address is not configured on a router interface.

If you choose to configure a global or site-local IPv6 address for an interface, IPv6 is also enabled on the interface. Further, when you configure a global or site-local IPv6 address, you must decide on one of the following in the low-order 64 bits:

- A manually configured interface ID.
- An automatically computed EUI-64 interface ID.

If you prefer to assign a link-local IPv6 address to the interface, you must explicitly enable IPv6 on the interface, which causes a link-local address to be automatically computed for the interface. If preferred, you can override the automatically configured link-local address with an address that you manually configure.

This section provides the following information:

- Configuring a global or site-local address with a manually configured or automatically computed interface ID for an interface.
- Automatically or manually configuring a link-local address for an interface.
- Configuring IPv6 anycast addresses
Configuring a global or site-local IPv6 address on an interface

Configuring a global or site-local IPv6 address on an interface does the following:

- Automatically configures an interface ID (a link-local address), if specified.
- Enables IPv6 on that interface.

Additionally, the configured interface automatically joins the following required multicast groups for that link:

- Solicited-node multicast group FF02:0:0:0:1:FF00::/104 for each unicast address assigned to the interface.
- Solicited-node for subnet anycast address for each unicast assigned address
- Solicited-node for anycast address FF02:0:0:0:1:FF00::0000
- All-nodes link-local multicast group FF02::1
- All-routers link-local multicast group FF02::2

The neighbor discovery feature sends messages to these multicast groups. For more information, refer to “Configuring IPv6 neighbor discovery” on page 238.

Configuring a global or site-local IPv6 address with a manually configured interface ID

To configure a global or site-local IPv6 address, including a manually configured interface ID, for an interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 address 2001:200:12D:1300::240:D0FF:FE48:4672:/64
```

These commands configure the global prefix 2001:200:12D:1300::/64 and the interface ID ::240:D0FF:FE48:4672, and enable IPv6 on Ethernet interface 3/1.

Syntax: `ipv6 address ipv6-prefix / prefix-length`

You must specify the `ipv6-prefix` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the `prefix-length` parameter as a decimal value. A slash mark (/) must follow the `ipv6-prefix` parameter and precede the `prefix-length` parameter.

To configure a /122 address on a VE enter commands similar to the following.

```
FastIron(config-vlan-11)# int ve11
FastIron(config-vif-11)# ipv6 add 2020::1/122
FastIron(config-vif-11)# sh ipv6 int
Routing Protocols : R - RIP  O - OSPF
Interface     Status     Routing  Global Unicast Address
VE 11          up/up               2020::1/122
FastIron(config-vif-11)# sh ipv6 route
IPv6 Routing Table - 1 entries:
Type Codes:  C - Connected, S - Static, R - RIP, O - OSPF, B - BGP
OSPF Sub Type Codes:  O - Intra, Oi - Inter, O1 - Type1 external, O2 - Type2 external
Type IPv6 Prefix Next Hop Router Interface Dis/Metric
C 2020::/122     :: ve 11 0/0
```

Configuring a global IPv6 address with an automatically computed EUI-64 interface ID
To configure a global IPv6 address with an automatically computed EUI-64 interface ID in the low-order 64-bits, enter commands such as the following.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 address 2001:200:12D:1300::/64 eui-64
```

These commands configure the global prefix 2001:200:12d:1300::/64 and an interface ID, and enable IPv6 on Ethernet interface 3/1.

**Syntax:** `ipv6 address ipv6-prefix / prefix-length eui-64`

You must specify the `ipv6-prefix` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the `prefix-length` parameter as a decimal value. A slash mark (/) must follow the `ipv6-prefix` parameter and precede the `prefix-length` parameter.

The `eui-64` keyword configures the global address with an EUI-64 interface ID in the low-order 64 bits. The interface ID is automatically constructed in IEEE EUI-64 format using the interface MAC address.

Configuring a link-local IPv6 address on an interface
To explicitly enable IPv6 on a router interface without configuring a global or site-local address for the interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 enable
```

These commands enable IPv6 on Ethernet interface 3/1 and specify that the interface is assigned an automatically computed link-local address.

**Syntax:** `[no] ipv6 enable`

**NOTE**
When configuring VLANs that share a common tagged interface with a physical or Virtual Ethernet (VE) interface, Brocade recommends that you override the automatically computed link-local address with a manually configured unique address for the interface. If the interface uses the automatically computed address, which in the case of physical and VE interfaces is derived from a global MAC address, all physical and VE interfaces will have the same MAC address.

To override a link-local address that is automatically computed for an interface with a manually configured address, enter commands such as the following.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 address FE80::240:D0FF:FE48:4672 link-local
```

These commands explicitly configure the link-local address FE80::240:D0FF:FE48:4672 for Ethernet interface 3/1.

**Syntax:** `ipv6 address ipv6-address link-local`

You must specify the `ipv6-address` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The `link-local` keyword indicates that the router interface should use the manually configured link-local address instead of the automatically computed link-local address.
Configuring an IPv6 anycast address on an interface

In IPv6, an anycast address is an address for a set of interfaces belonging to different nodes. Sending a packet to an anycast address results in the delivery of the packet to the closest interface configured with the anycast address.

An anycast address looks similar to a unicast address, because it is allocated from the unicast address space. If you assign an IPv6 unicast address to multiple interfaces, it is an anycast address. On the Brocade device, you configure an interface assigned an anycast address to recognize the address as an anycast address.

For example, the following commands configure an anycast address on interface 2/1.

```
FastIron(config)# int e 2/1
FastIron(config-if-e1000-2/1)# ipv6 address 2002::/64 anycast
```

Syntax: `ipv6 address ipv6-prefix / prefix-length [ anycast ]`

IPv6 anycast addresses are described in detail in RFC 1884. See RFC 2461 for a description of how the IPv6 Neighbor Discovery mechanism handles anycast addresses.

Configuring IPv4 and IPv6 protocol stacks

One situation in which you must configure a router to run both IPv4 and IPv6 protocol stacks is if it is deployed as an endpoint for an IPv6 over IPv4 tunnel.

Each router interface that will send and receive both IPv4 and IPv6 traffic must be configured with an IPv4 address and an IPv6 address. (An alternative to configuring a router interface with an IPv6 address is to explicitly enable IPv6 using the `ipv6 enable` command. For more information about using this command, refer to “Configuring a link-local IPv6 address on an interface” on page 216.)

To configure a router interface to support both the IPv4 and IPv6 protocol stacks, use commands such as the following.

```
FastIron(config)# ipv6 unicast-routing
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ip address 192.168.1.1 255.255.255.0
FastIron(config-if-e1000-3/1)# ipv6 address 2001:200:12d:1300::/64 eui-64
```

These commands globally enable IPv6 routing and configure an IPv4 address and an IPv6 address for Ethernet interface 3/1.

Syntax: `[no] ipv6 unicast-routing

To disable IPv6 traffic globally on the router, enter the `no` form of this command.

Syntax: `ip address ip-address sub-net-mask [ secondary ]`

You must specify the `ip-address` parameter using 8-bit values in dotted decimal notation.

You can specify the `sub-net-mask` parameter in either dotted decimal notation or as a decimal value preceded by a slash mark (/).

The `secondary` keyword specifies that the configured address is a secondary IPv4 address.

To remove the IPv4 address from the interface, enter the `no` form of this command.

Syntax: `ipv6 address ipv6-prefix / prefix-length [ eui-64 ]`

This syntax specifies a global or site-local IPv6 address. For information about configuring a link-local IPv6 address, refer to “Configuring a link-local IPv6 address on an interface” on page 216.
You must specify the `ipv6-prefix` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the `prefix-length` parameter as a decimal value. A slash mark (/) must follow the `ipv6-prefix` parameter and precede the `prefix-length` parameter.

The `eui-64` keyword configures the global address with an EUI-64 interface ID in the low-order 64 bits. The interface ID is automatically constructed in IEEE EUI-64 format using the interface MAC address. If you do not specify the `eui-64` keyword, you must manually configure the 64-bit interface ID as well as the 64-bit network prefix. For more information about manually configuring an interface ID, refer to “Configuring a global or site-local IPv6 address on an interface” on page 215.

### IPv6 management (IPv6 host support)

**Platform Support:**
- FastIron X Series devices running software release 02.4.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.2.00 and later

An **IPv6 host** has IPv6 addresses on its interfaces, but does not have full IPv6 routing enabled on it.

This section describes the following IPv6 host features:
- “IPv6 access control lists”
- “Restricting SNMP access to an IPv6 node”
- “Specifying an IPv6 SNMP trap receiver”
- “SNMP V3 over IPv6”
- “SNTP over IPv6”
- “Secure Shell, SCP, and IPv6”
- “IPv6 Telnet”
- “IPv6 Web management using HTTP and HTTPS”
- “Restricting Web management access”
- “Configuring name-to-IPv6 address resolution using IPv6 DNS resolver”
- “Defining an IPv6 DNS entry”
- “Using the IPv6 copy command”
- “Using the IPv6 ncopy command”
- “IPv6 ping”
- “Configuring an IPv6 Syslog server”
- “Viewing IPv6 SNMP server addresses”
- “Disabling router advertisement and solicitation messages”
- “IPv6 debug”
- “Disabling IPv6 on a Layer 2 switch”

The following IPv6 host feature is also supported:
- “Configuring a link-local IPv6 address as a system-wide address for a switch”

The following IPv6 host features are not supported in TurboIron 24x:
- IPv6 access control lists
IPv6 management (IPv6 host support)

- IPv6 Web management using HTTP and HTTPS

IPv6 access control lists

You can configure an IPv6 ACL to filter traffic to or from an IPv6 host. To do so, refer to Chapter 18, “Configuring IPv6 Access Control Lists (ACLs)”.

Restricting SNMP access to an IPv6 node

You can restrict SNMP access (which includes IronView Network Manager) to the device to the IPv6 host whose IP address you specify. To do so, enter a command such as the following.

```
FastIron(config)# snmp-client ipv6 2001:efff:89::23
```

Syntax: `snmp-client ipv6 ipv6-address`

- The `ipv6-address` you specify must be in hexadecimal format using 16-bit values between colons as documented in RFC 2373.

Specifying an IPv6 SNMP trap receiver

You can specify an IPv6 host as a trap receiver to ensure that all SNMP traps sent by the device will go to the same SNMP trap receiver or set of receivers, typically one or more host devices on the network. To do so, enter a command such as the following.

```
FastIron(config)# snmp-server host ipv6 2001:efff:89::13
```

Syntax: `snmp-server host ipv6 ipv6-address`

- The `ipv6-address` you specify must be in hexadecimal format using 16-bit values between colons as documented in RFC 2373.

SNMP V3 over IPv6

Brocade devices support IPv6 for SNMP version 3. For more information about how to configure SNMP, refer to Chapter 48, “Securing SNMP Access”.

SNTP over IPv6

To enable the Brocade device to send SNTP packets over IPv6, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)# sntp server ipv6 3000::400
```

Syntax: `sntp server ipv6 ipv6-address`

- The `ipv6-address` is the IPv6 address of the SNTP server. When you enter the IPv6 address, you do not need to specify the prefix length. A prefix length of 128 is implied.
Secure Shell, SCP, and IPv6

Secure Shell (SSH) is a mechanism that allows secure remote access to management functions on the Brocade device. SSH provides a function similar to Telnet. You can log in to and configure the Brocade device using a publicly or commercially available SSH client program, just as you can with Telnet. However, unlike Telnet, which provides no security, SSH provides a secure, encrypted connection to the Brocade device.

To open an SSH session between an IPv6 host running an SSH client program and the Brocade device, open the SSH client program and specify the IPv6 address of the device. For more information about configuring SSH on the Brocade device, refer to “SSH version 2 support” on page 1495.

IPv6 Telnet

Telnet sessions can be established between a Brocade device to a remote IPv6 host, and from a remote IPv6 host to the Brocade device using IPv6 addresses.

The `telnet` command establishes a Telnet connection from a Brocade device to a remote IPv6 host using the console. Up to five `read-access` Telnet sessions are supported on the router at one time. `Write-access` through Telnet is limited to one session, and only one outgoing Telnet session is supported on the router at one time. To see the number of open Telnet sessions at any time, enter the `show telnet` command.

Example

To establish a Telnet connection to a remote host with the IPv6 address of 3001:2837:3de2:c37::6, enter the following command.

```
FastIron# telnet 3001:2837:3de2:c37::6
```

Syntax: `telnet ipv6-address [ port-number | outgoing-interface ethernet port | ve number ]`

- The `ipv6-address` parameter specifies the address of a remote host. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The `port-number` parameter specifies the port number on which the Brocade device establishes the Telnet connection. You can specify a value between 1 - 65535. If you do not specify a port number, the Brocade device establishes the Telnet connection on port 23.
- If the IPv6 address you specify is a link-local address, you must specify the `outgoing-interface` Ethernet `port | ve number` parameter. This parameter identifies the interface that must be used to reach the remote host. If you specify an Ethernet interface, you must also specify the port number associated with the interface. If you specify a VE interface, also specify the VE number.

Establishing a Telnet session from an IPv6 host

To establish a Telnet session from an IPv6 host to the Brocade device, open your Telnet application and specify the IPv6 address of the Layer 3 Switch.

IPv6 Web management using HTTP and HTTPS

**NOTE**

Web management interface is not supported on TurboIron devices.
IPv6 management (IPv6 host support)

When you have an IPv6 management station connected to a switch with an IPv6 address applied to the management port, you can manage the switch from a Web browser by entering one of the following in the browser address field.

http://[ipv6 address]

or

https://[ipv6 address]

**NOTE**

You must enclose the IPv6 address with square brackets [ ] in order for the Web browser to work.

**Restricting Web management access**

You can restrict Web management access to include only management functions on a Brocade device that is acting as an IPv6 host, or restrict access so that the Brocade host can be reached by a specified IPv6 device.

**Restricting Web management access by specifying an IPv6 ACL**

You can specify an IPv6 ACL that restricts Web management access to management functions on the device that is acting as the IPv6 host.

```
FastIron(config)# access-list 12 deny host 2000:2383:e0bb::2/128 log
FastIron(config)# access-list 12 deny 30ff:3782::ff89/128 log
FastIron(config)# access-list 12 deny 3000:4828::fe19/128 log
FastIron(config)# access-list 12 permit any
FastIron(config)# web access-group ipv6 12
```

**Syntax:**  `web access-group ipv6 ipv6 ACL name`

where `ipv6 ACL name` is a valid IPv6 ACL.

**Restricting Web management access to an IPv6 host**

You can restrict Web management access to the device to the IPv6 host whose IP address you specify. No other device except the one with the specified IPv6 address can access the Web Management Interface.

```
FastIron(config)# web client ipv6 3000:2383:e0bb::2/128
```

**Syntax:**  `web client ipv6 ipv6-address`

- The `ipv6-address` you specify must be in hexadecimal format using 16-bit values between colons as documented in RFC 2373.

**Configuring name-to-IPv6 address resolution using IPv6 DNS resolver**

The Domain Name Server (DNS) resolver feature lets you use a host name to perform Telnet and ping commands. You can also define a DNS domain on a Brocade device and thereby recognize all hosts within that domain. After you define a domain name, the Brocade device automatically appends the appropriate domain to the host and forwards it to the domain name server.
For example, if the domain "newyork.com" is defined on a Brocade device, and you want to initiate a ping to host “NYC01” on that domain, you need to reference only the host name in the command instead of the host name and its domain name. For example, you could enter either of the following commands to initiate the ping.

```
FastIron# ping ipv6 nyc01
FastIron# ping ipv6 nyc01.newyork.com
```

### Defining an IPv6 DNS entry

IPv6 defines new DNS record types to resolve queries for domain names to IPv6 addresses, as well as IPv6 addresses to domain names. Brocade devices running IPv6 software support AAAA DNS records, which are defined in RFC 1886.

AAAA DNS records are analogous to the A DNS records used with IPv4. They store a complete IPv6 address in each record. AAAA records have a type value of 28.

To establish an IPv6 DNS entry for the device, enter the following command.

```
FastIron(config)# ipv6 dns domain-name companynet.com
```

**Syntax:**

```
[no] ipv6 dns domain-name domain name
```

To define an IPv6 DNS server address, enter the following command.

```
FastIron(config)# ipv6 dns server-address 200::1
```

**Syntax:**

```
[no] ipv6 dns server-address ipv6-addr [ipv6-addr] [ipv6-addr] [ipv6-addr]
```

As an example, in a configuration where ftp6.companynet.com is a server with an IPv6 protocol stack, when a user pings ftp6.companynet.com, the Brocade device attempts to resolve the AAAA DNS record. In addition, if the DNS server does not have an IPv6 address, as long as it is able to resolve AAAA records, it can still respond to DNS queries.

### Using the IPv6 copy command

The `copy` command for IPv6 allows you to do the following:

- Copy a file from a specified source to an IPv6 TFTP server.
- Copy a file from an IPv6 TFTP server to a specified destination.

#### Copying a file to an IPv6 TFTP server

You can copy a file from the following sources to an IPv6 TFTP server:

- Flash memory.
- Running configuration.
- Startup configuration.

**Copying a file from flash memory**

For example, to copy the primary or secondary boot image from the device flash memory to an IPv6 TFTP server, enter a command such as the following.

```
FastIron# copy flash tftp 2001:7382:e0ff:7837::3 test.img secondary
```

This command copies the secondary boot image named test.img from flash memory to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3.
IPv6 management (IPv6 host support)

Syntax: copy flash tftp ipv6-address source-file-name primary | secondary

- The `ipv6-address` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The `source-file-name` parameter specifies the name of the file you want to copy to the IPv6 TFTP server.
- The `primary` keyword specifies the primary boot image, while the `secondary` keyword specifies the secondary boot image.

Copying a file from the running or startup configuration

For example, to copy the running configuration to an IPv6 TFTP server, enter a command such as the following.

```
FastIron# copy running-config tftp 2001:7382:e0ff:7837::3 newrun.cfg
```

This command copies the running configuration to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 and names the file on the TFTP server newrun.cfg.

Syntax: copy running-config | startup-config tftp ipv6-address destination-file-name

- Specify the `running-config` keyword to copy the running configuration file to the specified IPv6 TFTP server.
- Specify the `startup-config` keyword to copy the startup configuration file to the specified IPv6 TFTP server.
- The `tftp ipv6-address` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The `destination-file-name` parameter specifies the name of the file that is copied to the IPv6 TFTP server.

Copying a file from an IPv6 TFTP server

You can copy a file from an IPv6 TFTP server to the following destinations:

- Flash memory.
- Running configuration.
- Startup configuration.

Copying a file to flash memory

For example, to copy a boot image from an IPv6 TFTP server to the primary or secondary storage location in the device flash memory, enter a command such as the following.

```
FastIron# copy tftp flash 2001:7382:e0ff:7837::3 test.img secondary
```

This command copies a boot image named test.img from an IPv6 TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the secondary storage location in the device flash memory.

Syntax: copy tftp flash ipv6-address source-file-name primary | secondary

- The `ipv6-address` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The `source-file-name` parameter specifies the name of the file you want to copy from the IPv6 TFTP server.
- The `primary` keyword specifies the primary storage location in the device flash memory, while the `secondary` keyword specifies the secondary storage location in the device flash memory.
Copying a file to the running or startup configuration
For example, to copy a configuration file from an IPv6 TFTP server to the router running or startup configuration, enter a command such as the following.

```
FastIron# copy tftp running-config 2001:7382:e0ff:7837::3 newrun.cfg overwrite
```

This command copies the new running .onfig file from the IPv6 TFTP server and overwrites the router running configuration file with the contents of newrun.cfg.

**NOTE**
To activate this configuration, you must reload (reset) the device.

**Syntax:** `copy tftp running-config | startup-config ipv6-address source-file-name [overwrite]`

- Specify the `running-config` keyword to copy the running configuration from the specified IPv6 TFTP server.
- Specify the `startup-config` keyword to copy the startup configuration from the specified IPv6 TFTP server.
- The `ipv6-address` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The `source-file-name` parameter specifies the name of the file that is copied from the IPv6 TFTP server.
- The `overwrite` keyword specifies that the device should overwrite the current configuration file with the copied file. If you do not specify this parameter, the device copies the file into the current running or startup configuration but does not overwrite the current configuration.

**NOTE**
You cannot use the overwrite option from non-console sessions, because it will disconnect the session.

Using the IPv6 ncopy command
The `ncopy` command for IPv6 allows you to do the following:

- Copy a primary or secondary boot image from flash memory to an IPv6 TFTP server.
- Copy the running configuration to an IPv6 TFTP server.
- Copy the startup configuration to an IPv6 TFTP server.
- Upload various files from an IPv6 TFTP server.

**Copying a primary or secondary boot image from flash memory to an IPv6 TFTP server**

For example, to copy the primary or secondary boot image from the device flash memory to an IPv6 TFTP server, enter a command such as the following.

```
FastIron# ncopy flash primary tftp 2001:7382:e0ff:7837::3 primary.img
```

This command copies the primary boot image named primary.img from flash memory to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3.

**Syntax:** `ncopy flash primary | secondary tftp ipv6-address source-file-name`
• The **primary** keyword specifies the primary boot image, while the **secondary** keyword specifies the secondary boot image.

• The **tftp ipv6-address** parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

• The **source-file-name** parameter specifies the name of the file you want to copy from flash memory.

**Copying the running or startup configuration to an IPv6 TFTP server**

For example, to copy a device running or startup configuration to an IPv6 TFTP server, enter a command such as the following.

FastIron# ncopy running-config tftp 2001:7382:e0ff:7837::3 bakrun.cfg

This command copies a device running configuration to a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 and names the destination file bakrun.cfg.

**Syntax:** ncopy running-config | startup-config tftp ipv6-address destination-file-name

• Specify the **running-config** keyword to copy the device running configuration or the **startup-config** keyword to copy the device startup configuration.

• The **tftp ipv6-address** parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

• The **destination-file-name** parameter specifies the name of the running configuration that is copied to the IPv6 TFTP server.

**Uploading files from an IPv6 TFTP server**

You can upload the following files from an IPv6 TFTP server:

• Primary boot image.

• Secondary boot image.

• Running configuration.

• Startup configuration.

**Uploading a primary or secondary boot image from an IPv6 TFTP server**

For example, to upload a primary or secondary boot image from an IPv6 TFTP server to a device flash memory, enter a command such as the following.

FastIron# ncopy tftp 2001:7382:e0ff:7837::3 primary.img flash primary

This command uploads the primary boot image named primary.img from a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the device primary storage location in flash memory.

**Syntax:** ncopy tftp ipv6-address source-file-name flash primary | secondary

• The **tftp ipv6-address** parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.

• The **source-file-name** parameter specifies the name of the file you want to copy from the TFTP server.

• The **primary** keyword specifies the primary location in flash memory, while the **secondary** keyword specifies the secondary location in flash memory.
Uploading a running or startup configuration from an IPv6 TFTP server
For example to upload a running or startup configuration from an IPv6 TFTP server to a device, enter a command such as the following.

```
FastIron# ncopy tftp 2001:7382:e0ff:7837::3 newrun.cfg running-config
```

This command uploads a file named newrun.cfg from a TFTP server with the IPv6 address of 2001:7382:e0ff:7837::3 to the device.

Syntax: `ncopy tftp ipv6-address source-file-name running-config | startup-config`

• The `tftp ipv6-address>` parameter specifies the address of the TFTP server. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
• The `source-file-name>` parameter specifies the name of the file you want to copy from the TFTP server.
• Specify the `running-config` keyword to upload the specified file from the IPv6 TFTP server to the device. The device copies the specified file into the current running configuration but does not overwrite the current configuration.

Specify the `startup-config` keyword to upload the specified file from the IPv6 TFTP server to the device. The device copies the specified file into the current startup configuration but does not overwrite the current configuration.

IPv6 ping

The `ping` command allows you to verify the connectivity from a Brocade device to an IPv6 device by performing an ICMP for IPv6 echo test.

For example, to ping a device with the IPv6 address of 2001:3424:847f:a385:34dd::45 from the Brocade device, enter the following command.

```
FastIron# ping ipv6 2001:3424:847f:a385:34dd::45
```

Syntax: `ping ipv6 ipv6-address [ outgoing-interface [ port | ve number ]] [ source ipv6-address ] [ count number ] [ timeout milliseconds ] [ ttl number ] [ size bytes ] [ quiet ] [ numeric ] [ no-fragment ] [ verify ] [ data 1-to-4 byte hex ] [ brief ]`

• The `ipv6-address` parameter specifies the address of the router. You must specify this address in hexadecimal using 16-bit values between colons as documented in RFC 2373.
• The `outgoing-interface` keyword specifies a physical interface over which you can verify connectivity. If you specify a physical interface, such as an Ethernet interface, you must also specify the port number of the interface. If you specify a virtual interface, such as a VE, you must specify the number associated with the VE.
• The `source ipv6-address` parameter specifies an IPv6 address to be used as the origin of the ping packets.

**NOTE**
The `outgoing-interface` and `source` options are available only on router code and not on switch code.

• The `count number` parameter specifies how many ping packets the router sends. You can specify from 1 - 4294967296. The default is 1.
• The `timeout milliseconds` parameter specifies how many milliseconds the router waits for a reply from the pinged device. You can specify a timeout from 1 - 4294967294 milliseconds. The default is 5000 (5 seconds).
IPv6 management (IPv6 host support)

- The **ttl** number parameter specifies the maximum number of hops. You can specify a TTL from 1 - 255. The default is 64.

- The **size** bytes parameter specifies the size of the ICMP data portion of the packet. This is the payload and does not include the header. You can specify from 0 - 10173. The default is 16.

- The **no-fragment** keyword turns on the "do not fragment" bit in the IPv6 header of the ping packet. This option is disabled by default.

  **NOTE**
  The **no-fragment** option is not supported on TurboIron devices.

- The **quiet** keyword hides informational messages such as a summary of the ping parameters sent to the device, and instead only displays messages indicating the success or failure of the ping. This option is disabled by default.

- The **verify** keyword verifies that the data in the echo packet (the reply packet) is the same as the data in the echo request (the ping). By default the device does not verify the data.

- The **data 1 - 4 byte hex** parameter lets you specify a specific data pattern for the payload instead of the default data pattern, "abcd", in the packet's data payload. The pattern repeats itself throughout the ICMP message (payload) portion of the packet.

  **NOTE**
  For parameters that require a numeric value, the CLI does not check that the value you enter is within the allowed range. Instead, if you do exceed the range for a numeric value, the software rounds the value to the nearest valid value.

- The **brief** keyword causes ping test characters to be displayed. The following ping test characters are supported.
  
<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>Indicates that a reply was received.</td>
</tr>
<tr>
<td>.</td>
<td>Indicates that the network server timed out while waiting for a reply.</td>
</tr>
<tr>
<td>U</td>
<td>Indicates that a destination unreachable error PDU was received.</td>
</tr>
<tr>
<td>I</td>
<td>Indicates that the user interrupted ping.</td>
</tr>
</tbody>
</table>

### Configuring an IPv6 Syslog server

To enable IPv6 logging, specify an IPv6 Syslog server. Enter a command such as the following.

```
FastIron(config)# log host ipv6 2000:2383:e0bb::4/128
```

**Syntax:** `log host ipv6 ipv6-address [ udp-port-num ]`

- The **ipv6-address** must be in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The **udp-port-num** optional parameter specifies the UDP application port used for the Syslog facility.

### Viewing IPv6 SNMP server addresses

Some of the `show` commands display IPv6 addresses for IPv6 SNMP servers. The following shows an example output for the `show snmp server` command.
IPv6 management (IPv6 host support)

FastIron# show snmp server

Disabling router advertisement and solicitation messages

Router advertisement and solicitation messages enable a node on a link to discover the routers on the same link. By default, router advertisement and solicitation messages are permitted on the device. To disable these messages, configure an IPv6 access control list that denies them. The following shows an example configuration.

Example

FastIron(config)# ipv6 access-list rtradvert
FastIron(config)# deny icmp any any router-advertisement
FastIron(config)# deny icmp any any router-solicitation
FastIron(config)# permit ipv6 any any

IPv6 debug

The debug ipv6 commands enable the collection of information about IPv6 configurations for troubleshooting.

Syntax: debug ipv6 address cache icmp mld nd packet ra

- address - IPv6 address
- cache - IPv6 cache entry
Configuring a static IPv6 route

You can configure a static IPv6 route to be redistributed into a routing protocol, but you cannot redistribute routes learned by a routing protocol into the static IPv6 routing table.

Before configuring a static IPv6 route, you must enable the forwarding of IPv6 traffic on the Layer 3 switch using the `ipv6 unicast-routing` command and enable IPv6 on at least one interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface. For more information on performing these configuration tasks, refer to "Configuring IPv4 and IPv6 protocol stacks" on page 217.

To configure a static IPv6 route for a destination network with the prefix 8eff::0/32, a next-hop gateway with the global address 4fee:2343:0:ee44::1, and an administrative distance of 110, enter the following command.

```
FastIron(config)# ipv6 route 8eff::0/32 4fee:2343:0:ee44::1 distance 110
```

**Syntax:** `ipv6 route dest-ipv6-prefix / prefix-length next-hop-ipv6-address> [ metric ] [ distance number ]`

To configure a static IPv6 route for a destination network with the prefix 8eff::0/32 and a next-hop gateway with the link-local address fe80::1 that the Layer 3 switch can access through Ethernet interface 3/1, enter the following command.

```
FastIron(config)# ipv6 route 8eff::0/32 ethernet 1 fe80::1
```

**Syntax:** `ipv6 route dest-ipv6-prefix / prefix-length [ ethernet slot/port | ve num | null0 ] next-hop-ipv6-address [ metric ] [ distance number ]`
To configure a static IPv6 route for a destination network with the prefix 8eff::0/32 and a next-hop gateway that the Layer 3 switch can access through tunnel 1, enter the following command.

FastIron(config)# ipv6 route 8eff::0/32 tunnel 1

**Syntax:** `ipv6 route dest-ipv6-prefix / prefix-length interface port [ metric ] [ distance number ]`

Table 55 describes the parameters associated with this command and indicates the status of each parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Configuration details</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>The IPv6 prefix and prefix length of the route destination network.</td>
<td>You must specify the <code>dest-ipv6-prefix&gt;</code> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the <code>prefix-length&gt;</code> parameter as a decimal value. A slash mark (<code>/</code>) must follow the <code>ipv6-prefix&gt;</code> parameter and precede the <code>prefix-length&gt;</code> parameter.</td>
<td>Mandatory for all static IPv6 routes.</td>
</tr>
<tr>
<td>The route next-hop gateway, which can be one of the following: The IPv6 address of a next-hop gateway. A tunnel interface.</td>
<td>You can specify the next-hop gateway as one of the following types of IPv6 addresses: A global address. A link-local address. If you specify a global address, you do not need to specify any additional parameters for the next-hop gateway. If you specify a link-local address, you must also specify the interface through which to access the address. You can specify one of the following interfaces: An Ethernet interface. A tunnel interface. A virtual interface (VE). If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE or tunnel interface, also specify the VE or tunnel number. You can also specify the next-hop gateway as a tunnel interface. If you specify a tunnel interface, also specify the tunnel number.</td>
<td>Mandatory for all static IPv6 routes.</td>
</tr>
<tr>
<td>The route metric.</td>
<td>You can specify a value from 1 – 16. Optional for all static IPv6 routes. (The default metric is 1.)</td>
<td></td>
</tr>
<tr>
<td>The route administrative distance.</td>
<td>You must specify the <code>distance</code> keyword and any numerical value. Optional for all static IPv6 routes. (The default administrative distance is 1.)</td>
<td></td>
</tr>
</tbody>
</table>

A metric is a value that the Layer 3 switch uses when comparing this route to other static routes in the IPv6 static route table that have the same destination. The metric applies only to routes that the Layer 3 switch has already placed in the IPv6 static route table.
The administrative distance is a value that the Layer 3 switch uses to compare this route with routes from other route sources that have the same destination. (The Layer 3 switch performs this comparison before placing a route in the IPv6 route table.) This parameter does not apply to routes that are already in the IPv6 route table. In general, a low administrative distance indicates a preferred route. By default, static routes take precedence over routes learned by routing protocols. If you want a dynamic route to be chosen over a static route, you can configure the static route with a higher administrative distance than the dynamic route.

**IPv6 over IPv4 tunnels**

**Platform Support:**
- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3

To enable communication between isolated IPv6 domains using the IPv4 infrastructure, you can manually configure IPv6 over IPv4 tunnels that provide static point-point connectivity.

As shown in **Figure 16**, these tunnels encapsulate an IPv6 packet within an IPv4 packet.

**FIGURE 16** IPv6 over an IPv4 tunnel

In general, a manually configured tunnel establishes a permanent link between switches in IPv6 domains. A manually configured tunnel has explicitly configured IPv4 addresses for the tunnel source and destination.

This tunneling mechanism requires that the Layer 3 switch at each end of the tunnel run both IPv4 and IPv6 protocol stacks. The Layer 3 switches running both protocol stacks, or dual-stack routers, can interoperate directly with both IPv4 and IPv6 end systems and routers. Refer to “Configuring IPv4 and IPv6 protocol stacks” on page 217.

**Configuration notes**
- The local tunnel configuration must include both source and destination addresses.
- The remote side of the tunnel must have the opposite source/destination pair.
- A tunnel interface supports static and dynamic IPv6 configuration settings and routing protocols.
- Duplicate Address Detection (DAD) is not currently supported with IPv6 tunnels. Make sure tunnel endpoints do not have duplicate IP addresses.
- Neighbor Discovery (ND) is not supported with IPv6 tunnels.
- If a tunnel source port is a multi-homed IPv4 source, the tunnel will use the first IPv4 address only. For proper tunnel operation, use the `ip address` option.
### Configuring a manual IPv6 tunnel

You can use a manually configured tunnel to connect two isolated IPv6 domains. You should deploy this point-to-point tunnelling mechanism if you need a permanent and stable connection.

To configure a manual IPv6 tunnel, enter commands such as the following on a Layer 3 Switch running both IPv4 and IPv6 protocol stacks on each end of the tunnel.

```
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# tunnel source ethernet 3/1
FastIron(config-tnif-1)# tunnel destination 198.162.100.1
FastIron(config-tnif-1)# tunnel mode ipv6ip
FastIron(config-tnif-1)# ipv6 enable
```

This example creates tunnel interface 1 and assigns a link local IPv6 address with an automatically computed EUI-64 interface ID to it. The IPv4 address assigned to Ethernet interface 3/1 is used as the tunnel source, while the IPv4 address 192.168.100.1 is configured as the tunnel destination. The tunnel mode is specified as a manual IPv6 tunnel. Finally, the tunnel is enabled. Note that instead of entering `ipv6 enable`, you could specify an IPv6 address, for example, `ipv6 address 2001:b78:384d:34::/64 eui-64`, which would also enable the tunnel.

**Syntax:**

```
[no] interface tunnel number
```

- For the `number` parameter, specify a value between 1 – 8.

**Syntax:**

```
[no] tunnel source ipv4-address | ethernet port | loopback number | ve number
```

- The `tunnel source` can be an IP address or an interface.
- For `ipv4-address`, use 8-bit values in dotted decimal notation.

The `ethernet` | `loopback` | `ve` parameters specify an interface as the tunnel source. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a loopback, VE, or interface, also specify the loopback, VE, or interface number, respectively.

**Syntax:**

```
[no] tunnel destination ipv4-address
```

- Specify the `ipv4-address` parameter using 8-bit values in dotted decimal notation.

**Syntax:**

```
[no] tunnel mode ipv6ip
```

- `ipv6ip` indicates that this is an IPv6 manual tunnel.

**Syntax:** `ipv6 enable`

This command enables the tunnel. You could specify an IPv6 address, which also enables the tunnel.

**Syntax:**

```
ipv6 address ipv6-prefix / prefix-length> [ eui-64 ]
```

The `ipv6 address` command enables the tunnel. You could also enter `ipv6 enable`, which enables the tunnel.

Specify the `ipv6-prefix` parameter in hexadecimal format using 16-bit values between colons as documented in RFC 2373.

Specify the `prefix-length` parameter as a decimal value. A slash mark (`/`) must follow the `ipv6-prefix` parameter and precede the `prefix-length>` parameter. The `eui-64` keyword configures the global address with an EUI-64 interface ID in the low-order 64 bits. The interface ID is automatically constructed in IEEE EUI-64 format using the interface MAC address.
Clearing IPv6 tunnel statistics

You can clear statistics (reset all fields to zero) for all IPv6 tunnels or for a specific tunnel interface. For example, to clear statistics for tunnel 1, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

FastIron\# clear ipv6 tunnel 1

To clear statistics for all IPv6 tunnels, enter the following command.

FastIron\# clear ipv6 tunnel

Syntax: clear ipv6 tunnel [number]
The number parameter specifies the tunnel number.

Displaying IPv6 tunnel information

Use the commands in this section to display the configuration, status, and counters associated with IPv6 tunnels.

Displaying a summary of tunnel information

To display a summary of tunnel information, enter the following command at any level of the CLI.

FastIron\# show ipv6 tunnel

Syntax: show ipv6 tunnel

This display shows the following information.

TABLE 56 IPv6 tunnel summary information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel</td>
<td>The tunnel interface number.</td>
</tr>
<tr>
<td>Mode</td>
<td>The tunnel mode. Possible modes include the following:</td>
</tr>
<tr>
<td></td>
<td>• configured – Indicates a manually configured tunnel.</td>
</tr>
<tr>
<td>Packet Received</td>
<td>The number of packets received by a tunnel interface. Note that this is the number of packets received by the CPU. It does not include the number of packets processed in hardware.</td>
</tr>
<tr>
<td>Packet Sent</td>
<td>The number of packets sent by a tunnel interface. Note that this is the number of packets sent by the CPU. It does not include the number of packets processed in hardware.</td>
</tr>
</tbody>
</table>

Displaying tunnel interface information

To display status and configuration information for tunnel interface 1, enter the following command at any level of the CLI.
IPv6 over IPv4 tunnels

FastIron# show interfaces tunnel 1
Tunnel1 is up, line protocol is up
  Hardware is Tunnel
  Tunnel source ve 30
  Tunnel destination is 2.2.2.10
  Tunnel mode ipv6ip
  No port name
  MTU 1480 bytes, encapsulation IPV4

Syntax:  

show interfaces tunnel number>

The  

number> parameter indicates the tunnel interface number for which you want to display information.

This display shows the following information.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel interface status</td>
<td>The status of the tunnel interface can be one of the following:</td>

<tr>
<td>MTU</td>
<td>The setting of the IPv6 maximum transmission unit (MTU).</td>
</tr>
</tbody>
</table>

**Displaying interface level IPv6 settings**

To display Interface level IPv6 settings for tunnel interface 1, enter the following command at any level of the CLI.
The display command above reflects the following configuration.

FastIron# show ipv6 inter tunnel 1
Interface Tunnel 1 is up, line protocol is up
IPv6 is enabled, link-local address is fe80::3:4:2 [Preferred]
Global unicast address(es):
  1001::1 [Preferred], subnet is 1001::/64
  1011::1 [Preferred], subnet is 1011::/64
Joined group address(es):
  ff02::1:ff04:2
  ff02::5
  ff02::1:ff00:1
  ff02::2
  ff02::1
MTU is 1480 bytes
ICMP redirects are enabled
No Inbound Access List Set
No Outbound Access List Set
OSPF enabled

This display shows the following information.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
</table>
| Interface Tunnel status | The status of the tunnel interface can be one of the following:  
  - **up** – IPv4 connectivity is established.  
  - **down** – The tunnel mode is not set.  
  - **administratively down** – The tunnel interface was disabled with the **disable** command. |
| Line protocol status | The status of the line protocol can be one of the following:  
  - **up** – IPv6 is enabled through the **ipv6 enable** or **ipv6 address** command.  
  - **down** – The line protocol is not functioning and is down. |

**ECMP load sharing for IPv6**

**NOTE**
This feature is not supported on TurboIron devices.
The IPv6 route table selects the best route to a given destination from among the routes in the tables maintained by the configured routing protocols (BGP4, OSPF, static, and so on). The IPv6 route table can contain more than one path to a given destination. When this occurs, the Brocade device selects the path with the lowest cost for insertion into the routing table. If more than one path with the lowest cost exists, all of these paths are inserted into the routing table, subject to the configured maximum number of load sharing paths (by default 4). The device uses **Equal-Cost Multi-Path (ECMP) load sharing** to select a path to a destination.

When a route is installed by routing protocols or configured static route for the first time, and the IPv6 route table contains multiple, equal-cost paths to that route, the device checks the IPv6 neighbor for each next hop. Every next hop where the link layer address has been resolved will be stored in hardware. The device will initiate neighbor discovery for the next hops whose link layer addresses are not resolved. The hardware will hash the packet and choose one of the paths. The number of paths would be updated in hardware as the link layer gets resolved for a next hop.

If the path selected by the device becomes unavailable, the IPv6 neighbor should change state and trigger the update of the destination in the hardware.

Brocade devices support network-based ECMP load-sharing methods for IPv6 traffic. The Brocade device distributes traffic across equal-cost paths based on a XOR of some bits from the MAC source address, MAC destination address, IPv6 source address, IPv6 destination address, IPv6 flow label, IPv6 next header. The software selects a path based on a calculation involving the maximum number of load-sharing paths allowed and the actual number of paths to the destination network. This is the default ECMP load-sharing method for IPv6.

You can manually disable or enable ECMP load sharing for IPv6 and specify the number of equal-cost paths the device can distribute traffic across. In addition, you can display information about the status of ECMP load-sharing on the device.

### Disabling or re-enabling ECMP load sharing for IPv6

ECMP load sharing for IPv6 is enabled by default. To disable the feature, enter the following command.

```
FastIron(config)# no ipv6 load-sharing
```

If you want to re-enable the feature after disabling it, you must specify the number of load-sharing paths. The maximum number of paths the device supports is a value from 2 – 6. By entering a command such as the following, IPv6 load-sharing will be re-enabled.

```
FastIron(config)# ipv6 load-sharing 4
```

**Syntax:** `[no] ipv6 load-sharing num`

The `num` parameter specifies the number of paths and can be from 2 – 6. The default is 4.

### Changing the maximum load sharing paths for IPv6

By default, IPv6 ECMP load sharing allows traffic to be balanced across up to four equal paths. You can change the maximum number of paths the device supports to a value from 2 – 6.

To change the number of ECMP load sharing paths for IPv6, enter a command such as the following.

```
FastIron(config)# ipv6 load-sharing 6
```

**Syntax:** `[no] ipv6 load-sharing [ num ]`
The `num` parameter specifies the number of paths and can be from 2 – 6. The default is 4.

### Enabling support for network-based ECMP

#### load sharing for IPv6

Network-based ECMP load sharing is supported. In this configuration, traffic is distributed across equal-cost paths based on the destination network address. Routes to each network are stored in CAM and accessed when a path to a network is required. Because multiple hosts are likely to reside on a network, this method uses fewer CAM entries.

### Displaying ECMP load-sharing information for IPv6

To display the status of ECMP load sharing for IPv6, enter the following command.

```
FastIron# show ipv6
Global Settings
  unicast-routing enabled, hop-limit 64
  No Inbound Access List Set
  No Outbound Access List Set
  Prefix-based IPv6 Load-sharing is Enabled, Number of load share paths: 4
```

Syntax: `show ipv6`

### Configuring IPv6 ICMP features

As with the Internet Control Message Protocol (ICMP) for IPv4, ICMP for IPv6 provides error and informational messages. Implementation of the stateless auto configuration, neighbor discovery, and path MTU discovery features use ICMP messages.

This section explains how to configure following IPv6 ICMP features:

- ICMP rate limiting
- ICMP redirects

### Configuring ICMP rate limiting

You can limit the rate at which IPv6 ICMP error messages are sent out on a network. IPv6 ICMP implements a token bucket algorithm.

To illustrate how this algorithm works, imagine a virtual bucket that contains a number of tokens. Each token represents the ability to send one ICMP error message. Tokens are placed in the bucket at a specified interval until the maximum number of tokens allowed in the bucket is reached. For each error message that ICMP sends, a token is removed from the bucket. If ICMP generates a series of error messages, messages can be sent until the bucket is empty. If the bucket is empty of tokens, error messages cannot be sent until a new token is placed in the bucket.

You can adjust the following elements related to the token bucket algorithm:

- The interval at which tokens are added to the bucket. The default is 100 milliseconds.
- The maximum number of tokens in the bucket. The default is 10 tokens.

For example, to adjust the interval to 1000 milliseconds and the number of tokens to 100 tokens, enter the following command.
Configuring IPv6 neighbor discovery

The neighbor discovery feature for IPv6 uses IPv6 ICMP messages to do the following:

- Determine the link-layer address of a neighbor on the same link.

---

Syntax: ipv6 icmp error-interval interval [ number-of-tokens ]

- The interval in milliseconds at which tokens are placed in the bucket can range from 0 – 2147483647. The maximum number of tokens stored in the bucket can range from 1 – 200.

**NOTE**

If you retain the default interval value or explicitly set the value to 100 milliseconds, output from the show run command does not include the setting of the ipv6 icmp error-interval command because the setting is the default.

Also, if you configure the interval value to a number that does not evenly divide into 100000 (100 milliseconds), the system rounds up the value to a next higher value that does divide evenly into 100000. For example, if you specify an interval value of 150, the system rounds up the value to 200.

ICMP rate limiting is enabled by default. To disable ICMP rate limiting, set the interval to zero.

---

Enabling IPv6 ICMP redirect messages

**Platform Support:**

- FastIron X Series devices running software release 04.2.00 and later – L3
- TurboIron X Series devices running software release 04.2.00 and later

You can enable a Layer 3 switch to send an IPv6 ICMP redirect message to a neighboring host to inform it of a better first-hop router on a path to a destination. By default, the sending of IPv6 ICMP redirect messages by a Layer 3 switch is disabled. (For more information about how ICMP redirect messages are implemented for IPv6, refer to “Configuring IPv6 neighbor discovery” on page 238.)

**NOTE**

This feature is supported on Virtual Ethernet (VE) interfaces only.

For example, to enable the sending of IPv6 ICMP redirect messages on VE 2, enter the following commands.

```
FastIron(config)# interface ve2
FastIron(config-vif-2)# ipv6 redirects
```

To disable the sending of IPv6 ICMP redirect messages after it has been enabled on VE 2, enter the following commands.

```
FastIron(config)# interface ve2
FastIron(config-vif-2)# no ipv6 redirects
```

**Syntax:** [no] ipv6 redirects

Use the show ipv6 interface command to verify that the sending of IPv6 ICMP redirect messages is enabled on a particular interface.
• Verify that a neighbor is reachable.
• Track neighbor routers.

An IPv6 host is required to listen for and recognize the following addresses that identify itself:
• Link-local address.
• Assigned unicast address.
• Loopback address.
• All-nodes multicast address.
• Solicited-node multicast address.
• Multicast address to all other groups to which it belongs.

You can adjust the following IPv6 neighbor discovery features:
• Neighbor solicitation messages for duplicate address detection.
• Router advertisement messages:
  • Interval between router advertisement messages.
  • Value that indicates a router is advertised as a default router (for use by all nodes on a given link).
  • Prefixes advertised in router advertisement messages.
  • Flags for host stateful autoconfiguration.
  • Amount of time during which an IPv6 node considers a remote node reachable (for use by all nodes on a given link).

### Configuration notes

**NOTE**
For all solicitation and advertisement messages, Brocade uses seconds as the unit of measure instead of milliseconds.

• If you add a port to a port-based VLAN, and the port has IPv6 neighbor discovery configuration, the system will clean up the neighbor discovery configuration from the port and display the following message on the console.

```
ND6 port config on the new member ports removed
```

• Neighbor discovery is not supported on tunnel interfaces.

### Neighbor solicitation and advertisement messages

Neighbor solicitation and advertisement messages enable a node to determine the link-layer address of another node (neighbor) on the same link. (This function is similar to the function provided by the Address Resolution Protocol [ARP] in IPv4.) For example, node 1 on a link wants to determine the link-layer address of node 2 on the same link. To do so, node 1, the source node, multicasts a neighbor solicitation message. The neighbor solicitation message, which has a value of 135 in the Type field of the ICMP packet header, contains the following information:

• **Source address:** IPv6 address of node 1 interface that sends the message.
• **Destination address:** solicited-node multicast address (FF02:0:0:0:1:FF00::/104) that corresponds the IPv6 address of node 2.
• Link-layer address of node 1.
• A query for the link-layer address of node 2.

After receiving the neighbor solicitation message from node 1, node 2 replies by sending a neighbor advertisement message, which has a value of 136 in the Type field of the ICMP packet header. The neighbor solicitation message contains the following information:

• **Source address**: IPv6 address of the node 2 interface that sends the message.
• **Destination address**: IPv6 address of node 1.
• **Link-layer address**: IPv6 address of node 2.

After node 1 receives the neighbor advertisement message from node 2, nodes 1 and 2 can now exchange packets on the link.

After the link-layer address of node 2 is determined, node 1 can send neighbor solicitation messages to node 2 to verify that it is reachable. Also, nodes 1, 2, or any other node on the same link can send a neighbor advertisement message to the all-nodes multicast address (FF02::1) if there is a change in their link-layer address.

### Router advertisement and solicitation messages

Router advertisement and solicitation messages enable a node on a link to discover the routers on the same link.

Each configured router interface on a link sends out a router advertisement message, which has a value of 134 in the Type field of the ICMP packet header, periodically to the all-nodes link-local multicast address (FF02::1).

A configured router interface can also send a router advertisement message in response to a router solicitation message from a node on the same link. This message is sent to the unicast IPv6 address of the node that sent the router solicitation message.

At system startup, a host on a link sends a router solicitation message to the all-routers multicast address (FF01). Sending a router solicitation message, which has a value of 133 in the Type field of the ICMP packet header, enables the host to automatically configure its IPv6 address immediately instead of awaiting the next periodic router advertisement message.

Because a host at system startup typically does not have a unicast IPv6 address, the source address in the router solicitation message is usually the unspecified IPv6 address (0:0:0:0:0:0:0:0). If the host has a unicast IPv6 address, the source address is the unicast IPv6 address of the host interface sending the router solicitation message.

Entering the `ipv6 unicast-routing` command automatically enables the sending of router advertisement messages on all configured router Ethernet interfaces. You can configure several router advertisement message parameters. For information about disabling the sending of router advertisement messages and the router advertisement parameters that you can configure, refer to “Enabling and disabling IPv6 router advertisements” on page 244 and “Setting IPv6 router advertisement parameters” on page 242.

### Neighbor redirect messages

After forwarding a packet, by default, a router can send a neighbor redirect message to a host to inform it of a better first-hop router. The host receiving the neighbor redirect message will then readdress the packet to the better router.
A router sends a neighbor redirect message only for unicast packets, only to the originating node, and to be processed by the node.

A neighbor redirect message has a value of 137 in the Type field of the ICMP packet header.

### Setting neighbor solicitation parameters for duplicate address detection

Although the stateless auto configuration feature assigns the 64-bit interface ID portion of an IPv6 address using the MAC address of the host NIC, duplicate MAC addresses can occur. Therefore, the duplicate address detection feature verifies that a unicast IPv6 address is unique before it is assigned to a host interface by the stateless auto configuration feature. Duplicate address detection verifies that a unicast IPv6 address is unique.

If duplicate address detection identifies a duplicate unicast IPv6 address, the address is not used. If the duplicate address is the link-local address of the host interface, the interface stops processing IPv6 packets.

**NOTE**
Duplicate Address Detection (DAD) is not currently supported with IPv6 tunnels. Make sure tunnel endpoints do not have duplicate IP addresses.

You can configure the following neighbor solicitation message parameters that affect duplicate address detection while it verifies that a tentative unicast IPv6 address is unique:

- The number of consecutive neighbor solicitation messages that duplicate address detection sends on an interface. By default, duplicate address detection sends three neighbor solicitation messages without any follow-up messages.
- The interval in seconds at which duplicate address detection sends a neighbor solicitation message on an interface. By default, duplicate address detection sends a neighbor solicitation message every 1000 milliseconds.

For example, to change the number of neighbor solicitation messages sent on Ethernet interface 3/1 to two and the interval between the transmission of the two messages to 9 seconds, enter the following commands.

```plaintext
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 nd dad attempt 2
FastIron(config-if-e1000-3/1)# ipv6 nd ns-interval 9000
```

**Syntax:** `[no] ipv6 nd dad attempt number`

For the number of neighbor solicitation messages, specify a number from 0 – 255. The default is 3. Configuring a value of 0 disables duplicate address detection processing on the specified interface. To restore the number of messages to the default value, use the `no` form of this command.

For the interval between neighbor solicitation messages and the value for the retrans timer in router advertisements, specify a number from 0 – 4294967295 milliseconds. The default value for the interval between neighbor solicitation messages is 1000 milliseconds. The default value for the retrans timer is 0. Brocade does not recommend very short intervals in normal IPv6 operation. When a non-default value is configured, the configured time is both advertised and used by the router itself. To restore the default interval, use the `no` form of this command.
Setting IPv6 router advertisement parameters

You can adjust the following parameters for router advertisement messages:

- The interval (in seconds) at which an interface sends router advertisement messages. By default, an interface sends a router advertisement message every 200 seconds.
- The "router lifetime" value, which is included in router advertisements sent from a particular interface. The value (in seconds) indicates if the router is advertised as a default router on this interface. If you set the value of this parameter to 0, the router is not advertised as a default router on an interface. If you set this parameter to a value that is not 0, the router is advertised as a default router on this interface. By default, the router lifetime value included in router advertisement messages sent from an interface is 1800 seconds.
- The hop limit to be advertised in the router advertisement.

When adjusting these parameter settings, Brocade recommends that the interval between router advertisement transmission be less than or equal to the router lifetime value if the router is advertised as a default router. For example, to adjust the interval of router advertisements to 300 seconds and the router lifetime value to 1900 seconds on Ethernet interface 3/1, enter the following commands.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 nd ra-interval 300
FastIron(config-if-e1000-3/1)# ipv6 nd ra-lifetime 1900
FastIron(config-if-e1000-3/1)# ipv6 nd ra-hop-limit 1
```

Here is another example with a specified range.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 nd ra-interval range 33 55
FastIron(config-if-e1000-3/1)# ipv6 nd ra-lifetime 1900
FastIron(config-if-e1000-3/1)# ipv6 nd ra-hop-limit 1
```

Syntax: `[no] ipv6 nd ra-interval number | min range value max range value`

Syntax: `[no] ipv6 nd ra-lifetime number`

Syntax: `ipv6 nd ra-hop-limit number`

- `number` is a value from 0 – 255. The default is 64.

The `ipv6 nd ra-interval number>` can be a value between 3 – 1800 seconds. The default is 200 seconds. The actual RA interval will be from .5 to 1.5 times the configured or default value. For example, in the above configuration, for `ipv6 nd ra-interval 300`, the range would be 150 – 450. To restore the default interval of 200 seconds, use the no form of the command.

The `ipv6 nd ra-interval range min range value max range value>` command lets you specify a range of values instead of a single value.

The `min range value` specifies the minimum number of seconds allowed between sending unsolicited multicast router advertisements from the interface. The default is 0.33 times the `max range value>` if the `max range value` is greater than or equal to 9 seconds. Otherwise, the default is the value specified by the `max range value>`. The `min range value` can be a number between -3 - (.75 x `max range value>.

The `max range value` parameter specifies the maximum number of seconds allowed between sending unsolicited multicast router advertisements from the interface. This number can be between 4 – 1800 seconds and must be greater than the `min range value x 1.33`. The default is 600 seconds.
Configuring IPv6 neighbor discovery

The `ipv6 nd ra-lifetime` number is a value between 0 – 9000 seconds. To restore the router lifetime value of 1800 seconds, use the `no` form of the command.

The `ipv6 nd ra-hop-limit` number is a value from 0 – 255. The default is 64.

**NOTE**
By default, router advertisements will always have the MTU option. To suppress the MTU option, use the following command at the Interface level of the CLI: `ipv6 nd suppress-mtu-option`.

Controlling prefixes advertised in IPv6 router advertisement messages

By default, router advertisement messages include prefixes configured as addresses on router interfaces using the `ipv6 address` command. You can use the `ipv6 nd prefix-advertisement` command to control exactly which prefixes are included in router advertisement messages. Along with which prefixes the router advertisement messages contain, you can also specify the following parameters:

- **Valid lifetime**—(Mandatory) The time interval (in seconds) in which the specified prefix is advertised as valid. The default is 2592000 seconds (30 days). When the timer expires, the prefix is no longer considered to be valid.

- **Preferred lifetime**—(Mandatory) The time interval (in seconds) in which the specified prefix is advertised as preferred. The default is 604800 seconds (7 days). When the timer expires, the prefix is no longer considered to be preferred.

- **Onlink flag**—(Optional) If this flag is set, the specified prefix is assigned to the link upon which it is advertised. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be reachable on the local link.

- **Autoconfiguration flag**—(Optional) If this flag is set, the stateless auto configuration feature can use the specified prefix in the automatic configuration of 128-bit IPv6 addresses for hosts on the local link, provided the specified prefix is aggregatable, as specified in RFC 2374.

For example, to advertise the prefix 2001:e077:a487:7365::/64 in router advertisement messages sent out on Ethernet interface 3/1 with a valid lifetime of 1000 seconds, a preferred lifetime of 800 seconds, and the Onlink and Autoconfig flags set, enter the following commands.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 nd prefix-advertisement 2001:e077:a487:7365::/64 1000 800 onlink autoconfig
```

**Syntax:**
```
[no] ipv6 nd prefix-advertisement ipv6-prefix / prefix-length valid-lifetime preferred-lifetime [ autoconfig ] [ onlink ]
```

- You must specify the `ipv6-prefix` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- You must specify the `prefix-length` parameter as a decimal value. A slash mark (/) must follow the `ipv6-prefix` parameter and precede the `prefix-length` parameter.
- The valid lifetime and preferred lifetime is a numerical value between 0 – 4294967295 seconds. The default valid lifetime is 2592000 seconds (30 days), while the default preferred lifetime is 604800 seconds (7 days).
- To remove a prefix from the router advertisement messages sent from a particular interface, use the `no` form of this command.
Setting flags in IPv6 router advertisement messages

An IPv6 router advertisement message can include the following flags:

- **Managed Address Configuration**—This flag indicates to hosts on a local link if they should use the stateful autoconfiguration feature to get IPv6 addresses for their interfaces. If the flag is set, the hosts use stateful autoconfiguration to get addresses as well as non-IPv6-address information. If the flag is not set, the hosts do not use stateful autoconfiguration to get addresses and if the hosts can get non-IPv6-address information from stateful autoconfiguration is determined by the setting of the Other Stateful Configuration flag.

- **Other Stateful Configuration**—This flag indicates to hosts on a local link if they can get non-IPv6 address autoconfiguration information. If the flag is set, the hosts can use stateful autoconfiguration to get non-IPv6-address information.

**NOTE**
When determining if hosts can use stateful autoconfiguration to get non-IPv6-address information, a set Managed Address Configuration flag overrides an unset Other Stateful Configuration flag. In this situation, the hosts can obtain nonaddress information. However, if the Managed Address Configuration flag is not set and the Other Stateful Configuration flag is set, then the setting of the Other Stateful Configuration flag is used.

By default, the Managed Address Configuration and Other Stateful Configuration flags are not set in router advertisement messages. For example, to set these flags in router advertisement messages sent from Ethernet interface 3/1, enter the following commands.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 nd managed-config-flag
FastIron(config-if-e1000-3/1)# ipv6 nd other-config-flag
```

**Syntax:**
```
[no] ipv6 nd managed-config-flag
[no] ipv6 nd other-config-flag
```

To remove either flag from router advertisement messages sent on an interface, use the `no` form of the respective command.

Enabling and disabling IPv6 router advertisements

If IPv6 unicast routing is enabled on an Ethernet interface, by default, this interface sends IPv6 router advertisement messages. However, by default, non-LAN interface types, for example, tunnel interfaces, do not send router advertisement messages.

To disable the sending of router advertisement messages on an Ethernet interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 nd suppress-ra
```

To enable the sending of router advertisement messages on a tunnel interface, enter commands such as the following.

```
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# no ipv6 nd suppress-ra
```

**Syntax:**
```
[no] ipv6 nd suppress-ra
```
Configuring reachable time for remote IPv6 nodes

You can configure the duration (in seconds) that a router considers a remote IPv6 node reachable. By default, a router interface uses the value of 30 seconds.

The router advertisement messages sent by a router interface include the amount of time specified by the `ipv6 nd reachable-time` command so that nodes on a link use the same reachable time duration. By default, the messages include a default value of 0.

Brocade does not recommend configuring a short reachable time duration, because a short duration causes the IPv6 network devices to process the information at a greater frequency.

For example, to configure the reachable time of 40 seconds for Ethernet interface 3/1, enter the following commands.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 nd reachable-time 40
```

**Syntax:** `[no] ipv6 nd reachable-time seconds`

For the `seconds` parameter, specify a number from 0 – 3600 seconds. To restore the default time, use the `no` form of this command.

**NOTE**
The actual reachable time will be from .5 to 1.5 times the configured or default value.

---

Changing the IPv6 MTU

The IPv6 MTU is the maximum length of an IPv6 packet that can be transmitted on a particular interface. If an IPv6 packet is longer than an MTU, the host that originated the packet fragments the packet and transmits its contents in multiple packets that are shorter than the configured MTU.

You can configure the MTU on individual interfaces. Per RFC 2460, the minimum IPv6 MTU for any interface is 1280 bytes.

For example, to configure the MTU on Ethernet interface 3/1 as 1280 bytes, enter the following commands.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e1000-3/1)# ipv6 mtu 1280
```

**Syntax:** `[no] ipv6 mtu bytes`

You can specify between 1280 – 1500 bytes. If a nondefault value is configured for an interface, router advertisements include an MTU option.

You can configure an IPv6 MTU greater than 1500 bytes, although the default remains at 1500 bytes. The value of the MTU you can define depends on the following:

- For a physical port, the maximum value of the MTU is the equal to the maximum frame size of the port minus 18 (Layer 2 MAC header + CRC).
- For a virtual routing interface, the maximum value of the MTU is the maximum frame size configured for the VLAN to which it is associated, minus 18 (Layer 2 MAC header + CRC). If a maximum frame size for a VLAN is not configured, then configure the MTU based on the smallest maximum frame size of all the ports of the VLAN that corresponds to the virtual routing interface, minus 18 (Layer 2 MAC header + CRC).

To define IPv6 MTU globally, enter the following command.
FastIron(config)# ipv6 mtu 1300

To define IPv6 MTU on an interface, enter the following command.

FastIron(config-if-e1000-2/1)# ipv6 mtu

Syntax: ipv6 mtu value

NOTE
If a the size of a jumbo packet received on a port is equal to the maximum frame size – 18 (Layer 2 MAC header + CRC) and if this value is greater than the outgoing port IPv4/IPv6 MTU, then it will be forwarded in the CPU.

Configuring static neighbor entries

In some special cases, a neighbor cannot be reached using the neighbor discovery feature. In this situation, you can add a static entry to the IPv6 neighbor discovery cache, which causes a neighbor to be reachable at all times without using neighbor discovery. (A static entry in the IPv6 neighbor discovery cache functions like a static ARP entry in IPv4.)

NOTE
A port that has a statically assigned IPv6 entry cannot be added to a VLAN.

NOTE
Static neighbor configurations will be cleared on secondary ports when a trunk is formed.

For example, to add a static entry for a neighbor with the IPv6 address 3001:ffe0:2678:47b and link-layer address 0004.6a2b.8641 that is reachable through Ethernet interface 3/1, enter the following command.

FastIron(config)# ipv6 neighbor 3001:ffe0:2678:47b ethernet 3/1 0004.6a2b.8641

Syntax: [no] ipv6 neighbor ipv6-address ethernet port | ve ve-number [ ethernet port ]

link-layer-address

The ipv6-address parameter specifies the address of the neighbor.

The ethernet | ve parameters specify the interface through which to reach a neighbor. If you specify an Ethernet interface, specify the port number of the Ethernet interface. If you specify a VE, specify the VE number and then the Ethernet port numbers associated with the VE. The link-layer address is a 48-bit hardware address of the neighbor.

If you attempt to add an entry that already exists in the neighbor discovery cache, the software changes the already existing entry to a static entry.

To remove a static IPv6 entry from the IPv6 neighbor discovery cache, use the no form of this command.

Limiting the number of hops an IPv6 packet can traverse

By default, the maximum number of hops an IPv6 packet can traverse is 64. You can change this value to between 0 – 255 hops. For example, to change the maximum number of hops to 70, enter the following command.
FastIron(config)# ipv6 hop-limit 70

**Syntax:** \[no\] ipv6 hop-limit *number*

- Use the **no** form of the command to restore the default value.
- **hop-limit 0** will transmit packets with default (64) hop limit.
- **number** can be from 0 – 255.

### Clearing global IPv6 information

You can clear the following global IPv6 information:

- Entries from the IPv6 cache.
- Entries from the IPv6 neighbor table.
- IPv6 routes from the IPv6 route table.
- IPv6 traffic statistics.

### Clearing the IPv6 cache

You can remove all entries from the IPv6 cache or specify an entry based on the following:

- IPv6 prefix.
- IPv6 address.
- Interface type.

For example, to remove entries for IPv6 address 2000:e0ff::1, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

```
FastIron# clear ipv6 cache 2000:e0ff::1
```

**Syntax:** clear ipv6 cache [ipv6-prefix / prefix-length | ipv6-address | ethernet port | tunnel number | ve number]

You must specify the **ipv6-prefix** parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the **prefix-length** parameter as a decimal value. A slash mark (/) must follow the **ipv6-prefix** parameter and precede the **prefix-length** parameter.

You must specify the **ipv6-address** parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

The **ethernet** | **tunnel** | **ve** parameters specify the interfaces for which you can remove cache entries. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE or tunnel interface, also specify the VE or tunnel number, respectively.

### Clearing IPv6 neighbor information

You can remove all entries from the IPv6 neighbor table or specify an entry based on the following:

- IPv6 prefix
- IPv6 address
- Interface type
Displaying global IPv6 information

For example, to remove entries for Ethernet interface 3/1, enter the following command at the Privileged EXEC level or any of the CONFIG levels of the CLI.

FastIron# clear ipv6 neighbor ethernet 3/1

Syntax: clear ipv6 neighbor [ ipv6-prefix / prefix-length | ipv6-address | ethernet port | ve number ]

• You must specify the ipv6-prefix parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the prefix-length parameter as a decimal value. A slash mark (/) must follow the ipv6-prefix parameter and precede the prefix-length parameter.

• You must specify the ipv6-address parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

• The ethernet | ve parameters specify the interfaces for which you can remove cache entries. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE, also specify the VE number.

Clearing IPv6 routes from the IPv6 route table

You can clear all IPv6 routes or only those routes associated with a particular IPv6 prefix from the IPv6 route table and reset the routes.

For example, to clear IPv6 routes associated with the prefix 2000:7838::/32, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

FastIron# clear ipv6 route 2000:7838::/32

Syntax: clear ipv6 route [ ipv6-prefix/> prefix-length> ]

• The ipv6-prefix / prefix-length parameter clears routes associated with a particular IPv6 prefix. You must specify the ipv6-prefix parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the prefix-length parameter as a decimal value. A slash mark (/) must follow the ipv6-prefix parameter and precede the prefix-length parameter.

Clearing IPv6 traffic statistics

To clear all IPv6 traffic statistics (reset all fields to zero), enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

FastIron(config)# clear ipv6 traffic

Syntax: clear ipv6 traffic

Displaying global IPv6 information

You can display output for the following global IPv6 parameters:

• IPv6 cache
• IPv6 interfaces
• IPv6 neighbors
• IPv6 route table
Displaying global IPv6 information

• Local IPv6 routers
• IPv6 TCP connections and the status of individual connections
• IPv6 traffic statistics

Displaying IPv6 cache information

The IPv6 cache contains an IPv6 host table that has indices to the next hop gateway and the router interface on which the route was learned.

To display IPv6 cache information, enter the following command at any CLI level.

FastIron# show ipv6 cache
Total number of cache entries: 10
IPv6 Address                       Next Hop                      Port
1   5000:2::2                          LOCAL                         tunnel 2
2   2000:4::106                        LOCAL                         ethe 3/2
3   2000:4::110                        LOCAL                         ethe 3/2
4   2002:c0a8:46a::1                   LOCAL                         ethe 3/2
5   5005::2e0:52ff:fe99:9737           LOCAL                         ethe 3/2
6   5005::ffff:ffff:feff:ffff           LOCAL                         loopback 2
7   5005::c0a8:46a                      LOCAL                         tunnel 2
8   5005::c0a8:46a                      LOCAL                         tunnel 6
9   2999::1                            LOCAL                         loopback 2
10  5005::2e0:52ff:fe99:9700           LOCAL                         ethe 3/1

Syntax: show ipv6 cache [ index-number | ipv6-prefix / prefix-length | ipv6-address | ethernet port | ve number | tunnel number ]

• The index-number parameter restricts the display to the entry for the specified index number and subsequent entries.
• The ipv6-prefix>/ prefix-length parameter restricts the display to the entries for the specified IPv6 prefix. You must specify the ipv6-prefix> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the prefix-length parameter as a decimal value. A slash mark (/) must follow the ipv6-prefix parameter and precede the prefix-length parameter.
• The ethernet | ve | tunnel parameters restrict the display to the entries for the specified interface. The ipv6-address parameter restricts the display to the entries for the specified IPv6 address. You must specify this parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.
• If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE interface, also specify the VE number. If you specify a tunnel interface, also specify the tunnel number.

This display shows the following information.

Displaying IPv6 interface information

To display IPv6 interface information, enter the following command at any CLI level.

```
FastIron# show ipv6 interface
Routing Protocols : R - RIP  O - OSPF
Interface      Status     Routing  Global Unicast Address
Ethernet 3/3   up/up       R        2017::c017:101/64
Ethernet 3/5   up/up               2019::c019:101/64
Ethernet 3/17  down/down          2017::c017:101/64
Ethernet 3/19  down/down          2019::c019:101/64
VE 4           up/up               ::1/128
VE 14          up/up               2024::c060:101/64
Loopback 1     up/up               ::1/128
Loopback 2     up/up               2005::303:303/128
Loopback 3     up/up
```

Syntax: `show ipv6 interface [ interface [ port-number | number ] ]`

- The `interface` parameter displays detailed information for a specified interface. For the `interface`, you can specify the Ethernet, loopback, tunnel, or VE keywords. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a loopback, tunnel, or VE interface, also specify the number associated with the interface.

This display shows the following information.

### TABLE 60  General IPv6 interface information fields

<table>

**Displaying IPv6 neighbor information**

You can display the IPv6 neighbor table, which contains an entry for each IPv6 neighbor with which the router exchanges IPv6 packets.
To display the IPv6 neighbor table, enter the following command at any CLI level.

FastIron(config)# show ipv6 neighbor
Total number of Neighbor entries: 3
IPv6 Address LinkLayer-Addr State Age Port vlan
IsR 5555::55 0002.0002.0002 *REACH 0 e 3/11 - 0
2000::110 00e0.5291.bb37 REACH 20 e 3/1 5 1
fe80::2e0:52ff:fe91:bb37 00e0.5291.bb37 DELAY 1 e 3/2 4 1
fe80::2e0:52ff:fe91:bb40 00e0.5291.bb40 STALE 5930e 3/3 5 1

Syntax: show ipv6 neighbor [ipv6-prefix / prefix-length | ipv6-address | interface [ port | number ]]

- The ipv6-prefix / prefix-length parameters restrict the display to the entries for the specified IPv6 prefix. You must specify the ipv6-prefix parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the prefix-length parameter as a decimal value. A slash mark (/) must follow the ipv6-prefix parameter and precede the prefix-length parameter.

- The ipv6-address parameter restricts the display to the entries for the specified IPv6 address. You must specify this parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

- The interface parameter restricts the display to the entries for the specified router interface. For this parameter, you can specify the Ethernet or VE keywords. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a VE interface, also specify the VE number.

This display shows the following information.

Displaying global IPv6 information

To display the IPv6 route table, enter the following command at any CLI level.

```
FastIron# show ipv6 route
IPv6 Routing Table - 7 entries:
Type Codes:  C - Connected, S - Static, R - RIP, O - OSPF, B - BGP
OSPF Sub Type Codes: O - Intra, O1 - Inter, O1 - Type1 external, O2 - Type2 external
Type IPv6 Prefix                Next Hop Router           Interface  Dis/Metric
C  2000:4::/64                  ::                        ethe 3/2    0/0
S  2002::/16                    ::                        tunnel 6    1/1
S  2002:1234::/32               ::                        tunnel 6    1/1
C  2002:c0a8:46a::/64           ::                        ethe 3/2    0/0
C  2999::1/128                  ::                        loopback 2  0/0
O  2999::2/128                  fe80::2e0:52ff:fe91:bb37 ethe 3/2    110/1
C  5000:2::/64                  ::                        tunnel 2    0/0
```

Syntax: `show ipv6 route [ipv6-address | ipv6-prefix / prefix-length | bgp | connect | ospf | rip | static | summary]`

- The `ipv6-address` parameter restricts the display to the entries for the specified IPv6 address. You must specify the `ipv6-address>` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.
- The `ipv6-prefix>/ prefix-length` parameters restrict the display to the entries for the specified IPv6 prefix. You must specify the `ipv6-prefix>` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the `prefix-length` parameter as a decimal value. A slash mark (/) must follow the `ipv6-prefix` parameter and precede the `prefix-length` parameter.
- The `bgp` keyword restricts the display to entries for BGP4+ routes.
- The `connect` keyword restricts the display to entries for directly connected interface IPv6 routes.
- The `ospf` keyword restricts the display to entries for OSPFv3 routes.
- The `rip` keyword restricts the display to entries for RIPng routes.
- The `static` keyword restricts the display to entries for static IPv6 routes.
- The `summary` keyword displays a summary of the prefixes and different route types.

The following table lists the information displayed by the `show ipv6 route` command.
To display a summary of the IPv6 route table, enter the following command at any CLI level.

```
FastIron# show ipv6 route summary
IPv6 Routing Table - 7 entries:
  4 connected, 2 static, 0 RIP, 1 OSPF, 0 BGP
Number of prefixes:
  /16: 1 /32: 1 /64: 3 /128: 2
```

The following table lists the information displayed by the `show ipv6 route summary` command.

**TABLE 64  IPv6 route table summary fields**

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of entries</td>
<td>The number of entries in the IPv6 route table.</td>
</tr>
<tr>
<td>Number of route types</td>
<td>The number of entries for each route type.</td>
</tr>
<tr>
<td>Number of prefixes</td>
<td>A summary of prefixes in the IPv6 route table, sorted by prefix length.</td>
</tr>
</tbody>
</table>

### Displaying local IPv6 routers

The Brocade device can function as an IPv6 host, instead of an IPv6 router, if you configure IPv6 addresses on its interfaces but do not enable IPv6 routing using the `ipv6 unicast-routing` command.

From the IPv6 host, you can display information about IPv6 routers to which the host is connected. The host learns about the routers through their router advertisement messages. To display information about the IPv6 routers connected to an IPv6 host, enter the following command at any CLI level.

```
FastIron# show ipv6 router
Router fe80::2e0:80ff:fe46:3431 on Ethernet 50, last update 0 min
Hops 64, Lifetime 1800 sec
Reachable time 0 msec, Retransmit time 0 msec
```

**Syntax:** `show ipv6 router`
Displaying global IPv6 information

If you configure your Brocade device to function as an IPv6 router (you configure IPv6 addresses on its interfaces and enable IPv6 routing using the `ipv6 unicast-routing` command) and you enter the `show ipv6 router` command, you will receive the following output.

No IPv6 router in table

Meaningful output for this command is generated for Brocade devices configured to function as IPv6 hosts only.

This display shows the following information.

**TABLE 65** IPv6 local router information fields

<table>
<thead>
<tr>
<th>This field...</th>

<tbody>
<tr>
<td>Router <code>ipv6 address</code> &gt; on <code>interface</code> &gt; <code>port</code> &gt;</td>
<td>The IPv6 address for a particular router interface.</td>
</tr>
<tr>
<td>Last update</td>
<td>The amount of elapsed time (in minutes) between the current and previous updates received from a router.</td>
</tr>
<tr>
<td>Hops</td>
<td>The default value that should be included in the Hop Count field of the IPv6 header for outgoing IPv6 packets. The hops value applies to the router for which you are displaying information and should be followed by IPv6 hosts attached to the router. A value of 0 indicates that the router leaves this field unspecified.</td>
</tr>
<tr>
<td>Lifetime</td>
<td>The amount of time (in seconds) that the router is useful as the default router.</td>
</tr>
<tr>
<td>Reachable time</td>
<td>The amount of time (in milliseconds) that a router assumes a neighbor is reachable after receiving a reachability confirmation. The reachable time value applies to the router for which you are displaying information and should be followed by IPv6 hosts attached to the router. A value of 0 indicates that the router leaves this field unspecified.</td>
</tr>
<tr>
<td>Retransmit time</td>
<td>The amount of time (in milliseconds) between retransmissions of neighbor solicitation messages. The retransmit time value applies to the router for which you are displaying information and should be followed by IPv6 hosts attached to the router. A value of 0 indicates that the router leaves this field unspecified.</td>
</tr>
</tbody>
</table>

**Displaying IPv6 TCP information**

You can display the following IPv6 TCP information:

- General information about each TCP connection on the router, including the percentage of free memory for each of the internal TCP buffers.
- Detailed information about a specified TCP connection.

To display general information about each TCP connection on the router, enter the following command at any CLI level.
FastIron\# show ipv6 tcp connections
Local IP address:port → Remote IP address:port TCP state
192.168.182.110:23 → 192.168.8.186:4933 ESTABLISHED
192.168.182.110:8218 → 192.168.182.106:179 ESTABLISHED
192.168.182.110:8039 → 192.168.2.119:179 SYN-SENT
192.168.182.110:8159 → 192.168.2.102:179 SYN-SENT
Total 5 TCP connections

TCP MEMORY USAGE PERCENTAGE
FREE TCP = 98 percent
FREE TCP QUEUE BUFFER = 99 percent
FREE TCP SEND BUFFER = 97 percent
FREE TCP RECEIVE BUFFER = 100 percent
FREE TCP OUT OF SEQUENCE BUFFER = 100 percent

Syntax: show ipv6 tcp connections
This display shows the following information.

**TABLE 66** General IPv6 TCP connection fields

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local IP address:port</td>
<td>The IPv4 or IPv6 address and port number of the local router interface over which the TCP connection occurs.</td>
</tr>
<tr>
<td>Remote IP address:port</td>
<td>The IPv4 or IPv6 address and port number of the remote router interface over which the TCP connection occurs.</td>
</tr>
<tr>
<td>TCP state</td>
<td>The state of the TCP connection. Possible states include the following:</td>
</tr>
<tr>
<td></td>
<td>• LISTEN – Waiting for a connection request.</td>
</tr>
<tr>
<td></td>
<td>• SYN-SENT – Waiting for a matching connection request after having sent a connection request.</td>
</tr>
<tr>
<td></td>
<td>• SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request.</td>
</tr>
<tr>
<td></td>
<td>• ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection.</td>
</tr>
<tr>
<td></td>
<td>• FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent.</td>
</tr>
<tr>
<td></td>
<td>• FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP.</td>
</tr>
<tr>
<td></td>
<td>• CLOSE-WAIT – Waiting for a connection termination request from the local user.</td>
</tr>
<tr>
<td></td>
<td>• CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP.</td>
</tr>
<tr>
<td></td>
<td>• LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request).</td>
</tr>
<tr>
<td></td>
<td>• TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request.</td>
</tr>
<tr>
<td></td>
<td>• CLOSED – There is no connection state.</td>
</tr>
</tbody>
</table>

FREE TCP = \text{percentage}\%

The percentage of free TCP control block (TCP) space.
To display detailed information about a specific TCP connection, enter a command such as the following at any CLI level.

```
FastIron# show ipv6 tcp status 2000:4::110 179 2000:4::106 8222
TCP: TCP = 0x217fc300
    Send: initial sequence number = 242365900
    Send: first unacknowledged sequence number = 242434080
    Send: current send pointer = 242434080
    Send: next sequence number to send = 242434080
    Send: remote received window = 16384
    Send: total unacknowledged sequence number = 0
    Send: total used buffers 0
    Receive: initial incoming sequence number = 740437769
    Receive: expected incoming sequence number = 740507227
    Receive: received window = 16384
    Receive: bytes in receive queue = 0
    Receive: congestion window = 1459
```

Syntax: `show ipv6 tcp status local-ip-address local-port-number remote-ip-address remote-port-number`

- The `local-ip-address` parameter can be the IPv4 or IPv6 address of the local interface over which the TCP connection is taking place.
- The `local-port-number` parameter is the local port number over which a TCP connection is taking place.
- The `remote-ip-address` parameter can be the IPv4 or IPv6 address of the remote interface over which the TCP connection is taking place.
- The `remote-port-number` parameter is the local port number over which a TCP connection is taking place.

This display shows the following information.

Chapter 9

Configuring Spanning Tree Protocol (STP) Related Features

STP overview

The Spanning Tree Protocol (STP) eliminates Layer 2 loops in networks, by selectively blocking some ports and allowing other ports to forward traffic, based on global (bridge) and local (port) parameters you can configure.

STP related features, such as RSTP and PVST, extend the operation of standard STP, enabling you to fine-tune standard STP and avoid some of its limitations.

You can enable or disable STP on a global basis (for the entire device), a port-based VLAN basis (for the individual Layer 2 broadcast domain), or an individual port basis.

Configuration procedures are provided for the standard STP bridge and port parameters as well as Brocade features listed in Table 74.

Configuring standard STP parameters

Brocade Layer 2 Switches and Layer 3 Switches support standard STP as described in the IEEE 802.1D specification. STP is enabled by default on Layer 2 Switches but disabled by default on Layer 3 Switches.

By default, each port-based VLAN on a Brocade device runs a separate spanning tree (a separate instance of STP). A Brocade device has one port-based VLAN (VLAN 1) by default that contains all the device ports. Thus, by default each Brocade device has one spanning tree. However, if you configure additional port-based VLANs on a Brocade device, then each of those VLANs on which STP is enabled and VLAN 1 all run separate spanning trees.

If you configure a port-based VLAN on the device, the VLAN has the same STP state as the default STP state on the device. Thus, on Layer 2 Switches, new VLANs have STP enabled by default. On Layer 3 Switches, new VLANs have STP disabled by default. You can enable or disable STP in each VLAN separately. In addition, you can enable or disable STP on individual ports.

STP parameters and defaults

Table 69 lists the default STP states for Brocade devices.

<table>
<thead>
<tr>
<th>Device type</th>
<th>Default STP type</th>
<th>Default STP state</th>
<th>Default STP state of new VLANs¹</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layer 2 Switch</td>
<td>MSTP²</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>Layer 3 Switch</td>
<td>MSTP</td>
<td>Disabled</td>
<td>Disabled</td>
</tr>
</tbody>
</table>

1. When you create a port-based VLAN, the new VLAN STP state is the same as the default STP state on the device. The new VLAN does not inherit the STP state of the default VLAN.
2. MSTP stands for “Multiple Spanning Tree Protocol”. In this type of STP, each port-based VLAN, including the default VLAN, has its own spanning tree. References in this documentation to “STP” apply to MSTP. The Single Spanning Tree Protocol (SSTP) is another type of STP. SSTP includes all VLANs on which STP is enabled in a single spanning tree. Refer to “Single Spanning Tree (SSTP)” on page 323.

Table 70 lists the default STP bridge parameters. The bridge parameters affect the entire spanning tree. If you are using MSTP, the parameters affect the VLAN. If you are using SSTP, the parameters affect all VLANs that are members of the single spanning tree.

**TABLE 70** Default STP bridge parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default and valid values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Forward Delay</td>
<td>The period of time spent by a port in the listening and learning state before moving on to the learning or forwarding state, respectively. The forward delay value is also used for the age time of dynamic entries in the filtering database, when a topology change occurs.</td>
<td>15 seconds Possible values: 4 – 30 seconds</td>
</tr>
<tr>
<td>Maximum Age</td>
<td>The interval a bridge will wait for a configuration BPDU from the root bridge before initiating a topology change.</td>
<td>20 seconds Possible values: 6 – 40 seconds</td>
</tr>
<tr>
<td>Hello Time</td>
<td>The interval of time between each configuration BPDU sent by the root bridge.</td>
<td>2 seconds Possible values: 1 – 10 seconds</td>
</tr>
<tr>
<td>Priority</td>
<td>A parameter used to identify the root bridge in a spanning tree (instance of STP). The bridge with the lowest value has the highest priority and is the root. A higher numerical value means a lower priority; thus, the highest priority is 0.</td>
<td>32768 Possible values: 0 – 65535</td>
</tr>
</tbody>
</table>

**NOTE**

If you plan to change STP bridge timers, Brocade recommends that you stay within the following ranges, from section 8.10.2 of the IEEE STP specification.

\[ 2 \times (\text{forward\_delay} - 1) \geq \text{max\_age} \]

\[ \text{max\_age} \geq 2 \times (\text{hello\_time} + 1) \]

Table 71 lists the default STP port parameters. The port parameters affect individual ports and are separately configurable on each port.
TABLE 71  Default STP port parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default and valid values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priority</td>
<td>The preference that STP gives this port relative to other ports for forwarding traffic out of the spanning tree. A higher numerical value means a lower priority.</td>
<td>128&lt;br&gt;Possible values in FastIron X Series pre-release 03.0.00, and in FGS pre-release 03.0.00: 8 – 252 (configurable in increments of 4)&lt;br&gt;Possible values in TurboIron X Series, and in FastIron X Series and FGS/FLS release 03.0.00 and later: 0 – 240 (configurable in increments of 16)</td>
</tr>
<tr>
<td>Path Cost</td>
<td>The cost of using the port to reach the root bridge. When selecting among multiple links to the root bridge, STP chooses the link with the lowest path cost and blocks the other paths. Each port type has its own default STP path cost.</td>
<td>10 Mbps – 100&lt;br&gt;100 Mbps – 19&lt;br&gt;Gbps – 4&lt;br&gt;10 Gbps – 2&lt;br&gt;Possible values are 0 – 65535</td>
</tr>
</tbody>
</table>

Enabling or disabling the Spanning Tree Protocol (STP)

STP is enabled by default on devices running Layer 2 code. STP is disabled by default on devices running Layer 3 code.

You can enable or disable STP on the following levels:

- **Globally** – Affects all ports and port-based VLANs on the device.
- **Port-based VLAN** – Affects all ports within the specified port-based VLAN. When you enable or disable STP within a port-based VLAN, the setting overrides the global setting. Thus, you can enable STP for the ports within a port-based VLAN even when STP is globally disabled, or disable the ports within a port-based VLAN when STP is globally enabled.
- **Individual port** – Affects only the individual port. However, if you change the STP state of the primary port in a trunk group, the change affects all ports in the trunk group.

**NOTE**
The CLI converts the STP groups into topology groups when you save the configuration. For backward compatibility, you can still use the STP group commands. However, the CLI converts the commands into the topology group syntax. Likewise, the `show stp-group` command displays STP topology groups.

**Enabling or disabling STP globally**

Use the following method to enable or disable STP on a device on which you have not configured port-based VLANs.

**NOTE**
When you configure a VLAN, the VLAN inherits the global STP settings. However, once you begin to define a VLAN, you can no longer configure standard STP parameters globally using the CLI. From that point on, you can configure STP only within individual VLANs.
To enable STP for all ports in all VLANs on a Brocade device, enter the following command.

FastIron(config)#spanning-tree

This command enables a separate spanning tree in each VLAN, including the default VLAN.

Syntax:  [no] spanning-tree

**Enabling or disabling STP in a port-based VLAN**

Use the following procedure to disable or enable STP on a device on which you have configured a port-based VLAN. Changing the STP state in a VLAN affects only that VLAN.

To enable STP for all ports in a port-based VLAN, enter commands such as the following.

FastIron(config)#vlan 10
FastIron(config-vlan-10)#spanning-tree

Syntax:  [no] spanning-tree

**Enabling or disabling STP on an individual port**

Use the following procedure to disable or enable STP on an individual port.

**NOTE**

If you change the STP state of the primary port in a trunk group, it affects all ports in the trunk group.

To enable STP on an individual port, enter commands such as the following.

FastIron(config)#interface 1/1
FastIron(config-if-e1000-1/1)#spanning-tree

Syntax:  [no] spanning-tree

**Changing STP bridge and port parameters**

Table 70 on page 264 and Table 71 on page 265 list the default STP parameters. If you need to change the default value for an STP parameter, use the following procedures.

**Changing STP bridge parameters**

**NOTE**

If you plan to change STP bridge timers, Brocade recommends that you stay within the following ranges, from section 8.10.2 of the IEEE STP specification.

\[
2 \times (\text{forward}\_\text{delay} - 1) \geq \text{max}\_\text{age}
\]

\[
\text{max}\_\text{age} \geq 2 \times (\text{hello}\_\text{time} + 1)
\]

To change a STP bridge priority on a Brocade device to the highest value to make the device the root bridge, enter the following command.

FastIron(config)#spanning-tree priority 0
The command in this example changes the priority on a device on which you have not configured port-based VLANs. The change applies to the default VLAN. If you have configured a port-based VLAN on the device, you can configure the parameters only at the configuration level for individual VLANs. Enter commands such as the following.

```
FastIron(config)#vlan 20
FastIron(config-vlan-20)#spanning-tree priority 0
```

To make this change in the default VLAN, enter the following commands.

```
FastIron(config)#vlan 1
FastIron(config-vlan-1)#spanning-tree priority 0
```

Syntax: `[no] spanning-tree [forward-delay <value>] | [hello-time <value>] | [maximum-age <value>] | [priority <value>]`

The `forward-delay <value>` parameter specifies the forward delay and can be a value from 4 – 30 seconds. The default is 15 seconds.

NOTE
You can configure a Brocade device for faster convergence (including a shorter forward delay) using Fast Span. Refer to “Configuring STP related features” on page 279.

The `hello-time <value>` parameter specifies the hello time and can be a value from 1 – 10 seconds. The default is 2 seconds.

NOTE
This parameter applies only when this device or VLAN is the root bridge for its spanning tree.

The `maximum-age <value>` parameter specifies the amount of time the device waits for receipt of a configuration BPDU from the root bridge before initiating a topology change. You can specify from 6 – 40 seconds. The default is 20 seconds.

The `priority <value>` parameter specifies the priority and can be a value from 0 – 65535. A higher numerical value means a lower priority. Thus, the highest priority is 0. The default is 32768.

You can specify some or all of these parameters on the same command line. If you specify more than one parameter, you must specify them in the order shown above, from left to right.

### Changing STP port parameters

To change the path and priority costs for a port, enter commands such as the following.

```
FastIron(config)#vlan 10
FastIron(config-vlan-10)#spanning-tree ethernet 5 path-cost 15 priority 64
```

Syntax: `spanning-tree ethernet [stack-unit]<slotnum>/]<portnum> path-cost <value> | priority <value> | disable | enable`

The `<portnum>` parameter specifies the interface. If you are configuring a chassis device, specify the stack number as well as the port number (`<slotnum>/` `<portnum>`).

The `path-cost <value>` parameter specifies the port cost as a path to the spanning tree root bridge. STP prefers the path with the lowest cost. You can specify a value from 0 – 65535.

The default depends on the port type:

- 10 Mbps - 100
- 100 Mbps - 19
Configuring standard STP parameters

- Gbps – 4
- 10 Gbps – 2

The priority <value> parameter specifies the preference that STP gives this port relative to other ports for forwarding traffic out of the spanning tree. The value you can specify depends on the software version running on the device, as follows:

- In releases prior to 03.0.00, you can specify a value from 8 – 252, in increments of 4. If you enter a value that is not divisible by four the software rounds to the nearest value that is. The default is 128. A higher numerical value means a lower priority; thus, the highest priority is 8.
- Starting in software release 03.0.00, you can specify a value from 0 – 240, in increments of 16. If you enter a value that is not divisible by 16, the software returns an error message. The default value is 128. A higher numerical value means a lower priority; thus, the highest priority is 0.

**NOTE**

If you are upgrading a device that has a configuration saved under an earlier software release, and the configuration contains a value from 0 – 7 for a port STP priority, the software changes the priority to the default when you save the configuration while running the new release.

The disable | enable parameter disables or re-enables STP on the port. The STP state change affects only this VLAN. The port STP state in other VLANs is not changed.

**STP protection enhancement**

**Platform Support:**

- FESX devices running software release 02.1.01 and later
- FSX and FWSX devices running software release 02.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

STP protection provides the ability to prohibit an end station from initiating or participating in an STP topology change.

The 802.1W Spanning Tree Protocol (STP) detects and eliminates logical loops in a redundant network by selectively blocking some data paths (ports) and allowing only the best data paths to forward traffic.

In an STP environment, switches, end stations, and other Layer 2 devices use Bridge Protocol Data Units (BPDUs) to exchange information that STP will use to determine the best path for data flow. When a Layer 2 device is powered ON and connected to the network, or when a Layer 2 device goes down, it sends out an STP BPDU, triggering an STP topology change.

In some instances, it is unnecessary for a connected device, such as an end station, to initiate or participate in an STP topology change. In this case, you can enable the STP Protection feature on the Brocade port to which the end station is connected. STP Protection disables the connected device ability to initiate or participate in an STP topology change, by dropping all BPDUs received from the connected device.

**Enabling STP protection**

You can enable STP Protection on a per-port basis.
To prevent an end station from initiating or participating in STP topology changes, enter the following command at the Interface level of the CLI.

```
FastIron#(config) interface e 2
FastIron#(config-if-e1000-2)#stp-protect
```

This command causes the port to drop STP BPDUs sent from the device on the other end of the link.

**Syntax:** `[no] stp-protect`

The `slotnum` parameter is required on chassis devices and on FastIron GS devices.

The `portnum` parameter is a valid port number.

Enter the **no** form of the command to disable STP protection on the port.

### Clearing BPDU drop counters

For each port that has STP Protection enabled, the Brocade device counts and records the number of dropped BPDUs. You can use CLI commands to clear the BPDU drop counters for all ports on the device, or for a specific port on the device.

To clear the BPDU drop counters for all ports on the device that have STP Protection enabled, enter the following command at the Global CONFIG level of the CLI.

```
FastIron(config)#clear stp-protect-statistics
```

To clear the BPDU drop counter for a specific port that has STP Protection enabled, enter the following command at the Global CONFIG level of the CLI.

```
FastIron#clear stp-protect-statistics e 2
```

**Syntax:** `clear stp-protect-statistics [ethernet [<stack-unit><slotnum>/]<port-num>] | [ethernet [<stack-unit><slotnum>/]portnum>]`

The `slotnum` parameter is required on chassis devices and on FastIron GS devices.

The `portnum` parameter is a valid port number.

### Viewing the STP Protection Configuration

You can view the STP Protection configuration for all ports on a device, or for a specific port only.

The `show stp-protect` command output shows the port number on which STP Protection is enabled, and the number of BPDUs dropped by each port.

To view the STP Protection configuration for all ports on the device, enter the following command at any level of the CLI.

```
FastIron#show stp-protect
```

<table>
<thead>
<tr>
<th>Port ID</th>
<th>BPDU Drop Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>478</td>
</tr>
<tr>
<td>5</td>
<td>213</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
</tr>
<tr>
<td>12</td>
<td>31</td>
</tr>
</tbody>
</table>
Configuring standard STP parameters

To view STP Protection configuration for a specific port, enter the following command at any level of the CLI.

```bash
FastIron#show stp-protect e 3
STP-protect is enabled on port 3. BPDU drop count is 478
```

If you enter the `show stp-protect` command for a port that does not have STP protection enabled, the following message displays on the console.

```bash
FastIron#show stp-protect e 4
STP-protect is not enabled on port 4.
```

**Syntax: show stp-protect [ethernet <stack-unit> | slotnum> | <portnum>]

**Displaying STP information**

You can display the following STP information:

- All the global and interface STP settings
- CPU utilization statistics (FastIron devices only)
- Detailed STP information for each interface
- STP state information for a port-based VLAN
- STP state information for an individual interface
Displaying STP information for an entire device

To display STP information, enter the following command at any level of the CLI.

FastIron#show span

VLAN 1 BPDU cam_index is 3 and the Master DMA Are(HEX)
STP instance owned by VLAN 1

Global STP (IEEE 802.1D) Parameters:

<table>
<thead>
<tr>
<th>VLAN Root ID</th>
<th>Root Root Prio Max He- Ho- Fwd Last Chg Bridge</th>
<th>VLAN 1 BPDU cam_index 3 and the Master DMA Are(HEX)</th>
<th>STP instance owned by VLAN 1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Port STP Parameters:

<table>
<thead>
<tr>
<th>Port</th>
<th>Prio</th>
<th>Path State</th>
<th>Fwd Design</th>
<th>Designated Bridge</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>

<tr>
<td>7</td>
<td>80</td>
<td>DISABLED</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Syntax: show span [vlan <vlan-id>] | [pvst-mode] | [num] | [detail] [vlan <vlan-id> [ethernet <stack-unit><slotnum>/]<portnum>]] | [num]]

The vlan <vlan-id> parameter displays STP information for the specified port-based VLAN.

The pvst-mode parameter displays STP information for the device Per VLAN Spanning Tree (PVST+) compatibility configuration. Refer to “PVST/PVST+ compatibility” on page 329

The slotnum parameter is required on chassis devices and on FastIron GS devices.

The portnum parameter is a valid port number.

The <num> parameter displays only the entries after the number you specify. For example, on a device with three port-based VLANs, if you enter 1, then information for the second and third VLANs is displayed, but information for the first VLAN is not displayed. Information is displayed according to VLAN number, in ascending order. The entry number is not the same as the VLAN number. For example, if you have port-based VLANs 1, 10, and 2048, then the command output has three STP entries. To display information for VLANs 10 and 2024 only, enter show span 1.

The detail parameter and its additional optional parameters display detailed information for individual ports. Refer to “Displaying detailed STP information for each interface” on page 275.

The show span command shows the following information.
### TABLE 72 CLI display of STP information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Global STP parameters</strong></td>
<td></td>
</tr>
<tr>
<td>VLAN ID</td>
<td>The port-based VLAN that contains this spanning tree (instance of STP). VLAN 1 is the default VLAN. If you have not configured port-based VLANs on this device, all STP information is for VLAN 1.</td>
</tr>
<tr>
<td>Root ID</td>
<td>The ID assigned by STP to the root bridge for this spanning tree.</td>
</tr>
<tr>
<td>Root Cost</td>
<td>The cumulative cost from this bridge to the root bridge. If this device is the root bridge, then the root cost is 0.</td>
</tr>
<tr>
<td>Root Port</td>
<td>The port on this device that connects to the root bridge. If this device is the root bridge, then the value is “Root” instead of a port number.</td>
</tr>
<tr>
<td>Priority Hex</td>
<td>This device or VLAN STP priority. The value is shown in hexadecimal format. <strong>NOTE:</strong> If you configure this value, specify it in decimal format. Refer to “Changing STP bridge parameters” on page 266.</td>
</tr>
<tr>
<td>Max age sec</td>
<td>The number of seconds this device or VLAN waits for a configuration BPDU from the root bridge before deciding the root has become unavailable and performing a reconvergence.</td>
</tr>
<tr>
<td>Hello sec</td>
<td>The interval between each configuration BPDU sent by the root bridge.</td>
</tr>
<tr>
<td>Hold sec</td>
<td>The minimum number of seconds that must elapse between transmissions of consecutive Configuration BPDUs on a port.</td>
</tr>
<tr>
<td>Fwd dly sec</td>
<td>The number of seconds this device or VLAN waits following a topology change and consequent reconvergence.</td>
</tr>
<tr>
<td>Last Chang sec</td>
<td>The number of seconds since the last time a topology change occurred.</td>
</tr>
<tr>
<td>Chg cnt</td>
<td>The number of times the topology has changed since this device was reloaded.</td>

</tr>
<tr>
<td>Path Cost</td>
<td>The port STP path cost.</td>
</tr>
</tbody>
</table>
Configuring standard STP parameters

### Displaying CPU utilization statistics

**NOTE**

CPU utilization statistics are not supported on TurboIron X Series devices.

You can display CPU utilization statistics for STP and the IP protocols.

To display CPU utilization statistics for STP for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI.

```
FastIron#show process cpu
```

<table>
<thead>
<tr>
<th>Process Name</th>
<th>5Sec(%)</th>
<th>1Min(%)</th>
<th>5Min(%)</th>
<th>15Min(%)</th>
<th>Runtime (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARP</td>
<td>0.01</td>
<td>0.03</td>
<td>0.09</td>
<td>0.22</td>
<td>9</td>
</tr>
<tr>
<td>BGP</td>
<td>0.04</td>
<td>0.06</td>
<td>0.08</td>
<td>0.14</td>
<td>13</td>
</tr>
<tr>
<td>GVRP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>ICMP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>IP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>OSPF</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>RIP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>STP</td>
<td>0.00</td>
<td>0.03</td>
<td>0.04</td>
<td>0.07</td>
<td>4</td>
</tr>
<tr>
<td>VRRP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
</tbody>
</table>

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.
To display utilization statistics for a specific number of seconds, enter a command such as the following:

```
FastIron#show process cpu 2
Statistics for last 1 sec and 80 ms
```

<table>
<thead>
<tr>
<th>Process Name</th>
<th>Sec(%)</th>
<th>Time(ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>BGP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>GVRP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>ICMP</td>
<td>0.01</td>
<td>1</td>
</tr>
<tr>
<td>IP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>OSPF</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>RIP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>STP</td>
<td>0.01</td>
<td>0</td>
</tr>
<tr>
<td>VRRP</td>
<td>0.00</td>
<td>0</td>
</tr>
</tbody>
</table>

When you specify how many seconds’ worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

**Syntax:** `show process cpu [<num>]`

The `<num>` parameter specifies the number of seconds and can be from 1 – 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.

### Displaying the STP state of a port-based VLAN

When you display information for a port-based VLAN, that information includes the STP state of the VLAN.

To display information for a port-based VLAN, enter a command such as the following at any level of the CLI. The STP state is shown in bold type in this example.
Configuring standard STP parameters

FastIron#show vlans
Total PORT-VLAN entries: 2
Maximum PORT-VLAN entries: 16

legend: [S=Slot]

PORT-VLAN 1, Name DEFAULT-VLAN, Priority level0, Spanning tree On
  Untagged Ports: (S3) 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
  Untagged Ports: (S3) 17 18 19 20 21 22 23 24
  Untagged Ports: (S4) 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17
  Untagged Ports: (S4) 18 19 20 21 22 23 24
  Tagged Ports: None
  Uplink Ports: None

PORT-VLAN 2, Name greenwell, Priority level0, Spanning tree Off
  Untagged Ports: (S1) 1 2 3 4 5 6 7 8
  Untagged Ports: (S4) 1
  Tagged Ports: None
  Uplink Ports: None

NOTE
The Uplink Ports field in the above output applies to FastIron devices only. Uplink ports are not supported on TurboIron X Series devices.

Syntax: show vlan [<vlan-id> | ethernet [<stack-unit> | <slotnum> | <portnum>]]

The <vlan-id> parameter specifies a VLAN for which you want to display the configuration information.

The <portnum> parameter specifies a port. If you use this parameter, the command lists all the VLAN memberships for the port. If you use this command on a chassis device, specify the slot number as well as the port number (<slotnum>/<portnum>).

Displaying detailed STP information for each interface

To display the detailed STP information, enter the following command at any level of the CLI.

FastIron#show span detail

VLAN 1 - MULTIPLE SPANNING TREE (MSTP) ACTIVE

Bridge identifier - 0x800000e0804d4a00
Active global timers - Hello: 0

Port 1/1 is FORWARDING
  Port - Path cost: 19, Priority: 128, Root: 0x800000e052a9bb00
  Designated - Bridge: 0x800000e052a9bb00, Interface: 1, Path cost: 0
  Active Timers - None
  BPDUs - Sent: 11, Received: 0

Port 1/2 is DISABLED
Port 1/3 is DISABLED
Port 1/4 is DISABLED

<lines for remaining ports excluded for brevity>
Configuring standard STP parameters

If a port is disabled, the only information shown by this command is “DISABLED”. If a port is enabled, this display shows the following information.

Syntax: show span detail [vlan <vlan-id> [ethernet [<stack-unit>/<slotnum>/<portnum> | <num>]]]

The vlan <vlan-id> parameter specifies a VLAN.

The <portnum> parameter specifies an individual port within the VLAN (if specified). If you use the command on a chassis device, specify the slot number as well as the port number (<slotnum>/<portnum>).

The <stack-unit> parameter is required on FastIron GS and LS devices running software release 02.5.00 or later, and FastIron GS-STK and FastIron LS-STK devices running software release 05.0.00 and later.

The <slotnum> parameter is required on chassis devices and on FastIron GS devices running software release 02.5.00 or later.

The <portnum> parameter is a valid port number.

The <num> parameter specifies the number of VLANs you want the CLI to skip before displaying detailed STP information. For example, if the device has six VLANs configured (VLAN IDs 1, 2, 3, 99, 128, and 256) and you enter the command show span detail 4, detailed STP information is displayed for VLANs 128 and 256 only.

NOTE
If the configuration includes VLAN groups, the show span detail command displays the master VLANs of each group but not the member VLANs within the groups. However, the command does indicate that the VLAN is a master VLAN. The show span detail vlan <vlan-id> command displays the information for the VLAN even if it is a member VLAN. To list all the member VLANs within a VLAN group, enter the show vlan-group [<group-id>] command.

The show span detail command shows the following information.

<table>
<thead>
<tr>
<th>TABLE 73</th>
<th>CLI display of detailed STP information for ports</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field...</strong></td>
<td><strong>Displays...</strong></td>
</tr>
</tbody>
</table>
| Active Spanning Tree protocol | The VLAN that contains the listed ports and the active Spanning Tree protocol. The STP type can be one of the following:  
• MULTIPLE SPANNING TREE (MSTP)  
• GLOBAL SINGLE SPANNING TREE (SSTP)  
NOTE: If STP is disabled on a VLAN, the command displays the following message instead: “Spanning-tree of port-vlan <vlan-id> is disabled.” |
| Bridge identifier | The STP identity of this device. |
| Active global timers | The global STP timers that are currently active, and their current values. The following timers can be listed:  
• Hello – The interval between Hello packets. This timer applies only to the root bridge.  
• Topology Change (TC) – The amount of time during which the topology change flag in Hello packets will be marked, indicating a topology change. This timer applies only to the root bridge.  
• Topology Change Notification (TCN) – The interval between Topology Change Notification packets sent by a non-root bridge toward the root bridge. This timer applies only to non-root bridges. |
Configuring standard STP parameters

### TABLE 73 CLI display of detailed STP information for ports (Continued)

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
</table>
| Port number and STP state | The internal port number and the port STP state. The internal port number is one of the following:  
- The port interface number, if the port is the designated port for the LAN.  
- The interface number of the designated port from the received BPDU, if the interface is not the designated port for the LAN.  
The state can be one of the following:  
- **BLOCKING** – STP has blocked Layer 2 traffic on this port to prevent a loop. The device or VLAN can reach the root bridge using another port, whose state is FORWARDING. When a port is in this state, the port does not transmit or receive user frames, but the port does continue to receive STP BPDUs.  
- **DISABLED** – The port is not participating in STP. This can occur when the port is disconnected or STP is administratively disabled on the port.  
- **FORWARDING** – STP is allowing the port to send and receive frames.  
- **LISTENING** – STP is responding to a topology change and this port is listening for a BPDU from neighboring bridges in order to determine the new topology. No user frames are transmitted or received during this state.  
- **LEARNING** – The port has passed through the LISTENING state and will change to the BLOCKING or FORWARDING state, depending on the results of STP reconvergence. The port does not transmit or receive user frames during this state. However, the device can learn the MAC addresses of frames that the port receives during this state and make corresponding entries in the MAC table.  
**NOTE:** If the state is DISABLED, no further STP information is displayed for the port.  |
| Port Path cost | The STP path cost for the port. |
| Port Priority | This STP priority for the port. The value is shown as a hexadecimal number. |
| Root | The ID assigned by STP to the root bridge for this spanning tree. |
| Designated Bridge | The MAC address of the designated bridge to which this port is connected. The designated bridge is the device that connects the network segment on the port to the root bridge. |
| Designated Port | The port number sent from the designated bridge. |
| Designated Path Cost | The cost to the root bridge as advertised by the designated bridge that is connected to this port. If the bridge is the root bridge itself, then the cost is 0. The identity of the designated bridge is shown in the Designated Bridge field. |
| Active Timers | The current values for the following timers, if active:  
- **Message age** – The number of seconds this port has been waiting for a hello message from the root bridge.  
- **Forward delay** – The number of seconds that have passed since the last topology change and consequent reconvergence.  
- **Hold time** – The number of seconds that have elapsed since transmission of the last Configuration BPDU. |
| BPDUs Sent and Received | The number of BPDUs sent and received on this port since the software was reloaded. |

### Displaying detailed STP information for a single port in a specific VLAN

Enter a command such as the following to display STP information for an individual port in a specific VLAN.

---

*Fastiron and Turbolron 24X Configuration Guide*  
53-1001719-01  
277
Configuring standard STP parameters

Syntax: show span detail vlan <vlan-id> [ethernet [stack-unit] | [slotnum] | [portnum] | [num]]

Displaying STP state information for an individual interface

To display STP state information for an individual port, you can use the methods in “Displaying STP information for an entire device” on page 271 or “Displaying detailed STP information for each interface” on page 275. You also can display STP state information for a specific port using the following method.

To display information for a specific port, enter a command such as the following at any level of the CLI.

FastIron#show span detail vlan 1 ethernet 7/1
Port 7/1 is FORWARDING
Port - Path cost: 19, Priority: 128, Root: 0x800000e052abbb00
Designated - Bridge: 0x800000e052abbb00, Interface: 7, Path cost: 0
Active Timers - None
BPDUs - Sent: 29, Received: 0

Syntax: show span detail [vlan <vlan-id>] [ethernet [stack-unit] | [slotnum] | [portnum] | [num]]

Displaying STP state information for an individual interface

To display STP state information for an individual port, you can use the methods in “Displaying STP information for an entire device” on page 271 or “Displaying detailed STP information for each interface” on page 275. You also can display STP state information for a specific port using the following method.

To display information for a specific port, enter a command such as the following at any level of the CLI.

FastIron#show interface ethernet 3/11
FastEthernet3/11 is up, line protocol is up
Hardware is FastEthernet, address is 00e0.52a9.bb49 (bia 00e0.52a9.bb49)
Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
Member of L2 VLAN ID 1, port is untagged, port state is FORWARDING
STP configured to ON, priority is level0, flow control enabled
mirror disabled, monitor disabled
Not member of any active trunks
Not member of any configured trunks
No port name
MTU 1518 bytes, encapsulation ethernet
5 minute input rate: 352 bits/sec, 0 packets/sec, 0.00% utilization
5 minute output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
1238 packets input, 79232 bytes, 0 no buffer
Received 686 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 ignored
529 multicast
918 packets output, 63766 bytes, 0 underruns
0 output errors, 0 collisions

The STP information is shown in bold type in this example.

Syntax: show interfaces [ethernet [stack-unit] | [slotnum] | [portnum]] | [loopback <num>] | [brief]

The <stack-unit> option is required on FGS and FLS devices running software release 2.5 and later, and on FGS-STK and FLS-STK devices running software version 5.0 and later.

You also can display the STP states of all ports by entering a command such as the following, which uses the brief parameter.

FastIron#show interface ethernet 3/11
FastEthernet3/11 is up, line protocol is up
Hardware is FastEthernet, address is 00e0.52a9.bb49 (bia 00e0.52a9.bb49)
Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
Member of L2 VLAN ID 1, port is untagged, port state is FORWARDING
STP configured to ON, priority is level0, flow control enabled
mirror disabled, monitor disabled
Not member of any active trunks
Not member of any configured trunks
No port name
MTU 1518 bytes, encapsulation ethernet
5 minute input rate: 352 bits/sec, 0 packets/sec, 0.00% utilization
5 minute output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
1238 packets input, 79232 bytes, 0 no buffer
Received 686 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 ignored
529 multicast
918 packets output, 63766 bytes, 0 underruns
0 output errors, 0 collisions

The STP information is shown in bold type in this example.

You also can display the STP states of all ports by entering a command such as the following, which uses the brief parameter.
In the example above, only one port, 3/11, is forwarding traffic toward the root bridge.

### Configuring STP related features

STP features extend the operation of standard STP, enabling you to fine tune standard STP and avoid some of its limitations.

This section describes how to configure these parameters on Brocade Layer 3 Switches using the CLI.

#### Fast port span

**Platform Support:**
- FCX-S devices running software release 06.0.00 and later

When STP is running on a device, message forwarding is delayed during the spanning tree recalculation period following a topology change. The STP forward delay parameter specifies the period of time a bridge waits before forwarding data packets. The forward delay controls the listening and learning periods of STP reconvergence. You can configure the forward delay to a value from 4 – 30 seconds. The default is 15 seconds. Thus, using the standard forward delay, convergence requires 30 seconds (15 seconds for listening and an additional 15 seconds for learning) when the default value is used.

This slow convergence is undesirable and unnecessary in some circumstances. The Fast Port Span feature allows certain ports to enter the forwarding state in four seconds. Specifically, Fast Port Span allows faster convergence on ports that are attached to end stations and thus do not present the potential to cause Layer 2 forwarding loops. Because the end stations cannot cause forwarding loops, they can safely go through the STP state changes (blocking to listening to learning to forwarding) more quickly than is allowed by the standard STP convergence time. Fast Port Span performs the convergence on these ports in four seconds (two seconds for learning and two seconds for learning).
In addition, Fast Port Span enhances overall network performance in the following ways:

- **Fast Port Span reduces the number of STP topology change notifications on the network.** When an end station attached to a Fast Span port comes up or down, the Brocade device does not generate a topology change notification for the port. In this situation, the notification is unnecessary since a change in the state of the host does not affect the network topology.

- **Fast Port Span eliminates unnecessary MAC cache aging that can be caused by topology change notifications.** Bridging devices age out the learned MAC addresses in their MAC caches if the addresses are unrefreshed for a given period of time, sometimes called the MAC aging interval. When STP sends a topology change notification, devices that receive the notification use the value of the STP forward delay to quickly age out their MAC caches. For example, if a device normal MAC aging interval is 5 minutes, the aging interval changes temporarily to the value of the forward delay (for example, 15 seconds) in response to an STP topology change. In normal STP, the accelerated cache aging occurs even when a single host goes up or down. Because Fast Port Span does not send a topology change notification when a host on a Fast Port Span port goes up or down, the unnecessary cache aging that can occur in these circumstances under normal STP is eliminated.

Fast Port Span is a system-wide parameter and is enabled by default. Thus, when you boot a device, all the ports that are attached only to end stations run Fast Port Span. For ports that are not eligible for Fast Port Span, such as ports connected to other networking devices, the device automatically uses the normal STP settings. If a port matches any of the following criteria, the port is ineligible for Fast Port Span and uses normal STP instead:

- The port is 802.1Q tagged
- The port is a member of a trunk group
- The port has learned more than one active MAC address
- An STP Configuration BPDU has been received on the port, thus indicating the presence of another bridge on the port.

You also can explicitly exclude individual ports from Fast Port Span if needed. For example, if the only uplink ports for a wiring closet switch are Gbps ports, you can exclude the ports from Fast Port Span.

**Disabling and re-enabling fast port span**

Fast Port Span is a system-wide parameter and is enabled by default. Thus all ports that are eligible for Fast Port Span use it.

To disable or re-enable Fast Port Span, enter the following commands.

```
FastIron(config)#no fast port-span
FastIron(config)#write memory
```

**Syntax:** `[no] fast port-span`

**NOTE**
The `fast port-span` command has additional parameters that let you exclude specific ports. These parameters are shown in the following section.

To re-enable Fast Port Span, enter the following commands.

```
FastIron(config)#fast port-span
FastIron(config)#write memory
```
**Excluding specific ports from fast port span**

To exclude a port from Fast Port Span while leaving Fast Port Span enabled globally, enter commands such as the following.

```
FastIron(config)#fast port-span exclude ethernet 1
FastIron(config)#write memory
```

To exclude a set of ports from Fast Port Span, enter commands such as the following.

```
FastIron(config)#fast port-span exclude ethernet 1 ethernet 2 ethernet 3
FastIron(config)#write memory
```

To exclude a contiguous (unbroken) range of ports from Fast Span, enter commands such as the following.

```
FastIron(config)#fast port-span exclude ethernet 1 to 24
FastIron(config)#write memory
```

**Syntax:** `[no] fast port-span [exclude ethernet [<stack-unit>/]<slotnum>/<portnum> | ethernet [<slotnum>/<portnum> | to [<slotnum>/<portnum>]]`

To re-enable Fast Port Span on a port, enter a command such as the following.

```
FastIron(config)#no fast port-span exclude ethernet 1
FastIron(config)#write memory
```

This command re-enables Fast Port Span on port 1 only and does not re-enable Fast Port Span on other excluded ports. You also can re-enable Fast Port Span on a list or range of ports using the syntax shown above this example.

To re-enable Fast Port Span on all excluded ports, disable and then re-enable Fast Port Span by entering the following commands.

```
FastIron(config)#no fast port-span
FastIron(config)#fast port-span
FastIron(config)#write memory
```

Disabling and then re-enabling Fast Port Span clears the exclude settings and thus enables Fast Port Span on all eligible ports. To make sure Fast Port Span remains enabled on the ports following a system reset, save the configuration changes to the startup-config file after you re-enable Fast Port Span. Otherwise, when the system resets, those ports will again be excluded from Fast Port Span.

**802.1W Rapid Spanning Tree (RSTP)**

Earlier implementation by Brocade of Rapid Spanning Tree Protocol (RSTP), which was 802.1W Draft 3, provided only a subset of the IEEE 802.1W standard; whereas the 802.1W RSTP feature provides the full standard. The implementation of the 802.1W Draft 3 is referred to as RSTP Draft 3.

RSTP Draft 3 will continue to be supported on Brocade devices for backward compatibility. However, customers who are currently using RSTP Draft 3 should migrate to 802.1W.

The 802.1W feature provides rapid traffic reconvergence for point-to-point links within a few milliseconds (0 – 500 milliseconds), following the failure of a bridge or bridge port. This reconvergence occurs more rapidly than the reconvergence provided by the 802.1D Spanning Tree Protocol (STP)) or by RSTP Draft 3.
NOTE
This rapid convergence will not occur on ports connected to shared media devices, such as hubs. To take advantage of the rapid convergence provided by 802.1W, make sure to explicitly configure all point-to-point links in a topology.

The convergence provided by the standard 802.1W protocol occurs more rapidly than the convergence provided by previous spanning tree protocols because of the following:

- Classic or legacy 802.1D STP protocol requires a newly selected Root port to go through listening and learning stages before traffic convergence can be achieved. The 802.1D traffic convergence time is calculated using the following formula.

  \[ 2 \times \text{FORWARD\_DELAY} + \text{BRIDGE\_MAX\_AGE} \]

  If default values are used in the parameter configuration, convergence can take up to 50 seconds. (In this document STP will be referred to as 802.1D.)

- RSTP Draft 3 works only on bridges that have Alternate ports, which are the precalculated “next best root port”. (Alternate ports provide back up paths to the root bridge.) Although convergence occurs from 0 – 500 milliseconds in RSTP Draft 3, the spanning tree topology reverts to the 802.1D convergence if an Alternate port is not found.

- Convergence in 802.1w bridge is not based on any timer values. Rather, it is based on the explicit handshakes between Designated ports and their connected Root ports to achieve convergence in less than 500 milliseconds.

**Bridges and bridge port roles**

A bridge in an 802.1W rapid spanning tree topology is assigned as the root bridge if it has the highest priority (lowest bridge identifier) in the topology. Other bridges are referred to as non-root bridges.

Unique roles are assigned to ports on the root and non-root bridges. Role assignments are based on the following information contained in the Rapid Spanning Tree Bridge Packet Data Unit (RST BPDU):

- Root bridge ID
- Path cost value
- Transmitting bridge ID
- Designated port ID

The 802.1W algorithm uses this information to determine if the RST BPDU received by a port is superior to the RST BPDU that the port transmits. The two values are compared in the order as given above, starting with the Root bridge ID. The RST BPDU with a lower value is considered superior. The superiority and inferiority of the RST BPDU is used to assign a role to a port.

If the value of the received RST BPDU is the same as that of the transmitted RST BPDU, then the port ID in the RST BPDUs are compared. The RST BPDU with the lower port ID is superior. Port roles are then calculated appropriately.

The port role is included in the BPDU that it transmits. The BPDU transmitted by an 802.1W port is referred to as an RST BPDU, while it is operating in 802.1W mode.

Ports can have one of the following roles:

- **Root** – Provides the lowest cost path to the root bridge from a specific bridge
Configuring STP related features

- **Designated** – Provides the lowest cost path to the root bridge from a LAN to which it is connected
- **Alternate** – Provides an alternate path to the root bridge when the root port goes down
- **Backup** – Provides a backup to the LAN when the Designated port goes down
- **Disabled** – Has no role in the topology

**Assignment of port roles**

At system start-up, all 802.1W-enabled bridge ports assume a Designated role. Once start-up is complete, the 802.1W algorithm calculates the superiority or inferiority of the RST BPDU that is received and transmitted on a port.

On a root bridge, each port is assigned a **Designated port** role, except for ports on the same bridge that are physically connected together. In these type of ports, the port that receives the superior RST BPDU becomes the **Backup port**, while the other port becomes the **Designated port**.

On non-root bridges, ports are assigned as follows:

- The port that receives the RST BPDU with the lowest path cost from the root bridge becomes the **Root port**.
- If two ports on the same bridge are physically connected, the port that receives the superior RST BPDU becomes the **Backup port**, while the other port becomes the **Designated port**.
- If a non-root bridge already has a Root port, then the port that receives an RST BPDU that is superior to those it can transmit becomes the **Alternate port**.
- If the RST BPDU that a port receives is inferior to the RST BPDUs it transmits, then the port becomes a **Designated port**.
- If the port is down or if 802.1W is disabled on the port, that port is given the role of **Disabled port**. Disabled ports have no role in the topology. However, if 802.1W is enabled on a port with a link down and the link of that port comes up, then that port assumes one of the following port roles: Root, Designated, Alternate, or Backup.

The following example (Figure 17) explains role assignments in a simple RSTP topology.

**NOTE**

All examples in this document assume that all ports in the illustrated topologies are point-to-point links and are homogeneous (they have the same path cost value) unless otherwise specified.
The topology in Figure 17 contains four bridges. Switch 1 is the root bridge since it has the lowest bridge priority. Switch 2 through Switch 4 are non-root bridges.

**FIGURE 17 Simple 802.1W topology**

**Ports on Switch 1**
All ports on Switch 1, the root bridge, are assigned Designated port roles.

**Ports on Switch 2**
Port 2 on Switch 2 directly connects to the root bridge; therefore, Port 2 is the Root port.

The bridge priority value on Switch 2 is superior to that of Switch 3 and Switch 4; therefore, the ports on Switch 2 that connect to Switch 3 and Switch 4 are given the Designated port role.

Furthermore, Port 7 and Port 8 on Switch 2 are physically connected. The RST BPDUs transmitted by Port 7 are superior to those Port 8 transmits. Therefore, Port 8 is the Backup port and Port 7 is the Designated port.

**Ports on Switch 3**
Port 2 on Switch 3 directly connects to the Designated port on the root bridge; therefore, it assumes the Root port role.

The root path cost of the RST BPDUs received on Port 4/Switch 3 is inferior to the RST BPDUs transmitted by the port; therefore, Port 4/Switch 3 becomes the Designated port.

Similarly Switch 3 has a bridge priority value inferior to Switch 2. Port 3 on Switch 3 connects to Port 3 on Switch 2. This port will be given the Alternate port role, since a Root port is already established on this bridge.

**Ports Switch 4**
Switch 4 is not directly connected to the root bridge. It has two ports with superior incoming RST BPDUs from two separate LANs: Port 3 and Port 4. The RST BPDUs received on Port 3 are superior to the RST BPDUs received on port 4; therefore, Port 3 becomes the Root port and Port 4 becomes the Alternate port.
**Edge ports and edge port roles**

The Brocade implementation of 802.1W allows ports that are configured as Edge ports to be present in an 802.1W topology. (Figure 18). Edge ports are ports of a bridge that connect to workstations or computers. Edge ports do not register any incoming BPDU activities.

Edge ports assume Designated port roles. Port flapping does not cause any topology change events on Edge ports since 802.1W does not consider Edge ports in the spanning tree calculations.

**FIGURE 18** Topology with edge ports

![Topology with edge ports](image)

However, if any incoming RST BPDU is received from a previously configured Edge port, 802.1W automatically makes the port as a non-edge port. This is extremely important to ensure a loop free Layer 2 operation since a non-edge port is part of the active RSTP topology.

The 802.1W protocol can auto-detect an Edge port and a non-edge port. An administrator can also configure a port to be an Edge port using the CLI. It is recommended that Edge ports are configured explicitly to take advantage of the Edge port feature, instead of allowing the protocol to auto-detect them.

**Point-to-point ports**

To take advantage of the 802.1W features, ports on an 802.1W topology should be explicitly configured as point-to-point links using the CLI. Shared media should not be configured as point-to-point links.
Configuring STP related features

**NOTE**
Configuring shared media or non-point-to-point links as point-to-point links could lead to Layer 2 loops.

The topology in Figure 19 is an example of shared media that should not be configured as point-to-point links. In Figure 19, a port on a bridge communicates or is connected to at least two ports.

**FIGURE 19** Example of shared media

---

**Bridge port states**

Ports roles can have one of the following states:

- **Forwarding** – 802.1W is allowing the port to send and receive all packets.
- **Discarding** – 802.1W has blocked data traffic on this port to prevent a loop. The device or VLAN can reach the root bridge using another port, whose state is forwarding. When a port is in this state, the port does not transmit or receive data frames, but the port does continue to receive RST BPDUs. This state corresponds to the listening and blocking states of 802.1D.
- **Learning** – 802.1W is allowing MAC entries to be added to the filtering database but does not permit forwarding of data frames. The device can learn the MAC addresses of frames that the port receives during this state and make corresponding entries in the MAC table.
- **Disabled** – The port is not participating in 802.1W. This can occur when the port is disconnected or 802.1W is administratively disabled on the port.

A port on a non-root bridge with the role of Root port is always in a forwarding state. If another port on that bridge assumes the Root port role, then the old Root port moves into a discarding state as it assumes another port role.

A port on a non-root bridge with a Designated role starts in the discarding state. When that port becomes elected to the Root port role, 802.1W quickly places it into a forwarding state. However, if the Designated port is an Edge port, then the port starts and stays in a forwarding state and it cannot be elected as a Root port.

A port with an Alternate or Backup role is always in a discarding state. If the port role changes to Designated, then the port changes into a forwarding state.

If a port on one bridge has a Designated role and that port is connected to a port on another bridge that has an Alternate or Backup role, the port with a Designated role cannot be given a Root port role until two instances of the forward delay timer expires on that port.
**Edge port and non-edge port states**

As soon as a port is configured as an Edge port using the CLI, it goes into a forwarding state instantly (in less than 100 msec).

When the link to a port comes up and 802.1W detects that the port is an Edge port, that port instantly goes into a forwarding state.

If 802.1W detects that port as a non-edge port, the port state is changed as determined by the result of processing the received RST BPDU. The port state change occurs within four seconds of link up or after two hello timer expires on the port.

**Changes to port roles and states**

To achieve convergence in a topology, a port role and state changes as it receives and transmits new RST BPDUs. Changes in a port role and state constitute a topology change. Besides the superiority and inferiority of the RST BPDU, bridge-wide and per-port state machines are used to determine a port role as well as a port state. Port state machines also determine when port role and state changes occur.

**State machines**

The bridge uses the Port Role Selection state machine to determine if port role changes are required on the bridge. This state machine performs a computation when one of the following events occur:

- New information is received on any port on the bridge
- The timer expires for the current information on a port on the bridge

Each port uses the following state machines:

- **Port Information** – This state machine keeps track of spanning-tree information currently used by the port. It records the origin of the information and ages out any information that was derived from an incoming BPDU.

- **Port Role Transition** – This state machine keeps track of the current port role and transitions the port to the appropriate role when required. It moves the Root port and the Designated port into forwarding states and moves the Alternate and Backup ports into discarding states.

- **Port Transmit** – This state machine is responsible for BPDU transmission. It checks to ensure only the maximum number of BPDUs per hello interval are sent every second. Based on what mode it is operating in, it sends out either legacy BPDUs or RST BPDUs. In this document legacy BPDUs are also referred to as STP BPDUs.

- **Port Protocol Migration** – This state machine deals with compatibility with 802.1D bridges. When a legacy BPDU is detected on a port, this state machine configures the port to transmit and receive legacy BPDUs and operate in the legacy mode.

- **Topology Change** – This state machine detects, generates, and propagates topology change notifications. It acknowledges Topology Change Notice (TCN) messages when operating in 802.1D mode. It also flushes the MAC table when a topology change event takes place.

- **Port State Transition** – This state machine transitions the port to a discarding, learning, or forwarding state and performs any necessary processing associated with the state changes.

- **Port Timers** – This state machine is responsible for triggering any of the state machines described above, based on expiration of specific port timers.
In contrast to the 802.1D standard, the 802.1W standard does not have any bridge specific timers. All timers in the CLI are applied on a per-port basis, even though they are configured under bridge parameters.

802.1W state machines attempt to quickly place the ports into either a forwarding or discarding state. Root ports are quickly placed in forwarding state when both of the following events occur:

- It is assigned to be the Root port.
- It receives an RST BPDU with a proposal flag from a Designated port. The proposal flag is sent by ports with a Designated role when they are ready to move into a forwarding state.

When a the role of Root port is given to another port, the old Root port is instructed to reroot. The old Root port goes into a discarding state and negotiates with its peer port for a new role and a new state. A peer port is the port on the other bridge to which the port is connected. For example, in Figure 20, Port1 of Switch 200 is the peer port of Port2 of Switch 100.

A port with a Designated role is quickly placed into a forwarding state if one of the following occurs:

- The Designated port receives an RST BPDU that contains an agreement flag from a Root port
- The Designated port is an Edge port

However, a Designated port that is attached to an Alternate port or a Backup port must wait until the forward delay timer expires twice on that port while it is still in a Designated role, before it can proceed to the forwarding state.

Backup ports are quickly placed into discarding states.

Alternate ports are quickly placed into discarding states.

A port operating in 802.1W mode may enter a learning state to allow MAC entries to be added to the filtering database; however, this state is transient and lasts only a few milliseconds, if the port is operating in 802.1W mode and if the port meets the conditions for rapid transition.

**Handshake mechanisms**

To rapidly transition a Designated or Root port into a forwarding state, the Port Role Transition state machine uses handshake mechanisms to ensure loop free operations. It uses one type of handshake if no Root port has been assigned on a bridge, and another type if a Root port has already been assigned.

**Handshake when no root port is elected**

If a Root port has not been assigned on a bridge, 802.1W uses the **Proposing -> Proposed -> Sync -> Synced -> Agreed handshake:**

- **Proposing** – The Designated port on the root bridge sends an RST BPDU packet to its peer port that contains a proposal flag. The proposal flag is a signal that indicates that the Designated port is ready to put itself in a forwarding state (Figure 20). The Designated port continues to send this flag in its RST BPDU until it is placed in a forwarding state (Figure 23) or is forced to operate in 802.1D mode. (Refer to “Compatibility of 802.1W with 802.1D” on page 309).
- **Proposed** – When a port receives an RST BPDU with a proposal flag from the Designated port on its point-to-point link, it asserts the Proposed signal and one of the following occurs (Figure 20):
  - If the RST BPDU that the port receives is superior to what it can transmit, the port assumes the role of a Root port. (Refer to the section on “Bridges and bridge port roles” on page 282.)
  - If the RST BPDU that the port receives is inferior to what it can transmit, then the port is given the role of Designated port.
NOTE
Proposed will never be asserted if the port is connected on a shared media link.

In Figure 20, Port3/Switch 200 is elected as the Root port.

FIGURE 20  Proposing and proposed stage
• **Sync** – Once the Root port is elected, it sets a sync signal on all the ports on the bridge. The signal tells the ports to synchronize their roles and states (Figure 21). Ports that are non-edge ports with a role of Designated port change into a discarding state. These ports have to negotiate with their peer ports to establish their new roles and states.

**FIGURE 21** Sync stage
• **Synced** – Once the Designated port changes into a discarding state, it asserts a synced signal. Immediately, Alternate ports and Backup ports are synced. The Root port monitors the synced signals from all the bridge ports. Once all bridge ports asserts a synced signal, the Root port asserts its own synced signal (Figure 22).

**FIGURE 22**  Synced stage
Configuring STP related features

- **Agreed** – The Root port sends back an RST BPDU containing an agreed flag to its peer Designated port and moves into the forwarding state. When the peer Designated port receives the RST BPDU, it rapidly transitions into a forwarding state.

**FIGURE 23** Agree stage

At this point, the handshake mechanism is complete between Switch 100, the root bridge, and Switch 200.

Switch 200 updates the information on the Switch 200 Designated ports (Port2 and Port3) and identifies the new root bridge. The Designated ports send RST BPDUs, containing proposal flags, to their downstream bridges, without waiting for the hello timers to expire on them. This process starts the handshake with the downstream bridges.

For example, Port2/Switch 200 sends an RST BPDU to Port2/Switch 300 that contains a proposal flag. Port2/Switch 300 asserts a proposed signal. Ports in Switch 300 then set sync signals on the ports to synchronize and negotiate their roles and states. Then the ports assert a synced signal and when the Root port in Switch 300 asserts its synced signal, it sends an RST BPDU to Switch 200 with an agreed flag.

This handshake is repeated between Switch 200 and Switch 400 until all Designated and Root ports are in forwarding states.
Handshake when a root port has been elected

If a non-root bridge already has a Root port, 802.1W uses a different type of handshake. For example, in Figure 24, a new root bridge is added to the topology.

**FIGURE 24**  Addition of a new root bridge

The handshake that occurs between Switch 60 and Switch 100 follows the one described in the previous section ("Handshake when no root port is elected" on page 288). The former root bridge becomes a non-root bridge and establishes a Root port (Figure 25).

However, since Switch 200 already had a Root port in a forwarding state, 802.1W uses the Proposing -> Proposed -> Sync and Reroot -> Sync and Rerooted -> Rerooted and Synced -> Agreed handshake:
• **Proposing and Proposed** - The Designated port on the new root bridge (Port4/Switch 60) sends an RST BPDU that contains a proposing signal to Port4/Switch 200 to inform the port that it is ready to put itself in a forwarding state (Figure 25). 802.1W algorithm determines that the RST BPDU that Port4/Switch 200 received is superior to what it can generate, so Port4/Switch 200 assumes a Root port role.

**FIGURE 25** New root bridge sending a proposal flag
• **Sync and Reroot** – The Root port then asserts a sync and a reroot signal on all the ports on the bridge. The signal tells the ports that a new Root port has been assigned and they are to renegotiate their new roles and states. The other ports on the bridge assert their sync and reroot signals. Information about the old Root port is discarded from all ports. Designated ports change into discarding states (Figure 26).

**FIGURE 26** Sync and reroot

![Sync and Reroot Diagram]

- Indicates a signal
• **Sync and Rerooted** – When the ports on Switch 200 have completed the reroot phase, they assert their rerooted signals and continue to assert their sync signals as they continue in their discarding states. They also continue to negotiate their roles and states with their peer ports (Figure 27).

**FIGURE 27**  Sync and rerooted

- Indicates an 802.1W signal controlled by the current Root port
• **Synced and Agree** – When all the ports on the bridge assert their synced signals, the new Root port asserts its own synced signal and sends an RST BPDU to Port4/Switch 60 that contains an agreed flag (Figure 27). The Root port also moves into a forwarding state.

**FIGURE 28** Rerooted, synced, and agreed

The old Root port on Switch 200 becomes an Alternate Port (Figure 29). Other ports on that bridge are elected to appropriate roles.
The Designated port on Switch 60 goes into a forwarding state once it receives the RST BPDU with the agreed flag.

**FIGURE 29** Handshake completed after election of new root port

Recall that Switch 200 sent the agreed flag to Port4/Switch 60 and not to Port1/Switch 100 (the port that connects Switch 100 to Switch 200). Therefore, Port1/Switch 100 does not go into forwarding state instantly. It waits until two instances of the forward delay timer expires on the port before it goes into forwarding state.

At this point the handshake between the Switch 60 and Switch 200 is complete.

The remaining bridges (Switch 300 and Switch 400) may have to go through the reroot handshake if a new Root port needs to be assigned.

**Convergence in a simple topology**

The examples in this section illustrate how 802.1W convergence occurs in a simple Layer 2 topology at start-up.

**NOTE**
The remaining examples assume that the appropriate handshake mechanisms occur as port roles and states change.
Convergence at start up

In Figure 30, two bridges Switch 2 and Switch 3 are powered up. There are point-to-point connections between Port3/Switch 2 and Port3/Switch 3.

**FIGURE 30  Convergence between two bridges**

At power up, all ports on Switch 2 and Switch 3 assume Designated port roles and are at discarding states before they receive any RST BPDU.

Port3/Switch 2, with a Designated role, transmits an RST BPDU with a proposal flag to Port3/Switch 3. A ports with a Designated role sends the proposal flag in its RST BPDU when they are ready to move to a forwarding state.

Port3/Switch 3, which starts with a role of Designated port, receives the RST BPDU and finds that it is superior to what it can transmit; therefore, Port3/Switch 3 assumes a new port role, that of a Root port. Port3/Switch 3 transmits an RST BPDU with an agreed flag back to Switch 2 and immediately goes into a forwarding state.

Port3/Switch 2 receives the RST BPDU from Port3/Switch 3 and immediately goes into a forwarding state.

Now 802.1W has fully converged between the two bridges, with Port3/Switch 3 as an operational root port in forwarding state and Port3/Switch 2 as an operational Designated port in forwarding state.
Next, Switch 1 is powered up (Figure 31).

**FIGURE 31** Simple Layer 2 topology

The point-to-point connections between the three bridges are as follows:

- Port2/Switch 1 and Port2/Switch 2
- Port4/Switch 1 and Port4/Switch 3
- Port3/Switch 2 and Port3/Switch 3

Ports 3 and 5 on Switch 1 are physically connected together.

At start up, the ports on Switch 1 assume Designated port roles, which are in discarding state. They begin sending RST BPDUs with proposal flags to move into a forwarding state.

When Port4/Switch 3 receives these RST BPDUs 802.1W algorithm determines that they are better than the RST BPDUs that were previously received on Port3/Switch 3. Port4/Switch 3 is now selected as Root port. This new assignment signals Port3/Switch 3 to begin entering the discarding state and to assume an Alternate port role. As it goes through the transition, Port3/Switch 3 negotiates a new role and state with its peer port, Port3/Switch 2.

Port4/Switch 3 sends an RST BPDU with an agreed flag to Port4/Switch 1. Both ports go into forwarding states.

Port2/Switch 2 receives an RST BPDU. The 802.1W algorithm determines that these RST BPDUs that are superior to any that any port on Switch 2 can transmit; therefore, Port2/Switch 2 assumes the role of a Root port.

The new Root port then signals all ports on the bridge to start synchronization. Since none of the ports are Edge ports, they all enter the discarding state and assume the role of Designated ports. Port3/Switch 2, which previously had a Designated role with a forwarding state, starts the discarding state. They also negotiate port roles and states with their peer ports. Port3/Switch 2 also sends an RST BPU to Port3/Switch 3 with a proposal flag to request permission go into a forwarding state.
The Port2/Switch 2 bridge also sends an RST BPDU with an agreed flag Port2/Switch 1 that Port2 is the new Root port. Both ports go into forwarding states.

Now, Port3/Switch 3 is currently in a discarding state and is negotiating a port role. It received RST BPDUs from Port3/Switch 2. The 802.1W algorithm determines that the RST BPDUs Port3/Switch 3 received are superior to those it can transmit; however, they are not superior to those that are currently being received by the current Root port (Port4). Therefore, Port3 retains the role of Alternate port.

Ports 3/Switch 1 and Port5/Switch 1 are physically connected. Port5/Switch 1 received RST BPDUs that are superior to those received on Port3/Switch 1; therefore, Port5/Switch 1 is given the Backup port role while Port3 is given the Designated port role. Port3/Switch 1, does not go directly into a forwarding state. It waits until the forward delay time expires twice on that port before it can proceed to the forwarding state.

Once convergence is achieved, the active Layer 2 forwarding path converges as shown in Figure 32.

**FIGURE 32** Active Layer 2 path

**Convergence after a link failure**

What happens if a link in the 802.1W topology fails?
For example, Port2/Switch, which is the port that connects Switch 2 to the root bridge (Switch 1), fails. Both Switch 2 and Switch 1 notice the topology change (Figure 33).

**FIGURE 33**  Link failure in the topology

Switch 1 sets its Port2 into a discarding state.

At the same time, Switch 2 assumes the role of a root bridge since its root port failed and it has no operational Alternate port. Port3/Switch 2, which currently has a Designated port role, sends an RST BPDU to Switch 3. The RST BPDU contains a proposal flag and a bridge ID of Switch 2 as its root bridge ID.

When Port3/Switch 3 receives the RST BPDU, 802.1W algorithm determines that they are inferior to those that the port can transmit. Therefore, Port3/Switch 3 is given a new role, that of a Designated port. Port3/Switch 3 then sends an RST BPDU with a proposal flag to Switch 2, along with the new role information. However, the root bridge ID transmitted in the RST BPDU is still Switch 1.

When Port3/Switch 2 receives the RST BPDU, 802.1W algorithm determines that it is superior to the RST BPDU that it can transmit; therefore, Port3/Switch 2 receives a new role; that of a Root port. Port3/Switch 2 then sends an RST BPDU with an agreed flag to Port3/Switch 3. Port3/Switch 2 goes into a forwarding state.

When Port3/Switch 3 receives the RST BPDU that Port3/Switch 2 sent, Port3/Switch 3 changes into a forwarding state, which then completes the full convergence of the topology.

**Convergence at link restoration**

When Port2/Switch 2 is restored, both Switch 2 and Switch 1 recognize the change. Port2/Switch 1 starts assuming the role of a Designated port and sends an RST BPDU containing a proposal flag to Port2/Switch 2.
When Port2/Switch 2 receives the RST BPDUs, 802.1W algorithm determines that the RST BPDUs the port received are better than those received on Port3/Switch 3; therefore, Port2/Switch 2 is given the role of a Root port. All the ports on Switch 2 are informed that a new Root port has been assigned which then signals all the ports to synchronize their roles and states. Port3/Switch 2, which was the previous Root port, enters a discarding state and negotiates with other ports on the bridge to establish its new role and state, until it finally assumes the role of a Designated port.

Next, the following happens:

- Port3/Switch 2, the Designated port, sends an RST BPDU, with a proposal flag to Port3/Switch 3.
- Port2/Switch 2 also sends an RST BPDU with an agreed flag to Port2/Switch 1 and then places itself into a forwarding state.

When Port2/Switch 1 receives the RST BPDU with an agreed flag sent by Port2/Switch 2, it puts that port into a forwarding state. The topology is now fully converged.

When Port3/Switch 3 receives the RST BPDU that Port3/Switch 2 sent, 802.1W algorithm determines that these RST BPDUs are superior to those that Port3/Switch 3 can transmit. Therefore, Port3/Switch 3 is given a new role, that of an Alternate port. Port3/Switch 3 immediately enters a discarding state.

Now Port3/Switch 2 does not go into a forwarding state instantly like the Root port. It waits until the forward delay timer expires twice on that port while it is still in a Designated role, before it can proceed to the forwarding state. The wait, however, does not cause a denial of service, since the essential connectivity in the topology has already been established.

When fully restored, the topology is the same as that shown on Figure 31.
Convergence in a complex 802.1W topology

The following is an example of a complex 802.1W topology.

**FIGURE 34** Complex 802.1W topology

In Figure 34, Switch 5 is selected as the root bridge since it is the bridge with the highest priority. Lines in the figure show the point-to-point connection to the bridges in the topology.

Switch 5 sends an RST BPDU that contains a proposal flag to Port5/Switch 2. When handshakes are completed in Switch 5, Port5/Switch 2 is selected as the Root port on Switch 2. All other ports on Switch 2 are given Designated port role with discarding states.

Port5/Switch 2 then sends an RST BPDU with an agreed flag to Switch 5 to confirm that it is the new Root port and the port enters a forwarding state. Port7 and Port8 are informed of the identity of the new Root port. 802.1W algorithm selects Port7 as the Designated port while Port8 becomes the Backup port.

Port3/Switch 5 sends an RST BPDU to Port3/Switch 6 with a proposal flag. When Port3/Switch 5 receives the RST BPDU, handshake mechanisms select Port3 as the Root port of Switch 6. All other ports on Switch 2 are given a Designated port role with discarding states. Port3/Switch 6 then sends an RST BPDU with an agreed flag to Port3/Switch 5 to confirm that it is the Root port. The Root port then goes into a forwarding state.

Now, Port4/Switch 6 receives RST BPDUs that are superior to what it can transmit; therefore, it is given the Alternate port role. The port remains in discarding state.

Port5/Switch 6 receives RST BPDUs that are inferior to what it can transmit. The port is then given a Designated port role.
Next Switch 2 sends RST BPDUs with a proposal flag to Port3/Switch 4. Port3 becomes the Root port for the bridge; all other ports are given a Designated port role with discarding states. Port3/Switch 4 sends an RST BPDU with an agreed flag to Switch 2 to confirm that it is the new Root port. The port then goes into a forwarding state.

Now Port4/Switch 4 receives an RST BPDU that is superior to what it can transmit. The port is then given an Alternate port role, and remains in discarding state.

Likewise, Port5/Switch 4 receives an RST BPDU that is superior to what it can transmit. The port is also given an Alternate port role, and remains in discarding state.

Port2/Switch 2 transmits an RST BPDU with a proposal flag to Port2/Switch 1. Port2/Switch 1 becomes the Root port. All other ports on Switch 1 are given Designated port roles with discarding states.

Port2/Switch 1 sends an RST BPDU with an agreed flag to Port2/Switch 2 and Port2/Switch 1 goes into a forwarding state.

Port3/Switch 1 receives an RST BPDUs that is inferior to what it can transmit; therefore, the port retains its Designated port role and goes into forwarding state only after the forward delay timer expires twice on that port while it is still in a Designated role.

Port3/Switch 2 sends an RST BPDU to Port3/Switch 3 that contains a proposal flag. Port3/Switch 3 becomes the Root port, while all other ports on Switch 3 are given Designated port roles and go into discarding states. Port3/Switch 3 sends an RST BPDU with an agreed flag to Port3/Switch 2 and Port3/Switch 3 goes into a forwarding state.

Now, Port2/Switch 3 receives an RST BPDUs that is superior to what it can transmit so that port is given an Alternate port state.

Port4/Switch 3 receives an RST BPDU that is inferior to what it can transmit; therefore, the port retains its Designated port role.

Ports on all the bridges in the topology with Designated port roles that received RST BPDUs with agreed flags go into forwarding states instantly. However, Designated ports that did not receive RST BPDUs with agreed flags must wait until the forward delay timer expires twice on those port. Only then will these port move into forwarding states.

The entire 802.1W topology converges in less than 300 msec and the essential connectivity is established between the designated ports and their connected root ports.
After convergence is complete, Figure 35 shows the active Layer 2 path of the topology in Figure 34.

**FIGURE 35  Active Layer 2 path in complex topology**

![Complex Topology Diagram](image)

**Propagation of topology change**

The Topology Change state machine generates and propagates the topology change notification messages on each port. When a Root port or a Designated port goes into a forwarding state, the Topology Change state machine on those ports send a topology change notice (TCN) to all the bridges in the topology to propagate the topology change.

**NOTE**

Edge ports, Alternate ports, or Backup ports do not need to propagate a topology change.

The TCN is sent in the RST BPDU that a port sends. Ports on other bridges in the topology then acknowledge the topology change once they receive the RST BPDU, and send the TCN to other bridges until all the bridges are informed of the topology change.
For example, Port3/Switch 2 in Figure 36, fails. Port4/Switch 3 becomes the new Root port. Port4/Switch 3 sends an RST BPDU with a TCN to Port4/Switch 4. To propagate the topology change, Port4/Switch 4 then starts a TCN timer on itself, on the bridge Root port, and on other ports on that bridge with a Designated role. Then Port3/Switch 4 sends RST BPDU with the TCN to Port4/Switch 2. (Note the new active Layer 2 path in Figure 36.)

**FIGURE 36  Beginning of topology change notice**

Switch 2 then starts the TCN timer on the Designated ports and sends RST BPDUs that contain the TCN as follows (Figure 37):

- Port5/Switch 2 sends the TCN to Port2/Switch 5
- Port4/Switch 2 sends the TCN to Port4/Switch 6
- Port2/Switch 2 sends the TCN to Port2/Switch 1

**FIGURE 37  Sending TCN to bridges connected to Switch 2**

Indicates the active Layer 2 path

Indicates direction of TCN
Then Switch 1, Switch 5, and Switch 6 send RST BPDUs that contain the TCN to Switch 3 and Switch 4 to complete the TCN propagation (Figure 38).

**FIGURE 38  Completing the TCN propagation**

Compatibility of 802.1W with 802.1D

802.1W-enabled bridges are backward compatible with IEEE 802.1D bridges. This compatibility is managed on a per-port basis by the Port Migration state machine. However, intermixing the two types of bridges in the network topology is not advisable if you want to take advantage of the rapid convergence feature.

Compatibility with 802.1D means that an 802.1W-enabled port can send BPDUs in the STP or 802.1D format when one of the following events occur:

- The port receives a legacy BPDU. A legacy BPDU is an STP BPDU or a BPDU in an 802.1D format. The port that receives the legacy BPDU automatically configures itself to behave like a legacy port. It sends and receives legacy BPDUs only.
- The entire bridge is configured to operate in an 802.1D mode when an administrator sets the bridge parameter to zero at the CLI, forcing all ports on the bridge to send legacy BPDUs only.

Once a port operates in the 802.1D mode, 802.1D convergence times are used and rapid convergence is not realized.
For example, in Figure 39, Switch 10 and Switch 30 receive legacy BPDUs from Switch 20. Ports on Switch 10 and Switch 30 begin sending BPDUs in STP format to allow them to operate transparently with Switch 20.

**FIGURE 39  802.1W bridges with an 802.1D bridge**

![Diagram of 802.1W bridges with an 802.1D bridge](image)

Once Switch 20 is removed from the LAN, Switch 10 and Switch 30 receive and transmit BPDUs in the STP format to and from each other. This state will continue until the administrator enables the `force-migration-check` command to force the bridge to send RSTP BPDU during a migrate time period. If ports on the bridges continue to hear only STP BPDUs after this migrate time period, those ports will return to sending STP BPDUs. However, when the ports receive RST BPDUs during the migrate time period, the ports begin sending RST BPDUs. The migrate time period is non-configurable. It has a value of three seconds.

**NOTE**
The IEEE standards state that 802.1W bridges need to interoperate with 802.1D bridges. IEEE standards set the path cost of 802.1W bridges to be between 1 and 200,000,000; whereas path cost of 802.1D bridges are set between 1 and 65,535. In order for the two bridge types to be able to interoperate in the same topology, the administrator needs to configure the bridge path cost appropriately. Path costs for either 802.1W bridges or 802.1D bridges need to be changed; in most cases, path costs for 802.1W bridges need to be changed.

**Configuring 802.1W parameters on a Brocade device**

The remaining 802.1W sections explain how to configure the 802.1W protocol in a Brocade device.

**NOTE**
With RSTP running, enabling static trunk on ports that are members of VLAN 4000 will keep the system busy for 20 to 25 seconds.

Brocade devices are shipped from the factory with 802.1W disabled. Use the following methods to enable or disable 802.1W. You can enable or disable 802.1W at the following levels:

- **Port-based VLAN** – Affects all ports within the specified port-based VLAN. When you enable or disable 802.1W within a port-based VLAN, the setting overrides the global setting. Thus, you can enable 802.1W for the ports within a port-based VLAN even when 802.1W is globally disabled, or disable the ports within a port-based VLAN when 802.1W is globally enabled.
- **Individual port** – Affects only the individual port. However, if you change the 802.1W state of the primary port in a trunk group, the change affects all ports in the trunk group.

**Enabling or disabling 802.1W in a port-based VLAN**

Use the following procedure to disable or enable 802.1W on a device on which you have configured a port-based VLAN. Changing the 802.1W state in a VLAN affects only that VLAN.
To enable 802.1W for all ports in a port-based VLAN, enter commands such as the following.

```
FastIron(config)#vlan 10
FastIron(config-vlan-10)#spanning-tree 802-1w
```

**Syntax:** `[no] spanning-tree 802-1w`

**Note regarding pasting 802.1W settings into the running configuration**

If you paste 802.1W settings into the running configuration, and the pasted configuration includes ports that are already up, the ports will initially operate in STP legacy mode before operating in 802.1W RSTP mode. For example, the following pasted configuration will cause ports e 1 and e 2 to temporarily operate in STP legacy mode, because these ports are already up and running.

```
conf t
vlan 120
tag e 1 to e 2
spanning-tree 802-1w
spanning-tree 802-1w priority 1001
end
```

To avoid this issue, 802.1W commands/settings that are pasted into the configuration should be in the following order.

1. Ports that are not yet connected
2. 802.1W RSTP settings
3. Ports that are already up

**Example**

```
conf t
vlan 120
untag e 3
spanning-tree 802-1w
spanning-tree 802-1w priority 1001
tag e 1 to 2
end
```

In the above configuration, untagged port e3 is added to VLAN 120 before the 802.1W RSTP settings, and ports e1 and e2 are added after the 802.1W RSTP settings. When these commands are pasted into the running configuration, the ports will properly operate in 802.1W RSTP mode.

**Enabling or disabling 802.1W on a single spanning tree**

To enable 802.1W for all ports of a single spanning tree, enter a command such as the following.

```
FastIron(config-vlan-10)#spanning-tree single 802-1w
```

**Syntax:** `[no] spanning-tree single 802-1w`

**Disabling or enabling 802.1W on an individual port**

The `spanning-tree 802-1w` or `spanning-tree single 802-1w` command must be used to initially enable 802.1W on ports. Both commands enable 802.1W on all ports that belong to the VLAN or to the single spanning tree.

Once 802.1W is enabled on a port, it can be disabled on individual ports. 802.1W that have been disabled on individual ports can then be enabled as required.
NOTE
If you change the 802.1W state of the primary port in a trunk group, the change affects all ports in that trunk group.

To disable or enable 802.1W on an individual port, enter commands such as the following.

FastIron(config)#interface e 1
FastIron(config-if-e1000-1)#no spanning-tree

Syntax: [no] spanning-tree

Changing 802.1W bridge parameters
When you make changes to 802.1W bridge parameters, the changes are applied to individual ports on the bridge. To change 802.1W bridge parameters, use the following methods.

To designate a priority for a bridge, enter a command such as the following.

FastIron(config)#spanning-tree 802-1w priority 10

The command in this example changes the priority on a device on which you have not configured port-based VLANs. The change applies to the default VLAN. If you have configured a port-based VLAN on the device, you can configure the parameters only at the configuration level for individual VLANs. Enter commands such as the following.

FastIron(config)#vlan 20
FastIron(config-vlan-20)#spanning-tree 802-1w priority 0

To make this change in the default VLAN, enter the following commands.

FastIron(config)#vlan 1
FastIron(config-vlan-1)#spanning-tree 802-1w priority 0

Syntax: spanning-tree 802-1w [forward-delay <value>] | [hello-time <value>] | [max-age <time>] | [force-version <value>] | [priority <value>]

The forward-delay <value> parameter specifies how long a port waits before it forwards an RST BPDU after a topology change. This can be a value from 4 – 30 seconds. The default is 15 seconds.

The hello-time <value> parameter specifies the interval between two hello packets. This parameter can have a value from 1 – 10 seconds. The default is 2 seconds.

The max-age <value> parameter specifies the amount of time the device waits to receive a hello packet before it initiates a topology change. You can specify a value from 6 – 40 seconds. The default is 20 seconds.

The value of max-age must be greater than the value of forward-delay to ensure that the downstream bridges do not age out faster than the upstream bridges (those bridges that are closer to the root bridge).

The force-version <value> parameter forces the bridge to send BPDUs in a specific format. You can specify one of the following values:

- 0 – The STP compatibility mode. Only STP (or legacy) BPDUs will be sent.
- 2 – The default. RST BPDUs will be sent unless a legacy bridge is detected. If a legacy bridge is detected, STP BPDUs will be sent instead.

The default is 2.
The **priority** `<value>` parameter specifies the priority of the bridge. You can enter a value from 0 – 65535. A lower numerical value means the bridge has a higher priority. Thus, the highest priority is 0. The default is 32768.

You can specify some or all of these parameters on the same command line. If you specify more than one parameter, you must specify them in the order shown above, from left to right.

**Changing port parameters**

The 802.1W port commands can be enabled on individual ports or on multiple ports, such as all ports that belong to a VLAN.

The 802.1W port parameters are preconfigured with default values. If the default parameters meet your network requirements, no other action is required.

You can change the following 802.1W port parameters using the following method.

```
FastIron(config)#vlan 10
FastIron(config-vlan-10)#spanning-tree 802-1w ethernet 5 path-cost 15 priority 64
```

**Syntax:** `spanning-tree 802-1w ethernet [<stack-unit>/]<slotnum/>[<portnum>] path-cost <value> | priority <value> | [admin-edge-port] | [admin-pt2pt-mac] | [force-migration-check]`

The `<portnum>` parameter specifies the interface used. If you are configuring a chassis device, specify the slot number as well as the port number (`<slotnum>/` `<portnum>`).

The **path-cost** `<value>` parameter specifies the cost of the port path to the root bridge. 802.1W prefers the path with the lowest cost. You can specify a value from 1 – 20,000,000. Table 74 shows the recommended path cost values from the IEEE standards.

**TABLE 74** Recommended path cost values of 802.1W

<table>
<thead>

</tr>
</tbody>
</table>

The **priority** `<value>` parameter specifies the preference that 802.1W gives to this port relative to other ports for forwarding traffic out of the topology. Y

- In releases prior to 03.0.00, you can specify a value from 8 – 252, in increments of 4. If you enter a value that is not divisible by four the software rounds to the nearest value that is. The default is 128. A higher numerical value means a lower priority; thus, the highest priority is 8.
- Starting in software release 03.0.00, you can specify a value from 0 – 240, in increments of 16. If you enter a value that is not divisible by 16, the software returns an error message. The default value is 128. A higher numerical value means a lower priority; thus, the highest priority is 0.
Set the **admin-edge-port** to enabled or disabled. If set to enabled, then the port becomes an edge port in the domain.

Set the **admin-pt2pt-mac** to enabled or disabled. If set to enabled, then a port is connected to another port through a point-to-point link. The point-to-point link increases the speed of convergence. This parameter, however, does not auto-detect whether or not the link is a physical point-to-point link.

The **force-migration-check** parameter forces the specified port to sent one RST BPDU. If only STP BPDUs are received in response to the sent RST BPDU, then the port will go return to sending STP BPDUs.

**Example**

Suppose you want to enable 802.1W on a system with no active port-based VLANs and change the hello-time from the default value of 2 to 8 seconds. Additionally, suppose you want to change the path and priority costs for port 5 only. To do so, enter the following commands.

```
FastIron(config)#spanning-tree 802-1w hello-time 8
FastIron(config)#spanning-tree 802-1w ethernet 5 path-cost 15 priority 64
```

**Displaying information about 802-1W**

To display a summary of 802-1W, use the following command.

```
FastIron#show 802-1w
```

```

<tr>
<td>Root Port</td>
<td>The port on which the root information was received. This is the port that is connected to the Designated Bridge.</td>
</tr>
<tr>
<td>Max Age</td>
<td>The max age is derived from the Root port. An 802.1W-enabled bridge uses this value, along with the hello and message age parameters to compute the effective age of an RST BPDU. The message age parameter is generated by the Designated port and transmitted in the RST BPDU. RST BPDU transmitted by a Designated port of the root bridge contains a message value of zero. Effective age is the amount of time the Root port, Alternate port, or Backup port retains the information it received from its peer Designated port. Effective age is reset every time a port receives an RST BPDU from its Designated port. If a Root port does not receive an RST BPDU from its peer Designated port for a duration more than the effective age, the Root port ages out the existing information and recomputes the topology. If the port is operating in 802.1D compatible mode, then max age functionality is the same as in 802.1D (STP).</td>

</tbody>
</table>
As an alternative to full 802.1W, you can configure 802.1W Draft 3. 802.1W Draft 3 provides a subset of the RSTP capabilities described in the 802.1W STP specification.

802.1W Draft 3 support is disabled by default. When the feature is enabled, if a root port on a Brocade device that is not the root bridge becomes unavailable, the device can automatically Switch over to an alternate root port, without reconvergence delays. 802.1W Draft 3 does not apply to the root bridge, since all the root bridge ports are always in the forwarding state.

Figure 40 shows an example of an optimal STP topology. In this topology, all the non-root bridges have at least two paths to the root bridge (Switch 1 in this example). One of the paths is through the root port. The other path is a backup and is through the alternate port. While the root port is in the forwarding state, the alternate port is in the blocking state.

</table>
If the root port on a Switch becomes unavailable, 802.1W Draft 3 immediately fails over to the alternate port, as shown in Figure 41.

**FIGURE 41** 802.1W Draft 3 RSTP failover to alternate root port
In this example, port 3/3 on Switch 3 has become unavailable. In standard STP (802.1D), if the root port becomes unavailable, the Switch must go through the listening and learning stages on the alternate port to reconverge with the spanning tree. Thus, port 3/4 must go through the listening and learning states before entering the forwarding state and thus reconverging with the spanning tree.

802.1W Draft 3 avoids the reconvergence delay by calculating an alternate root port, and immediately failing over to the alternate port if the root port becomes unavailable. The alternate port is in the blocking state as long as the root port is in the forwarding state, but moves immediately to the active state if the root port becomes unavailable. Thus, using 802.1W Draft 3, Switch 3 immediately fails over to port 3/4, without the delays caused by the listening and learning states.

802.1W Draft 3 selects the port with the next-best cost to the root bridge. For example, on Switch 3, port 3/3 has the best cost to the root bridge and thus is selected by STP as the root port. Port 3/4 has the next-best cost to the root bridge, and thus is selected by 802.1W Draft 3 as the alternate path to the root bridge.
Once a failover occurs, the Switch no longer has an alternate root port. If the port that was an alternate port but became the root port fails, standard STP is used to reconverge with the network. You can minimize the reconvergence delay in this case by setting the forwarding delay on the root bridge to a lower value. For example, if the forwarding delay is set to 15 seconds (the default), change the forwarding delay to a value from 3 – 10 seconds.

During failover, 802.1W Draft 3 flushes the MAC addresses leaned on the unavailable root port, selects the alternate port as the new root port, and places that port in the forwarding state. If traffic is flowing in both directions on the new root port, addresses are flushed (moved) in the rest of the spanning tree automatically.

**Reconvergence time**

Spanning tree reconvergence using 802.1W Draft 3 can occur within one second.

After the spanning tree reconverges following the topology change, traffic also must reconverge on all the bridges attached to the spanning tree. This is true regardless of whether 802.1W Draft 3 or standard STP is used to reconverge the spanning tree.

Traffic reconvergence happens after the spanning tree reconvergence, and is achieved by flushing the Layer 2 information on the bridges:

- Following 802.1W Draft 3 reconvergence of the spanning tree, traffic reconvergence occurs in the time it takes for the bridge to detect the link changes plus the STP maximum age set on the bridge.
- If standard STP reconvergence occurs instead, traffic reconvergence takes two times the forward delay plus the maximum age.

**NOTE**

802.1W Draft 3 does not apply when a failed root port comes back up. When this happens, standard STP is used.

**Configuration considerations**

802.1W Draft 3 is disabled by default. To ensure optimal performance of the feature before you enable it, do the following:

- Configure the bridge priorities so that the root bridge is one that supports 802.1W Draft 3. (Use a Brocade device or third-party device that supports 802.1W Draft 3.)
- Change the forwarding delay on the root bridge to a value lower than the default 15 seconds. Brocade recommends a value from 3 – 10 seconds. The lower forwarding delay helps reduce reconvergence delays in cases where 802.1W Draft 3 is not applicable, such as when a failed root port comes back up.
- Configure the bridge priorities and root port costs so that each device has an active path to the root bridge if its root port becomes unavailable. For example, port 3/4 is connected to port 2/4 on Switch 2, which has the second most favorable bridge priority in the spanning tree.

**NOTE**

If reconvergence involves changing the state of a root port on a bridge that supports 802.1D STP but not 802.1W Draft 3, then reconvergence still requires the amount of time it takes for the ports on the 802.1D bridge to change state to forwarding (as needed), and receive BPDUs from the root bridge for the new topology.
Enabling 802.1W Draft 3

802.1W Draft 3 is disabled by default. The procedure for enabling the feature differs depending on whether single STP is enabled on the device.

NOTE
STP must be enabled before you can enable 802.1W Draft 3.

Enabling 802.1W Draft 3 when single STP is not enabled

By default, each port-based VLAN on the device has its own spanning tree. To enable 802.1W Draft 3 in a port-based VLAN, enter commands such as the following.

FastIron(config)#vlan 10
FastIron(config-vlan-10)#spanning-tree rstp

Syntax: [no] spanning-tree rstp

This command enables 802.1W Draft 3. You must enter the command separately in each port-based VLAN in which you want to run 802.1W Draft 3.

NOTE
This command does not also enable STP. To enable STP, first enter the spanning-tree command without the rstp parameter. After you enable STP, enter the spanning-tree rstp command to enable 802.1W Draft 3.

To disable 802.1W Draft 3, enter the following command.

FastIron(config-vlan-10)#no spanning-tree rstp

Enabling 802.1W Draft 3 when single STP is enabled

To enable 802.1W Draft 3 on a device that is running single STP, enter the following command at the global CONFIG level of the CLI.

FastIron(config)#spanning-tree single rstp

Syntax: [no] spanning-tree single rstp

This command enables 802.1W Draft 3 on the whole device.

NOTE
This command does not also enable single STP. To enable single STP, first enter the spanning-tree single command without the rstp parameter. After you enable single STP, enter the spanning-tree single rstp command to enable 802.1W Draft 3.

To disable 802.1W Draft 3 on a device that is running single STP, enter the following command.

FastIron(config)#no spanning-tree single rstp

Single Spanning Tree (SSTP)

By default, each port-based VLAN on a Brocade device runs a separate spanning tree, which you can enable or disable on an individual VLAN basis.
Alternatively, you can configure a Brocade device to run a single spanning tree across all ports and VLANs on the device. The Single STP feature (SSTP) is especially useful for connecting a Brocade device to third-party devices that run a single spanning tree in accordance with the 802.1Q specification.

SSTP uses the same parameters, with the same value ranges and defaults, as the default STP support on Brocade devices. Refer to “STP parameters and defaults” on page 263.

**SSTP defaults**

SSTP is disabled by default. When you enable the feature, all VLANs on which STP is enabled become members of a single spanning tree. All VLANs on which STP is disabled are excluded from the single spanning tree.

To add a VLAN to the single spanning tree, enable STP on that VLAN. To remove a VLAN from the single spanning tree, disable STP on that VLAN.

When you enable SSTP, all the ports that are in port-based VLANs with STP enabled become members of a single spanning tree domain. Thus, the ports share a single BPDU broadcast domain. The Brocade device places all the ports in a non-configurable VLAN, 4094, to implement the SSTP domain. However, this VLAN does not affect port membership in the port-based VLANs you have configured. Other broadcast traffic is still contained within the individual port-based VLANs. Therefore, you can use SSTP while still using your existing VLAN configurations without changing your network. In addition, SSTP does not affect 802.1Q tagging. Tagged and untagged ports alike can be members of the single spanning tree domain.

**NOTE**

When SSTP is enabled, the BPDUs on tagged ports go out untagged.

If you disable SSTP, all VLANs that were members of the single spanning tree run MSTP instead. In MSTP, each VLAN has its own spanning tree. VLANs that were not members of the single spanning tree were not enabled for STP. Therefore, STP remains disabled on those VLANs.

**Enabling SSTP**

To enable SSTP, use one of the following methods.

**NOTE**

If the device has only one port-based VLAN (the default VLAN), then the device is already running a single instance of STP. In this case, you do not need to enable SSTP. You need to enable SSTP only if the device contains more than one port-based VLAN and you want all the ports to be in the same STP broadcast domain.

To change a global STP parameter, enter a command such as the following at the global CONFIG level.

```
FastIron(config)#spanning-tree single
```

**NOTE**

If the device has only one port-based VLAN, the CLI command for enabling SSTP is not listed in the CLI. The command is listed only if you have configured a port-based VLAN.
Configuring STP related features

FastIron(config) spanning-tree single priority 2
This command changes the STP priority for all ports to 2.

To change an STP parameter for a specific port, enter commands such as the following.

FastIron(config) spanning-tree single ethernet 1 priority 10
The commands shown above override the global setting for STP priority and set the priority to 10 for port 1/1.

Here is the syntax for the global STP parameters.

Syntax: [no] spanning-tree single [forward-delay <value>] [hello-time <value>] | [maximum-age <time>] | [priority <value>]

Here is the syntax for the STP port parameters.

Syntax: [no] spanning-tree single [ethernet [<stack-unit>/<slotnum>/]portnum] path-cost <value> | priority <value>

NOTE
Both commands listed above are entered at the global CONFIG level.

Displaying SSTP information

To verify that SSTP is in effect, enter the following commands at any level of the CLI.

FastIron#show span

Syntax: show span [vlan <vlan-id>] | [pvst-mode] | [<num>] | [detail [vlan <vlan-id> [ethernet [<stack-unit>/<slotnum>/]portnum] | <num>]]

The vlan <vlan-id> parameter displays STP information for the specified port-based VLAN.

The pvst-mode parameter displays STP information for the device Per VLAN Spanning Tree (PVST+) compatibility configuration. Refer to “PVST/PVST+ compatibility” on page 329.

The <num> parameter displays only the entries after the number you specify. For example, on a device with three port-based VLANs, if you enter 1, then information for the second and third VLANs is displayed, but information for the first VLAN is not displayed. Information is displayed according to VLAN number, in ascending order. The entry number is not the same as the VLAN number. For example, if you have port-based VLANs 1, 10, and 2024, then the command output has three STP entries. To display information for VLANs 10 and 2024 only, enter show span 1.

The detail parameter and its additional optional parameters display detailed information for individual ports. Refer to “Displaying detailed STP information for each interface” on page 275.

STP per VLAN group

NOTE
This feature is not supported on TurboIron X Series devices.

STP per VLAN group is an STP enhancement that provides scalability while overcoming the limitations of the following scalability alternatives:

- **Standard STP** – You can configure up to 254 instances of standard STP on a Brocade device. It is possible to need more instances of STP than this in large configurations. Using STP per VLAN group, you can aggregate STP instances.
• **Single STP** – Single STP allows all the VLANs to run STP, but each VLAN runs the same instance of STP, resulting in numerous blocked ports that do not pass any Layer 2 traffic. STP per VLAN group uses all available links by load balancing traffic for different instances of STP on different ports. A port that blocks traffic for one spanning tree forwards traffic for another spanning tree.

STP per VLAN group allows you to group VLANs and apply the same STP parameter settings to all the VLANs in the group. **Figure 42** shows an example of a STP per VLAN group implementation.

**STP load balancing**

Notice that the STP groups each have different STP priorities. In configurations that use the STP groups on multiple devices, you can use the STP priorities to load balance the STP traffic. By setting the STP priorities for the same STP group to different values on each device, you can cause each of the devices to be the root bridge for a different STP group. This type of configuration distributes the traffic evenly across the devices and also ensures that ports that are blocked in one STP group spanning tree are used by another STP group spanning tree for forwarding. Refer to “Configuration example for STP load sharing” on page 328 for an example using STP load sharing.

**Configuring STP per VLAN group**

To configure STP per VLAN group, do the following:

- Configure the member VLANs.
- Optionally, configure master VLANs to contain the member VLANs. This is useful when you have a lot of member VLANs and you do not want to individually configure STP on each one. Each of the member VLANs in the STP group uses the STP settings of the master VLAN.
- Configure the STP groups. Each STP group runs a separate instance of STP.
Here are the CLI commands for implementing the STP per VLAN group configuration shown in Figure 42. The following commands configure the member VLANs (3, 4, 13, and 14) and the master VLANs (2 and 12). Notice that changes to STP parameters are made in the master VLANs only, not in the member VLANs.

```plaintext
FastIron(config)#vlan 2  
FastIron(config-vlan-2)#spanning-tree priority 1  
FastIron(config-vlan-2)#tagged ethernet 1/1 to 1/4  
FastIron(config-vlan-2)#vlan 3  
FastIron(config-vlan-3)#tagged ethernet 1/1 to 1/4  
FastIron(config-vlan-3)#vlan 4  
FastIron(config-vlan-4)#tagged ethernet 1/1 to 1/4  
FastIron(config-vlan-4)#vlan 12  
FastIron(config-vlan-12)#spanning-tree priority 2  
FastIron(config-vlan-12)#tagged ethernet 1/1 to 1/4  
FastIron(config-vlan-12)#vlan 13  
FastIron(config-vlan-13)#tagged ethernet 1/1 to 1/4  
FastIron(config-vlan-13)#vlan 14  
FastIron(config-vlan-14)#tagged ethernet 1/1 to 1/4  
FastIron(config-vlan-14)#exit
```

The following commands configure the STP groups.

```plaintext
FastIron(config)#stp-group 1  
FastIron(config-stp-group-1)#master-vlan 2  
FastIron(config-stp-group-1)#member-vlan 3 to 4  
FastIron(config-stp-group-1)#exit  
FastIron(config)#stp-group 2  
FastIron(config-stp-group-2)#master-vlan 12  
FastIron(config-stp-group-2)#member-vlan 13 to 14
```

**Syntax: [no] stp-group <num>**

This command changes the CLI to the STP group configuration level. The following commands are valid at this level. The `<num>` parameter specifies the STP group ID and can be from 1 – 32.

**Syntax: [no] master-vlan <num>**

This command adds a master VLAN to the STP group. The master VLAN contains the STP settings for all the VLANs in the STP per VLAN group. The `<num>` parameter specifies the VLAN ID. An STP group can contain one master VLAN.

**NOTE**

If you delete the master VLAN from an STP group, the software automatically assigns the first member VLAN in the group to be the new master VLAN for the group.

**Syntax: [no] member-vlan <num> [to <num>]**

This command adds additional VLANs to the STP group. These VLANs also inherit the STP settings of the master VLAN in the group.

**Syntax: [no] member-group <num>**

This command adds a member group (a VLAN group) to the STP group. All the VLANs in the member group inherit the STP settings of the master VLAN in the group. The `<num>` parameter specifies the VLAN group ID.

**NOTE**

This command is optional and is not used in the example above. For an example of this command, refer to “Configuration example for STP load sharing”.

Configuration example for STP load sharing

Figure 43 shows another example of a STP per VLAN group implementation.  

**FIGURE 43** More complex STP per VLAN group example

In this example, each of the devices in the core is configured with a common set of master VLANs, each of which contains one or more member VLANs. Each of the member VLANs in an STP group runs the same instance of STP and uses the STP parameters configured for the master VLAN.

The STP group ID identifies the STP instance. All VLANs within an STP group run the same instance of STP. The master VLAN specifies the bridge STP parameters for the STP group, including the bridge priority. In this example, each of the devices in the core is configured to be the default root bridge for a different master VLAN. This configuration ensures that each link can be used for forwarding some traffic. For example, all the ports on the root bridge for master VLAN 1 are configured to forward BPDUs for master VLAN spanning tree. Ports on the other devices block or forward VLAN 1 traffic based on STP convergence. All the ports on the root bridge for VLAN 2 forward VLAN 2 traffic, and so on.

All the ports are tagged. The ports must be tagged so that they can be in both a member VLAN and the member's master VLAN. For example, port 1/1 - and ports 5/1, 5/2, and 5/3 are in member VLAN 2 and master VLAN 1 (since master VLAN a contains member VLAN 2).

Here are the commands for configuring the root bridge for master VLAN 1 in figure Figure 42 for STP per VLAN group. The first group of commands configures the master VLANs. Notice that the STP priority is set to a different value for each VLAN. In addition, the same VLAN has a different STP priority on each device. This provides load balancing by making each of the devices a root bridge for a different spanning tree.

```
FastIron(config)#vlan 1
FastIron(config-vlan-1)#spanning-tree priority 1
FastIron(config-vlan-1)#tag ethernet 1/1 ethernet 5/1 to 5/3
FastIron(config-vlan-1)#vlan 201
FastIron(config-vlan-201)#spanning-tree priority 2
```
PVST/PVST+ compatibility

The FastIron and TurboIron family of switches support Cisco's Per VLAN Spanning Tree plus (PVST+), by allowing the device to run multiple spanning trees (MSTP) while also interoperating with IEEE 802.1Q devices.¹
NOTE
Brocade ports automatically detect PVST+ BPDUs and enable support for the BPDUs once detected. You do not need to perform any configuration steps to enable PVST+ support. However, to support the IEEE 802.1Q BPDUs, you might need to enable dual-mode support.

Support for Cisco’s Per VLAN Spanning Tree plus (PVST+), allows a Brocade device to run multiple spanning trees (MSTP) while also interoperating with IEEE 802.1Q devices. Brocade ports automatically detect PVST+ BPDUs and enable support for the BPDUs once detected. The enhancement allows a port that is in PVST+ compatibility mode due to auto-detection to revert to the default MSTP mode when one of the following events occurs:

- The link is disconnected or broken
- The link is administratively disabled
- The link is disabled by interaction with the link-keepalive protocol

This enhancement allows a port that was originally interoperating with PVST+ to revert to MSTP when connected to a Brocade device.

Overview of PVST and PVST+

**Per VLAN Spanning Tree (PVST)** is a Cisco proprietary protocol that allows a Cisco device to have multiple spanning trees. The Cisco device can interoperate with spanning trees on other PVST devices but cannot interoperate with IEEE 802.1Q devices. An IEEE 802.1Q device has all its ports running a single spanning tree. **PVST+** is an extension of PVST that allows a Cisco device to also interoperate with devices that are running a single spanning tree (IEEE 802.1Q).

Enhanced PVST+ support allows a Brocade device to interoperate with PVST spanning trees and the IEEE 802.1Q spanning tree at the same time.

IEEE 802.1Q and PVST regions cannot interoperate directly but can interoperate indirectly through PVST+ regions. PVST BPDUs are tunneled through 802.1Q regions, while PVST BPDUs for VLAN 1 (the IEEE 802.1Q VLAN) are processed by PVST+ regions. Figure 44 shows the interaction of IEEE 802.1Q, PVST, and PVST+ regions.

**FIGURE 44** Interaction of IEEE 802.1Q, PVST, and PVST+ regions

1. Cisco user documentation for PVST/PVST+ refers to the IEEE 802.1Q spanning tree as the Common Spanning Tree (CST).
VLAN tags and dual mode

The **dual-mode** feature enables a port to send and receive both tagged and untagged frames. When the dual-mode feature is enabled on a port, the port is an untagged member of one of its VLANs and is at the same time a tagged member of all its other VLANs. The untagged frames are supported on the port **Port Native VLAN**.

The dual-mode feature must be enabled on a Brocade port in order to interoperate with another vendor device. Some vendors use VLAN 1 by default to support the IEEE 802.1Q-based standard spanning tree protocols, such as 802.1d and 802.1w for sending untagged frames on VLAN 1. On Brocade switches, by default, the **Port Native VLAN** is the same as the **Default VLAN**, which is VLAN 1. Thus, to support IEEE 802.1Q in a typical configuration, a port must be able to send and receive untagged frames for VLAN 1 and tagged frames for the other VLANs, and interoperate with other vendor devices using VLAN 1.

If you want to use tagged frames on VLAN 1, you can change the default VLAN ID to an ID other than 1. You also can specify the VLAN on which you want the port to send and receive untagged frames (the Port Native VLAN). The Port Native VLAN ID does not need to be the same as the default VLAN. Make sure that the untagged (native) VLAN is also changed on the interoperating vendor side to match that on the Brocade side.

To support the IEEE 802.1Q with non-standard proprietary protocols such as PVST and PVST+, a port must always send and receive untagged frames on VLAN 1 on both sides. In this case, enable the dual-mode 1 feature to allow untagged BPDUs on VLAN 1 and use Native VLAN 1 on the interoperating vendor side. You should not use VLAN 1 for tagged frames in this case.
Configuring PVST+ support

PVST+ support is automatically enabled when the port receives a PVST BPDU. You can manually enable the support at any time or disable the support if desired.

If you want a tagged port to also support IEEE 802.1Q BPDUs, you need to enable the dual-mode feature on the port. The dual-mode feature is disabled by default and must be enabled manually.

A port that is in PVST+ compatibility mode due to auto-detection reverts to the default MSTP mode when one of the following events occurs:

- The link is disconnected or broken
- The link is administratively disabled
- The link is disabled by interaction with the link-keepalive protocol

This allows a port that was originally interoperating with PVST+ to revert to MSTP when connected to a Brocade device.

Enabling PVST+ support manually

To immediately enable PVST+ support on a port, enter commands such as the following.

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-1/1)#pvst-mode
```

Syntax: `[no] pvst-mode`

**NOTE**

If you disable PVST+ support, the software still automatically enables PVST+ support if the port receives a BPDU with PVST+ format.

**NOTE**

If 802.1W and pvst-mode (either by auto-detection or by explicit configuration) are enabled on a tagged VLAN port, 802.1W will treat the PVST BPDUs as legacy 802.1D BPDUs.

Enabling dual-mode support

To enable the dual-mode feature on a port, enter the following command at the interface configuration level for the port.

```
FastIron(config-if-1/1)#dual-mode
```

Syntax: `[no] dual-mode [<vlan-id>]`

The `<vlan-id>` specifies the port Port Native VLAN. This is the VLAN on which the port will support untagged frames. By default, the Port Native VLAN is the same as the default VLAN (which is VLAN 1 by default).

For more information about the dual-mode feature, refer to “Dual-mode VLAN ports” on page 535.

Displaying PVST+ support information

To display PVST+ information for ports on a Brocade device, enter the following command at any level of the CLI.
Syntax: show span pvst-mode

This command displays the following information.

TABLE 77 CLI display of PVST+ information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The Brocade port number.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> The command lists information only for the ports on which PVST+ support is enabled.</td>
</tr>
<tr>
<td>Method</td>
<td>The method by which PVST+ support was enabled on the port. The method can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Set by configuration – You enabled the support.</td>
</tr>
<tr>
<td></td>
<td>• Set by auto-detect – The support was enabled automatically when the port received a PVST+ BPDU.</td>
</tr>
</tbody>
</table>

Configuration examples

The following examples show configuration examples for two common configurations:

- Untagged IEEE 802.1Q BPDUs on VLAN 1 and tagged PVST+ BPDUs on other VLANs
- Tagged IEEE 802.1Q BPDUs on VLAN 1 and untagged BPDUs on another VLAN

**Tagged port using default VLAN 1 as its port native VLAN**

Figure 45 shows an example of a PVST+ configuration that uses VLAN 1 as the untagged default VLAN and VLANs 2, 3, and 4 as tagged VLANs.

**FIGURE 45** Default VLAN 1 for untagged BPDU

To implement this configuration, enter the following commands.
PVST/PVST+ compatibility

Commands on the Brocade Device

FastIron(config)#vlan-group 1 vlan 2 to 4
FastIron(config-vlan-group-1)#tagged ethernet 1/1
FastIron(config-vlan-group-1)#exit
FastIron(config)#interface ethernet 1/1
FastIron(config-if-1/1)#dual-mode
FastIron(config-if-1/1)#pvst-mode

These commands configure a VLAN group containing VLANs 2, 3, and 4, add port 1/1 as a tagged port to the VLANs, and enable the dual-mode feature and PVST+ support on the port. The dual-mode feature allows the port to send and receive untagged frames for the default VLAN (VLAN 1 in this case) in addition to tagged frames for VLANs 2, 3, and 4. Enabling the PVST+ support ensures that the port is ready to send and receive PVST+ BPDUs. If you do not manually enable PVST+ support, the support is not enabled until the port receives a PVST+ BPDU.

The configuration leaves the default VLAN and the port Port Native VLAN unchanged. The default VLAN is 1 and the port Port Native VLAN also is 1. The dual-mode feature supports untagged frames on the default VLAN only. Thus, port 1/1 can send and receive untagged BPDUs for VLAN 1 and can send and receive tagged BPDUs for the other VLANs.

Port 1/1 will process BPDUs as follows:

- Process IEEE 802.1Q BPDUs for VLAN 1.
- Process tagged PVST BPDUs for VLANs 2, 3, and 4.
- Drop untagged PVST BPDUs for VLAN 1.

Untagged port using VLAN 2 as port native VLAN

Figure 46 shows an example in which a port Port Native VLAN is not VLAN 1. In this case, VLAN 1 uses tagged frames and VLAN 2 uses untagged frames.

FIGURE 46 Port Native VLAN 2 for Untagged BPDUs

To implement this configuration, enter the following commands.

Commands on the Brocade Device

FastIron(config)#default-vlan-id 4000
FastIron(config)#vlan 1
FastIron(config-vlan-1)#tagged ethernet 1/1
FastIron(config-vlan-1)#exit
FastIron(config)#vlan 2
FastIron(config-vlan-2)#tagged ethernet 1/1
FastIron(config-vlan-2)#exit
FastIron(config)#interface ethernet 1/1
FastIron(config-if-1/1)#dual-mode 2
FastIron(config-if-1/1)#pvst-mode
FastIron(config-if-1/1)#exit
These commands change the default VLAN ID, configure port 1/1 as a tagged member of VLANs 1 and 2, and enable the dual-mode feature and PVST+ support on port 1/1. Since VLAN 1 is tagged in this configuration, the default VLAN ID must be changed from VLAN 1 to another VLAN ID. Changing the default VLAN ID from 1 allows the port to process tagged frames for VLAN 1. VLAN 2 is specified with the dual-mode command, which makes VLAN 2 the port Port Native VLAN. As a result, the port processes untagged frames and untagged PVST BPDUs on VLAN 2.

**NOTE**
Although VLAN 2 becomes the port untagged VLAN, the CLI still requires that you add the port to the VLAN as a tagged port, since the port is a member of more than one VLAN.

Port 1/1 will process BPDUs as follows:

- Process IEEE 802.1Q BPDUs for VLAN 1.
- Process untagged PVST BPDUs for VLAN 2.
- Drop tagged PVST BPDUs for VLAN 1.

Note that when VLAN 1 is not the default VLAN, the ports must have the dual-mode feature enabled in order to process IEEE 802.1Q BPDUs.

For example, the following configuration is incorrect.

```
FastIron(config)#default-vlan-id 1000
FastIron(config)#vlan 1
FastIron(config-vlan-1)#tagged ethernet 1/1 to 1/2
FastIron(config-vlan-1)#exit
FastIron(config)#interface ethernet 1/1
FastIron(config-if-1/1)#pvst-mode
FastIron(config-if-1/1)#exit
FastIron(config)#interface ethernet 1/2
FastIron(config-if-1/2)#pvst-mode
FastIron(config-if-1/2)#exit
```

In the configuration above, all PVST BPDUs associated with VLAN 1 would be discarded. Since IEEE BPDUs associated with VLAN 1 are untagged, they are discarded because the ports in VLAN 1 are tagged. Effectively, the BPDUs are never processed by the Spanning Tree Protocol. STP assumes that there is no better bridge on the network and sets the ports to FORWARDING. This could cause a Layer 2 loop.

The following configuration is correct.

```
FastIron(config)#default-vlan-id 1000
FastIron(config)#vlan 1
FastIron(config-vlan-1)#tagged ethernet 1/1 to 1/2
FastIron(config-vlan-1)#exit
FastIron(config)#interface ethernet 1/1
FastIron(config-if-1/1)#pvst-mode
FastIron(config-if-1/1)#dual-mode
FastIron(config-if-1/1)#exit
FastIron(config)#interface ethernet 1/2
FastIron(config-if-1/2)#pvst-mode
FastIron(config-if-1/2)#dual-mode
FastIron(config-if-1/2)#exit
```

Setting the ports as dual-mode ensures that the untagged IEEE 802.1Q BPDUs reach the VLAN 1 instance.
PVRST compatibility

Platform Support:
- FastIron X Series devices running software release 02.5.00 and later
- FGS and FLS devices running software release 02.5.00 and later
- TurboIron X Series devices running software release 04.1.00 and later

PVRST, the "rapid" version of per-VLAN spanning tree (PVST), is a Cisco proprietary protocol. PVRST corresponds to the Brocade full implementation of IEEE 802.1w (RSTP). Likewise, PVST, also a Cisco proprietary protocol, corresponds to the Brocade implementation of IEEE 802.1D (STP).

The following apply to FastIron devices:
- In releases prior to 02.5.00, when a Brocade device receives a PVRST packet on a port running 802.1w, the 802.1w state machines for that port falls back to the classic or legacy, 802.1D compatibility mode. Once moved to the legacy 802.1D mode, the Brocade device works in the standard STP mode and the rapid convergence advantage of 802.1w is no longer available.
- Software release 02.5.00 implements compatibility with PVRST on FastIron X Series and FastIron GS devices. When a Brocade device receives PVRST BPDUs on a port configured to run 802.1w, it recognizes and processes these BPDUs and continues to operate in 802.1w mode.

TurboIron X Series devices also support PVRST compatibility. When it receives PVRST BPDUs on a port configured to run 802.1w, it recognizes and processes these BPDUs and continues to operate in 802.1w mode.

PVRST compatibility is automatically enabled in software release 02.5.00 and later when a port receives a PVRST BPU.

BPDU guard

Platform Support:
- FastIron X Series devices running software release 03.2.00 and later
- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

In an STP environment, switches, end stations, and other Layer 2 devices use Bridge Protocol Data Units (BPDUs) to exchange information that STP will use to determine the best path for data flow.

The BPDU guard, an enhancement to STP, removes a node that reflects BPDUs back in the network. It enforces the STP domain borders and keeps the active topology predictable by not allowing any network devices behind a BPDU guard-enabled port to participate in STP.

In some instances, it is unnecessary for a connected device, such as an end station, to initiate or participate in an STP topology change. In this case, you can enable the STP BPDU guard feature on the Brocade port to which the end station is connected. STP BPDU guard shuts down the port and puts it into an errdisable state. This disables the connected device’s ability to initiate or participate...
in an STP topology. A log message is then generated for a BPDU guard violation, and a CLI message is displayed to warn the network administrator of a severe invalid configuration. The BPDU guard feature provides a secure response to invalid configurations because the administrator must manually put the interface back in service if errdisable recovery is not enabled.

**Enabling BPDU protection by port**

You enable STP BPDU guard on individual interfaces. The feature is disabled by default.

To enable STP BPDU guard on a specific port, enter commands such as the following.

```
FastIron(config) interface ethe 2/1
FastIron(config-if-e1000-2/1)#stp-bpdu-guard
```

or

```
FGS624P Switch(config) interface ethe 0/1/2
FGS624P Switch(config-if-e1000-0/1/2)#stp-bpdu-guard
```

**Syntax:** `[no] stp-bpdu-guard`

The `no` parameter disables the BPDU guard on this interface.

You can also use the multiple interface command to enable this feature on multiple ports at once.

**Example**

```
FastIron(config)#interface ethernet 1/1 to 1/9
FastIron(config-mif-1/1-1/9)#stp-bpdu-guard
```

or

```
FGS624P Switch(config)#interface ethernet 0/1/1 to 0/1/9
FGS624P Switch(config-mif-0/1/1-0/1/9)#stp-bpdu-guard
```

This will enable stp-bpdu-guard on ports 0/1/1 to 0/1/9

**Re-enabling ports disabled by BPDU guard**

When a BPSU Guard-enabled port is disabled by BPSU Guard, the Brocade device will place the port in errdisable state and display a message on the console indicating that the port is errdisabled (refer to “Example console messages” on page 339). In addition, the `show interface` command output will indicate that the port is errdisabled.

**Example**

```
FastIron#show int e 2
Gigabit Ethernet2 is ERR-DISABLED (bpduguard), line protocol is down
```

To re-enable a port that is in errdisable state, you must first disable the port then re-enable it. Enter commands such as the following.

```
FastIron(config)#int e 2
FastIron(config-if-e1000-2)#disable
FastIron(config-if-e1000-2)#enable
```

If you attempt to enable an errdisabled port without first disabling it, the following error message will appear on the console.
BPDU guard

FastIron(config-if-e1000-2)#enable
Port 2 is errdisabled, do disable first and then enable to enable it

Displaying the BPDU guard status

To display the BPDU guard state, enter the `show running configuration` or the `show stp-bpdu-guard` command.

For FastIron X Series devices, enter the following commands.

FastIron#show stp-bpdu-guard
BPDU Guard Enabled on:
Interface Violation
Port 1 No
Port 2 No
Port 3 No
Port 4 No
Port 5 No
Port 6 No
Port 7 No
Port 8 No
Port 9 No
Port 10 No
Port 11 No
Port 12 Yes
Port 13 No

For FGS and FLS, and FGS-STK and FLS-STK devices, enter the following commands.

FGS624P Switch#show stp-bpdu-guard
BPDU Guard Enabled on:
Ports: (Stk0/S1)   2   3   4   5   9  10  11  12  13  14  15  16
Ports: (Stk0/S1)  17  18  19  20  21  22  23  24

Syntax:  show stp-bpdu-guard

Example configurations

Example

The following example shows how to configure BPDU guard at the interface level and to verify the configuration by issuing the `show stp-bpdu-guard` and the `show interface` commands.

FastIron Router(config)#interface ethernet 1
FastIron Router(config-if-e1000-1)#stp-bpdu-guard
FastIron Router(config-if-e1000-1)#
FastIron Router(config-if-e1000-1)#show stp-bpdu-guard
BPDU Guard Enabled on:
Port
1
FastIron(config-if-e1000-1)#
FastIron(config-if-e1000-1)#show interfaces ethernet 1
GigabitEthernet1 is up, line protocol is up
Hardware is GigabitEthernet, address is 000c.dba0.7100 (bia 000c.dba0.7100)
Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
Configured mdi mode AUTO, actual MDI
Member of L2 VLAN ID 2, port is untagged, port state is FORWARDING
BPDU guard is Enabled, ROOT protect is Disabled
STP configured to ON, priority is level0, flow control enabled
mirror disabled, monitor disabled
BPDU guard

FastIron and TurboIron 24X Configuration Guide

For FGS and FLS devices running software release 03.0.00, enter the following commands.

FGS624P Switch(config)#interface ethernet 0/1/1
FGS624P Switch(config-if-e1000-0/1/1)#stp-bpdu-guard
FGS624P Switch(config-if-e1000-0/1/1)#exit

FGS624P Switch#show stp-bpdu-guard
BPDU Guard Enabled on:
Ports: (Stk0/S1) 1

FGS624P Switch#show interfaces ethernet 0/1/1
GigabitEthernet0/1/1 is down, line protocol is down
  Hardware is GigabitEthernet, address is 00e0.5204.4000 (bia 00e0.5204.4000)
  Configured speed auto, actual unknown, configured duplex fdx, actual unknown
  Configured mdi mode AUTO, actual unknown
  Member of L2 VLAN ID 1, port is untagged, port state is BLOCKING
  BPDU Guard is enabled, Root Protect is disabled
  STP configured to ON, priority is level0
  Flow Control is config enabled, oper disabled, negotiation disabled
  Mirror disabled, Monitor disabled
  Not member of any active trunks
  Not member of any configured trunks
  No port name
  Inter-Packet Gap (IPG) is 96 bit times
  300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
  300 second output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
  0 packets input, 0 bytes, 0 no buffer
  Received 0 broadcasts, 0 multicasts, 0 unicasts
  0 input errors, 0 CRC, 0 frame, 0 ignored
  0 runts, 0 giants
  0 packets output, 0 bytes, 0 underruns
  Transmitted 0 broadcasts, 0 multicasts, 0 unicasts
  0 output errors, 0 collisions

Example console messages

A console message such as the following is generated after a BPDU guard violation occurs on a system that is running MSTP.

FastIron(config-if-e1000-23)#MSTP: Received BPDU on BPDU guard enabled Port 23, errdisable Port 23

A console message such as the following is generated after a BPDU guard violation occurs on a system that is running STP.
Root guard

Platform Support:
- FastIron X Series devices running software release 03.2.00 and later
- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

The standard STP (802.1D), RSTP (802.1W) or 802.1S does not provide any way for a network administrator to securely enforce the topology of a switched layer 2 network. The forwarding topology of a switched network is calculated based on the root bridge position, along with other parameters. This means any switch can be the root bridge in a network as long as it has the lowest bridge ID. The administrator cannot enforce the position of the root bridge. A better forwarding topology comes with the requirement to place the root bridge at a specific predetermined location. Root Guard can be used to predetermine a root bridge location and prevent rogue or unwanted switches from becoming the root bridge.

When root guard is enabled on a port, it keeps the port in a designated role. If the port receives a superior STP Bridge Protocol Data Units (BPDU), it puts the port into a ROOT-INCONSISTANT state and triggers a log message and an SNMP trap. The ROOT-INCONSISTANT state is equivalent to the BLOCKING state in 802.1D and to the DISCARDING state in 802.1W. No further traffic is forwarded on this port. This allows the bridge to prevent traffic from being forwarded on ports connected to rogue or misconfigured STP bridges.

Once the port stops receiving superior BPDUs, root guard automatically sets the port back to learning, and eventually to a forwarding state through the spanning-tree algorithm.

Configure root guard on all ports where the root bridge should not appear. This establishes a protective network perimeter around the core bridged network, cutting it off from the user network.

NOTE
Root guard may prevent network connectivity if it is improperly configured. Root guard must be configured on the perimeter of the network rather than the core.

NOTE
Root guard is not supported when MSTP is enabled.

Enabling STP root guard

An STP root guard is configured on an interface by entering commands similar to the following.
FastIron(config)#interface ethernet 5/5
FastIron(config-if-e10000-5/5)spanning-tree root-protect

Syntax: [no] spanning-tree root-protect
Enter the no form of the command to disable STP root guard on the port.

Displaying the STP root guard

To display the STP root guard state, enter the show running configuration or the show spanning-tree root-protect command.

FastIron#show spanning-tree root-protect
Root Protection Enabled on:
Port 1

Syntax: show spanning-tree root-protect

Displaying the root guard by VLAN

You can display root guard information for all VLANs or for a specific VLAN. For example, to display root guard violation information for VLAN 7.

Syntax: show spanning-tree [vlan-id]

If you do not specify a vlan-id, information for all VLANs is displayed. For example, to display root guard violation information for VLAN 7.

FastIron#show spanning-tree vlan 7
STP instance owned by VLAN 7
Global STP (IEEE 802.1D) Parameters:
VLAN Root Root Root Prio Max He- Ho- Fwd Last Chg Bridge
ID ID Cost Port rity Age 11o 1d dly Chang cnt Address
Hex sec sec sec sec sec

Port STP Parameters:
Port Prio Path State Fwd Design Designated Designated
Num rity Cost Trans Cost Root Bridge
Hex
1 80 19 ROOT-INCONS 2 0 a000000011112220 a000000011112220

Error disable recovery

Platform Support:
- FCX-S devices running software release 06.0.00 and later

In case a BPDU guard violation occurs, a port is placed into an errdisable state which is functionally equivalent to a Disable state. Once in an errdisable state, it remains in that state until one of the following methods is used to return the port to an Enabled state.

1. Manually disabling and enabling that interface
2. Automatically, through the errdisable recovery mechanism

The errdisable recovery interval command is used to configure a time-out for ports in errdisable state, after which the ports are re-enabled automatically.
When BPDU guard puts a port into errdisabled state, the port remains in errdisabled state unless it is enabled manually by issuing a `disable` command and then the `enable` command on the associated interface or you have errdisable recovery turned on. The `errdisable` command allows you to choose the type of error that automatically reenables the port after a specified amount of time.

**Enabling error disable recovery**

To enable errdisable recovery for BPDU Guard, enter a command such as the following.

```plaintext
FastIron(config)#errdisable recovery cause bpduguard
```

To enable error disable recovery for any reason, enter a command such as the following.

```plaintext
FastIron(config)#errdisable recovery cause all
```

**Syntax:** `errdisable recovery [cause < bpduguard I all >]`

The `cause` is the reason why the port is in the errdisabled state. Valid values are `bpduguard` and `all`.

Use the `bpduguard` parameter to allow the port to recover from the errdisabled state, if the state was caused by a BPDU Guard violation.

The `all` parameter allows ports to recover from an errdisabled state, if the state was caused by any reason other than a BPDU Guard violation.

**Setting the recovery interval**

The `errdisable recovery interval` command allows you to configure a timeout for ports in errdisabled state, after which the ports are reenabled automatically. To set the errdisable recovery time-out interval, enter a command such as the following.

```plaintext
FastIron(config)#errdisable recovery interval 20
```

**Syntax:** `[no] errdisable recovery interval <seconds>`

The `seconds` parameter allows you to set the timeout value for the recovery mechanism when the port is in an errdisabled state. Once this timeout value expires, the ports are automatically re-enabled. Valid values are from 10 to 65535 seconds (10 seconds to 24 hours).

**Displaying the error disable recovery state by interface**

The port status of errdisabled displays in the output of the `show interface` and the `show interface brief` commands. In this example, errdisable is enabled on interface ethernet 1 and errdisable is enabled because of a BPDU guard violation.

```plaintext
FastIron#show interfaces ethernet 1
GigabitEthernet1 is ERR-DISABLED (bpduguard), line protocol is down
BPDU guard is Enabled, ROOT protect is Disabled
Hardware is GigabitEthernet, address is 000c.dba0.7100 (bia 000c.dba0.7100)
Configured speed auto, actual unknown, configured duplex fdx, actual unknown
Configured mdi mode AUTO, actual unknown
Member of L2 VLAN ID 2, port is untagged, port state is DISABLED
STP configured to ON, priority is level0, flow control enabled
mirror disabled, monitor disabled
Not member of any active trunks
Not member of any configured trunks
No port name
```
IPG MII 96 bits-time, IPG GMII 96 bits-time
IP MTU 1500 bytes
300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
300 second output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
145 packets input, 23561 bytes, 0 no buffer
Received 124 broadcasts, 21 multicasts, 0 unicast
1 input errors, 0 CRC, 0 frame, 0 ignored
0 runts, 0 giants
5067 packets output, 330420 bytes, 0 underruns
Transmitted 90 broadcasts, 4977 multicasts, 0 unicast
0 output errors, 0 collisions

Displaying the recovery state for all conditions

Use the `show errdisable recovery` command to display all the default error disable recovery state for all possible conditions. In this example, port 6 is undergoing a recovery.

```
FastIron#show errdisable recovery
ErrDisable Reason Timer Status
--------------------------------------
all reason Disabled
bpduguard Enabled
Timeout Value: 300 seconds
Interface that will be enabled at the next timeout:
Interface Errdisable reason Time left (sec)
----------------- ----------------- ---------------
Port 6 bpduguard 297
```

Syntax: `show errdisable recovery`

Displaying the recovery state by port number and cause

To see which ports are under an errdisabled state, use the `show errdisable summary` command. This command not only shows the port number, but also displays the reason why the port is in an errdisable state and the method used to recover the port. In this example, port 6 is errdisabled for a BPDU guard violation.

```
FastIron#show errdisable summary
Port 6 ERR_DISABLED for bpduguard
```

Syntax: `show errdisable summary`

Errdisable Syslog messages

When the system places a port into an errdisabled state for BPDU guard, a log message is generated. When the errdisable recovery timer expires, a log message is also generated.

A Syslog message such as the following is generated after a port is placed into an errdisable state for BPDU guard.

```
STP: VLAN 50 BPDU-guard port 3 detect (Received BPDU), putting into err-disable state
```

A Syslog message such as the following is generated after the recovery timer expires.

```
ERR_DISABLED: Interface ethernet 3, err-disable recovery timeout
```
802.1s Multiple Spanning Tree Protocol

Platform Support:

- FastIron X Series devices running software release 03.2.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- Turbolon X Series devices running software release 04.1.00 and later

Multiple Spanning Tree Protocol (MSTP), as defined in IEEE 802.1s, allows multiple VLANs to be managed by a single STP instance and supports per-VLAN STP. As a result, several VLANs can be mapped to a reduced number of spanning-tree instances. This ensures loop-free topology for one or more VLANs that have the similar layer-2 topology. The Brocade implementation supports up to 16 spanning tree instances in an MSTP enabled bridge which means that it can support up to 16 different Layer 2 topologies. The spanning tree algorithm used by MSTP is RSTP which provides quick convergence.

Multiple spanning-tree regions

Using MSTP, the entire network runs a common instance of RSTP. Within that common instance, one or more VLANs can be individually configured into distinct regions. The entire network runs the common spanning tree instance (CST) and the regions run a local instance. The local instance is known as Internal Spanning Tree (IST). The CST treats each instance of IST as a single bridge. Consequently, ports are blocked to prevent loops that might occur within an IST and also throughout the CST. With the exception of the provisions for multiple instances, MSTP operates exactly like RSTP.

For example, in Figure 47 a network is configured with two regions: Region 1 and Region 2. The entire network is running an instance of CST. Each of the regions is running an instance of IST. In addition, this network contains Switch 1 running MSTP that is not configured in a region and consequently is running in the CIST instance. In this configuration, the regions are each regarded as a single bridge to the rest of the network, as is Switch 1. The CST prevents loops from occurring across the network. Consequently, a port is blocked at port 1/2 of switch 4.

Additionally, loops must be prevented in each of the IST instances. Within the IST Region 1, a port is blocked at port 1/2 of switch 4 to prevent a loop in that region. Within Region 2, a port is blocked at port 3/2 of switch 3 to prevent a loop in that region.

FIGURE 47  MSTP configured network
The following definitions describe the STP instances that define an MSTP configuration.

**Common Spanning (CST)** – CST is defined in 802.1q and assumes one spanning-tree instance for the entire bridged network regardless of the number of VLANs. In MSTP, an MSTP region appears as a virtual bridge that runs CST.

**Internal Spanning Tree (IST)** – IST is a new terminology introduced in 802.1s. An MSTP bridge must handle at least these two instances: one IST and one or more MSTIs (Multiple Spanning Tree Instances). Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance known as IST, which extends CST inside the MST region. IST always exists if the switch runs MSTP. Besides IST, this implementation supports up to 15 MSTIs, numbered from 1 to 4094.

**Common and Internal Spanning Trees (CIST)** – CIST is a collection of the ISTs in each MST region and the CST that interconnects the MST regions and single spanning trees.

**Multiple Spanning Tree Instance (MSTI)** – The MSTI is identified by an MST identifier (MSTid) value between 1 and 4094.

**MSTP Region** – These are clusters of bridges that run multiple instances of the MSTP protocol. Multiple bridges detect that they are in the same region by exchanging their configuration (instance to VLAN mapping), name, and revision-level. Therefore, if you need to have two bridges in the same region, the two bridges must have identical configurations, names, and revision-levels. Also, one or more VLANs can be mapped to one MSTP instance (IST or MSTI) but a VLAN cannot be mapped to multiple MSTP instances.

**NOTE**
One or more VLANs can be mapped to one MSTP instance (IST or MSTI) but a VLAN cannot be mapped to multiple MSTP instances.
Configuration notes

When configuring MSTP, note the following:

- With MSTP running, enabling static trunk on ports that are members of many VLANs (4000 or more VLANs) will keep the system busy for 20 to 25 seconds.

Configuring MSTP mode and scope

With the introduction of MSTP, a system can be either under MSTP mode or not under MSTP mode. The default state is to not be under MSTP mode. MSTP configuration can only be performed in a system under MSTP mode.

With a system configured under MSTP mode, there is a concept called MSTP scope. MSTP scope defines the VLANs that are under direct MSTP control. You cannot run 802.1D or 802.1w on any VLAN (even outside of MSTP scope) and you cannot create topology groups when a system is under MSTP mode. While a VLAN group will still be supported when a system is under MSTP mode, the member VLAN should either be all in the MSTP scope or all out of the MSTP scope.

When a system is configured from non-MSTP mode to MSTP mode, the following changes are made to the system configuration:

- All 802.1D and 802.1w STP instances are deleted regardless of whether the VLAN is inside the MSTP scope or not
- All topology groups are deleted
- Any GVRP configuration is deleted
- Any VSRP configuration is deleted
- Single-span (if configured) is deleted
- MRP running on a VLAN inside MSTP scope is deleted
- The CIST is created and all VLANS inside the MSTP scope are attached with the CIST

Make sure that no physical layer-2 loops exist prior to switching from non-MSTP mode to MSTP mode. If, for example, you have an L2 loop topology configured as a redundancy mechanism before you perform the switch, a Layer 2 storm should be expected.

To configure a system into MSTP mode, use the following command at the Global Configuration level.

```
FastIron(config)#mstp scope all
```

**Syntax:** `[no] mstp scope all`

**NOTE**
MSTP is not operational however until the `mstp start` command is issued as described in “Activating MSTP on a switch” on page 353.

Once the system is configured into MSTP mode, CIST (sometimes referred to as “instance 0”) is created and all existing VLANs inside the MSTP scope are controlled by CIST. In addition, whenever you create a new VLAN inside MSTP scope, it is put under CIST control by default. In the Brocade MSTP implementation however, a VLAN ID can be pre-mapped to another MSTI as described in “Configuring an MSTP instance” on page 350. A VLAN whose ID is pre-mapped, will attach to the specified MSTI instead of to the CIST when created.
NOTE
Once under MSTP mode, CIST always controls all ports in the system. If you do not want a port to run MSTP, configure the `no spanning-tree` command under the specified interface configuration.

Using the `[no]` option on a system that is configured for MSTP mode changes the system to non-MSTP mode. When this switch is made, all MSTP instances are deleted together with all MSTP configurations. ALL VLANs inside the original MSTP scope will not run any Layer-2 protocols after the switch.

Reduced occurrences of MSTP reconvergence

Platform Support:
- FastIron X Series devices running software release FSX 04.2.00b and later

In releases prior to FSX 04.2.00b, reconvergence of MSTP occurs whenever a VLAN is created or deleted. Reconvergence is triggered when the VLAN to MSTI mapping for a newly created VLAN is added to the running configuration, and when an existing VLAN to MSTI mapping is deleted from the running configuration.

Starting with release FSX 04.2.00b, when a VLAN is deleted, the Brocade device retains the associated VLAN to MSTI mapping instead of deleting it from the configuration. This way, a VLAN can be pre-mapped to an MSTI and MSTP reconvergence may not be necessary when a VLAN is added to or deleted from the configuration. As long as the VLAN being created or deleted is pre-mapped to an MSTI, and the VLAN to MSTI mapping has not changed, MSTP reconvergence will not occur.

NOTE
MSTP reconvergence occurs when the VLAN to MSTI mapping is changed using the `mstp instance` command.

You can optionally remove VLAN to MSTI mappings from the configuration. Refer to “Deleting a VLAN to MSTI mapping” on page 348.

The following shows an example application.

**Example application**

The following example shows the running configuration file before and after deleting a VLAN from the configuration. In releases FSX 04.2.00b and later, as shown below, the VLAN to MSTI mapping is retained in the running configuration, even after the VLAN is deleted.
Deleting a VLAN to MSTI mapping

You can optionally remove a VLAN to MSTI mapping using the `no mstp instance` command. To do so, enter a command such as the following.

```
FastIron(config)#no mstp instance 7 vlan 4 to 7
```

This command deletes the VLAN to MSTI mapping from the running configuration and triggers an MSTP reconvergence.

**Syntax:** `no mstp instance <instance-number> vlan <vlan-id> | vlan-group <group-id>`
The `instance` parameter defines the number for the instance of MSTP that you are deleting. 

The `vlan` parameter identifies one or more VLANs or a range of VLANs to the instance defined in this command. 

The `vlan-group` parameter identifies one or more VLAN groups to the instance defined in this command. 

**Viewing the MSTP configuration digest**

The MSTP Configuration Digest indicates the occurrence of an MSTP reconvergence. The Configuration Digest is recalculated whenever an MSTP reconvergence occurs. To view the Configuration Digest, use the `show mstp config` command. The following shows an example output.

```
SW-FESX624F+2XG Switch(config-vlan-20)#show mstp config
MSTP CONFIGURATION
------------------
Scope : all system
Name : 
Revision : 0
Version : 3 (MSTP mode)
Config Digest: 0x9bbda9c70d91f633e1e145fbcbf8d321
Status : Started

Instance VLANs
-------- ------------------------------------------------------
0        1                                           
1        10 20
```

Syntax: `show mstp config`

**Configuring additional MSTP parameters**

To configure a switch for MSTP, you could configure the name and the revision on each switch that is being configured for MSTP. You must then create an MSTP Instance and assign an ID. VLANs are then assigned to MSTP instances. These instances must be configured on all switches that interoperate with the same VLAN assignments. Port cost, priority and global parameters can then be configured for individual ports and instances. In addition, operational edge ports and point-to-point links can be created and MSTP can be disabled on individual ports.

Each of the commands used to configure and operate MSTP are described in the following:

- “Setting the MSTP name”
- “Setting the MSTP revision number”
- “Configuring an MSTP instance”
- “Configuring bridge priority for an MSTP instance”
- “Setting the MSTP global parameters”
- “Setting ports to be operational edge ports”
- “Setting automatic operational edge ports”
- “Setting point-to-point link”
- “Disabling MSTP on a port”
- “Forcing ports to transmit an MSTP BPDU”
- “Activating MSTP on a switch”

**Setting the MSTP name**

Each switch that is running MSTP is configured with a name. It applies to the switch which can have many different VLANs that can belong to many different MSTP regions.

To configure an MSTP name, use a command such as the following at the Global Configuration level.

```
FastIron(config)#mstp name Brocade
```

**Syntax:** `[no] mstp name <name>`

The `name` parameter defines an ASCII name for the MSTP configuration. The default name is for the name variable to be blank.

**Setting the MSTP revision number**

Each switch that is running MSTP is configured with a revision number. It applies to the switch which can have many different VLANs that can belong to many different MSTP regions.

To configure an MSTP revision number, use a command such as the following at the Global Configuration level.

```
FastIron(config)#mstp revision 4
```

**Syntax:** `[no] mstp revision <revision-number>`

The `revision` parameter specifies the revision level for MSTP that you are configuring on the switch. It can be a number from 0 and 65535. The default revision number is 0.

**Configuring an MSTP instance**

An MSTP instance is configured with an MSTP ID for each region. Each region can contain one or more VLANs. The Brocade implementation of MSTP allows you to assign VLANs or ranges of VLANs to an MSTP instance before or after they have been defined. If pre-defined, a VLAN will be placed in the MSTI that it was assigned to immediately when the VLAN is created. Otherwise, the default operation is to condition of assign all new VLANs to the CIST. VLANs assigned to the CIST by default can be moved later to a specified MSTI.

To configure an MSTP instance and map one or more VLANs to that MSTI, use a command such as the following at the Global Configuration level.

```
FastIron(config)#mstp instance 7 vlan 4 to 7
```

**Syntax:** `[no] mstp instance <instance-number> [vlan <vlan-id> | vlan-group <group-id>]`

The `instance` parameter defines the number for the instance of MSTP that you are configuring. The value 0 (which identifies the CIST) cannot be used. You can have up to 15 instances, number 1 – 4094.

The `vlan` parameter assigns one or more VLANs or a range of VLANs to the instance defined in this command.

The `vlan-group` parameter assigns one or more VLAN groups to the instance defined in this command.
The **no** option moves a VLAN or VLAN group from its assigned MSTI back into the CIST.

**NOTE**
The system does not allow an MSTI without any VLANs mapped to it. Consequently, removing all VLANs from an MSTI, deletes the MSTI from the system. The CIST by contrast will exist regardless of whether or not any VLANs are assigned to it or not. Consequently, if all VLANs are moved out of a CIST, the CIST will still exist and functional.

---

**Configuring bridge priority for an MSTP instance**

Priority can be configured for a specified instance. To configure priority for an MSTP instance, use a command such as the following at the Global Configuration level.

FastIron(config)#mstp instance 1 priority 8192

**Syntax:** 

```
[no] mstp instance <instance-number> priority <priority-value>
```

The `<instance-number>` variable is the number for the instance of MSTP that you are configuring.

You can set a **priority** to the instance that gives it forwarding preference over lower priority instances within a VLAN or on the switch. A higher number for the priority variable means a lower forwarding priority. Acceptable values are 0 - 61440 in increments of 4096. The default value is 32768.

---

**Setting the MSTP global parameters**

MSTP has many of the options available in RSTP as well as some unique options. To configure MSTP Global parameters for all instances on a switch.

FastIron(config)#mstp force-version 0 forward-delay 10 hello-time 4 max-age 12 max-hops 9

**Syntax:** 

```
[no] mstp force-version <mode-number> forward-delay <value> hello-time <value> max-age <value> max-hops <value>
```

The **force-version** parameter forces the bridge to send BPDUs in a specific format. You can specify one of the following `<mode-number>` values:

- **0** – The STP compatibility mode. Only STP BPDUs will be sent. This is equivalent to single STP.
- **2** – The RSTP compatibility mode. Only RSTP BPDUs will be sent. This is equivalent to single STP.
- **3** – MSTP mode. In this default mode, only MSTP BPDUs will be sent.

The **forward-delay** `<value>` specifies how long a port waits before it forwards an RST BPDU after a topology change. This can be a value from 4 – 30 seconds. The default is 15 seconds.

The **hello-time** `<value>` parameter specifies the interval between two hello packets. The parameter can have a value from 1 – 10 seconds. The default is 2 seconds.

The **max-age** `<value>` parameter specifies the amount of time the device waits to receive a hello packet before it initiates a topology change. You can specify a value from 6 – 40 seconds, where the value adheres to the following formula.

max age equal to or greater than 2 x (hello-time + 1) AND max age equal to or greater than 2 x (forward-delay - 1)

The default max-age is 20 seconds.
The `max-hops <value>` parameter specifies the maximum hop count. You can specify a value from 1 – 40 hops. The default value is 20 hops.

**Setting ports to be operational edge ports**

You can define specific ports as edge ports for the region in which they are configured to connect to devices (such as a host) that are not running STP, RSTP, or MSTP. If a port is connected to an end device such as a PC, the port can be configured as an edge port. To configure ports as operational edge ports enter a command such as the following.

```
FastIron(config)#mstp admin-edge-port ethernet 3/1
```

**Syntax:** `[no] mstp admin-edge-port ethernet <stack-unit/slotnum/portnum>

The `<stack-unit>` parameter is required on FGS and FLS devices running software version 2.5 and later, and on FGS-STK and FLS-STK devices running software version 5.0 and later.

The `<slotnum/portnum>` parameter specifies a port or range of ports as edge ports in the instance in which they are configured.

**Setting automatic operational edge ports**

You can configure a Layer 3 switch to automatically set a port as an operational edge port if the port does not receive any BPDUs since link-up. If the port receives a BPDU later, it is automatically reset to become an operational non-edge port. This feature is set globally to apply to all ports on a router where it is configured. This feature is configured as shown in the following.

```
FastIron(config)#mstp edge-port-auto-detect
```

**Syntax:** `[no] mstp edge-port-auto-detect

**NOTE**

If this feature is enabled, it takes the port about 3 seconds longer to come to the enable state.

**Setting point-to-point link**

You can set a point-to-point link between ports to increase the speed of convergence. To create a point-to-point link between ports, use a command such as the following at the Global Configuration level.

```
FastIron(config)#mstp admin-pt2pt-mac ethernet 2/5 ethernet 4/5
```

**Syntax:** `[no] mstp admin-pt2pt-mac ethernet <stack-unit/slotnum/portnum>

The `<stack-unit>` parameter is required on FGS and FLS devices running software version 2.5 and later, and on FGS-STK and FLS-STK devices running software version 5.0 and later.

The `<slotnum/portnum>` parameter specifies a port or range of ports as edge ports in the instance in which they are configured.

**Disabling MSTP on a port**

To disable MSTP on a specific port, use a command such as the following at the Global Configuration level.

```
FastIron(config)#mstp disable ethernet 2/1
```
Syntax: [no] mstp disable ethernet <stack-unit/slotnum/portnum>

The <stack-unit> parameter is required on FGS and FLS devices running software version 2.5 and later, and on FGS-STK and FLS-STK devices running software version 5.0 and later.

The <slotnum/portnum> variable specifies the location of the port for which you want to disable MSTP.

**NOTE**
When a port is disabled for MSTP, it behaves as blocking for all the VLAN traffic that is controlled by MSTIs and the CIST.

**Forcing ports to transmit an MSTP BPDU**

To force a port to transmit an MSTP BPDU, use a command such as the following at the Global Configuration level.

FastIron(config)#mstp force-migration-check ethernet 3/1

Syntax: [no] mstp force-migration-check ethernet <stack-unit/slotnum/portnum>

The <stack-unit> parameter is required on FGS and FLS devices running software version 2.5 and later, and on FGS-STK and FLS-STK devices running software version 5.0 and later.

The <slotnum/portnum> variable specifies the port or ports from which you want to transmit an MSTP BPDU.

**Activating MSTP on a switch**

MSTP scope must be enabled on the switch as described in “Configuring MSTP mode and scope” on page 346 before MSTP can be enabled.

To enable MSTP on your switch, use the following at the Global Configuration level.

FastIron(config)#mstp start

Syntax: [no] mstp start

The [no] option disables MSTP from operating on a switch.
Example

In Figure 48 four Brocade device routers are configured in two regions. There are four VLANs in four instances in Region 2. Region 1 is in the CIST.

Displaying MSTP statistics

MSTP statistics can be displayed using the commands shown below.

To display all general MSTP information, enter the following command.
Syntax: show mstp <instance-number>

The <instance-number> variable specifies the MSTP instance that you want to display information for.

**TABLE 78** Output from Show MSTP

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSTP Instance</td>
<td>The ID of the MSTP instance whose statistics are being displayed. For the CIST, this number is 0.</td>

**Displaying MSTP information for a specified instance**

The following example displays MSTP information specified for an MSTP instance.
FastIron#show mstp 1
MSTP Instance 1 - VLANs: 2
----------------------------------------------------------------------------
Bridge Identifier          Max RegionalRoot IntPath Designated Root Root
hex     cnt hex                        hex                    cnt
8001000cdb80af01 20 8001000cd02b0af01 0 8001000cdb80af01 Root 20

Port Pri PortPath  Role       State  Designated cost  Designated
Num    Cost      Mac Port                       cost  bridge
3/1    128 2000      T   F    ROOT       FORWARDING 0 8001000cd80af01

Refer to Table 78 for details about the display parameters.

**Displaying MSTP information for CIST instance 0**

Instance 0 is the Common and Internal Spanning Tree Instance (CIST). When you display information for this instance there are some differences with displaying other instances. The following example displays MSTP information for CIST Instance 0.

FastIron#show mstp 0
MSTP Instance 0 (CIST) - VLANs: 1
----------------------------------------------------------------------------
Bridge Identifier          Bridge Bridge Bridge Bridge Root Root Root Root
hex     MaxAge Hello FwdDly Hop MaxAge Hello FwdDly Hop
8000000cd80af01 20     2      15     20     20     2     15     19
Root ExtPath RegionalRoot IntPath Designated Root
Bridge Cost Bridge Cost Bridge Port
hex                        hex
8000000480bb9876 2000 8000000cd80af01 0 8000000480bb9876 3/1
Port Pri PortPath P2P Edge Role       State  Designated cost  Designated
Num    Cost      Mac Port  Cost  Bridge
3/1    128 2000      T   F    ROOT       FORWARDING 0 8000000480bb9876

To display details about the MSTP configuration, enter the following command.

FastIron#show mstp conf
MSTP CONFIGURATION
Name    : Regl
Revision : 1
Version  : 3 (MSTP mode)
Status   : Started

Instance VLANs
----------- ----------------------------------
0 4093

To display details about the MSTP that is configured on the device, enter the following command.
FastIron#show mstp detail
MSTP Instance 0 (CIST) - VLANs: 4093
----------------------------------------------------------------------------
Bridge: 800000b000c00000 [Priority 32768, SysId 0, Mac 00b00c00000]  
FwdDelay 15, HelloTime 2, MaxHops 20, TxHoldCount 6  
Port 6/54 - Role: DESIGNATED - State: FORWARDING  
PathCost 20000, Priority 128, OperEdge T, OperPt2PtMac F, Boundary T  
Designated - Root 800000b000c00000, RegionalRoot 800000b000c00000,  
Bridge 800000b000c00000, ExtCost 0, IntCost 0  
ActiveTimers - helloWhen 1  
MachineState - PRX-DISCARD, PTX-IDLE, PPM-SENDING_RSTP, PIM-CURRENT  
PRT-ACTIVE_PORT, PST-FORWARDING, TCM-INACTIVE  
BPDUs - Rcvd MST 0, RST 0, Config 0, TCN 0  
Sent MST 6, RST 0, Config 0, TCN 0

Refer to Table 78 for explanation about the parameters in the output.

Syntax: show mstp [<mstp-id>] | configuration | detail] [ | begin <string> | exclude <string> |  
include <string>]

Enter an MSTP ID for <mstp-id>.
802.1s Multiple Spanning Tree Protocol
The procedures in this chapter describe how to configure basic Layer 2 parameters.

Brocade devices are configured at the factory with default parameters that allow you to begin using the basic features of the system immediately. However, many of the advanced features such as VLANs or routing protocols for the device must first be enabled at the system (global) level before they can be configured. If you use the Command Line Interface (CLI) to configure system parameters, you can find these system level parameters at the Global CONFIG level of the CLI.

NOTES:

- Before assigning or modifying any router parameters, you must assign the IP subnet (interface) addresses for each port.
- For information about configuring IP addresses, DNS resolver, DHCP assist, and other IP-related parameters, refer to Chapter 30, “Configuring IP”.
- For information about the Syslog buffer and messages, refer to Chapter 50, “Using Syslog”.

About port regions

Ports on the FastIron X Series devices are grouped into regions. For a few features, you will need to know the region to which a port belongs. However, for most features, a port region does not affect configuration or operation of the feature.

NOTE
Port regions do not apply to TurboIron Series devices or to trunk group configurations on the FastIron X Series devices. However, port regions do apply to port monitoring and unknown unicast configurations on FastIron X Series devices.

FastIron Edge Switch X424 and X424HF, and FastIron Workgroup Switch X424:
- Ports 1 – 12
- Ports 13 – 24
- Port 25
- Port 26

FastIron Edge Switch X448 and FastIron Workgroup Switch X448:
- Ports 1 – 12
- Ports 13 – 24
- Port 25 – 36
- Port 37 – 48
- Port 49
- Port 50
Enabling or disabling the Spanning Tree Protocol (STP)

STP (IEEE 802.1D bridge protocol) is supported on all Brocade devices. STP detects and eliminates logical loops in the network. STP also ensures that the least cost path is taken when multiple paths exist between ports or VLANs. If the selected path fails, STP searches for and then establishes an alternate path to prevent or limit retransmission of data.

**NOTE**
This section provides instructions for enabling and disabling STP. For configuration procedures and more information about STP, refer to Chapter 9, “Configuring Spanning Tree Protocol (STP) Related Features” in this guide.

STP must be enabled at the system level to allow assignment of this capability on the VLAN level. On devices running Layer 2 code, STP is enabled by default. On devices running Layer 3 code, STP is disabled by default.

To enable STP for all ports on a Brocade device, enter the following command.

```
FastIron(config)#spanning tree
```

**Syntax:** `[no] spanning-tree`

You can also enable and disable spanning tree on a port-based VLAN and on an individual port basis, and enable advanced STP features. Refer to Chapter 9, “Configuring Spanning Tree Protocol (STP) Related Features”.

**Modifying STP bridge and port parameters**

You can modify the following STP Parameters:

- Bridge parameters – forward delay, maximum age, hello time, and priority
- Port parameters – priority and path cost

For configuration details, refer to “Changing STP bridge and port parameters” on page 266.
Management MAC address for stackable devices

Platform Support:
• FGS-STK and FLS-STK devices running software release 05.0.00 and later

In an IronStack consisting of FGS-STK and FLS-STK devices, the management MAC address of the Active Controller is always used as the STP bridge ID. The Active Controller management MAC address is always used for control protocols for the following reasons:
• Unlike standalone devices, each stack member has a different range of MAC addresses
• In a stack, the management MAC address is software generated, and is always the MAC address of the Active Controller first port. This ensures consistency across the stack during resets, assuming that the Active Controller is always the same unit.
• This helps avoid the disruption of frequent topology changes in the stack.

MAC learning rate control

Platform Support:
• FGS and FLS devices running software version 03.0.00 and later

FGS software release 03.0.00 adds support for a new CLI command that allows users to set a rate limit to control CPU address updating. The range for this rate limit is 200 - 50,000 per second. The MAC learning rate limit applies to each packet processor, which means that for a system with two packet processors, each processor can send address messages to the CPU at the established rate limit.

Syntax: [no] cpu-limit addr-msgs <msgsRateLimit>

NOTE
Actual rates in hardware may have a variance of +200 or -100.

Changing the MAC age time and disabling MAC address learning

To change the MAC address age timer, enter a command such as the following.

FastIron(config)#mac-age-time 60

Syntax: [no] mac-age-time <secs>

<secs> specifies the number of seconds. Possible values differ depending on the version of software running on your device, as follows:
• On FastIron X Series devices running pre-release 02.5.00 software, and on FastIron GS, LS, and WS and FCX devices, learned MAC address entries do not age out until they are unused for 300 – 600 seconds. If necessary, you can change the MAC address age timer to 0 or a value from 60 – 600 (seconds), in 60-second intervals. For example, you can specify 60 or 120, but not 100. If you set the MAC age time to 0, aging is disabled.
On FastIron X Series devices running software release 02.5.00 through 03.1.00x, you can configure 0 or a value from 10 – 14000 (seconds), in 10-second intervals. For example, you can specify 10, 20, or 14000, but not 122. If you set the MAC age time to 0, aging is disabled.

On FastIron X Series devices running software FSX release 03.2.00 or later, you can configure 0 or a value from 10 – 86,400 (seconds), in 10-second intervals. If you set the MAC age time to 0, aging is disabled.

On TurboIron X Series devices, you can configure 0 or a value from 10 – 86,400 (seconds), in 1-second intervals. If you set the MAC age time to 0, aging is disabled.

**NOTES:** Usually, the actual MAC age time is from one to two times the configured value. For example, if you set the MAC age timer to 60 seconds, learned MAC entries age out after remaining unused for between 60 – 120 seconds. However, if all of the following conditions are met, then the MAC entries age out after a longer than expected duration:

- The MAC age timer is greater than 630 seconds.
- The number of MAC entries is over 6000.
- All MAC entries are learned from the same packet processor.
- All MAC entries age out at the same time.

**Disabling the automatic learning of MAC addresses**

**Platform Support:**
- FastIron X Series devices running software release 03.2.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- Turbolron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

By default, when a packet with an unknown Source MAC address is received on a port, the Brocade device learns this MAC address on the port.

You can prevent a physical port from learning MAC addresses by entering the following command.

```
FastIron(config)#interface ethernet 3/1
FastIron(config-if-e1000-3/1)#mac-learn-disable
```

**Syntax:** `[no] mac-learn disable`

Use the no form of the command to allow a physical port to learn MAC addresses.

**Configuration notes and feature limitations**

- This command is not available on virtual routing interfaces. Also, if this command is configured on the primary port of a trunk, MAC address learning will be disabled on all the ports in the trunk.

- Entering the `mac-learn-disable` command on tagged ports disables MAC learning for that port in all VLANs to which that port is a member. For example, if tagged port 3/1 is a member of VLAN 10, 20, and 30 and you issue the `mac-learn-disable` command on port 3/1, port 3/1 will not learn MAC addresses, even if it is a member of VLAN 10, 20, and 30.
Displaying the MAC address table

To display the MAC table, enter the following command.

```
FastIron#show mac-address
Total active entries from all ports = 3
Total static entries from all ports = 1

<table>
<thead>
<tr>
<th>MAC-Address</th>
<th>Port</th>
<th>Type</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234.1234.1234</td>
<td>15</td>
<td>Static</td>
<td>1</td>
</tr>
<tr>
<td>0004.8038.2f24</td>
<td>14</td>
<td>Dynamic</td>
<td>1</td>
</tr>
<tr>
<td>0004.8038.2f00</td>
<td>13</td>
<td>Dynamic</td>
<td>1</td>
</tr>
<tr>
<td>0010.5a86.b159</td>
<td>10</td>
<td>Dynamic</td>
<td>1</td>
</tr>
</tbody>
</table>
```

In the output of the `show mac-address` command, the **Type** column indicates whether the MAC entry is static or dynamic. A static entry is one you create using the `static-mac-address` command. A dynamic entry is one that is learned by the software from network traffic.

The output of the `show mac-address` command on TIX, FESX, FSX, and FWSX devices include an **Index** column which indicates the index where the entry exists in the hardware MAC table.

**NOTE**
The `show mac-address` command output does not include MAC addresses for management ports, since these ports do not support typical MAC learning and MAC-based forwarding.

Configuring static MAC entries

Static MAC addresses can be assigned to Brocade devices.

**NOTE**
Brocade devices running Layer 3 code also support the assignment of static IP Routes, static ARP, and static RARP entries. For details on configuring these types of static entries, refer to “Configuring static routes” on page 1015 and “Creating static ARP entries” on page 1009.

**NOTE**
TurboIron X Series devices support static MAC entries with unicast addresses only. This differs from FastIron devices, which support static MAC entries with unicast and multicast addresses.

You can manually input the MAC address of a device to prevent it from being aged out of the system address table.

This option can be used to prevent traffic for a specific device, such as a server, from flooding the network with traffic when it is down. Additionally, the static MAC address entry is used to assign higher priorities to specific MAC addresses.

You can specify traffic priority (QoS) and VLAN membership (VLAN ID) for the MAC Address as well as specify the device type of either router or host.

The default and maximum configurable MAC table sizes can differ depending on the device. To determine the default and maximum MAC table sizes for your device, display the system parameter values. Refer to “Displaying and modifying system parameter default settings” on page 380.
Multi-port static MAC address

Platform Support:
- FGS and FLS devices running software release 04.1.00 and later
- FWS devices running software release 04.3.00 or later
- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

Many applications, such as Microsoft NLB, Juniper IPS, and Netscreen Firewall, use the same MAC address to announce load-balancing services. As a result, a switch must be able to learn the same MAC address on several ports. Multi-port static MAC allows you to statically configure a MAC address on multiple ports using a single command.

Configuration notes

- On TurboIron X Series devices, this feature can be used to configure unicast MAC addresses on one or more ports; Multicast addresses are not supported.
- On FastIron X Series devices, starting in software release FSX 04.2.00, this feature can be used to configure unicast as well as IPv4 and IPv6 multicast MAC addresses on one or more ports. However, when a multicast MAC address is configured, the corresponding MAC address entry cannot be used for IGMP snooping. In releases prior to FSX 04.2.00, this feature can be used to configure unicast MAC addresses on one or more ports. For IPv4 multicast addresses (range 0100.5e00.000 to 0100.5e7f.ffff) and IPv6 multicast addresses (range 3333.0000.0000 to 3333.ffff.ffff), use IGMP/MLD snooping. Other multicast addresses can also be configured on the ports using this feature.
- The FastIron GS and LS, and GS-STK and LS-STK support a maximum of 7 multi-port static MAC addresses.
- Hosts or physical interfaces normally join multicast groups dynamically, but you can also statically configure a host or an interface to join a multicast group.
- The following limitations apply to FastIron GS and LS, and GS-STK and LS-STK devices, TurboIron X Series devices, FastIron X Series devices running pre-release FSX 04.2.00 software, and FastIron X Series devices running release FSX 04.2.00 or later that have the source_port_group_suppression_enable flag enabled:
  - This feature is not supported on ports that are already deployed on a trunk. If attempted, the system will return a port overlap error.
  - External trunks cannot be created and deployed on ports on which static MAC addresses are configured.
  - This feature is not supported on a set of ports that overlap with a set of ports on which static MAC entries are configured, unless the port list in both sets is identical

NOTE
For more information about source port group suppression, refer to “Configuring a multi-port static MAC address with source port group suppression” on page 367.
Configuring a multi-port static MAC address

For example, to add a static entry for a server with a MAC address of 0045.5563.67ff and a priority of 7, enter the following command.

```
FastIron(config)#static-mac-address 0045.5563.67ff ethernet 4/2 ethernet 4/3 ethernet 4/4 priority 7
```

To specify a range of ports, enter the following command.

```
FastIron(config)#static-mac-address 0045.5563.67ff ethernet 4/2 to 4/6 priority 7
```

Syntax: `[no] static-mac-address <mac-addr> ethernet [<slotnum>]/<portnum> ethernet [<slotnum>]/<portnum> ethernet [<slotnum>]/<portnum> ... [priority <num>]`

or

Syntax: `[no] static-mac-address <mac-addr> ethernet [<slotnum>]/<portnum> to ethernet [<slotnum>]/<portnum> [priority <num>]`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The priority `<num>` is optional and can be a value from 0 – 7 (0 is lowest priority and 7 is highest priority). The default priority is 0.

**NOTE**

The location of the `static-mac-address` command in the CLI depends on whether you configure port-based VLANs on the device. If the device does not have more than one port-based VLAN (VLAN 1, which is the default VLAN that contains all the ports), the `static-mac-address` command is at the global CONFIG level of the CLI. If the device has more than one port-based VLAN, then the `static-mac-address` command is not available at the global CONFIG level. In this case, the command is available at the configuration level for each port-based VLAN.

Configuring a multi-port static MAC address with source port group suppression

Platform Support:

- FastIron X Series devices running software release 04.2.00 and later – L2, BL3, L3

In releases prior to FSX 04.2.00, multi-port static MAC entries are not supported on ports that are part of a trunk group. This is because the Brocade device creates an internal trunk to bundle the ports together for the multi-port static MAC configuration. Since a switch port can be a member of only one trunk at a time, trunking is not supported with multi-port static MAC entries.

Starting in software release 04.2.00, by default, multi-port static MAC entries are supported on ports that are part of a trunk group. If desired, you can configure the device to work as in pre-release FSX 04.2.00, by enabling source port group suppression. When enabled, packets coming in through one of the specified ports with a destination MAC address equal to the configured static MAC address, will not be forwarded back to these set of ports.

When source port group suppression is enabled, the following limitations apply:

- Multi-port static MAC address entries are not supported on ports that are already deployed in a trunk. If configuration is attempted, the system will return a port overlap error.
- External trunks cannot be created and deployed on ports on which static MAC addresses with source port group suppression is enabled.
• Multi-port static MAC address entries are not supported on a set of ports that overlap with a set of ports on which static MAC entries are configured, unless the port list in both sets is identical.

To add a static entry for a server with a MAC address of 0045.5563.67ff and enable source port group suppression, enter a command such as the following.

```
FastIron(config)#static-mac-address 0045.5563.67ff ethernet 4/2 to 4/6
source_port_group_suppression_enable priority 7
```

Syntax: `[no] static-mac-address <mac-addr> ethernet [<slotnum>][<portnum>] ethernet ...

`[source_port_group_suppression_enable] [priority <num>]`

or

Syntax: `[no] static-mac-address <mac-addr> ethernet [<slotnum>][<portnum>] to ethernet ...

`[source_port_group_suppression_enable] [priority <num>]`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The `source_port_group_suppression_enable` parameter is optional. This creates an internal trunk for the specified ports.

The priority `<num>` is optional and can be a value from 0 – 7 (0 is lowest priority and 7 is highest priority). The default priority is 0.

NOTE
The location of the static-mac-address command in the CLI depends on whether you configure port-based VLANs on the device. If the device does not have more than one port-based VLAN (VLAN 1, which is the default VLAN that contains all the ports), the static-mac-address command is at the global CONFIG level of the CLI. If the device has more than one port-based VLAN, then the static-mac-address command is not available at the global CONFIG level. In this case, the command is available at the configuration level for each port-based VLAN.

### Configuring VLAN-based static MAC entries

**Platform Support:**

- FastIron X Series devices running software release 04.0.00 and later – L2, BL3, and L3
- FGS and FLS devices running software release 04.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later

You can configure a VLAN to drop packets that have a particular source or destination MAC address.

You can configure a maximum of 2048 static MAC address drop entries on a Brocade device.

Use the CLI command `show running-config` to view the static MAC address drop entries currently configured on the device.
### Clearing MAC address entries

You can remove learned MAC address entries from the MAC address table. The types of MAC address can be removed as follows:

- All MAC address entries
- All MAC address entries for a specified Ethernet port
- All MAC address entries for a specified VLAN
- All specified MAC address entry in all VLANs

For example, to remove entries for the MAC address 000d.cd80.00d0 in all VLANs, enter the following command at the Privilege EXEC level of the CLI.

```
FastIron#clear mac-address 000d.cd80.00d0
```

**Syntax:** `clear mac-address <mac-address> | ethernet <port-num> | vlan <vlan-num>`

If you enter `clear mac-address` without any parameter, the software removes all MAC address entries.

Use the `<mac-address>` parameter to remove a specific MAC address from all VLANs. Specify the MAC address in the following format: HHHH.HHHH.HHHH.

Use the `ethernet <port-num>` parameter to remove all MAC addresses for a specific Ethernet port.

Use the `vlan <num>` parameter to remove all MAC addresses for a specific VLAN.

### Flow-based MAC address learning

This section describes flow-based MAC address learning and how to enable it on a FastIron switch.

**Platform Support:**

- FESX, FSX and SX devices running software release FSX 05.1.00 and later

**Feature overview**

With regular MAC address learning, when a new MAC address is learned, it is programmed in the same location (hardware index) in all packet processors in a FastIron Layer 2 or Layer 3 switch. There are multiple packet processors (one per port region) in a compact switch, and in each module in a chassis-based switch. With regular MAC address learning, MAC addresses are **global**, meaning the hardware MAC table is identical across all packet processors.
With the introduction of **flow-based MAC address learning**, when a new source MAC address is learned, it is programmed only in the source packet processor (the processor that received the packet). The destination MAC address gets added to other packet processors on demand, whenever a traffic flow that needs it is detected. With flow-based MAC address learning, the MAC address is programmed in different hardware locations and the hardware MAC table is different across all packet processors.

**The benefits of flow-based learning**

With global MAC address learning, all MAC addresses are programmed in all packet processors, even though they may not be required and are never used by all packet processors. Global MAC address learning wastes some space in the hardware MAC table and limits the number of supported MAC addresses to 16K.

With flow-based MAC address learning, MAC addresses are learned and programmed selectively, only in the packet processors that need them. Since the MAC addresses are distributed across several packet processors, flow-based learning frees up space in the hardware MAC table and increases the number of supported MAC addresses from 16K to 32K.

**How flow-based learning works**

When a packet processor, let call it PP 1, receives an incoming packet with source MAC address X, it sends a new address message to the CPU. The system learns MAC address X by adding it to the software MAC table in the CPU, then programming it in the hardware MAC table in the source packet processor, in this case PP 1. If the MAC address is learned on a trunk port, the MAC address is also programmed on all of the packet processors that have ports in the same trunk group.

When another packet processor, let call it PP 2, receives an incoming packet and the packet destination MAC address matches source MAC address X, it floods the packet in hardware as an unknown unicast packet and copies the packet to the CPU. The system locates the MAC address in the software MAC table, then programs the MAC address in the hardware MAC table in PP 2. If the MAC address is learned on a trunk port, the MAC address is also programmed on all of the packet processors that have ports in the same trunk group. Once the MAC address is programmed in hardware, subsequent packets with this destination MAC are forwarded as known unicast packets and are not copied to the CPU.

Flow-based MAC addresses are aged out by the source packet processor according to the MAC age time learned on the local port. Furthermore, when a flow-based MAC address is aged out from the source packet processor, it is also aged out from all other packet processors on which the address is programmed. In the above example, when MAC address X is aged out from PP 1, it is also aged out from PP2.

**NOTE**

Even when flow-based MAC address learning is enabled, some MAC addresses, including but not limited to control MACs, static MACs, multicast MACs, and MAC addresses resolved through ARP, will continue to be global MAC addresses. These MAC addresses are always programmed in all packet processors in a Layer 2 or Layer 3 switch.
NOTE
Global MAC addresses have priority over dynamic flow-based MAC addresses. To ensure that global MAC addresses are in sync across all packet processors, flow-based MAC addresses may be overwritten in one or more packet processors. The MAC addresses will be relearned and reprogrammed using the flow-based method as needed by incoming traffic flows.

Configuration considerations
When configuring flow-based MAC learning, consider the rules and limitations in this section.

- Flow-based MAC learning is not supported with the following features:
  - Disabling the automatic learning of MAC addresses (CLI command `mac-learn-disable`).
  - Globally disabling Layer 2 switching (CLI command `route-only`).
- When flow-based MAC learning is enabled, unknown unicast packets are copied to the CPU. Therefore, flow-based MAC learning should not be enabled if a continuous high rate of unknown unicast packet flooding is expected, as this will cause high CPU utilization.
- Unknown unicast flooding can occur for a known destination MAC address, if the system fails to program that destination MAC address because the hardware MAC table or hash bucket is full. This condition can also lead to high CPU utilization.
- A source MAC address is learned only on the ingress (source) packet processor. The MAC address is added to other packet processors as needed by their incoming traffic flows. During a brief period until the destination MAC address is successfully added to the hardware MAC table, unknown unicast flooding is expected on the VLAN.
- When a flow-based MAC address moves, it is deleted from all of the packet processors, then relearned on each packet processor individually, as needed by incoming traffic flows.
- The software MAC address table in the CPU uses a hashing algorithm. Because hash collisions can occur and may consume software resources, the FastIron may not be able to support up to 32K MAC addresses.
- The system can scale up to 32K MAC addresses, however, each packet processor is limited to a maximum of 16K MAC addresses. This limit still applies, as this is a hardware limitation.

Configuring flow-based MAC address learning
To configure flow-based MAC address learning, simply enable it globally. If necessary, increase the capacity of the MAC address table as well.

Enabling flow-based MAC address learning
To enable flow-based MAC address learning, enter the following command at the Global CONFIG level of the CLI.

```plaintext
FastIron(config)#mac-learning-flow-based
```
This command enables flow-based MAC address learning. All dynamically-learned MAC addresses are flushed from the hardware and software MAC tables and are subsequently learned using flow-based MAC address learning.

```plaintext
[no] mac-learning-flow-based
```
Flow-based MAC address learning

Use the **no** form of the command to disable flow-based MAC address learning. When disabled, all dynamically-learned MAC addresses are flushed from the hardware and software MAC tables and are subsequently learned using global MAC address learning.

**Increasing the capacity of the MAC address table (optional)**

After enabling support for flow-based MACs, you can increase the capacity of the MAC address table of up to 32K MAC addresses. By default, up to 16K MAC addresses are supported.

**NOTE**

The system can scale up to 32K MAC addresses when flow-based MAC address learning is enabled. If flow-based learning is disabled, the system cannot scale more than 16K MAC addresses.

To increase the capacity of the MAC table, enter commands such as the following.

```plaintext
FastIron(config)#system-max mac 32768
FastIron(config)#write memory
FastIron(config)#exit
FastIron#reload
```

**NOTE**

You must save the configuration and reload the software to place the **system-max mac** change into effect.

**Syntax:**  
`system-max mac <max-flow-MACs>`

The `<max-flow-MACs>` parameter specifies the maximum number of MAC addresses in the MAC table. For flow-based MACs, the minimum value is 16K and the maximum value is 32K. The default is 16K.

Use the command **show default values** to display the default, maximum, and currently configured values for the MAC address table.

**Displaying information about flow-based MACs**

The **show mac-address** command includes information related to flow-based MAC address learning. The following shows an example **show mac** output.

```plaintext
FastIron# show mac
Total active entries from all ports = 15
MAC-Address     Port     Type     Index
0000.0000.0001  1/1      Dynamic  NA
0000.0000.0002  1/1      Dynamic  NA
```

In the above example, since both MAC address entries are flow-based and are located on different packet processors (hardware index), the **Index** field displays **NA** (not applicable).

**Syntax:** **show mac**

To display all of the packet processors that have a particular flow-based MAC address, use the **show mac-address vlan** command.

```plaintext
FastIron#show mac-address vlan 1 0000.0000.0001
Total active entries from all ports = 16
MAC-Address     Port     Type     Index
0000.0000.0001  1/1      Dynamic  NA
```
Present in following devices (at hw index) :-

0  (8196 )       4  (8196 )

In the above example, the MAC address 0000.0000.0001 is programmed in packet processors 0 and 4, and the hardware index is 8196.

Syntax: show mac-address vlan <vlan-num> <mac address>

Clearing flow-based MAC address entries

To remove dynamically-learned MAC addresses from the MAC table, use the CLI command clear mac. This command clears all dynamically-learned MACs from the hardware and software MAC tables.

Enabling port-based VLANs

When using the CLI, port and protocol-based VLANs are created by entering one of the following commands at the global CONFIG level of the CLI.

To create a port-based VLAN, enter commands such as the following.

```
FastIron(config)#vlan 222 by port
FastIron(config)#vlan 222 name Mktg
```

Syntax: vlan <num> by port

Syntax: vlan <num> name <string>

The <num> parameter specifies the VLAN ID. The valid range for VLAN IDs starts at 1 on all systems but the upper limit of the range differs depending on the device. In addition, you can change the upper limit on some devices using the system max-vlans... command.

The <string> parameter is the VLAN name and can be a string up to 32 characters. You can use blank spaces in the name if you enclose the name in double quotes (for example, “Product Marketing”).

You can configure up to 4063 port-based VLANs on a device running Layer 2 code or 4061 port-based VLANs on a device running Layer 3 code. Each port-based VLAN can contain either tagged or untagged ports. A port cannot be a member of more than one port-based VLAN unless the port is tagged. On both device types, valid VLAN IDs are 1 – 4095. You can configure up to the maximum number of VLANs within that ID range.

**NOTE**

VLAN IDs 4087, 4090, and 4093 are reserved for Brocade internal use only. VLAN 4094 is reserved for use by Single STP. Also, in releases prior to 04.0.00, VLAN IDs 4091 and 4092 are reserved for Brocade internal use only. Starting in release 04.0.00, if you want to use VLANs 4091 and 4092 as configurable VLANs, you can assign them to different VLAN IDs. For more information, refer to “Assigning different VLAN IDs to reserved VLANs 4091 and 4092” on page 483.

**NOTE**

The second command is optional and also creates the VLAN if the VLAN does not already exist. You can enter the first command after you enter the second command if you first exit to the global CONFIG level of the CLI.
Assigning IEEE 802.1Q tagging to a port

When a port is tagged, it allows communication among the different VLANs to which it is assigned. A common use for this might be to place an email server that multiple groups may need access to on a tagged port, which in turn, is resident in all VLANs that need access to the server.

**NOTE**
Tagging does not apply to the default VLAN.

When using the CLI, ports are defined as either tagged or untagged at the VLAN level.

**Command syntax**

Suppose you want to make port 5 a member of port-based VLAN 4, a tagged port. To do so, enter the following.

```
FastIron(config)#vlan 4
FastIron(config-vlan-4)#tagged e 5
```

**Syntax:** `tagged ethernet [ [<slotnum>/]<portnum> ] [to [ [<slotnum>/]<portnum> ] [ ethernet [ [<slotnum>/]<portnum> ]... ] ]`

The `<slotnum>` parameter is required on chassis devices.

**Defining MAC address filters**

MAC layer filtering enables you to build access lists based on MAC layer headers in the Ethernet/IEEE 802.3 frame. You can filter on the source and destination MAC addresses. The filters apply to incoming traffic only.

You configure MAC filters globally, then apply them to individual interfaces. To apply MAC filters to an interface, you add the filters to that interface MAC filter group.

**NOTE**
FastIron GS-STK and FastIron LS-STK devices do not support the configuration of both global DoS attack and MAC filters.

The device takes the action associated with the first matching filter. If the packet does not match any of the filters in the access list, the default action is to drop the packet. If you want the system to permit traffic by default, you must specifically indicate this by making the last entry in the access list a permit filter. An example is given below.

**Syntax:** `mac filter <last-index-number> permit any`.

For devices running Layer 3 code, the MAC filter is applied to all inbound Ethernet packets, including routed traffic. This includes those port associated with a virtual routing interface. However, the filter is not applied to the virtual routing interface. It is applied to the physical port.

When you create a MAC filter, it takes effect immediately. You do not need to reset the system. However, you do need to save the configuration to flash memory to retain the filters across system resets.
Configuration notes and limitations

- MAC filtering on FastIron devices is performed in hardware.
- MAC filtering on FastIron devices differ from other Brocade devices in that you can only filter on source and destination MAC addresses. Other Brocade devices allow you to also filter on the encapsulation type and frame type.
- MAC filtering differs from the FES and BigIron in that MAC filtering applies to all traffic, including management traffic. To exclude management traffic from being filtered, configure a MAC filter that explicitly permits all traffic headed to the management MAC (destination) address. The MAC address for management traffic is always the MAC address of port 1.
- MAC filters that have a global deny statement can cause the device to block all BPDUs. In this case, include exception statements for control protocols in the MAC filter configuration. On TurboIron X Series devices, BPDUs are not blocked by MAC filters.

The following configuration notes apply to Brocade Layer 3 devices:

- MAC filters apply to both switched and routed traffic. If a routing protocol (for example, OSPF) is configured on an interface, the configuration must include a MAC filter rule that allows the routing protocol MAC and the neighbor system MAC address.
- You cannot use Layer 2 filters to filter Layer 4 information.
- Starting in software release FSX 05.1.00 for FESX, FSX, and SX devices, MAC Layer 2 filters are supported on tagged ports in the base layer 3 and full Layer 3 images. In software releases prior to FSX 05.1.00, and on devices other than the FESX, FSX, and SX, MAC filters are not supported on tagged ports in the base Layer 3 and full Layer 3 images.

Command syntax

To configure and apply a MAC filter, enter commands such as the following.

```
FastIron(config)#mac filter 1 deny 3565.3475.3676 ffff.0000.0000
FastIron(config)#mac filter 1024 permit any any
FastIron(config)#int e 1
FastIron(config-if-e1000-1)#mac filter-group 1 1024
```

These commands configure a filter to deny traffic with a source MAC address that begins with “3565” to any destination. The second filter permits all traffic that is not denied by another filter.

**NOTE**

Once you apply a MAC filter to a port, the device drops all Ethernet traffic on the port that does not match a MAC permit filter on the port.

Syntax: `[no] mac filter <filter-num> permit | deny <src-mac> <mask> | any <dest-mac> <mask> | any

The **permit | deny** argument determines the action the software takes when a match occurs.

The `<src-mac> <mask> | any` parameter specifies the source MAC address. You can enter a specific address value and a comparison mask or the keyword any to filter on all MAC addresses. Specify the mask using (ones) and zeros. For example, to match on the first two bytes of the address aabb.ccdd.eeff, use the mask ffff.0000.0000. In this case, the filter matches on all MAC addresses that contain "aabb" as the first two bytes. The filter accepts any value for the remaining bytes of the MAC address. If you specify any, do not specify a mask. In this case, the filter matches on all MAC addresses.
Defining MAC address filters

The \(<\text{dest-mac}\>\ <\text{mask}\>\ |\ \text{any}\) parameter specifies the destination MAC address. The syntax rules are the same as those for the \(<\text{src-mac}\>\ <\text{mask}\>\ |\ \text{any}\) parameter.

**Syntax:** \([\text{no}]\ \text{mac filter log-enable}\)

Globally enables logging for filtered packets.

**Syntax:** \([\text{no}]\ \text{mac filter-group log-enable}\)

Enables logging for filtered packets on a specific port.

**Syntax:** \([\text{no}]\ \text{mac filter-group}\ <\text{filter-list}\>

Applies MAC filters to a port.

On TurboIron devices running software release 04.2.00 and later, you can filter packets based on the Ethernet type using the new \text{etype} optional keyword.

**Syntax:** \([\text{no}]\ \text{mac filter}\ <\text{filter-num}\>\ \text{permit} | \text{deny}\ <\text{src-mac}\>\ <\text{mask}\>\ |\ \text{any}\ <\text{dest-mac}\>\ <\text{mask}\>\ |\ \text{any}\ \text{[etype}\ <\text{eq} | \text{gt} | \text{lt} | \text{neq}>\ <\text{type}\>\ ]}\)

- \text{eq}\ - Matches packet with a given Ethernet type
- \text{gt}\ - Matches packet with a greater Ethernet type
- \text{lt}\ - Matches packet with a lower Ethernet type
- \text{neq}\ - Matches packet not with a given Ethernet type

**NOTE**
The filters must be applied as a group. For example, if you want to apply four filters to an interface, they must all appear on the same command line.

**NOTE**
You cannot add or remove individual filters in the group. To add or remove a filter on an interface, apply the filter group again containing all the filters you want to apply to the port.

**NOTE**
If you apply a filter group to a port that already has a filter group applied, the older filter group is replaced by the new filter group.

When a MAC filter is applied to or removed from an interface, a Syslog message such as the following is generated.

SYSLOG: <14>Jan 1 00:00:00 10.44.9.11 MAC Filter applied to port 0/1/2 by tester from telnet session (filter id=5 ).
SYSLOG: <14>Jan 1 00:00:00 10.44.9.11 MAC Filter removed from port 0/1/2 by tester from telnet session (filter id=5 ).

The Syslog messages indicate that a MAC filter was applied to the specified port by the specified user during the specified session type. Session type can be Console, Telnet, SSH, Web, SNMP, or others. The filter IDs that were added or removed are listed.
Enabling logging of management traffic permitted by MAC filters

You can configure the Brocade device to generate Syslog entries and SNMP traps for management traffic that is permitted by MAC filters. Management traffic applies to packets that are destined for the CPU, such as control packets. You can enable logging of permitted management traffic on a global basis or an individual port basis.

The first time an entry in a MAC filter permits a management packet and logging is enabled for that entry, the software generates a Syslog message and an SNMP trap. Messages for management packets permitted by MAC filters are at the warning level of the Syslog.

When the first Syslog entry for a management packet permitted by a MAC filter is generated, the software starts a five-minute timer. After this, the software sends Syslog messages every five minutes. The messages list the number of management packets permitted by each MAC filter during the previous five-minute interval. If a MAC filter does not permit any packets during the five-minute interval, the software does not generate a Syslog entry for that MAC filter.

**NOTE**

For a MAC filter to be eligible to generate a Syslog entry for permitted management packets, logging must be enabled for the filter. The Syslog contains entries only for the MAC filters that permit packets and have logging enabled.

When the software places the first entry in the log, the software also starts the five-minute timer for subsequent log entries. Thus, five minutes after the first log entry, the software generates another log entry and SNMP trap for permitted management packets.

**Configuration notes**

MAC filter logging is supported in the following FastIron configurations:

- FESX devices running software release 02.1.01 or later
- All FSX devices and associated software releases
- All FWSX devices and associated software releases
- All TIX devices and associated software releases

These releases support MAC filter logging of management traffic only.

**Command syntax**

To configure MAC filter logging globally, enter the following CLI commands at the global CONFIG level.

```
FastIron(config)#mac filter log-enable
FastIron(config)#write memory
```

Syntax: `[no] mac filter log-enable`

To configure MAC filter logging for MAC filters applied to ports 1 and 3, enter the following CLI commands.
Defining MAC address filters

```
FastIron(config)#int ethernet 1
FastIron(config-if-e1000-1)#mac filter-group log-enable
FastIron(config-if-e1000-1)#int ethernet 3
FastIron(config-if-e1000-3)#mac filter-group log-enable
FastIron(config-if-e1000-3)#write memory
```

Syntax: [no] mac filter-group log-enable

**MAC filter override for 802.1X-enabled ports**

**Platform Support:**

- FastIron X Series devices running software release 03.1.00a and later
- FGS and FLS devices running software release 4.1 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later

The MAC filtering feature on an 802.1X-enabled port allows 802.1X and non-802.1X devices to share the same physical port. For example, this feature enables you to connect a PC and a non-802.1X device, such as a Voice Over IP (VOIP) phone, to the same 802.1X-enabled port on the Brocade device. The IP phone will bypass 802.1X authentication and the PC will require 802.1X authentication.

To enable this feature, first create a MAC filter, then bind it to an interface on which 802.1X is enabled. The MAC filter includes a mask that can match on any number of bytes in the MAC address. The mask can eliminate the need to enter MAC addresses for all non-802.1X devices connected to the Brocade device, and the ports to which these devices are connected.

**Configuration notes**

- This feature is supported on untagged, tagged, and dual-mode ports.
- You can configure this feature on ports that have ACLs and MAC filters defined.
- This feature is not supported on TurboIron X Series devices.

**Configuration syntax**

To configure MAC filtering on an 802.1X-enabled port, enter commands such as the following.

```
FastIron#(config)#mac filter 1 permit 0050.04ab.9429 ffff.ffff.0000 any
FastIron#(config)#int e1/2
FastIron#(config-if-e1000-1/2)#dot1x auth-filter 1 3 to 5 10
```

The first line defines a MAC filter that matches on the first four bytes (ffff.ffff.0000) of the source MAC address 0050.04ab.9429, and any destination MAC address. The permit action creates an 802.1X session in the FORCE AUTHORIZE state, meaning that the device is placed unconditionally in the authorized state, bypassing 802.1X authentication and allowing all traffic from the specified MAC address. If no match is found, the implicit action is to authenticate the client.

The last line binds MAC filters 1, 3, 4, 5, and 10 to interface 2.

Syntax: mac filter <filter-num> permit | deny <src-mac> <mask> | any <dest-mac> <mask> | any

Syntax: dot1x auth-filter <filter-list>
The `permit` | `deny` argument determines the action the software takes when a match occurs. In the previous example, the `permit` action creates an 802.1X session in the FORCE AUTHORIZE state, meaning that the device is placed unconditionally in the authorized state, bypassing 802.1X authentication and allowing all traffic from the specified MAC address. The `deny` action creates an 802.1X session in the FORCE UNAUTHORIZE state, meaning that the device will never be authorized, even if it has the appropriate credentials.

The `<src-mac> | any` parameter specifies the source MAC address. You can enter a specific address value and a comparison mask, or the keyword `any` to filter on all MAC addresses. Specify the mask using f (ones) and zeros. For example, to match on the first two bytes of the address aabb.ccdd.eeff, use the mask ffff.0000.0000. The filter matches on all MAC addresses that contain aabb as the first two bytes and accepts any value for the remaining bytes of the MAC address. If you specify `any`, do not specify a mask. In this case, the filter matches on all MAC addresses. If no match is found, the implicit action is to authenticate the client.

The `<dest-mac> | any` parameter specifies the destination MAC address. The syntax rules are the same as those for the `<src-mac> | any` parameter. Note that the 802.1X Authentication filter (dot1x auth-filter) does not use the destination MAC address in the MAC filter.

The `<filter-num>` command identifies the MAC filter. The maximum number of supported MAC filters is determined by the `mac-filter-sys` default or configured value.

The `dot1x auth-filter <filter-list>` command binds MAC filters to a port.

The following rules apply when using the `dot1x auth-filter` command:

- When you add filters to or modify the `dot1x auth-filter`, the system clears all 802.1X sessions on the port. Consequently, all users that are logged in will need to be re-authenticated.
- The maximum number of filters that can be bound to a port is limited by the `mac-filter-port` default or configured value.
- The filters must be applied as a group. For example, if you want to apply four filters to an interface, they must all appear on the same command line.
- You cannot add or remove individual filters in the group. To add or remove a filter on an interface, apply the filter group again containing all the filters you want to apply to the port.

If you apply a filter group to a port that already has a filter group applied, the older filter group is replaced by the new filter group.

### Locking a port to restrict addresses

**NOTE**
This feature is not supported on TurboIron devices.

Address-lock filters allow you to limit the number of devices that have access to a specific port. Access violations are reported as SNMP traps. This feature is disabled by default. A maximum of 2048 entries can be specified for access. The default address count is eight.

### Configuration notes

- Static trunk ports and link-aggregation configured ports do not support the lock-address option.
Displaying and modifying system parameter default settings

• The MAC port security feature is a more robust version of this feature. Refer to Chapter 43, “Using the MAC Port Security Feature”.
• This feature is not supported on TurboIron X Series devices.

Command syntax

To enable address locking for port 2 and place a limit of 15 entries, enter a command such as the following.

FastIron(config)# lock e 2 addr 15

Syntax: lock-address ethernet [stack-unit]/<slotnum>/<portnum> [addr-count <num>]

The slotnum parameter is required on chassis devices and on FastIron GS devices.

The portnum parameter is a valid port number.

The <num> parameter is a value from 1 – 2048.

Displaying and modifying system parameter default settings

Brocade devices have default table sizes for the system parameters shown in the following display outputs. The table sizes determine the maximum number of entries the tables can hold. You can adjust individual table sizes to accommodate your configuration needs.

The tables you can configure, as well as the default values and valid ranges for each table, differ depending on the Brocade device you are configuring. To display the adjustable tables on your Brocade device, use the show default values command. The following shows example outputs.

Configuration considerations

• Changing the table size for a parameter reconfigures the device memory. Whenever you reconfigure the memory on a Brocade device, you must save the change to the startup-config file, then reload the software to place the change into effect.
• Configurable tables and their defaults and maximum values differ on Brocade IPv4 devices versus IPv6-capable devices.
• For more information about Layer 3 system parameter limits, refer to “Modifying and displaying layer 3 system parameter limits” on page 713.

Displaying system parameter default values

To display the configurable tables and their defaults and maximum values, enter the show default values command at any level of the CLI.

The following shows an example output of the show default values command on a FastIron Layer 2 device.
Displaying and modifying system parameter default settings

```
FastIron# show default values
sys log buffers:50     mac age time:300 sec     telnet sessions:5
System Parameters    Default    Maximum    Current
igmp-max-group-addr  255        1024       255

Displaying and modifying system parameter default settings

Modifying system parameter default values

Information for the configurable tables appears under the columns that are shown in bold type in the above examples. To simplify configuration, the command parameter you enter to configure the table is used for the table name. For example, to increase the capacity of the IP route table, enter the following commands.

```
FastIron(config)#system-max ip-route 120000
FastIron(config)#write memory
FastIron(config)#exit
FastIron#reload
```

**Syntax: system-max ip-route <num>**

The `<num>` parameter specifies the maximum number of routes in the IP route table. The minimum value is 4096. The maximum value is 524288 starting in software release FSX 04.1.00. In releases prior to FSX 04.1.00, the maximum value is 262144 or 128000, depending on the software version. The default is 80000 IP routes.

**NOTE**

If you accidentally enter a value that is not within the valid range of values, the CLI will display the valid range for you.

To increase the number of IP subnet interfaces you can configure on each port on a device running Layer 3 code from 24 to 64, then increase the total number of IP interfaces you can configure on the device from 256 to 512, enter the following commands.

```
FastIron(config)#system-max subnet-per-interface 64
FastIron(config)#write memory
FastIron(config)#exit
FastIron#reload
```

**Syntax: system-max subnet-per-interface <num>**

The `<num>` parameter specifies the maximum number of subnet addresses per port and can be from 1 – 64. The default is 24.
Dynamic buffer allocation for QoS priorities for FastIron X Series devices

Platform Support:
- FastIron X Series devices running software release 02.4.00 and later

NOTE
This section does not apply to TurboIron X Series devices or FGS, FLS, FWS, FGS-STK, FLS-STK, and FCX devices. To configure dynamic buffer limits on the TurboIron X Series, refer to “Egress buffer thresholds for QoS priorities” on page 393. To configure dynamic buffer limits on FGS, FLS, FWS, FGS-STK, FLS-STK, and FCX devices, see “Dynamic buffer allocation for FGS, FLS, FWS, and FCX stackable and standalone devices” on page 389.

By default, Brocade Ironware software allocates a certain number of buffers to the outbound transmit queue for each port, based on QoS priority (traffic class). The buffers control the total number of packets permitted in the outbound transmit queue of the port. For each port, the Brocade device defines the maximum outbound transmit buffers, also called queue depth limits, as follows:

- **Total Transmit Queue Depth Limit** – The total maximum number of transmit buffers allocated for all outbound packets on a port. Packets are added to the outbound queue for the port as long as the number of buffers currently being used is less than the total transmit queue depth limit. When this limit is reached, any new packets attempting to enter the port transmit queue will be dropped until at least one buffer is freed.

- **Transmit Queue Depth Limit for a Given Traffic Class** – The maximum number of transmit buffers allocated for packets with a given traffic class (0 – 7) on a port. Packets with the specified traffic class are added to the port outbound queue as long as the number of buffers currently being used for that traffic class is less than the transmit queue depth limit for the traffic class. When this limit is reached, any new packets with the specified traffic class attempting to enter the port transmit queue will be dropped.

In releases prior to 02.4.00 for the FastIron X Series, the above queue depth limits are fixed and cannot be modified.
Starting with release 02.4.00 for the FastIron X Series, you can increase or decrease both of these queue depth limits per port. This feature is useful in situations where applications have intermittent bursts of oversubscription. For example, by increasing the buffers on the egress port, the Brocade device will be able to forward oversubscribed packets instead of dropping them.

Brocade devices use the default maximum queue depths listed in Table 80.

**Default queue depth limits for FastIron X Series devices**

Table 80 defines the default maximum queue depth values per port, per traffic class. The Brocade device drops the packets that cause the port to exceed these limits.

<table>
<thead>
<tr>
<th>Port type</th>
<th>Maximum queue depth per port, per priority 0 – 6</th>
<th>Maximum queue depth per port, per priority 7</th>
<th>Total maximum queue depth</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Gbps port</td>
<td>96</td>
<td>224</td>
<td>896</td>
</tr>
<tr>
<td>10 Gbps port without jumbo enabled</td>
<td>400</td>
<td>1104</td>
<td>3904</td>
</tr>
<tr>
<td>10 Gbps port with jumbo enabled</td>
<td>352</td>
<td>640</td>
<td>3104</td>
</tr>
</tbody>
</table>

**Configuring the total transmit queue depth limit for FastIron X Series devices**

To set the total transmit queue depth limit on a port, enter a command such as the following.

```
FastIron(config)#qd 2 2049
```

This command sets the queue depth limit on port 2 to 2049. Packets are added to the port's outbound queue as long as the packets do not cause the port to exceed 2048 buffers. If the port reaches its queue depth limit of 2049, any new packets attempting to enter the port transmit queue will be dropped until at least one buffer is freed.

**Syntax:** $qd\ [<\text{slotnum}>]/<\text{portnum}> <\text{limit}>$

The $<\text{slotnum}>$ parameter is required on chassis devices.

The $<\text{portnum}>$ parameter specifies on which port to apply the queue depth limit.

The $<\text{limit}>$ parameter can be a value from 0 – 4095. Table 80 lists the default values.

**Configuring the transmit queue depth limit for a given traffic class on FastIron X Series devices**

To set the transmit queue depth limit on a port for a given traffic class, first enter the transmit queue depth limit for the traffic class, then specify the traffic class.

**Example**

```
FastIron(config)#qd 2 200 7
```

This command sets the queue depth limit on port 2 to 200 for packets with a traffic class of 7. Packets with priority 7 are added to port 2 outbound queue as long as the packets do not exceed 199 buffers. When the port reaches its queue depth limit of 200, packets with the given traffic class will be dropped.
Dynamic buffer allocation for QoS priorities for FastIron X Series devices

Syntax: qd [<slotnum>/]<portnum> <limit> <traffic-class>

The <slotnum> parameter is required on chassis devices.

The <portnum> parameter specifies on which port to apply the queue depth limit.

The <limit> parameter can be a value from 0 – 4095 and cannot exceed the total transmit queue depth limit configured for the port. Table 80 lists the default values.

The sum of the queue depth limits for individual traffic classes on a port does not need to equal the total queue depth limit for the port:

- If the sum of the individual traffic class queue depth limits exceeds the total port limit and the total port limit is reached, any buffer that gets released can be used by any traffic class queue that has not reached its individual limit.
- If the sum of the individual traffic class queue depth limits is less than the total port limit, the remaining buffers can be used only by packets with a priority of 7.

The <traffic-class> parameter can be a value from 0 – 7, where 7 is the highest priority queue.

Removing buffer allocation limits on FastIron X Series devices

Platform Support:

- FastIron X Series devices running software release 03.2.00 and later

You can remove buffer allocation limits on all ports and all Traffic Classes globally. This permits all available buffers in a port region to be used in a first-come-first-serve basis by any of its ports, regardless of priority. This can be done using the following command.

FastIron(config)#buffer-sharing-full

Syntax: [no] buffer-sharing-full

Entering this command sets the Total Transmit Queue Depth Limit as well as the Transmit Queue Depth Limits for each Traffic Class to 4095 for all ports of the device. The command overrides any existing individually configured queue depth limits.

NOTE
This command should be used carefully! By entering this command, there is no limit on the number of buffers a port or a specific priority on a port can use. So one port could potentially use up all the available buffers of its port region and cause starvation on other ports of the port region.

Generic buffer profiles for FastIron X Series devices

Platform Support:

- FCX-S devices running software release 06.0.00 and later

Default buffer settings are currently optimized for 1GE-to-1GE traffic. This feature adds buffer profiles for 1GE-to-100Mbit traffic, simplifying configuration and improving performance.

This feature allows users to configure a pre-defined set of buffers and descriptors for priority 0 and 7. The buffer profile supports VoIP traffic that uses priority 7, with 10/100 uplink ports and 1000 downlink ports.
NOTE
In previous versions, users could manually configure buffers and descriptors using QD commands. This feature cannot co-exist with QD commands. You may use one or the other, but not both types at the same time.

**Configuring buffer profiles**

To configure predefined buffers, enter a command similar to the following.

```
FastIron#buffer-profile port-region 0 voip downlink 100 uplink 1000
```

**Syntax:** `[no] buffer-profile port-region <num> voip downlink 100 uplink 1000`

**NOTE**
The port-region num can be either 0 (ports 0/1/1 to 0/1/24) or 1 (ports 0/1/25 to 0/1/48).

**Deleting buffer profiles**

To delete an existing buffer profile configuration, use the `[no]` form of the command.

```
FastIron#no buffer-profile port-region 0 voip downlink 100 uplink 1000
```

**Dynamic buffer allocation for FGS, FLS, FWS, and FCX stackable and standalone devices**

**Platform Support:**

- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later

The devices listed above all operate using the FGS architecture, which by default allocates fixed buffers on a per-priority-queue per packet-processor basis. Where the FastIron X Series devices configure buffers on a per-port basis, FGS architecture devices configures buffers on a per-device basis, and applies the configuration to all ports on the device. In instances of heavy traffic bursts to aggregation links, such as in stacking configurations or mixed speed environments, momentary oversubscription of buffers and descriptors may occur. This can lead to dropped packets during egress queuing.

Brocade FastIron stackable devices a capable of allocating additional egress buffering and descriptors to handle momentary burst traffic periods, especially when other priority queues may not be in use, or may not be experiencing heavy levels of traffic. This allows users to allocate and fine tune the depth of priority buffer queues for each packet processor. The CLI commands for this feature are `qd descriptor` and `qd-buffer`. A descriptor points to one or more packet buffers.

The 48-port Brocade stackable switch has 2 packet processors. The 24-port Brocade stackable switch has a single packet processor. In an IronStack, each stack unit has the possibility of two packet processors, but the second processor for a 24-port stack unit cannot be configured. The number of actual available packet processors depends on the type and number of switches in the stack.
For example, for an 8-unit stack of 48 ports, the packet processor numbering scheme is as follows:

Stack unit 1 - packet processors 0 and 1
Stack unit 2 - packet processors 2 and 3
Stack unit 3 - packet processors 4 and 5
Stack unit 4 - packet processors 6 and 7
Stack unit 5 - packet processors 8 and 9
Stack unit 6 - packet processors 10 and 11
Stack unit 7 - packet processors 12 and 13
Stack unit 8 - packet processors 14 and 15

In this configuration, if stack unit 3 and stack unit 7 are 24-port devices, the odd-numbered packet processors 5 and 13 cannot be configured, and do not exist, although they are reserved.

### Configuring dynamic buffer allocation for FGS, FLS, FWS, and FCX stackable and standalone devices

The buffer and descriptor allocation process occurs in four sequential steps:

1. **Configure the allowable port descriptors by entering a command similar to the following:**

   ```
   FastIron648S Switch#qd-descriptor 1 2 76
   Syntax: qd-descriptor <DeviceNum> <PortTypeVal> <NumDescriptors>
   "DeviceNum: 1-x
   "PortTypeVal : 1 for 1Gbps, 2 for 10Gbps
   "NumDescriptors : Number of descriptors to allocate (minimum 1, maximum 4095)
   ```

   **NOTE**
   FWS, FGS, FLS, and FGS-STK and FLS-STK devices support a maximum of 4095 descriptors. FCX devices support a maximum of 8192 descriptors.

2. **Configure the port descriptors for the queue by entering a command similar to the following:**

   ```
   FastIron648S Switch#qd-descriptor 1 2 76 2
   Syntax: qd-descriptor <DeviceNum> <PortTypeVal> <NumDescriptors> <PriorityQueue>
   "DeviceNum: 1-x
   "PortTypeVal : 1 for 1Gbps, 2 for 10Gbps
   "NumDescriptors : Number of descriptors to allocate (minimum 1, maximum 4095)
   "PriorityQueue: Designates a specific queue (0 to 7)
   ```

3. **Configure the allowable packet buffers by entering a command similar to the following:**

   ```
   FastIron648S Switch#qd-buffer 1 2 76
   Syntax: qd-buffer <DeviceNum> <PortTypeVal> <NumBuffers>
   "DeviceNum: 1-x
   "PortTypeVal : 1 for 1Gbps, 2 for 10Gbps
   "NumBuffers : Number of descriptors to allocate (minimum 1, maximum 4095)
   ```

4. **Configure the allowable packet buffers for the queue by entering a command similar to the following:**

   ```
   FastIron648S Switch#qd-buffer 1 2 76 2
   Syntax: qd-buffer <DeviceNum> <PortTypeVal> <NumBuffers> <PriorityQueue>
   "DeviceNum: 0-x
   "PortTypeVal: 1 for 1 Gbps or 2 for 10 Gbps
   ```
Dynamic buffer allocation for FGS, FLS, FWS, and FCX stackable and standalone devices

"NumBuffers: Number of buffers to allocate (minimum 1, maximum 4095)
"PriorityQueue: Designates a specific queue (0 to 7).

Sample Configuration

This sample configuration assumes a four-unit stack with the following topology. Note that there is no packet processor number 3 or 7, because stack units 2 and 4 are 24-port devices.

Stack unit 1, 48 ports - packet processor numbers 0 and 1
Stack unit 2, 24 ports - packet processor number 2
Stack unit 3, 48 ports - packet processors 4 and 5
Stack unit 4, 24 ports - packet processor number 6

Configuration Command Example

The following commands allocate available buffers to be used by priority 0 queues in the four-unit stack:

```
qd-descriptor 0 1 4095
qd-descriptor 1 1 4095
qd-descriptor 2 1 4095
qd-descriptor 4 1 4095
qd-descriptor 5 1 4095
qd-descriptor 6 1 4095
qd-descriptor 0 2 4095
qd-descriptor 1 2 4095
qd-descriptor 2 2 4095
qd-descriptor 4 2 4095
qd-descriptor 5 2 4095
qd-descriptor 6 2 4095
qd-descriptor 0 1 4095 0
qd-descriptor 1 1 4095 0
qd-descriptor 2 1 4095 0
qd-descriptor 4 1 4095 0
qd-descriptor 5 1 4095 0
qd-descriptor 6 1 4095 0
qd-descriptor 0 2 4095 0
qd-descriptor 1 2 4095 0
qd-descriptor 2 2 4095 0
qd-descriptor 4 2 4095 0
qd-descriptor 5 2 4095 0
qd-descriptor 6 2 4095 0
qd-buffer 0 1 4095
qd-buffer 1 1 4095
qd-buffer 2 1 4095
qd-buffer 4 1 4095
qd-buffer 5 1 4095
qd-buffer 6 1 4095
qd-buffer 0 2 4095
qd-buffer 1 2 4095
qd-buffer 2 2 4095
qd-buffer 4 2 4095
qd-buffer 5 2 4095
qd-buffer 6 2 4095
qd-buffer 0 1 4095 0
qd-buffer 1 1 4095 0
qd-buffer 2 1 4095 0
qd-buffer 4 1 4095 0
```
Removing buffer allocation limits on FGS, FLS, FWS, and FCX stackable and standalone devices

**Platform Support:**
- FGS and FLS devices running software release 04.1.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later

You can remove buffer allocation limits on all ports and all Traffic Classes globally. This permits all available buffers in a port region to be used in a first-come-first-serve basis by any of its ports, regardless of priority. This can be done using the following command.

```
FastIron(config)#buffer-sharing-full
```

**Syntax:** `[no] buffer-sharing-full`

Entering this command sets the Total Transmit Queue Depth Limit as well as the Transmit Queue Depth Limits for each Traffic Class to 4095 for all ports of the device. The command overrides any existing individually configured queue depth limits.

---

**NOTE**
This command should be used carefully! By entering this command, there is no limit on the number of buffers a port or a specific priority on a port can use. So one port could potentially use up all the available buffers of its port region and cause starvation on other ports of the port region.

---

Generic buffer profiles for FGS, FLS, FWS, and FCX stackable and standalone devices

**Platform Support:**
- FGS and FLS devices running software release 04.1.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later

Default buffer settings are currently optimized for 1GE-to-1GE traffic. This feature adds buffer profiles for 1GE-to-100Mbit traffic, simplifying configuration and improving performance.

This feature allows users to configure a pre-defined set of buffers and descriptors for priority 0 and 7. The buffer profile supports VoIP traffic that uses priority 7, with 10/100 uplink ports and 1000 downlink ports.

```
qd-buffer 5 1 4095 0
qd-buffer 6 1 4095 0
qd-buffer 0 2 4095 0
qd-buffer 1 2 4095 0
qd-buffer 2 2 4095 0
qd-buffer 4 2 4095 0
qd-buffer 5 2 4095 0
qd-buffer 6 2 4095 0
```
NOTE
In previous versions, users could manually configure buffers and descriptors using QD commands. This feature cannot co-exist with QD commands. You may use one or the other, but not both types at the same time.

Configuring buffer profiles

To configure predefined buffers, enter a command similar to the following.

FastIron#buffer-profile port-region 0 voip downlink 100 uplink 1000

Syntax: [no] buffer-profile port-region <num> voip downlink 100 uplink 1000

NOTE
The port-region num can be either 0 (ports 0/1/1 to 0/1/24) or 1 (ports 0/1/25 to 0/1/48).

Deleting buffer profiles

To delete an existing buffer profile configuration, use the [no] form of the command.

FastIron#no buffer-profile port-region 0 voip downlink 100 uplink 1000

Egress buffer thresholds for QoS priorities

Platform Support:

- TurboIron X Series devices running software release 04.1.00 and later

NOTES:

- The terms QoS priority and traffic class are used interchangeably in this section and mean the same thing.
- Buffer threshold level-3 to maximum does not change the buffering behavior of the device in release 04.2.00 and later.

The TurboIron switch uses egress buffer threshold levels to dynamically adjust each port egress queue (outbound transmit queue) based on QoS priority (traffic class) and jumbo frame support. When the egress queue is full, any new packets destined for the egress queue will be dropped.

The following egress buffer thresholds can be adjusted by an administrator:

- **Egress Buffer Threshold for all Traffic Classes for a port** – When this is configured, the specified egress buffer threshold will be applied to all traffic classes (0 – 7) on a port.
- **Egress Buffer Threshold for a given Traffic Class for a port** – When this is configured, the specified egress buffer threshold will be applied to a specific traffic class (0 – 7) on a port.

The egress buffer thresholds can be modified to various levels. The default settings are described in the section “Default settings for egress buffer thresholds” on page 394. Note that based on the egress buffer threshold assigned, the system will dynamically control the egress CoS queue size for a port based on the current buffer usage information from the system.
FIGURE 49 shows the egress buffer thresholds.

**FIGURE 49**  Egress buffer thresholds on TurboIron devices

<table>

</tbody>
</table>

Manually increasing buffer thresholds may be useful in situations where applications have intermittent bursts of oversubscription. For example, by increasing a port egress buffer threshold, the TurboIron will be able to forward oversubscribed packets instead of dropping them.

**Cut-Through Switching Support on TurboIron 24X Series Switches**

The TurboIron X Series operates in cut-through switching mode, meaning it starts forwarding a frame even before the whole frame has been received. However, if there is any oversubscription on the egress port, either due to speed mismatch (10-Gbps to 1-Gbps) or network topology (traffic from two 10-Gig ports going out of one 10-Gig port), the switch will buffer the packets and the forwarding behavior will be similar to store-and-forward mode.

**Cut-Through Switching Mode and CRC Error Packet Handling**

In the cut-through switching mode, if a packet is detected with a CRC error, the whole packet will be dropped if the packet size is less than or equal to 384 bytes. If the packet size is larger than 384 bytes, the last few bytes will be trimmed off the frames.

**Default settings for egress buffer thresholds**

*Figure 49* illustrates the egress buffer threshold levels. For both non-jumbo and jumbo frame forwarding, the default egress buffer threshold is level-4 for all QoS priorities.

The TurboIron X Series is automatically configured to use the default thresholds for egress buffers. If you want to change the default threshold values, you must first disable the default values. The next section shows how.
Disabling and re-enabling the default settings for egress buffer thresholds

To disable the device from using the default settings for egress buffer thresholds, enter the following command.

```
TurboIron 24X(config)#no enable egress-buffer-default
```

This command disables the default values for all traffic classes on all ports. Once disabled, you can configure new threshold values as instructed in “Setting the egress buffer threshold for all QoS priorities on a port or group of ports” on page 395 and “Setting the egress buffer threshold for a specific QoS priority on a port or group of ports” on page 396.

**Syntax:** no enable egress-buffer-default

To re-enable the default settings for egress buffer thresholds once they have been disabled, enter the following command.

```
TurboIron 24X(config)#enable egress-buffer-default
```

The TurboIron X Series will revert to using the default values for all traffic classes on all ports, as described in “Default settings for egress buffer thresholds” on page 394.

**Syntax:** enable egress-buffer-default

Setting the egress buffer threshold for all QoS priorities on a port or group of ports

**NOTE**

Be sure to disable the default settings before performing the tasks in this section. Refer to “Disabling and re-enabling the default settings for egress buffer thresholds”.

To set the egress buffer threshold for all QoS priorities (0 – 7) on a port, enter commands such as the following.

```
TurboIron 24X(config)#int e 3
TurboIron 24X(conf-if-e10000-3)#egress-buffer-threshold min
```

To set the egress buffer threshold for all QoS priorities on multiple ports, enter commands such as the following.

```
TurboIron 24X(config)#int e 4 to 5
TurboIron 24X(config-mif-e10000-4-5)#egress-buffer-threshold min
```

These commands set the egress buffer threshold for all QoS priorities on ports e 1/3, and ports e 1/4 and 1/5, to the minimum (min) threshold.

**Syntax:** [no] egress-buffer-threshold min|level-1|level-2|level-3|level-4|level-5|level-6|max

Use the no form of the command to revert back to the default values for all QoS priorities on the port. For the default values, refer to “Default settings for egress buffer thresholds” on page 394.
Setting the egress buffer threshold for a specific QoS priority on a port or group of ports

**NOTE**
Be sure to disable the default settings before performing the tasks in this section. Refer to “Disabling and re-enabling the default settings for egress buffer thresholds”.

To set the egress buffer threshold for a specific QoS priority on a port, enter commands such as the following.

```
TurboIron 24X(config)#int e 3
TurboIron 24X(conf-if-e10000-3)#egress-buffer-threshold level-6 6
```

These commands set the egress buffer threshold for packets with QoS priority 6 to the **level-6** threshold.

To set the egress buffer threshold for a specific QoS priority on multiple ports, enter commands such as the following.

```
TurboIron 24X(config)#int e 4 to 5
TurboIron 24X(config-mif-4-5)#egress-buffer-threshold high 6
```

These commands set the egress buffer threshold for packets with QoS priority 6 to the **high** threshold.

**Syntax:** `[no] egress-buffer-threshold` `min|level-1|level-2|level-3|level-4|level-5|level-6|max` `<QoS-priority>`

For `<QoS-priority>`, enter a specific QoS priority (0 – 7).

Use the `no` form of the command to revert back to the default value for the QoS priority. For the default values, refer to “Default settings for egress buffer thresholds” on page 394.

Remote Fault Notification (RFN) on 1G fiber connections

**Platform Support:**
- FGS and FLS devices running software release 02.6.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FastIron X Series devices – all software releases
- FCX-S devices running software release 06.0.00 and later

**NOTE**
This feature is only available for Gbps Ethernet Fiber ports. It is not available for 10/100 ports and Gbps Ethernet Copper ports.

**NOTE**
This feature is not supported on TurboIron X Series devices.

For fiber-optic connections, you can optionally configure a transmit port to notify the receive port on the remote device whenever the transmit port becomes disabled.
When you enable this feature, the transmit port notifies the remote port whenever the fiber cable is either physically disconnected or has failed. When this occurs and the feature is enabled, the device disables the link and turns OFF both LEDs associated with the ports.

By default, RFN is enabled.

You can configure RFN as follows:

- Globally, on the entire device
- On a trunk group
- On an individual interface

### Enabling and disabling remote fault notification

RFN is ON by default. To disable RFN, use the following command.

```plaintext
FastIron(config)#interface e 0/1/1
FastIron(config-if-e1000-0/1/1)#gig-default neg-off
```

To re-enable RFN, use the following command.

```plaintext
FastIron(config)#interface e 0/1/1
FastIron(config-if-e1000-0/1/1)#gig-default auto-on
```

### Link Fault Signaling (LFS) for 10G

**Platform Support:**

- FGS and FLS devices running software release 02.6.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FastIron X Series devices - all software releases
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

Link Fault Signaling (LFS) is a physical layer protocol that enables communication on a link between two 10 Gbps Ethernet devices. When configured on a Brocade 10 Gbps Ethernet port, the port can detect and report fault conditions on transmit and receive ports. Brocade recommends enabling LFS on both ends of a link.

**NOTE**

LFS is always enabled on TurboIron X Series devices and cannot be disabled. The TurboIron devices support LFS only with other TurboIron devices.

When LFS is enabled on an interface, the following Syslog messages are generated when the link goes up or down, or when the TX or RX fiber is removed from one or both sides of the link that has LFS enabled.

```plaintext
Interface ethernet1/1, state down - link down
Interface ethernet1/1, state up
```

When a link fault occurs, the Link and Activity LEDs turn OFF.
The Link and Activity LEDs turn ON when there is traffic traversing the link after the fiber is installed.

### Enabling LFS

To enable LFS between two 10 Gbps Ethernet devices, enter commands such as the following on both ends of the link.

```
FastIron(config)#interface e 1/1
FastIron(config-if-e1000-1/1)#link-fault-signal
```

**Syntax:** `[no] link-fault-signal`

Use the `no` form of the command to disable LFS.

**NOTE**
The `no` form of the command is not supported on TurboIron X Series devices.

LFS is OFF by default.

### Viewing the status of LFS-enabled links

**Platform Support:**
- FastIron X Series devices running software release 04.2.00 and later

The status of an LFS-enabled link is shown in the output of the `show interface` and `show interface brief` commands, as shown in the following examples.

```
FastIron#show interface e 10/1
10GigabitEthernet10/1 is down (remote fault), line protocol is down
  Hardware is 10GigabitEthernet, address is 0012.f227.79d8 (bia 0012.f227.79d8)
  Configured speed 10Gbit, actual unknown, configured duplex fdx, actual unknown
  Member of L2 VLAN ID 1, port is untagged, port state is BLOCKING
  BPDU guard is Disabled, ROOT protect is Disabled
  Link Fault Signaling is Enabled, Link Error Dampening is Disabled
  STP configured to ON, priority is level0
  Flow Control is disabled
  mirror disabled, monitor disabled

some lines omitted for brevity...
```

The bold text in the above output shows that the LFS-enabled link (port 10/1) is down because of an error on the remote port, as indicated by `remote fault`.

**Syntax:** `show interface ethernet [<slotnum>/]<portnum>`

The `<slotnum>` parameter is required on chassis devices.

```
FastIron#show interfaces brief
Port Link State Dupl Speed Trunk Tag Pvid Pri MAC Name
10/1 Err-LFS None None None None No 1 0 0012.f227.79d8
```

The bold text in the above output indicates that there is an error on the LFS-enabled link on port 10/1 and the link is down.

**Syntax:** `show interfaces brief`
Jumbo frame support

Ethernet traffic moves in units called frames. The maximum size of frames is called the Maximum Transmission Unit (MTU). When a network device receives a frame larger than its MTU, the data is either fragmented or dropped. Historically, Ethernet has a maximum frame size of 1500 bytes, so most devices use 1500 as their default MTU.

Jumbo frames are Ethernet frames with more than 1,500 bytes MTU. Conventionally, jumbo frames can carry up to 9,000 bytes MTU. Brocade FastIron devices support Layer 2 jumbo frames on 10/100, 100/100/1000, and 10GbE ports. Brocade devices also support jumbo frames per VLAN.
Jumbo frame support
Chapter 11

Configuring Metro Features

Topology groups

A topology group is a named set of VLANs that share a Layer 2 topology. Topology groups simplify configuration and enhance scalability of Layer 2 protocols by allowing you to run a single instance of a Layer 2 protocol on multiple VLANs.

You can use topology groups with the following Layer 2 protocols:

- STP
- MRP
- VSRP
- 802.1W

Topology groups simplify Layer 2 configuration and provide scalability by enabling you to use the same instance of a Layer 2 protocol for multiple VLANs. For example, if a Brocade device is deployed in a Metro network and provides forwarding for two MRP rings that each contain 128 VLANs, you can configure a topology group for each ring. If a link failure in a ring causes a topology change, the change is applied to all the VLANs in the ring topology group. Without topology groups, you would need to configure a separate ring for each VLAN.

**NOTE**
If you plan to use a configuration saved under an earlier software release and the configuration contains STP groups, the CLI converts the STP groups into topology groups when you save the configuration. For backward compatibility, you can still use the STP group commands. However, the CLI converts the commands into the topology group syntax. Likewise, the `show stp-group` command displays STP topology groups.

Master VLAN and member VLANs

Each topology group contains a master VLAN and can contain one or more member VLANs and VLAN groups:

- **Master VLAN** – The master VLAN contains the configuration information for the Layer 2 protocol. For example, if you plan to use the topology group for MRP, the topology group master VLAN contains the ring configuration information.

- **Member VLANs** – The member VLANs are additional VLANs that share ports with the master VLAN. The Layer 2 protocol settings for the ports in the master VLAN apply to the same ports in the member VLANs. A change to the master VLAN Layer 2 protocol configuration or Layer 2 topology affects all the member VLANs. Member VLANs do not independently run a Layer 2 protocol.

- **Member VLAN groups** – A VLAN group is a named set of VLANs. The VLANs within a VLAN group have the same ports and use the same values for other VLAN parameters.
When a Layer 2 topology change occurs on a port in the master VLAN, the same change is applied to that port in all the member VLANs that contain the port. For example, if you configure a topology group whose master VLAN contains ports 1/1 and 1/2, a Layer 2 state change on port 1/1 applies to port 1/1 in all the member VLANs that contain that port. However, the state change does not affect port 1/1 in VLANs that are not members of the topology group.

Control ports and free ports

A port that is in a topology group can be a control port or a free port:

- **Control port** – A control port is a port in the master VLAN, and is therefore controlled by the Layer 2 protocol configured in the master VLAN. The same port in all the member VLANs is controlled by the master VLAN Layer 2 protocol. Each member VLAN must contain all of the control ports and can contain additional ports.

- **Free port** – A free port is not controlled by the master VLAN Layer 2 protocol. The master VLAN can contain free ports. (In this case, the Layer 2 protocol is disabled on those ports.) In addition, any ports in the member VLANs that are not also in the master VLAN are free ports.

**NOTE**
Since free ports are not controlled by the master port Layer 2 protocol, they are assumed to always be in the Forwarding state.

Configuration considerations

- Topology groups are supported on all FESX, FSX, FWSX devices and associated software releases.
- Topology groups are supported on FCX devices running software release 06.0.00 and later.
- Topology groups are supported on TurboIron X Series devices running software release 04.2.00 and later.
- You must configure the master VLAN and member VLANs or member VLAN groups before you configure the topology group.
- You can configure up to 256 topology groups. Each group can control up to 4096 VLANs. A VLAN cannot be controlled by more than one topology group.
- The topology group must contain a master VLAN and can also contain individual member VLANs, VLAN groups, or a combination of individual member VLANs and VLAN groups.
- Once you add a VLAN as a member of a topology group, all the Layer 2 protocol information on the VLAN is deleted.

Configuring a topology group

To configure a topology group, enter commands such as the following.

```
FastIron(config)# topology-group 2
FastIron(config-topo-group-2)# master-vlan 2
FastIron(config-topo-group-2)# member-vlan 3
FastIron(config-topo-group-2)# member-vlan 4
FastIron(config-topo-group-2)# member-vlan 5
FastIron(config-topo-group-2)# member-group 2
```

These commands create topology group 2 and add the following:
Topology groups

- Master VLAN 2
- Member VLANs 2, 3, and 4
- Member VLAN group 2

**Syntax:** `[no] topology-group <group-id>`

The `<group-id>` parameter specifies the topology group ID and can be from 1 – 256.

**Syntax:** `[no] master-vlan <vlan-id>`

This command adds the master VLAN. The VLAN must already be configured. Make sure all the Layer 2 protocol settings in the VLAN are correct for your configuration before you add the VLAN to the topology group. A topology group can have only one master VLAN.

**NOTE**
If you remove the master VLAN (by entering `no master-vlan <vlan-id>`), the software selects the new master VLAN from member VLANs. For example, if you remove master VLAN 2 from the example above, the CLI converts member VLAN 3 into the new master VLAN. The new master VLAN inherits the Layer 2 protocol settings of the older master VLAN.

**NOTE**
If you add a new master VLAN to a topology group that already has a master VLAN, the new master VLAN replaces the older master VLAN. All member VLANs and VLAN groups follow the Layer 2 protocol settings of the new master VLAN.

**Syntax:** `[no] member-vlan <vlan-id>`

The `<vlan-id>` parameter specifies a VLAN ID. The VLAN must already be configured.

**Syntax:** `[no] member-group <num>`

The `<num>` specifies a VLAN group ID. The VLAN group must already be configured.

**NOTE**
Once you add a VLAN or VLAN group as a member of a topology group, all the Layer 2 protocol configuration information for the VLAN or group is deleted. For example, if STP is configured on a VLAN and you add the VLAN to a topology group, the STP configuration is removed from the VLAN. Once you add the VLAN to a topology group, the VLAN uses the Layer 2 protocol settings of the master VLAN.

If you remove a member VLAN or VLAN group from a topology group, you will need to reconfigure the Layer 2 protocol information in the VLAN or VLAN group.

**Displaying topology group information**

The following sections show how to display STP information and topology group information for VLANs.

**Displaying STP information**

To display STP information for a VLAN, enter a command such as the following.
Displaying topology group information

To display topology group information, enter the following command.

FastIron# show topology-group

Syntax: show topology-group [<group-id>]

This display shows the following information.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-vlan</td>
<td>The master VLAN for the topology group. The settings for STP, MRP, or VSRP on the control ports in the master VLAN apply to all control ports in the member VLANs within the topology group.</td>
</tr>
<tr>

</table>
Metro Ring Protocol (MRP)

Metro Ring Protocol (MRP) was introduced in two phases:

- **MRP Phase 1** is supported in all software releases and on all Brocade FastIron X Series and FGS, FWS, and FLS, and FCX devices, and TurboIron X Series devices running software release 04.2.00 and later. Refer to “MRP rings without shared interfaces (MRP Phase 1)” on page 407.

- **MRP Phase 2** is supported in all software releases starting with 4.3.00 for all Brocade FastIron X Series, and on all FGS, FWS, and FLS, and FCX devices, and TurboIron X Series devices running software release 04.2.00 and later. Refer to “MRP rings with shared interfaces (MRP Phase 2)” on page 408.

MRP is a Brocade proprietary protocol that prevents Layer 2 loops and provides fast reconvergence in Layer 2 ring topologies. It is an alternative to STP and is especially useful in Metropolitan Area Networks (MANs) where using STP has the following drawbacks:

- STP allows a maximum of seven nodes. Metro rings can easily contain more nodes than this.
- STP has a slow reconvergence time, taking many seconds or even minutes. MRP can detect and heal a break in the ring in sub-second time.
Figure 50 shows an example of an MRP metro ring.

**FIGURE 50  Metro ring – normal state**

The ring in this example consists of four MRP nodes (Brocade switches). Each node has two interfaces with the ring. Each node also is connected to a separate customer network. The nodes forward Layer 2 traffic to and from the customer networks through the ring. The ring interfaces are all in one port-based VLAN. Each customer interface can be in the same VLAN as the ring or in a separate VLAN.

One node is configured as the master node of the MRP ring. One of the two interfaces on the master node is configured as the primary interface; the other is the secondary interface. The primary interface originates Ring Health Packets (RHPs), which are used to monitor the health of the ring. An RHP is forwarded on the ring to the next interface until it reaches the secondary interface of the master node. The secondary interface blocks the packet to prevent a Layer 2 loops. When the master node transmits or receives RHPs, the CPU goes high on the master node.
Configuration notes

- When you configure MRP, Brocade recommends that you disable one of the ring interfaces before beginning the ring configuration. Disabling an interface prevents a Layer 2 loop from occurring while you are configuring MRP on the ring nodes. Once MRP is configured and enabled on all the nodes, you can re-enable the interface.
- MRP 2 support was added in release 04.3.00 for the FastIron X Series devices.
- MRP 1 and MRP 2 support are added in release 04.2.00 for the TurboIron X Series devices.
- The above configurations can be configured as MRP masters or MRP members (for different rings).
- Due to hardware limitations on FGS, FGS-STK, FLS, FLS-STK, and FCX platforms, configuring 40 or more MRP instances may cause errors.
- On TurboIron platforms running software release 04.2.00 and later, you can configure maximum of 32 metro rings.

MRP rings without shared interfaces (MRP Phase 1)

MRP Phase 1 allows you to configure multiple MRP rings, as shown in Figure 51, but the rings cannot share the same link. For example, you cannot configure ring 1 and ring 2 to each have interfaces 1/1 and 1/2.

Also, when you configure an MRP ring, any node on the ring can be designated as the master node for the ring. A master node can be the master node of more than one ring. (Refer to Figure 51.) Each ring is an independent ring and RHP packets are processed within each ring.

FIGURE 51 Metro ring – multiple rings
In this example, two nodes are each configured with two MRP rings. Any node in a ring can be the master for its ring. A node also can be the master for more than one ring.

### MRP rings with shared interfaces (MRP Phase 2)

**Platform Support:**
- FastIron X Series devices running software release 03.0.00 and later, in Layer 3 router code and in Layer 2 switch code
- FastIron GS, LS, and WS devices running software release 04.3.01 and later
- FCX-S devices running software release 06.0.00 and later
- TurboIron X Series devices running software release 04.2.00 and later

With MRP Phase 2, MRP rings can be configured to share the same interfaces as long as the interfaces belong to the same VLAN. Figure 52 shows examples of multiple MRP rings that share the same interface.

**FIGURE 52** Examples of multiple rings sharing the same interface - MRP Phase 2
On each node that will participate in the ring, you specify the ring ID and the interfaces that will be used for ring traffic. In a multiple ring configuration, a ring ID determines its priority. The lower the ring ID, the higher priority of a ring.

A ring ID is also used to identify the interfaces that belong to a ring.

**FIGURE 53** Interface IDs and types

For example, in Figure 53, the ID of all interfaces on all nodes on Ring 1 is 1 and all interfaces on all nodes on Ring 2 is 2. Port 1/1 on node S1 and Port 2/2 on S2 have the IDs of 1 and 2 since the interfaces are shared by Rings 1 and 2.
The ring ID is also used to determine an interface priority. Generally, a ring ID is also the ring priority and the priority of all interfaces on that ring. However, if the interface is shared by two or more rings, then the highest priority (lowest ID) becomes the priority of the interface. For example, in Figure 53, all interfaces on Ring 1, except for Port 1/1 on node S1 and Port 2/2 on node S2 have a priority of 1. Likewise, all interfaces on Ring 2, except for Port 1/1 on node S1 and Port 2/2 on node S2 have a priority of 2. Port 1/1 on S1 and Port 2/2 on S2 have a priority of 1 since 1 is the highest priority (lowest ID) of the rings that share the interface.

If a node has interfaces that have different IDs, the interfaces that belong to the ring with the highest priority become regular ports. Those interfaces that do not belong to the ring with the highest priority become tunnel ports. In Figure 53, nodes S1 and S2 have interfaces that belong to Rings 1 and 2. Those interfaces with a priority of 1 are regular ports. The interfaces with a priority of 2 are the tunnel ports since they belong to Ring 2, which has a lower priority than Ring 1.

**Selection of master node**

Allowing MRP rings to share interfaces limits the nodes that can be designated as the master node. Any node on an MRP ring that does not have a shared interface can be designated as the ring master node. However, if all nodes on the ring have shared interfaces, nodes that do not have tunnel ports can be designated as the master node of that ring. If none of the nodes meet these criteria, you must change the rings’ priorities by reconfiguring the rings’ ID.

In Figure 53, any of the nodes on Ring 1, even S1 or S2, can be a master node since none of its interfaces are tunnel ports. However in Ring 2, neither S1 nor S2 can be a master node since these nodes contain tunnel ports.

**Ring initialization**

The ring shown in Figure 50 shows the port states in a fully initialized ring without any broken links. Figure 54 shows the initial state of the ring, when MRP is first enabled on the ring switches. All ring interfaces on the master node and member nodes begin in the Preforwarding state (PF).

**FIGURE 54** Metro ring – initial state
MRP uses Ring Health Packets (RHPs) to monitor the health of the ring. An RHP is an MRP protocol packet. The source address is the MAC address of the master node and the destination MAC address is a protocol address for MRP. The master node generates RHPs and sends them on the ring. The state of a ring port depends on the RHPs.

**RHP processing in MRP Phase 1**

A ring interface can have one of the following MRP states:

- **Preforwarding (PF)** – The interface can forward RHPs but cannot forward data. All ring ports begin in this state when you enable MRP.
• **Forwarding (F)** – The interface can forward data as well as RHPs. An interface changes from Preforwarding to Forwarding when the port preforwarding time expires. This occurs if the port does not receive an RHP from the master, or if the forwarding bit in the RHPs received by the port is off. This indicates a break in the ring. The port heals the ring by changing its state to Forwarding. The preforwarding time is the number of milliseconds the port will remain in the Preforwarding state before changing to the Forwarding state, even without receiving an RHP.

• **Blocking (B)** – The interface cannot forward data. Only the secondary interface on the master node can be Blocking.

When MRP is enabled, all ports begin in the Preforwarding state. The primary interface on the master node, although it is in the Preforwarding state like the other ports, immediately sends an RHP onto the ring. The secondary port on the master node listens for the RHP.

• If the secondary port receives the RHP, all links in the ring are up and the port changes its state to Blocking. The primary port then sends another MRP with its forwarding bit set on. As each of the member ports receives the RHP, the ports changes their state to Forwarding. Typically, this occurs in sub-second time. The ring very quickly enters the fully initialized state.

• If the secondary port does not receive the RHP by the time the preforwarding time expires, a break has occurred in the ring. The port changes its state to Forwarding. The member ports also change their states from Preforwarding to Forwarding as their preforwarding timers expire. The ring is not intact, but data can still travel among the nodes using the links that are up.

Figure 55 shows an example.

**FIGURE 55** Metro ring – from preforwarding to forwarding
Each RHP also has a sequence number. MRP can use the sequence number to determine the round-trip time for RHPs in the ring. Refer to “Using MRP diagnostics” on page 422.

**RHP processing in MRP Phase 2**

*Figure 56* shows an example of how RHP packets are processed normally in MRP rings with shared interfaces.

**FIGURE 56** Flow of RHP packets on MRP rings with shared interfaces
Port 2/1 on Ring 1 master node is the primary interface of the master node. The primary interface forwards an RHP packet on the ring. Since all the interfaces on Ring 1 are regular ports, the RHP packet is forwarded to all the interfaces until it reaches Port 2/2, the secondary interface of the master node. Port 2/2 then blocks the packet to complete the process.

On Ring 2, Port 3/1, is the primary interface of the master node. It sends an RHP packet on the ring. Since all ports on S4 are regular ports, the RHP packet is forwarded on those interfaces. When the packet reaches S2, the receiving interface is a tunnel port. The port compares the packet priority to its priority. Since the packet priority is the same as the tunnel port priority, the packet is forwarded up the link shared by Rings 1 and 2.

When the RHP packet reaches the interface on node S2 shared by Rings 1 and 2, the packet is forwarded since its priority is less than the interface priority. The packet continues to be forwarded to node S1 until it reaches the tunnel port on S1. That tunnel port determines that the RHP packet priority is equal to the port priority and forwards the packet. The RHP packet is forwarded to the remaining interfaces on Ring 2 until it reaches port 3/2, the secondary interface of the master node. Port 3/2 then blocks the packet to prevent a loop.

When the RHP packet from Ring 2 reached S2, it was also forwarded from S2 to S3 on Ring 1 since the port on S2 has a higher priority than the RHP packet. The packets is forwarded around Ring 1 until it reaches port 2/2, Ring 1 the secondary port. The RHP packet is then blocked by that port.

**How ring breaks are detected and healed**

Figure 57 shows ring interface states following a link break. MRP quickly heals the ring and preserves connectivity among the customer networks.

**FIGURE 57** Metro ring – ring break
If a break in the ring occurs, MRP heals the ring by changing the states of some of the ring interfaces:

- **Blocking interface** – The Blocking interface on the master node has a dead timer. If the dead time expires before the interface receives one of its ring RHPs, the interface changes state to Preforwarding. Once the secondary interface changes state to Preforwarding:
  
  - If the interface receives an RHP, the interface changes back to the Blocking state and resets the dead timer.
  
  - If the interface does not receive an RHP for its ring before the Preforwarding time expires, the interface changes to the Forwarding state, as shown in Figure 57.

- **Forwarding interfaces** – Each member interface remains in the Forwarding state.
When the broken link is repaired, the link interfaces come up in the Preforwarding state, which allows RHPs to travel through the restored interfaces and reach the secondary interface on the master node:

- If an RHP reaches the master node secondary interface, the ring is intact. The secondary interface changes to Blocking. The master node sets the forwarding bit on in the next RHP. When the restored interfaces receive this RHP, they immediately change state to Forwarding.
- If an RHP does not reach the master node secondary interface, the ring is still broken. The master node does not send an RHP with the forwarding bit on. In this case, the restored interfaces remain in the Preforwarding state until the preforwarding timer expires, then change to the Forwarding state.

If the link between shared interfaces breaks (Figure 58), the secondary interface on Ring 1 master node changes to a preforwarding state. The RHP packet sent by port 3/1 on Ring 2 is forwarded through the interfaces on S4, then to S2. The packet is then forwarded through S2 to S3, but not from S2 to S1 since the link between the two nodes is not available. When the packet reaches Ring 1 master node, the packet is forwarded through the secondary interface since it is currently in a preforwarding state. A secondary interface in preforwarding mode ignores any RHP packet that is not from its ring. The secondary interface changes to blocking mode only when the RHP packet forwarded by its primary interface is returned.

The packet then continues around Ring 1, through the interfaces on S1 to Ring 2 until it reaches Ring 2 master node. Port 3/2, the secondary interface on Ring 2 changes to blocking mode since it received its own packet, then blocks the packet to prevent a loop.

**FIGURE 58** Flow of RHP packets when a link for shared interfaces breaks

RHP packets follow this flow until the link is restored; then the RHP packet returns to its normal flow as shown in Figure 56.
Alarm RHP

Previously, detection of MRP ring breaks was completely timer based. An absence of Ring Health Packets (RHP) for a period of 3 "hello times" indicated to the MRP master that the ring is broken. This initiated the transition to a topology change as described in the previous section. The convergence time associated with such an event could take several hundreds of milliseconds.

Now, each MRP node is made a more active participant in detecting link failures. When a link is detected to be down by its "downstream" neighbor, a special packet (called the Alarm RHP packet) is sent to the MRP master, indicating that the link is down.

This MRP packet is sent from the MRP member to the MRP master only when the secondary link goes down and it is sent on the primary link. The destination MAC address in the packet is the ring MAC address. This allows the packet to be hardware forwarded all the way to the MRP master. When the Master switch in the ring receives this packet, it is notified of a break in the ring. At that point, the secondary interface is immediately transitioned from "Blocked" to "Forwarding".

NOTE
The Alarm RHP packet is only sent by the secondary link owner ring to prevent multiple MRP masters going into forward where shared rings are configured.

Operation of the MRP alarm RHP is as follows.

When the link between Switch B and Switch C fails, the "downstream" neighbor (Switch C) detects the failure of the link and triggers corrective action. The following is the complete sequence of events that occurs.

- The downstream neighbor (Switch C) detects a link down event of the link between Switch B and Switch C.
- Switch C sends a single RHP packet with a special Alarm bit set. The RHP packet is sent in the same direction of flow as that of the normal RHP packets (i.e. on the link to Switch D)
- Switch A receives the special RHP packet (on the secondary interface) that was sent by Switch C. It is now aware that the ring is broken even though the dead_interval may not have expired.
- Switch A immediately transitions its secondary interface (previously in Blocked state) to the Forwarding state.
- RHP packets continue to be sent on the primary interface by Switch A to detect if the ring has been healed.

From a user perspective, there is no difference in the behavior of the ring. The only noticeable difference is a rapid convergence in the event of ring failure. There is no CLI command required to enable this feature.

FIGURE 59 A MRP ring under normal operation (A) and after detection of a failure in the ring (B)
Master VLANs and customer VLANs

All the ring ports must be in the same VLAN. Placing the ring ports in the same VLAN provides Layer 2 connectivity for a given customer across the ring. Figure 60 shows an example.

Figure 60 Metro ring – ring VLAN and customer VLANs
Notice that each customer has their own VLAN. Customer A has VLAN 30 and Customer B has VLAN 40. Customer A host attached to Switch D can reach the Customer A host attached to Switch B at Layer 2 through the ring. Since Customer A and Customer B are on different VLANs, they will not receive each other traffic.

You can configure MRP separately on each customer VLAN. However, this is impractical if you have many customers. To simplify configuration when you have a lot of customers (and therefore a lot of VLANs), you can use a topology group.

A topology group enables you to control forwarding in multiple VLANs using a single instance of a Layer 2 protocol such as MRP. A topology group contains a master VLAN and member VLANs. The master VLAN contains all the configuration parameters for the Layer 2 protocol (STP, MRP, or VSRP). The member VLANs use the Layer 2 configuration of the master VLAN.
In Figure 60, VLAN 2 is the master VLAN and contains the MRP configuration parameters for ring 1. VLAN 30 and VLAN 40, the customer VLANs, are member VLANs in the topology group. Since a topology group is used, a single instance of MRP provides redundancy and loop prevention for both the customer VLANs.

If you use a topology group:

- The master VLAN must contain the ring interfaces. The ports must be tagged, since they will be shared by multiple VLANs.
- The member VLAN for a customer must contain the two ring interfaces and the interfaces for the customer. Since these interfaces are shared with the master VLAN, they must be tagged. Do not add another customer interfaces to the VLAN.

For more information about topology groups, refer to “Topology groups” on page 401.

Refer to “MRP CLI example” on page 426 for the configuration commands required to implement the MRP configuration shown in Figure 60.

Configuring MRP

To configure MRP, perform the following tasks. You need to perform the first task on only one of the nodes. Perform the remaining tasks on all the nodes.

**NOTE**
There are no new commands or parameters to configure MRP with shared interfaces (MRP Phase 2).

- Disable one of the ring interfaces. This prevents a Layer 2 loop from occurring while you are configuring the devices for MRP.
- Add an MRP ring to a port-based VLAN. When you add a ring, the CLI changes to the configuration level for the ring, where you can perform the following tasks.
  - Optionally, specify a name for the ring.
  - On the master node only, enable the device to be the master for the ring. Each ring can have only one master node.
  - Specify the MRP interfaces. Each device has two interfaces to an MRP ring.
  - Optionally, change the hello time and the preforwarding time. These parameters control how quickly failover occurs following a change in the state of a link in the ring.
  - Enable the ring.
- Optionally, add the ring VLAN to a topology group to add more VLANs to the ring. If you use a topology group, make sure you configure MRP on the group master VLAN. Refer to “Topology groups” on page 401.
- Re-enable the interface you disabled to prevent a Layer 2 loop. Once MRP is enabled, MRP will prevent the Layer 2 loop.
- On FGS and FLS devices running software release 4.3 and later, and on FCX devices running software version 06.0.00 and later, when configuring MRP 1 or MRP 2 ring on a VLAN, using the `metro-rings` command in addition to the `metro-ring` command is highly recommended. Since these devices do not support mac-range filtering, the `metro-rings` command greatly reduces the number of FDB entries.

Adding an MRP ring to a VLAN

To add an MRP ring to a VLAN, enter commands such as the following.
NOTE
If you plan to use a topology group to add VLANs to the ring, make sure you configure MRP on the topology group master VLAN.

FastIron(config)# vlan 2
FastIron(config-vlan-2)# metro-ring 1
FastIron(config-vlan-2-mrp-1)# name CustomerA
FastIron(config-vlan-2-mrp-1)# master
FastIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
FastIron(config-vlan-2-mrp-1)# enable

These commands configure an MRP ring on VLAN 2. The ring ID is 1, the ring name is CustomerA, and this node (this Brocade device) is the master for the ring. The ring interfaces are 1/1 and 1/2. Interface 1/1 is the primary interface and 1/2 is the secondary interface. The primary interface will initiate RHPs by default. The ring takes effect in VLAN 2.

FastIron(config)# vlan 2
FastIron(config-vlan-2)# metro-ring 1
FastIron(config-vlan-2-mrp-1)# name CustomerA
FastIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
FastIron(config-vlan-2-mrp-1)# enable
FastIron(config-vlan-2-mrp-1)# metro-ring 2
FastIron(config-vlan-2-mrp-2)# name CustomerB
FastIron(config-vlan-2-mrp-2)# ring-interface ethernet 1/1 ethernet 1/2
FastIron(config-vlan-2-mrp-2)# enable

Syntax: [no] metro-ring <ring id>

The <ring-id> parameter specifies the ring ID. In software releases prior to 03.0.00 and in the FGS, FWS, and FLS, the ring ID can be a value from 1 – 255. Starting in release 03.0.00, the <ring-id> can be from 1 – 1023; ID 256 is reserved for VSRP.

On FGS and FLS devices running software release 4.3 and later, and on FCX devices running software version 06.0.00 and later, enter the metro-rings in addition to the metro-ring command as shown below.

FastIron(config)# vlan 2
FastIron(config-vlan-2)# metro-rings 1 2
FastIron(config-vlan-2)# metro-ring 1
FastIron(config-vlan-2-mrp-1)# name CustomerA
FastIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
FastIron(config-vlan-2-mrp-1)# enable
FastIron(config-vlan-2-mrp-1)# metro-ring 2
FastIron(config-vlan-2-mrp-2)# name CustomerB
FastIron(config-vlan-2-mrp-2)# ring-interface ethernet 1/1 ethernet 1/2
FastIron(config-vlan-2-mrp-2)# enable

Syntax: [no] metro-rings <ring id> <ring id> . . .

The <ring id> variables identify the metro rings you want to configure on the VLAN.

Syntax: [no] name <string>

The <string> parameter specifies a name for the ring. The name is optional, but it can be up to 20 characters long and can include blank spaces. If you use a name that has blank spaces, enclose the name in double quotation marks (for example: "Customer A").

Syntax: [no] master

Configures this node as the master node for the ring. Enter this command only on one node in the ring. The node is a member (non-master) node by default.
Syntax: [no] ring-interface ethernet <primary-if> ethernet <secondary-if>

The ethernet <primary-if> parameter specifies the primary interface. On the master node, the primary interface is the one that originates RHPs. Ring control traffic and Layer 2 data traffic will flow in the outward direction from this interface by default. On member nodes, the direction of traffic flow depends on the traffic direction selected by the master node. Therefore, on a member node, the order in which you enter the interfaces does not matter.

The ethernet <secondary-if> parameter specifies the secondary interface.

NOTE
To take advantage of every interface in a Metro network, you can configure another MRP ring and either configure a different master node for the ring or reverse the configuration of the primary and secondary interfaces on the master node. Configuring multiple rings enables you to use all the ports in the ring. The same port can forward traffic one ring while blocking traffic for another ring.

Syntax: [no] enable

The enable command enables the ring.

Changing the hello and preforwarding times

You also can change the RHP hello time and preforwarding time. To do so, enter commands such as the following.

FastIron(config-vlan-2-mrp-1)# hello-time 200
FastIron(config-vlan-2-mrp-1)# preforwarding-time 400

These commands change the hello time to 200 ms and change the preforwarding time to 400 ms.

Syntax: [no] hello-time <ms>

Syntax: [no] preforwarding-time <ms>

The <ms> specifies the number of milliseconds. For the hello time, you can specify from 100 – 1000 (one second). The default hello time is 100 ms. The preforwarding time can be from 200 – 5000 ms, but must be at least twice the value of the hello time and must be a multiple of the hello time. The default preforwarding time is 300 ms. A change to the hello time or preforwarding time takes effect as soon as you enter the command.

Configuration notes

- The preforwarding time must be at least twice the value of the hello time and must be a multiple of the hello time.
- If UDLD is also enabled on the device, Brocade recommends that you set the MRP preforwarding time slightly higher than the default of 300 ms; for example, to 400 or 500 ms.
- You can use MRP ring diagnostics to determine whether you need to change the hello time and preforwarding time. Refer to “Using MRP diagnostics”.

Using MRP diagnostics

The MRP diagnostics feature calculates how long it takes for RHP packets to travel through the ring. When you enable MRP diagnostics, the software tracks RHP packets according to their sequence numbers and calculates how long it takes an RHP packet to travel one time through the entire ring. When you display the diagnostics, the CLI shows the average round-trip time for the RHP packets sent since you enabled diagnostics. The calculated results have a granularity of 1 microsecond.
Enabling MRP diagnostics

To enable MRP diagnostics for a ring, enter the following command on the master node, at the configuration level for the ring.

```
FastIron(config-vlan-2-mrp-1)# diagnostics
```

**Syntax:** `[no] diagnostics`  

**NOTE**  
This command is valid only on the master node.

Displaying MRP diagnostics

To display MRP diagnostics results, enter the following command on the master node.

```
FastIron# show metro 1 diag
```

```
Metro Ring 1 - CustomerA
---------------
diagnostics results

<table>

<td>The interval, in milliseconds, at which the Forwarding port on the ring master node sends Ring hello Packets (RHPs).</td>
</tr>
<tr>
<td>Prefwing time</td>
<td>The number of milliseconds an MRP interface that has entered the Preforwarding state will wait before changing to the Forwarding state. If a member port in the Preforwarding state does not receive an RHP within the Preforwarding time (Prefwing time), the port assumes that a topology change has occurred and changes to the Forwarding state. The secondary port on the master node changes to Blocking if it receives an RHP, but changes to Forwarding if the port does not receive an RHP before the preforwarding time expires. <strong>NOTE:</strong> A member node Preforwarding interface also changes from Preforwarding to Forwarding if it receives an RHP whose forwarding bit is on.</td>
</tr>
<tr>
<td>Ring interfaces</td>
<td>The device two interfaces with the ring. <strong>NOTE:</strong> If the interfaces are trunk groups, only the primary ports of the groups are listed.</td>
</tr>
</tbody>
</table>
| Interface role | The interface role can be one of the following:  
  • **primary**  
    • Master node – The interface generates RHPs.  
    • Member node – The interface forwards RHPs received on the other interface (the secondary interface).  
  • **secondary** – The interface does not generate RHPs.  
    • Master node – The interface listens for RHPs.  
    • Member node – The interface receives RHPs. |
| Forwarding state | Whether MRP Forwarding is enabled on the interface. The forwarding state can be one of the following:  
  • **blocking** – The interface is blocking Layer 2 data traffic and RHPs  
  • **disabled** – The interface is down  
  • **forwarding** – The interface is forwarding Layer 2 data traffic and RHPs  
  • **preforwarding** – The interface is listening for RHPs but is blocking Layer 2 data traffic |
| Active interface | The physical interfaces that are sending and receiving RHPs. **NOTE:** If a port is disabled, its state is shown as “disabled”. **NOTE:** If an interface is a trunk group, only the primary port of the group is listed. |
| Interface Type | Shows if the interface is a regular port or a tunnel port. |
| RHPs sent | The number of RHPs sent on the interface. **NOTE:** This field applies only to the master node. On non-master nodes, this field contains 0. This is because the RHPs are forwarded in hardware on the non-master nodes. |
| RHPs rcvd | The number of RHPs received on the interface. **NOTE:** On most Brocade devices, this field applies only to the master node. On non-master nodes, this field contains 0. This is because the RHPs are forwarded in hardware on the non-master nodes. However, on the FastIron devices, the RHP received counter on non-master MRP nodes increment. This is because, on FastIron devices, the CPU receives a copy of the RHPs forwarded in hardware. |
### MRP CLI example

The following examples show the CLI commands required to implement the MRP configuration shown in Figure 60 on page 418.

**NOTE**

For simplicity, the figure shows the VLANs on only two switches. The CLI examples implement the ring on all four switches.

### Commands on Switch A (master node)

The following commands configure a VLAN for the ring. The ring VLAN must contain both of the node interfaces with the ring. Add these interfaces as tagged interfaces, since the interfaces also must be in each of the customer VLANs configured on the node.

```
FastIron(config)# vlan 2
FastIron(config-vlan-2)# tag ethernet 1/1 to 1/2
FastIron(config-vlan-2)# metro-ring 1
FastIron(config-vlan-2)# name "Metro A"
FastIron(config-vlan-2-mrp-1)# master
FastIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
FastIron(config-vlan-2-mrp-1)# enable
FastIron(config-vlan-2-mrp-1)# exit
FastIron(config-vlan-2)# exit
```

The following commands configure the customer VLANs. The customer VLANs must contain both the ring interfaces as well as the customer interfaces.

```
FastIron(config)# vlan 30
FastIron(config-vlan-30)# tag ethernet 1/1 to 1/2
FastIron(config-vlan-30)# tag ethernet 2/1
FastIron(config-vlan-30)# exit
FastIron(config)# vlan 40
FastIron(config-vlan-40)# tag ethernet 1/1 to 1/2
FastIron(config-vlan-40)# tag ethernet 4/1
FastIron(config-vlan-40)# exit
```

The following commands configure topology group 1 on VLAN 2. The master VLAN is the one that contains the MRP configuration. The member VLANs use the MRP parameters of the master VLAN. The control interfaces (the ones shared by the master VLAN and member VLAN) also share MRP state.

```
FastIron(config)# topology-group 1
FastIron(config-topo-group-1)# master-vlan 2
FastIron(config-topo-group-1)# member-vlan 30
FastIron(config-topo-group-1)# member-vlan 40
```
Commands on Switch B

The commands for configuring Switches B, C, and D are similar to the commands for configuring Switch A, with two differences: the nodes are not configured to be the ring master. Omitting the master command is required for non-master nodes.

FastIron(config)# vlan 2
FastIron(config-vlan-2)# tag ethernet 1/1 to 1/2
FastIron(config-vlan-2)# metro-ring 1
FastIron(config-vlan-2-mrp-1)# name “Metro A”
FastIron(config-vlan-2-mrp-1)# ring-interface ethernet 1/1 ethernet 1/2
FastIron(config-vlan-2-mrp-1)# enable
FastIron(config-vlan-2)# exit
FastIron(config)#vlan 30
FastIron(config-vlan-30)# tag ethernet 1/1 to 1/2
FastIron(config-vlan-30)# tag ethernet 2/1

Virtual Switch Redundancy Protocol (VSRP)

Virtual Switch Redundancy Protocol (VSRP) is a Brocade proprietary protocol that provides redundancy and sub-second failover in Layer 2 and Layer 3 mesh topologies. Based on the Brocade Virtual Router Redundancy Protocol Extended (VRRPE), VSRP provides one or more backups for a Layer 2 Switch or Layer 3 Switch. If the active Layer 2 Switch or Layer 3 Switch becomes unavailable, one of the backups takes over as the active device and continues forwarding traffic for the network.

The FastIron family of switches and TurboIron X Series devices running software release 04.2.00 and later support full VSRP and VSRP-awareness. A Brocade device that is not itself configured for VSRP, but is connected to a Brocade device that is configured for VSRP, is VSRP aware.

You can use VSRP for Layer 2, Layer 3, or for both layers. On Layer 3 Switches, Layer 2 and Layer 3 share the same VSRP configuration information. On Layer 2 Switches, VSRP applies only to Layer 2.

Figure 61 shows an example of a VSRP configuration.

FIGURE 61  VSRP mesh – redundant paths for Layer 2 and Layer 3 traffic
In this example, two Brocade devices are configured as redundant paths for VRID 1. On each of the devices, a Virtual Router ID (VRID) is configured on a port-based VLAN. Since VSRP is primarily a Layer 2 redundancy protocol, the VRID applies to the entire VLAN. However, you can selectively remove individual ports from the VRID if needed.

Following master election (described below), one of the Brocade devices becomes the master for the VRID and sets the state of all the VLAN ports to Forwarding. The other device is a backup and sets all the ports in its VRID VLAN to Blocking.

If a failover occurs, the backup becomes the new master and changes all its VRID ports to the Forwarding state.

Other Brocade devices can use the redundant paths provided by the VSRP devices. In this example, three Brocade devices use the redundant paths. A Brocade device that is not itself configured for VSRP but is connected to a Brocade device that is configured for VSRP, is VSRP aware. In this example, the three Brocade devices connected to the VSRP devices are VSRP aware. A Brocade device that is VSRP aware can failover its link to the new master in sub-second time, by changing the MAC address associated with the redundant path.

When you configure VSRP, make sure each of the non-VSRP Brocade devices connected to the VSRP devices has a separate link to each of the VSRP devices.

Configuration notes

- VSRP and 802.1Q-n-Q tagging are not supported together on the same device.
- VSRP and Super Aggregated VLANs are not supported together on the same device.
- VSRP does not work on a VLAN which has multicast enabled.
- Turbolon X Series devices running software release 04.1.00 and later support VSRP awareness, and VSRP-aware security features. Turbolon devices support VSRP in release 04.2.00.
Layer 2 and Layer 3 redundancy

You can configure VSRP to provide redundancy for Layer 2 only or also for Layer 3:

- **Layer 2 only** – The Layer 2 links are backed up but specific IP addresses are not backed up.
- **Layer 2 and Layer 3** – The Layer 2 links are backed up and a specific IP address is also backed up. Layer 3 VSRP is the same as VRRPE. However, using VSRP provides redundancy at both layers at the same time.

Layer 2 Switches support Layer 2 VSRP only. Layer 3 Switches support Layer 2 and Layer 3 redundancy. You can configure a Layer 3 Switch for either Layer 2 only or Layer 2 and Layer 3. To configure for Layer 3, specify the IP address you are backing up.

**NOTE**

If you want to provide Layer 3 redundancy only, disable VSRP and use VRRPE.

Master election and failover

Each VSRP device advertises its VSRP priority in hello messages. During master election, the VSRP device with the highest priority for a given VRID becomes the master for that VRID. After master election, the master sends hello messages at regular intervals to inform the backups that the master is healthy.

If there is a tie for highest VSRP priority, the tie is resolved as follows:

- **Layer 2 Switches** – The Layer 2 Switch with the higher management IP address becomes the master.
  - Switches with management IP addresses are preferred over switches without management IP addresses.
  - If neither of the switches has a management IP address, then the switch with the higher MAC address becomes the master. (VSRP compares the MAC addresses of the ports configured for the VRID, not the base MAC addresses of the switches.)
- **Layer 3 Switches** – The Layer 3 Switch whose virtual routing interface has a higher IP address becomes the master.

**VSRP failover**

Each backup listens for hello messages from the master. The hello messages indicate that the master is still available. If the backups stop receiving hello messages from the master, the election process occurs again and the backup with the highest priority becomes the new master.

Each backup waits for a specific period of time, the dead Interval, to receive a new hello message from the master. If the backup does not receive a hello message from the master by the time the dead interval expires, the backup sends a hello message of its own, which includes the backup's VSRP priority, to advertise the backup's intent to become the master. If there are multiple backups for the VRID, each backup sends a hello message.

When a backup sends a hello message announcing its intent to become the master, the backup also starts a hold-down timer. During the hold-down time, the backup listens for a hello message with a higher priority than its own.

- If the backup receives a hello message with a higher priority than its own, the backup resets its dead interval and returns to normal backup status.
If the backup does not receive a hello message with a higher priority than its own by the time the hold-down timer expires, the backup becomes the new master and starts forwarding Layer 2 traffic on all ports.

If you increase the timer scale value, each timer value is divided by the scale value. To achieve sub-second failover times, you can change the scale to a value up to 10. This shortens all the VSRP timers to 10 percent of their configured values.

**VSRP priority calculation**

Each VSRP device has a VSRP priority for each VRID and its VLAN. The VRID is used during master election for the VRID. By default, a device VSRP priority is the value configured on the device (which is 100 by default). However, to ensure that a backup with a high number of up ports for a given VRID is elected, the device reduces the priority if a port in the VRID VLAN goes down. For example, if two backups each have a configured priority of 100, and have three ports in VRID 1 in VLAN 10, each backup begins with an equal priority, 100. This is shown in Figure 62.

**FIGURE 62  VSRP priority**

![VSRP priority diagram](image)

However, if one of the VRID ports goes down on one of the backups, that backup priority is reduced. If the master priority is reduced enough to make the priority lower than a backup priority, the VRID fails over to the backup. Figure 63 shows an example.

**FIGURE 63  VSRP priority recalculation**

![VSRP priority recalculation diagram](image)
You can reduce the sensitivity of a VSRP device to failover by increasing its configured VSRP priority. For example, you can increase the configured priority of the VSRP device on the left in Figure 63 to 150. In this case, failure of a single link does not cause failover. The link failure caused the priority to be reduced to 100, which is still equal to the priority of the other device. This is shown in Figure 64.

**FIGURE 64**  VSRP priority bias

---

**Track ports**

Optionally, you can configure track ports to be included during VSRP priority calculation. In VSRP, a track port is a port that is not a member of the VRID VLAN, but whose state is nonetheless considered when the priority is calculated. Typically, a track port represents the exit side of traffic received on the VRID ports. By default, no track ports are configured.
When you configure a track port, you assign a priority value to the port. If the port goes down, VSRP subtracts the track port priority value from the configured VSRP priority. For example, if you configure a track port with priority 20 and the configured VSRP priority is 100, the software subtracts 20 from 100 if the track port goes down, resulting in a VSRP priority of 80. The new priority value is used when calculating the VSRP priority. Figure 65 shows an example.

**FIGURE 65**  Track port priority

![Diagram showing Track port priority](image)

In Figure 65, the track port is up. Since the port is up, the track priority does not affect the VSRP priority calculation. If the track port goes down, the track priority does affect VSRP priority calculation, as shown in Figure 66.

**FIGURE 66**  Track port priority subtracted during priority calculation

![Diagram showing Track port priority subtracted during priority calculation](image)
**MAC address failover on VSRP-aware devices**

VSRP-aware devices maintain a record of each VRID and its VLAN. When the device has received a hello message for a VRID in a given VLAN, the device creates a record for that VRID and VLAN and includes the port number in the record. Each subsequent time the device receives a hello message for the same VRID and VLAN, the device checks the port number:

- If the port number is the same as the port that previously received a hello message, the VSRP-aware device assumes that the message came from the same VSRP master that sent the previous message.
- If the port number does not match, the VSRP-aware device assumes that a VSRP failover has occurred to a new master, and moves the MAC addresses learned on the previous port to the new port.

The VRID records age out if unused. This can occur if the VSRP-aware device becomes disconnected from the master. The VSRP-aware device will wait for a hello message for the period of time equal to the following.

\[ \text{VRID Age} = \text{Dead Interval} + \text{Hold-down Interval} + (3 \times \text{Hello Interval}) \]

The values for these timers are determined by the VSRP device sending the hello messages. If the master uses the default timer values, the age time for VRID records on the VSRP-aware devices is as follows.

\[ 3 + 2 + (3 \times 1) = 8 \text{ seconds} \]

In this case, if the VSRP-aware device does not receive a new hello message for a VRID in a given VLAN, on any port, the device assumes the connection to the master is unavailable and removes the VRID record.

**VSRP-Aware security features**

**Platform Support:**

- FastIron X Series devices running software release 03.0.00 and later
- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- Turbolron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

This feature protects against unauthorized VSRP hello packets by enabling you to configure VSRP-aware security parameters. Without VSRP-aware security, a VSRP-aware device passively learns the authentication method conveyed by the received VSRP hello packet. The VSRP-aware device then stores the authentication method until it ages out with the aware entry.

The VSRP-aware security feature enables you to perform the following:

- Define the specific authentication parameters that a VSRP-aware device will use on a VSRP backup switch. The authentication parameters that you define will not age out.
• Define a list of ports that have authentic VSRP backup switch connections. For ports included in the list, the VSRP-aware switch will process VSRP hello packets using the VSRP-aware security configuration. Conversely, for ports not included in the list, the VSRP-aware switch will not use the VSRP-aware security configuration.

If VSRP hello packets do not meet the acceptance criteria, the VSRP-aware device forwards the packets normally, without any VSRP-aware security processing.

To configure VSRP-Aware Security features, refer to “Configuring security features on a VSRP-aware device” on page 440.

**VSRP parameters**

Table 84 lists the VSRP parameters.

| Parameter          | Description                                                                 | Default  | See page...
|--------------------|-----------------------------------------------------------------------------|----------|-------------
| **Protocol**       | VSRP state                                                                  | Enabled  | page 438    |
| **Virtual Router ID (VRID)** | The ID of the virtual switch you are creating by configuring multiple devices as redundant links. You must configure the same VRID on each device that you want to use to back up the links. | None     | page 437    |
| **Timer scale**    | The value used by the software to calculate all VSRP timers. Increasing the timer scale value decreases the length of all the VSRP timers equally, without changing the ratio of one timer to another. | 1        | page 439    |

**Interface parameters**

<table>
<thead>
<tr>
<th>Authentication type</th>
<th>The type of authentication the VSRP devices use to validate VSRP packets. On Layer 3 Switches, the authentication type must match the authentication type the VRID port uses with other routing protocols such as OSPF.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• No authentication – The interfaces do not use authentication. This is the VRRP default.</td>
<td>No authentication</td>
</tr>
<tr>
<td>• Simple – The interface uses a simple text-string as a password in packets sent on the interface. If the interface uses simple password authentication, the VRID configured on the interface must use the same authentication type and the same password.</td>
<td></td>
</tr>
<tr>
<td><strong>NOTE:</strong> MD5 is not supported.</td>
<td></td>
</tr>
</tbody>
</table>

**VSRP-Aware Security Parameters**

<table>

<tr>
<td>Suppression of RIP advertisements</td>
<td>A Layer 3 Switch that is running RIP normally advertises routes to a backed up VRID even when the Layer 3 Switch is not currently the active Layer 3 Switch for the VRID. Suppression of these advertisements helps ensure that other Layer 3 Switches do not receive invalid route paths for the VRID. This parameter is valid only on Layer 3 Switches.</td>
<td>Disabled (routes are advertised)</td>
<td>page 446</td>
</tr>
</tbody>
</table>

**NOTE**
To configure VSRP, ensure that spanning tree is disabled on the VLAN.

**Configuring basic VSRP parameters**

To configure VSRP, perform the following required tasks:

- Configure a port-based VLAN containing the ports for which you want to provide VSRP service.
NOTE
If you already have a port-based VLAN but only want to use VSRP on a sub-set of the VLANs ports, you can selectively remove ports from VSRP service in the VLAN. Refer to “Removing a port from the VRID VLAN” on page 441.

• Configure a VRID:
  • Specify that the device is a backup. Since VSRP, like VRRPE, does not have an “owner”, all VSRP devices are backups. The active device for a VRID is elected based on the VRID priority, which is configurable.
  • Activate the VRID.

The following example shows a simple VSRP configuration.

```
FastIron(config)# vlan 200
FastIron(config-vlan-200)# tag ethernet 1/1 to 1/8
FastIron(config-vlan-200)# vsrp vrid 1
FastIron(config-vlan-200-vrid-1)# backup
FastIron(config-vlan-200-vrid-1)# activate
```

Syntax: `[no] vsrp vrid <num>`

The `<num>` parameter specifies the VRID and can be from 1 – 255.

Syntax: `[no] backup [priority <value>] [track-priority <value>]`

This command is required. In VSRP, all devices on which a VRID are configured are backups. The master is then elected based on the VSRP priority of each device. There is no “owner” device as there is in VRRP.

For information about the command optional parameters, refer to the following:

• “Changing the backup priority” on page 442
• “Changing the default track priority” on page 445

Syntax: `[no] activate`

or

Syntax: enable | disable

Configuring optional VSRP parameters

The following sections describe how to configure optional VSRP parameters.

_Disabling or re-enabling VSRP_

VSRP is enabled by default on Layer 2 Switches and Layer 3 Switches. On a Layer 3 Switch, if you want to use VRRP or VRRPE for Layer 3 redundancy instead of VSRP, you need to disable VSRP first. To do so, enter the following command at the global CONFIG level.

```
FastIron(config)# no router vsrp
router vsrp is disabled. All vsrp config data will be lost when writing to flash
```

To re-enable the protocol, enter the following command.

```
FastIron(config)# router vsrp
```

Syntax: `[no] router vsrp`
Since VRRP and VRRPE do not apply to Layer 2 Switches, there is no need to disable VSRP and there is no command to do so. The protocol is always enabled.

**Timer scale**

The VSRP hello interval, dead interval, backup hello interval, and hold-down interval timers are individually configurable. You also can easily change all the timers at the same time while preserving the ratios among their values. To do so, change the timer scale. The timer scale is a value used by the software to calculate the timers. The software divides a timer value by the timer scale value. By default, the scale is 1. This means the VSRP timer values are the same as the values in the configuration. For more information on timer scale parameters and how it affects the timers, refer to Table 84.

**Changing the timer scale**

To achieve sub-second failover times, you can shorten the duration of all scale timers for VSRP, VRRP, and VRRP-E by adjusting the timer scale. The **timer scale** is a value used by the software to calculate the timers. By default, the scale value is 1. If you increase the timer scale, each timer value is divided by the scale value. Using the timer scale to adjust timer values enables you to easily change all the timers while preserving the ratios among their values. Here is an example.

<table>
<thead>
<tr>
<th>Timer</th>
<th>Timer scale</th>
<th>Timer value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hello interval</td>
<td>1</td>
<td>1 second</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>0.5 seconds</td>
</tr>
<tr>
<td>Dead interval</td>
<td>1</td>
<td>3 seconds</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>1.5 seconds</td>
</tr>
<tr>
<td>Backup Hello interval</td>
<td>1</td>
<td>60 seconds</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>30 seconds</td>
</tr>
<tr>
<td>Hold-down interval</td>
<td>1</td>
<td>2 seconds</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>1 second</td>
</tr>
</tbody>
</table>

If you configure the device to receive its timer values from the master, the backup also receives the timer scale value from the master.

**NOTE**

The backups always use the value of the timer scale received from the master, regardless of whether the timer values that are saved in the configuration are the values configured on the backup or the values received from the master.

To change the timer scale, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)# scale-timer 2
```

This command changes the scale to 2. All VSRP, VRRP, and VRRP-E timer values will be divided by 2.

**Syntax:** `[no] scale-timer <num>`

The `<num>` parameter specifies the multiplier. You can specify a timer scale from 1 – 10.
Configuring authentication

If the interfaces on which you configure the VRID use authentication, the VSRP packets on those interfaces also must use the same authentication. VSRP supports the following authentication types:

- **No authentication** – The interfaces do not use authentication. This is the default.
- **Simple** – The interfaces use a simple text-string as a password in packets sent on the interface. If the interfaces use simple password authentication, the VRID configured on the interfaces must use the same authentication type and the same password.

To configure a simple password, enter a command such as the following at the interface configuration level.

```
FastIron(config-if-1/6)# ip vsrp auth-type simple-text-auth ourpword
```

This command configures the simple text password “ourpword”.

**Syntax:** `[no] ip vsrp auth-type no-auth | simple-text-auth <auth-data>`

- The `auth-type no-auth` parameter indicates that the VRID and the interface it is configured on do not use authentication.
- The `auth-type simple-text-auth <auth-data>` parameter indicates that the VRID and the interface it is configured on use a simple text password for authentication. The `<auth-data>` value is the password. If you use this parameter, make sure all interfaces on all the devices supporting this VRID are configured for simple password authentication and use the same password.

Configuring security features on a VSRP-aware device

**Platform Support:**

- FastIron X Series devices running software release 03.0.00 and later
- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

This section shows how to configure security features on a VSRP-aware device. For an overview of this feature, refer to “VSRP-Aware security features” on page 434.

**Specifying an authentication string for VSRP hello packets**

The following configuration defines `pri-key` as the authentication string for accepting incoming VSRP hello packets. In this example, the VSRP-aware device will accept all incoming packets that have this authorization string.

```
FastIron(config)# vlan 10
FastIron(config-vlan-10)# vsrp-aware vrid 3 simple-text-auth pri-key
```

**Syntax:** `vsrp-aware vrid <vrid number> simple text auth <string>`

**Specifying no authentication for VSRP hello packets**

The following configuration specifies no authentication as the preferred VSRP-aware security method. In this case, the VSRP device will not accept incoming packets that have authentication strings.
FastIron(config)# vlan 10
FastIron(config-vlan-10)# vsrp-aware vrid 2 no-auth

Syntax: vsrp-aware vrid <vrid number> no-auth

The following configuration specifies no authentication for VSRP hello packets received on ports 1/1, 1/2, 1/3, and 1/4 in VRID 4. For these ports, the VSRP device will not accept incoming packets that have authentication strings.

FastIron(config)# vlan 10
FastIron(config-vlan-10)# vsrp-aware vrid 4 no-auth port-list ethe 1/1 to 1/4

Syntax: vsrp-aware vrid <vrid number> no-auth port-list <port range>

ports listed retain their VLAN membership but their forwarding state is not controlled by VSRP. If you are configuring a chassis device, specify the slot number as well as the port number (<slotnum>/</portnum>).

Configuring a VRID IP address

If you are configuring a Layer 3 Switch for VSRP, you can specify an IP address to back up. When you specify an IP address, VSRP provides redundancy for the address. This is useful if you want to back up the gateway address used by hosts attached to the VSRP backups.

VSRP does not require you to specify an IP address. If you do not specify an address, VSRP provides Layer 2 redundancy. If you do specify an address, VSRP provides Layer 2 and Layer 3 redundancy.

The Layer 3 redundancy support is the same as VRRPE support. For information, refer to Chapter 37, “Configuring VRRP and VRRPE”.
### Virtual Switch Redundancy Protocol (VSRP)

**NOTE**

The VRID IP address must be in the same subnet as a real IP address configured on the VSRP interface, but cannot be the same as a real IP address configured on the interface.

**NOTE**

Failover applies to both Layer 2 and Layer 3.

To specify an IP address to back up, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# ip-address 10.10.10.1
```

**Syntax:** 

```
[ip-address <ip-addr>]
```

or

```
[no] ip address <ip-addr>
```

### Changing the backup priority

When you enter the backup command to configure the device as a VSRP backup for the VRID, you also can change the backup priority and the track priority:

- The backup priority is used for election of the master. The VSRP backup with the highest priority value for the VRID is elected as the master for that VRID. The default priority is 100. If two or more backups are tied with the highest priority, the backup with the highest IP address becomes the master for the VRID.

- The track priority is used with the track port feature. Refer to "VSRP priority calculation" on page 431 and "Changing the default track priority" on page 445.

To change the backup priority, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# backup priority 75
```

**Syntax:**

```
backup [priority <value>] [track-priority <value>]
```

The **priority** parameter specifies the VRRP priority for this interface and VRID. You can specify a value from 3 – 254. The default is 100.

For a description of the **track-priority** parameter, refer to "Changing the default track priority" on page 445.

### Example

Following is an example to configure a simple VSRP interface.

Enter the following commands to add tagged ports to a VLAN.

```
TurboIron(config)# vlan 30
TurboIron(config-vlan-30)# tag ethernet 28
```

Enter the following command to add the IP address.

```
TurboIron(config-vlan-30)# router-int ve 30
```

Enter the following command to change the VSRP interface state and initiate VRID state.

```
TurboIron(config-vlan-30)# interface ve 30
TurboIron(config-vlan-30)# ip address 30.0.0.2/24
```

Enter the following commands to change the VSRP interface state and initiate VRID state.

```
TurboIron(config-vlan-30)# vlan 30
```
Virtual Switch Redundancy Protocol (VSRP)

TurboIron(config-vlan-30)# vsrp vri 30
TurboIron(config-vlan-30-vrid-30)# backup
TurboIron(config-vlan-30-vrid-30)# ip-address 30.0.0.1
TurboIron(config-vlan-30-vrid-30)# enable

Saving the timer values received from the master

The hello messages sent by a VRID master contain the VRID values for the following VSRP timers:

- Hello interval
- Dead interval
- Backup hello interval
- Hold-down interval

By default, each backup saves the configured timer values to its startup-config file when you save the device configuration.

You can configure a backup to instead save the current timer values received from the master when you save the configuration. Saving the current timer values instead of the configured ones helps ensure consistent timer usage for all the VRID devices.

**NOTE**
The backups always use the value of the timer scale received from the master, regardless of whether the timer values that are saved in the configuration are the values configured on the backup or the values received from the master.

To configure a backup to save the VSRP timer values received from the master instead of the timer values configured on the backup, enter the following command.

```
FastIron(config-vlan-200-vrid-1)# save-current-values
```

**Syntax:** `[no] save-current-values`

Changing the Time-To-Live (TTL)

A VSRP hello packet TTL specifies how many hops the packet can traverse before being dropped. A hop can be a Layer 3 Switch or a Layer 2 Switch. You can specify from 1 – 255. The default TTL is 2. When a VSRP device (master or backup) sends a VSRP HEllO packet, the device subtracts one from the TTL. Thus, if the TTL is 2, the device that originates the hello packet sends it out with a TTL of 1. Each subsequent device that receives the packet also subtracts one from the packet TTL. When the packet has a TTL of 1, the receiving device subtracts 1 and then drops the packet because the TTL is zero.

**NOTE**
An MRP ring is considered to be a single hop, regardless of the number of nodes in the ring.

To change the TTL for a VRID, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# initial-ttl 5
```

**Syntax:** `[no] initial-ttl <num>`

The `<num>` parameter specifies the TTL and can be from 1 – 255. The default TTL is 2.
Changing the hello interval

The master periodically sends hello messages to the backups. To change the hello interval, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# hello-interval 10
```

**Syntax:** `[no] hello-interval <num>`

The `<num>` parameter specifies the interval and can be from 1 – 84 seconds. The default is 1 second.

---

**NOTE**

The default dead interval is three times the hello interval plus one-half second. Generally, if you change the hello interval, you also should change the dead interval on the backups.

---

**NOTE**

If you change the timer scale, the change affects the actual number of seconds.

Changing the dead interval

The dead interval is the number of seconds a backup waits for a hello message from the master before determining that the master is dead. The default is 3 seconds. This is three times the default hello interval.

To change the dead interval, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# dead-interval 30
```

**Syntax:** `[no] dead-interval <num>`

The `<num>` parameter specifies the interval and can be from 1 – 84 seconds. The default is 3 seconds.

---

**NOTE**

If you change the timer scale, the change affects the actual number of seconds.

Changing the backup hello state and interval

By default, backups do not send hello messages to advertise themselves to the master. You can enable these messages if desired and also change the message interval.

To enable a backup to send hello messages to the master, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# advertise backup
```

**Syntax:** `[no] advertise backup`

When a backup is enabled to send hello messages, the backup sends a hello message to the master every 60 seconds by default. You can change the interval to be up to 3600 seconds.

To change the backup hello interval, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# backup-hello-interval 180
```
Syntax: [no] backup-hello-interval <num>

The <num> parameter specifies the message interval and can be from 60 – 3600 seconds. The default is 60 seconds.

**NOTE**
If you change the timer scale, the change affects the actual number of seconds.

*Changing the hold-down interval*

The hold-down interval prevents Layer 2 loops from occurring during failover, by delaying the new master from forwarding traffic long enough to ensure that the failed master is really unavailable.

To change the Hold-down interval, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# hold-down-interval 4
```

Syntax: [no] hold-down-interval <num>

The <num> parameter specifies the hold-down interval and can be from 1 – 84 seconds. The default is 2 seconds.

**NOTE**
If you change the timer scale, the change affects the actual number of seconds.

*Changing the default track priority*

When you configure a VRID to track the link state of other interfaces, if one of the tracked interface goes down, the software changes the VSRP priority of the VRID interface.

The software reduces the VRID priority by the amount of the priority of the tracked interface that went down. For example, if the VSRP interface priority is 100 and a tracked interface with track priority 60 goes down, the software changes the VSRP interface priority to 40. If another tracked interface goes down, the software reduces the VRID priority again, by the amount of the tracked interface track priority.

The default track priority for all track ports is 1. You can change the default track priority or override the default for an individual track port.

- To change the default track priority, use the backup track-priority command, described below.
- To override the default track priority for a specific track port, use the track-port command. Refer to “Specifying a track port” on page 445.

To change the track priority, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# backup track-priority 2
```

Syntax: [no] backup [priority <value>] [track-priority <value>]

*Specifying a track port*

You can configure the VRID on one interface to track the link state of another interface on the device. This capability is useful for tracking the state of the exit interface for the path for which the VRID is providing redundancy. Refer to “VSRP priority calculation” on page 431.
To configure a VRID to track an interface, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# track-port e 2/4
```

**Syntax:** `[no] track-port ethernet `<slotnum>`/`<portnum>` | ve `<num>` [priority `<num>`]

The `priority `<num>` parameter changes the VSRP priority of the interface. If this interface goes down, the VRID VSRP priority is reduced by the amount of the track port priority you specify here.

**NOTE**
The priority `<num>` option changes the priority of the specified interface, overriding the default track port priority. To change the default track port priority, use the `backup track-priority `<num>`` command.

**Disabling or re-enabling backup pre-emption**

By default, a backup that has a higher priority than another backup that has become the master can preempt the master, and take over the role of master. If you want to prevent this behavior, disable preemption.

Preemption applies only to backups and takes effect only when the master has failed and a backup has assumed ownership of the VRID. The feature prevents a backup with a higher priority from taking over as master from another backup that has a lower priority but has already become the master of the VRID.

Preemption is especially useful for preventing flapping in situations where there are multiple backups and a backup with a lower priority than another backup has assumed ownership, because the backup with the higher priority was unavailable when ownership changed.

If you enable the non-preempt mode (thus disabling the preemption feature) on all the backups, the backup that becomes the master following the disappearance of the master continues to be the master. The new master is not preempted.

To disable preemption on a backup, enter a command such as the following at the configuration level for the VRID.

```
FastIron(config-vlan-200-vrid-1)# non-preempt-mode
```

**Syntax:** `[no] non-preempt-mode

**Suppressing RIP advertisement from backups**

Normally, for Layer 3 a VSRP backup includes route information for a backed up IP address in RIP advertisements. As a result, other Layer 3 Switches receive multiple paths for the backed up interface and might sometimes unsuccessfully use the path to the backup rather than the path to the master.

You can prevent the backups from advertising route information for the backed up interface by enabling suppression of the advertisements.

**NOTE**
This parameter applies only if you specified an IP address to back up and is valid only on Layer 3 Switches.

To suppress RIP advertisements, enter the following commands.
Router2(config)# router rip
Router2(config-rip-router)# use-vrrp-path

Syntax: [no] use-vrrp-path

**VSRP-aware interoperability**

The `vsrp-aware tc-vlan-flush` command should be used in network configurations in which the Brocade switch operates as the VSRP-Aware device connecting to a Brocade BigIron RX, NetIron XMR, or NetIron MLX configured as a VSRP master.

The command is available at the VLAN level, and is issued per a specific VRID, as shown here for VRID 11.

`FastIron(config-vlan-10)# vsrp-aware vrid 11 tc-vlan-flush`

**Syntax: vsrp-aware vrid <num> tc-vlan-flush**

When this command is enabled, MAC addresses will be flushed at the VLAN level, instead of at the port level. MAC addresses will be flushed for every topology change (TC) received on the VSRP-aware ports.

When this command is enabled, the results of the `show vsrp-aware vlan` command resemble the following.

```
FastIron(config-vlan-10)#vsrp-aware vrid 11 tc-vlan-flush
FastIron(config-vlan-10)#show vsrp aware vlan 10
Aware Port Listing
  VLAN ID  VRID  Last Port  Auth Type  Mac-Flush  Age
  10       11     N/A       no-auth    Configured  Enabled   00:00:00.0
```

**Displaying VSRP information**

You can display the following VSRP information:

- Configuration information and current parameter values for a VRID or VLAN
- The interfaces on a VSRP-aware device that are active for the VRID

**Displaying VRID information**

To display VSRP information, enter the following command.
FastIron# show vsrp vrid 1
Total number of VSRP routers defined: 2
VLAN 200
  auth-type no authentication
VRID 1
  State        Administrative-status Advertise-backup Preempt-mode save-current
  standby enabled disabled true false

**TABLE 85** CLI display of VSRP VRID or VLAN information (Continued)

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
</table>
| Preempt-mode  | Whether the device can be pre-empted by a device with a higher VSRP priority after this device becomes the master. This field can have one of the following values:  
• disabled – The device cannot be pre-empted.  
• enabled – The device can be pre-empted. |
| save-current  | The source of VSRP timer values preferred when you save the configuration. This field can have one of the following values:  
• false – The timer values configured on this device are saved.  
• true – The timer values most recently received from the master are saved instead of the locally configured values. |

**NOTE:** For the following fields:  
• Configured – indicates the parameter value configured on this device.  
• Current – indicates the parameter value received from the master.  
• Unit – indicates the formula used for calculating the VSRP priority and the timer scales in effect for the VSRP timers. A timer true value is the value listed in the Configured or Current field divided by the scale value.

| priority | The device preferability for becoming the master for the VRID. During negotiation, the backup with the highest priority becomes the master.  
If two or more backups are tied with the highest priority, the backup interface with the highest IP address becomes the master for the VRID. |
| hello-interval | The number of seconds between hello messages from the master to the backups for a given VRID. |
| dead-interval | The configured value for the dead interval. The dead interval is the number of seconds a backup waits for a hello message from the master for the VRID before determining that the master is no longer active.  
If the master does not send a hello message before the dead interval expires, the backups negotiate (compare priorities) to select a new master for the VRID.  
**NOTE:** If the value is 0, then you have not configured this parameter. |
| hold-interval | The number of seconds a backup that intends to become the master will wait before actually beginning to forward Layer 2 traffic for the VRID.  
If the backup receives a hello message with a higher priority than its own before the hold-down interval expires, the backup remains in the backup state and does not become the new master. |
| initial-ttl | The number of hops a hello message can traverse after leaving the device before the hello message is dropped.  
**NOTE:** An MRP ring counts as one hop, regardless of the number of nodes in the ring. |
| next hello sent in | The amount of time until the master dead interval expires.  
If the backup does not receive a hello message from the master by the time the interval expires, either the IP address listed for the master will change to the IP address of the new master, or this Layer 3 Switch itself will become the master.  
**NOTE:** This field applies only when this device is a backup. |
| Member ports | The ports in the VRID. |
| Operational ports | The member ports that are currently up. |
| Forwarding ports | The member ports that are currently in the Forwarding state. Ports that are forwarding on the master are listed. Ports on the Standby, which are in the Blocking state, are not listed. |
**Displaying the active interfaces for a VRID**

On a VSRP-aware device, you can display VLAN and port information for the connections to the VSRP devices (master and backups).

To display the active VRID interfaces, enter the following command on the VSRP-aware device.

```
FastIron# show vsrp aware
Aware port listing
VLAN ID  VRID  Last Port
100      1     3/2
200      2     4/1
```

**Syntax: show vsrp aware**

This display shows the following information when you use the `aware` parameter. For information about the display when you use the `vrid <num>` or `vlan <vlan-id>` parameter, refer to “Displaying VRID information” on page 447.

**TABLE 86 CLI display of VSRP-aware information**

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN ID</td>
<td>The VLAN that contains the VSRP-aware device connection with the VSRP master and backups.</td>
</tr>
<tr>
<td>VRID</td>
<td>The VRID.</td>
</tr>
<tr>
<td>Last Port</td>
<td>The most recent active port connection to the VRID. This is the port connected to the current master. If a failover occurs, the VSRP-aware device changes the port to the port connected to the new master. The VSRP-aware device uses this port to send and receive data through the backed up node.</td>
</tr>
</tbody>
</table>

**VSRP fast start**

**Platform Support:**

- FastIron X Series devices
- FCX-S devices running software release 06.0.00 and later
- TurboIron devices running software release 04.2.00 and later

VSRP fast start allows non-Brocade or non-VSRP aware devices that are connected to a Brocade device that is the VSRP master to quickly switchover to the new master when a VSRP failover occurs.

This feature causes the port on a VSRP master to restart when a VSRP failover occurs. When the port shuts down at the start of the restart, ports on the non-VSRP aware devices that are connected to the VSRP master flush the MAC address they have learned for the VSRP master. After a specified time, the port on the previous VSRP master (which now becomes the backup) returns back online. Ports on the non-VSRP aware devices switch over to the new master and learn its MAC address.

**Configuring VSRP fast start**

The VSRP fast start feature can be enabled on a VSRP-configured Brocade device, either on the VLAN to which the VRID of the VSRP-configured device belongs (globally) or on a port that belongs to the VRID.
To globally configure a VSRP-configured device to shut down its ports when a failover occurs, then restart after five seconds, enter the following command.

```
FastIron(configure)# vlan 100
FastIron(configure-vlan-100)# vsrp vrid 1
FastIron(configure-vlan-100-vrid-1)# restart-ports 5
```

**Syntax: [no] restart-ports <seconds>**

This command shuts down all the ports that belong to the VLAN when a failover occurs. All the ports will have the specified VRID.

To configure a single port on a VSRP-configured device to shut down when a failover occurs, then restart after a period of time, enter the following command.

```
FastIron(configure)# interface ethernet 1/1
FastIron(configure-if-1/1)# vsrp restart-port 5
```

**Syntax: [no] vsrp restart-port <seconds>**

In both commands, the `<seconds>` parameter instructs the VSRP master to shut down its port for the specified number of seconds before it starts back up. Enter a value between 1 – 120 seconds. The default is 1 second.

**Displaying ports that Have the VSRP fast start feature enabled**

The `show vsrp vrid` command shows the ports on which the VSRP fast start feature is enabled.

```
FastIron# show vsrp vrid 100
VLAN 100
   auth-type no authentication
VRID 100
--------
State      Administrative-status Advertise-backup Preempt-mode save-current
master     enabled               disabled         true         false
Parameter        Configured Current    Unit/Formula
priority         100        50         (100-0)*(2.0/4.0)
hello-interval   1          1          sec/1
dead-interval    3          3          sec/1
hold-interval    3          3          sec/1
initial-ttl      2          2          hops
next hello sent in 00:00:00.3
Member ports:      ethe 2/5 to 2/8
Operational ports: ethe 2/5 ethe 2/8
Forwarding ports:  ethe 2/5 ethe 2/8
Restart ports:     2/5(1) 2/6(1) 2/7(1) 2/8(1)
```

The "Restart ports:" line lists the ports that have the VSRP fast start enabled, and the downtime for each port. Refer to Table 85 on page 448 to interpret the remaining information on the display.

**VSRP and MRP signaling**

**Platform Support:**
- FastIron X Series devices
- FCX-S devices running software release 06.0.00 and later
- Turbolron X Series devices running software release 04.2.00 and later
A device may connect to an MRP ring through VSRP to provide a redundant path between the device and the MRP ring. VSRP and MRP signaling ensures rapid failover by flushing MAC addresses appropriately. The host on the MRP ring learns the MAC addresses of all devices on the MRP ring and VSRP link. From these MAC addresses, the host creates a MAC database (table), which is used to establish a data path from the host to a VSRP-linked device. Figure 67 below shows two possible data paths from the host to Device 1.

**FIGURE 67** Two data paths from host on an MRP ring to a VSRP-linked device

If a VSRP failover from master to backup occurs, VSRP needs to inform MRP of the topology change; otherwise, data from the host continues along the obsolete learned path and never reach the VSRP-linked device, as shown in Figure 68.

**FIGURE 68** VSRP on MRP rings that failed over

A signaling process for the interaction between VSRP and MRP ensures that MRP is informed of the topology change and achieves convergence rapidly. When a VSRP node fails, a new VSRP master is selected. The new VSRP master finds all MRP instances impacted by the failover. Then each MRP instance does the following:

- The MRP node sends out an MRP PDU with the mac-flush flag set three times on the MRP ring.
• The MRP node that receives this MRP PDU empties all the MAC entries from its interfaces that participate on the MRP ring.

• The MRP node then forwards the MRP PDU with the mac-flush flag set to the next MRP node that is in forwarding state.

The process continues until the master MRP node secondary (blocking) interface blocks the packet. Once the MAC address entries have been flushed, the MAC table can be rebuilt for the new path from the host to the VSRP-linked device (Figure 69).

FIGURE 69  New path established

There are no CLI commands used to configure this process.
11  Virtual Switch Redundancy Protocol (VSRP)
Configuring Uni-Directional Link Detection (UDLD) and Protected Link Groups

UDLD overview

Platform Support:
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FGS and FLS devices running software release 2.5 and later
- FastIron X Series devices running software release 04.0.00 and later – L2, BL3, L3
- Turbolron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

Uni-Directional Link Detection (UDLD) monitors a link between two Brocade devices and brings the ports on both ends of the link down if the link goes down at any point between the two devices. This feature is useful for links that are individual ports and for trunk links. Figure 70 shows an example.

**FIGURE 70** UDLD example

Normally, a Brocade device load balances traffic across the ports in a trunk group. In this example, each Brocade device load balances traffic across two ports. Without the UDLD feature, a link failure on a link that is not directly attached to one of the Brocade devices is undetected by the Brocade devices. As a result, the Brocade devices continue to send traffic on the ports connected to the failed link.

When UDLD is enabled on the trunk ports on each Brocade device, the devices detect the failed link, disable the ports connected to the failed link, and use the remaining ports in the trunk group to forward the traffic.

Ports enabled for UDLD exchange proprietary health-check packets once every second (the keepalive interval). If a port does not receive a health-check packet from the port at the other end of the link within the keepalive interval, the port waits for two more intervals. If the port still does not receive a health-check packet after waiting for three intervals, the port concludes that the link has failed and takes the port down.
Configuration considerations

- This feature is supported only on Ethernet ports.
- To configure UDLD on a trunk group, you must enable and configure the feature on each port of the group individually. Configuring UDLD on a trunk group primary port enables the feature on that port only.
- When UDLD is enabled on a trunk port, trunk threshold is not supported.
- Dynamic trunking is not supported. If you want to configure a trunk group that contains ports on which UDLD is enabled, you must remove the UDLD configuration from the ports. After you create the trunk group, you can re-add the UDLD configuration.
- If MRP is also enabled on the device, Brocade recommends that you set the MRP preforwarding time slightly higher than the default of 300 ms; for example, to 400 or 500 ms. Refer to “Changing the hello and preforwarding times” on page 422.

Enabling UDLD

To enable UDLD on a port, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)#link-keepalive ethernet 0/1/1
```

To enable the feature on a trunk group, enter commands such as the following.

```
FastIron(config)#link-keepalive ethernet 0/1/1 ethernet 0/1/2
FastIron(config)#link-keepalive ethernet 0/1/3 ethernet 0/1/4
```

Syntax: `[no] link-keepalive ethernet [slotnum/portnum] ethernet [<stack-unit>]/slotnum/portnum]

The `<stack-unit>` parameter is required on stackable devices.
The `<slotnum>` parameter is required on chassis devices.

These commands enable UDLD on ports 1/1 – 1/4.

For releases prior to FGS 03.0.00, you can specify up to two ports on the same command line. FGS software release 03.0.00 adds the capability to configure multiple ports with a single command, such as the following.

```
FastIron(config)#link-keepalive ethernet 0/1/1 to 0/1/5 ethernet 0/1/7
```

Syntax: `[no] link-keepalive ethernet [portlist]

Changing the Keepalive interval

By default, ports enabled for UDLD send a link health-check packet once every 500 ms. You can change the interval to a value from 1 – 60, where 1 is 100 ms, 2 is 200 ms, and so on. To change the interval, enter a command such as the following.

```
FastIron(config)#link-keepalive interval 3
```

Syntax: `[no] link-keepalive interval `<num>`

The `<num>` parameter specifies how often the ports send a UDLD packet. You can specify from 1 – 60, in 100 ms increments. The default is 5 (500 ms).
Changing the Keepalive retries

By default, a port waits one second to receive a health-check reply packet from the port at the other end of the link. If the port does not receive a reply, the port tries four more times by sending up to four more health-check packets. If the port still does not receive a reply after the maximum number of retries, the port goes down.

You can change the maximum number of keepalive attempts to a value from 3 – 64. To change the maximum number of attempts, enter a command such as the following.

```
FastIron(config)#link-keepalive retries 4
```

**Syntax:** 

```
[no] link-keepalive retries <num>
```

The `<num>` parameter specifies the maximum number of times the port will try the health check. You can specify a value from 3 – 64. The default is 7.

UDLD for tagged ports

**Platform Support:**

- FastIron X Series devices running software release 04.0.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

The default implementation of UDLD sends the packets untagged, even across tagged ports. If the untagged UDLD packet is received by a third-party switch, that switch may reject the packet. As a result, UDLD may be limited only to Brocade devices, since UDLD may not function on third-party switches.

You can configure ports to send out UDLD control packets that are tagged with a specific VLAN ID as tagged UDLD control packets. This feature also enables third party switches to receive the control packets that are tagged with the specified VLAN.

To enable ports to receive and send UDLD control packets tagged with a specific VLAN ID, enter commands such as the following.

```
FastIron(config)#link-keepalive ethernet 1/18 vlan 22
```

This command enables UDLD on port 1/18 and allows UDLD control packet tagged with VLAN 22 to be received and sent on port 1/18.

**Syntax:** 

```
[no] link-keepalive ethernet [<stack-unit>]<slotnum>/]<portnum> [vlan <vlan-ID>]
```

The `<stack-unit>` parameter is required for stackable devices.

The `<slotnum>` parameter is required on chassis devices.

Enter the ID of the VLAN that the UDLD control packets can contain to be received and sent on the port. If a VLAN ID is not specified, then UDLD control packets are sent out of the port as untagged packets.

**NOTE**

You must configure the same VLANs that will be used for UDLD on all devices across the network; otherwise, the UDLD link cannot be maintained.
Displaying UDLD information

This section describes the commands used to display information about a UDLD configuration.

Displaying information for all ports

To display UDLD information for all ports, enter the following command.

```
FastIron#show link-keepalive
Total link-keepalive enabled ports: 4
Keepalive Retries: 3  Keepalive Interval: 1 Sec.
```

```
Port       Physical Link   Logical Link   State        Link-vlan
4/1        up              up              FORWARDING   3
4/2        up              up              FORWARDING
4/3        down            down            DISABLED
4/4        up              down            DISABLED
```

Syntax:  show link-keepalive

### TABLE 87  CLI display of UDLD information

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total link-keepalive enabled ports</td>
<td>The total number of ports on which UDLD is enabled.</td>
</tr>
<tr>
<td>Keepalive Retries</td>
<td>The number of times a port will attempt the health check before concluding that the link is down.</td>
</tr>
<tr>
<td>Keepalive Interval</td>
<td>The number of seconds between health check packets.</td>
</tr>
<tr>
<td>Port</td>
<td>The port number.</td>
</tr>
<tr>
<td>Physical Link</td>
<td>The state of the physical link. This is the link between the Brocade port and the directly connected device.</td>
</tr>
<tr>
<td>Logical Link</td>
<td>The state of the logical link. This is the state of the link between this Brocade port and the Brocade port on the other end of the link.</td>
</tr>
<tr>
<td>State</td>
<td>The traffic state of the port.</td>
</tr>
<tr>
<td>Link-vlan</td>
<td>The ID of the tagged VLAN in the UDLD packet.</td>
</tr>
</tbody>
</table>

If a port is disabled by UDLD, the change also is indicated in the output of the `show interfaces brief` command. An example is given below.

```
FastIron#show interfaces brief
```

```
Port Link State Dupl Speed Trunk Tag Priori MAC           Name
1/1 Up  **LK-DISABLE** None None None No  level0 00e0.52a9.bb00
1/2 Down None None None None  No  level0 00e0.52a9.bb01
1/3 Down None None None None  No  level0 00e0.52a9.bb02
1/4 Down None None None None  No  level0 00e0.52a9.bb03
```

If the port was already down before you enabled UDLD for the port, the port state is listed as None.

Syntax:  show interfaces brief
**Displaying information for a single port**

To display detailed UDLD information for a specific port, enter a command such as the following.

```
FastIron#show link-keepalive ethernet 4/1
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current State</td>
<td>The state of the logical link. This is the link between this Brocade port and the Brocade port on the other end of the link.</td>
</tr>
<tr>
<td>Remote MAC Addr</td>
<td>The MAC address of the port or device at the remote end of the logical link.</td>
</tr>
<tr>
<td>Local Port</td>
<td>The port number on this Brocade device.</td>
</tr>
<tr>
<td>Remote Port</td>
<td>The port number on the Brocade device at the remote end of the link.</td>
</tr>
<tr>
<td>Local System ID</td>
<td>A unique value that identifies this Brocade device. The ID can be used by Brocade technical support for troubleshooting.</td>
</tr>
<tr>
<td>Remote System ID</td>
<td>A unique value that identifies the Brocade device at the remote end of the link.</td>
</tr>
<tr>
<td>Packets sent</td>
<td>The number of UDLD health-check packets sent on this port.</td>
</tr>
<tr>
<td>Packets received</td>
<td>The number of UDLD health-check packets received on this port.</td>
</tr>
<tr>
<td>Transitions</td>
<td>The number of times the logical link state has changed between up and down.</td>
</tr>
<tr>
<td>Port blocking</td>
<td>Information used by Brocade technical support for troubleshooting.</td>
</tr>
<tr>
<td>Link-vlan</td>
<td>The ID of the tagged VLAN in the UDLD packet.</td>
</tr>
<tr>
<td>BM disabled</td>
<td>Information used by Brocade technical support for troubleshooting.</td>
</tr>
</tbody>
</table>

The `show interface ethernet` command also displays the UDLD state for an individual port. In addition, the line protocol state listed in the first line will say “down” if UDLD has brought the port down. An example is given below.

```
FastIron#show interface ethernet 4/1
Current State   : down            Remote MAC Addr  : 00e0.52d2.5100
Local Port      : 4/1           Remote Port      : 2/1
Local System ID : e0927400      Remote System ID : e0d25100
Packets sent    : 254           Packets received : 255
Transitions     : 1             Link-vlan        : 100
Port blocking   : No            BM disabled      : No
```

**Syntax:**  `show link-keepalive [ethernet [<slotnum>/]<portnum>]`
FastIron\#show interface ethernet 1/1
FastEthernet1/1 is down, line protocol is down, link keepalive is enabled
   Hardware is FastEthernet, address is 00e0.52a9.bbca (bia 00e0.52a9.bbca)
   Configured speed auto, actual unknown, configured duplex fdx, actual unknown
   Member of L2 VLAN ID 1, port is untagged, port state is DISABLED
   STP configured to ON, priority is level0, flow control enabled
   mirror disabled, monitor disabled
   Not member of any active trunks
   Not member of any configured trunks
   No port name
   300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
   300 second output rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
   0 packets input, 0 bytes, 0 no buffer
   Received 0 broadcasts, 0 multicasts, 0 unicast
   0 input errors, 0 CRC, 0 frame, 0 ignored
   0 runts, 0 giants, DMA received 0 packets
   19 packets output, 1216 bytes, 0 underruns
   Transmitted 0 broadcasts, 19 multicasts, 0 unicast
   0 output errors, 0 collisions, DMA transmitted 19 packets

In this example, the port has been brought down by UDLD. Notice that in addition to the information in the first line, the port state on the fourth line of the display is listed as DISABLED.

Clearing UDLD statistics

To clear UDLD statistics, enter the following command.

FastIron\#clear link-keepalive statistics

Syntax: clear link-keepalive statistics

This command clears the Packets sent, Packets received, and Transitions counters in the show link keepalive ethernet [<slotnum>/]<portnum> display.

Protected link groups

Platform Support:
- FastIron X Series devices running software release 03.0.00 and later – L2, BL3, L3
- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later

A protected link group minimizes disruption to the network by protecting critical links from loss of data and power. In a protected link group, one port in the group acts as the primary or active link, and the other ports act as secondary or standby links. The active link carries the traffic. If the active link goes down, one of the standby links takes over.

During normal operation, the active port in a protected link group is enabled and the standby ports are logically disabled. If the active port fails, the Brocade device immediately enables one of the standby ports, and switches traffic to the standby port. The standby port becomes the new, active port.
About active ports

When you create a protected link group, you can optionally specify which port in the protected link group is the active port. If you do not explicitly configure an active port, the Brocade device dynamically assigns one. A dynamic active port is the first port in the protected link group that comes up (usually the lowest numbered port in the group).

Static and dynamic active ports operate as follows:

- A static active port (an active port that you explicitly configured) pre-empts other ports in the protected link group. So, if a static active link comes back up after a failure, the Brocade device will revert to this link as the active link.
- A dynamic active port (an active port assigned by the software) is non-pre-emptive. Therefore, if a dynamic active link comes back up after a failure, the Brocade device does not revert to this link, but continues carrying traffic on the current active link.

Using UDLD with protected link groups

You can use UDLD with protected link groups to detect uni-directional link failures and to improve the speed at which the device detects a failure in the link. Use UDLD and protected link groups simultaneously when the FastIron X Series device is connected to a device with slower link detection times.

NOTE
When UDLD and protected links are configured on a port and the link goes down, protected links will not come up after UDLD becomes “healthy” again without first physically disabling then re-enabling the link.

Configuration notes

- You can configure a maximum of 32 protected link groups.
- There is no restriction on the number of ports in a protected link group.
- Each port can belong to one protected link group at a time.
- There is no restriction on the type of ports in a protected link group. A protected link group can consist of 10-GbE ports, Gbps fiber ports, 10/100/1000 copper ports, and 10/100 ports, or any combination thereof.
- This feature is supported with tagged and untagged ports.
- This feature is supported with trunk ports.
- The protected link groups feature is not supported with LACP.
- There is no restriction on the properties of ports in a protected link group. For example, member ports can be in the same VLAN or in different VLANs.
- When two switches are connected together with links in a protected link group, and the ports connecting the switches together are part of a protected link group, you must configure two connecting ports (one port on each switch) as active ports of the protected link group. The following example illustrates this scenario.
Creating a protected link group and assigning an active port

Follow the steps given below to create a protected link group.

1. Specify the member ports in the protected link group. Enter a command such as the following.

   FastIron(config)# protected-link-group 10 e 1 to 4

2. Optionally specify which port will be the active port for the protected link group. Enter a command such as the following.

   FastIron(config)# protected-link-group 10 active-port e 1

   **NOTE**
   If you do not explicitly configure an active port, the Brocade device automatically assigns one as the first port in the protected link group to come up.

These commands configure port e1 as the active port and ports e2 – e4 as standby ports. If port 1 goes down, the Brocade device enables the first available standby port, and switches the traffic to that port. Since the above configuration consists of a statically configured active port, the active port pre-empts other ports in the protected link group. Refer to “About active ports” on page 461.

**Syntax:**

```
[no] protected-link-group <group-ID> ethernet [stack-unit]/<slotnum>/]portnum> to [stack-unit]/<slotnum>/]portnum>
```

The `<group-ID>` parameter specifies the protected link group number. Enter a number from 1 – 32. Each `ethernet` parameter introduces a port group.

The `[/]portnum` to `[/]portnum` parameters specify the ports in the protected link group. The `/<slotnum>` parameter is required on chassis devices.

**Syntax:**

```
[no] protected-link-group <group-ID> active-port ethernet <[stack-unit]/slotnum ApplicationUser Port e 1
```

These commands configure port e1 as the active port and ports e2 – e4 as standby ports. If port 1 goes down, the Brocade device enables the first available standby port, and switches the traffic to that port. Since the above configuration consists of a statically configured active port, the active port pre-empts other ports in the protected link group. Refer to “About active ports” on page 461.
The `<group-ID>` parameter specifies the protected link group number. Enter a number from 1 – 32.
The `active-port ethernet <stack-unit>[/<slotnum>]/portnum` parameter defines the active port.
The `<stack-unit>` parameter is required on stackable devices.
The `<slotnum>` parameter is required on chassis devices.

**Viewing information about protected link groups**

You can use the following `show` commands to view information about protected link groups:

- `show protected-link-group`
- `show interface brief`
- `show interface`

The following shows example output for the `show protected-link-group` command.

```
FastIron#show protected-link-group
Group ID: 1
Member Port(s): ethe 1 to 7
Configured Active Port: 7
Current Active Port: 7
Standby Port(s): ethe 5
Total Number of Protected Link Groups: 1
```

**Syntax:** `show protected-link-group [group-ID]`

<table>
<thead>
<tr>
<th>TABLE 89</th>
<th>CLI display of protected link group information</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field...</strong></td>
<td><strong>Displays...</strong></td>
</tr>
<tr>
<td>Group ID</td>
<td>The ID number of the protected link group.</td>
</tr>
<tr>
<td>Member Port(s)</td>
<td>The ports that are members of the protected link group.</td>
</tr>
<tr>
<td>Configured Active Port</td>
<td>The statically configured active port. If you do not statically configure an active port, this value will be &quot;None&quot;.</td>
</tr>
<tr>
<td>Current Active Port</td>
<td>The current active port for the protected link group. If all member ports are down, this value will be &quot;None&quot;.</td>
</tr>
<tr>
<td>Standby Port(s)</td>
<td>The member ports that are on standby.</td>
</tr>
</tbody>
</table>

The `show interface brief` command also displays information about protected link groups.

**Example**

```
FastIron#show int brief e 3 to 4
Port Link State Dupl Speed Trunk Tag Priori MAC            Name
 3  Up  Inactive  Full Auto  None  Yes  leve10 0012.f2a8.7140
 4  Up  Forward   Full 1G   None  Yes  leve10 0012.f2a8.7140
```

In the above output, the **State** of port 3 is **Inactive**, which means port 3 is an inactive port in a protected link group. For active ports in a protected link group, the **State** will be **Active**.

**Syntax:** `show interface brief ethernet <stack-unit>[/<slotnum>]/<port-num>`

The `show interface` command also displays information about protected link groups.
12  Protected link groups

Example

FastIron#show int e 3
GigabitEthernet3 is up, line protocol is up, link keepalive is enabled
   Hardware is GigabitEthernet, address is 0012.f2a8.7140 (bia 0012.f2a8.7142)
   Configured speed auto, actual 1Gbit, configured duplex fdx, actual fdx
   Configured mdi mode AUTO, actual MDIX
   Member of 3 L2 VLANs, port is tagged, **port state is protected-link-inactive**
   BPDU guard is Disabled, ROOT protect is Disabled
   Link Error Dampening is Disabled
   STP configured to ON, priority is level0
   ....
   some lines omitted for brevity

In the above output, the port state is **protected-link-inactive** which means port 3 is an inactive port in a protected link group.

**Syntax:** show interface ethernet <stack-unit>/<slotnum>/<port-num>
Chapter 13

Configuring Virtual LANs (VLANs)

VLAN overview

The following sections provide details about the VLAN types and features supported on the FastIron and TurboIron 24X family of switches.

Types of VLANs

This section describes the VLAN types supported on Brocade devices.

VLAN support on FastIron devices

You can configure the following types of VLANs on FastIron devices:

- **Layer 2 port-based VLAN** – a set of physical ports that share a common, exclusive Layer 2 broadcast domain
- **Layer 3 protocol VLANs** – a subset of ports within a port-based VLAN that share a common, exclusive broadcast domain for Layer 3 broadcasts of the specified protocol type
- **IP subnet VLANs** – a subset of ports in a port-based VLAN that share a common, exclusive subnet broadcast domain for a specified IP subnet
- **IPv6 VLANs** – a subset of ports in a port-based VLAN that share a common, exclusive network broadcast domain for IPv6 packets
- **IPX network VLANs** – a subset of ports in a port-based VLAN that share a common, exclusive network broadcast domain for a specified IPX network
- **AppleTalk cable VLANs** – a subset of ports in a port-based-based VLAN that share a common, exclusive network broadcast domain for a specified AppleTalk cable range

When a FastIron device receives a packet on a port that is a member of a VLAN, the device forwards the packet based on the following VLAN hierarchy:

- If the port belongs to an IP subnet VLAN, IPX network VLAN, or AppleTalk cable VLAN and the packet belongs to the corresponding IP subnet, IPX network, or AppleTalk cable range, the device forwards the packet to all the ports within that VLAN.
- If the packet is a Layer 3 packet but cannot be forwarded as described above, but the port is a member of a Layer 3 protocol VLAN for the packet protocol, the device forwards the packet on all the Layer 3 protocol VLAN ports.
- If the packet cannot be forwarded based on either of the VLAN membership types listed above, but the packet can be forwarded at Layer 2, the device forwards the packet on all the ports within the receiving port port-based VLAN.

Protocol VLANs differ from IP subnet, IPX network, and AppleTalk VLANs in an important way. Protocol VLANs accept any broadcast of the specified protocol type. An IP subnet, IPX network, or AppleTalk VLAN accepts only broadcasts for the specified IP subnet, IPX network, or AppleTalk cable range.
NOTE
Protocol VLANs are different from IP subnet, IPX network, and AppleTalk cable VLANs. A port-based VLAN cannot contain both an IP subnet, IPX network, or AppleTalk cable VLAN and a protocol VLAN for the same protocol. For example, a port-based VLAN cannot contain both an IP protocol VLAN and an IP subnet VLAN.

**VLAN support on TurboIron devices**

The first software release for the TurboIron X Series supports Layer 2 port-based VLANs only. A Layer 2 port-based VLAN is a set of physical ports that share a common, exclusive Layer 2 broadcast domain. The next section provides more details.

**Layer 2 port-based VLANs**

On all Brocade devices, you can configure port-based VLANs. A port-based VLAN is a subset of ports on a Brocade device that constitutes a Layer 2 broadcast domain.

By default, all the ports on a Brocade device are members of the default VLAN. Thus, all the ports on the device constitute a single Layer 2 broadcast domain. You can configure multiple port-based VLANs. When you configure a port-based VLAN, the device automatically removes the ports you add to the VLAN from the default VLAN.

You can configure up to 4094 port-based VLANs on a Layer 2 Switch or Layer 3 Switch. On both device types, valid VLAN IDs are 1 – 4095. You can configure up to the maximum number of VLANs within that ID range.

NOTE
VLAN IDs 4087, 4090, and 4093 are reserved for Brocade internal use only. VLAN 4094 is reserved for use by Single STP. Also, in releases prior to 04.0.00, VLAN IDs 4091 and 4092 are reserved for Brocade internal use only. Starting in release 04.0.00, if you want to use VLANs 4091 and 4092 as configurable VLANs, you can assign them to different VLAN IDs. For more information, refer to “Assigning different VLAN IDs to reserved VLANs 4091 and 4092” on page 483.

Each port-based VLAN can contain either tagged or untagged ports. A port cannot be a member of more than one port-based VLAN unless the port is tagged. **802.1Q tagging** allows the port to add a four-byte tag field, which contains the VLAN ID, to each packet sent on the port. You also can configure port-based VLANs that span multiple devices by tagging the ports within the VLAN. The tag enables each device that receives the packet to determine the VLAN the packet belongs to. 802.1Q tagging applies only to Layer 2 VLANs, not to Layer 3 VLANs.

Since each port-based VLAN is a separate Layer 2 broadcast domain, by default each VLAN runs a separate instance of the Spanning Tree Protocol (STP).

Layer 2 traffic is bridged within a port-based VLAN and Layer 2 broadcasts are sent to all the ports within the VLAN.

**Figure 71** shows an example of a Brocade device on which a Layer 2 port-based VLAN has been configured.

**FIGURE 71** Brocade device containing user-defined Layer 2 port-based VLAN
Layer 3 protocol-based VLANs

If you want some or all of the ports within a port-based VLAN to be organized according to Layer 3 protocol, you must configure a Layer 3 protocol-based VLAN within the port-based VLAN.

You can configure each of the following types of protocol-based VLAN within a port-based VLAN. All the ports in the Layer 3 VLAN must be in the same Layer 2 VLAN.

Layer 3 protocol-based VLANs are as follows:

- **AppleTalk** – The device sends AppleTalk broadcasts to all ports within the AppleTalk protocol VLAN.
- **IP** – The device sends IP broadcasts to all ports within the IP protocol VLAN.
- **IPv6** – The device sends IPv6 broadcasts to all ports within the IPv6 protocol VLAN.
- **IPX** – The device sends IPX broadcasts to all ports within the IPX protocol VLAN.
- **DECnet** – The device sends DECnet broadcasts to all ports within the DECnet protocol VLAN.
- **NetBIOS** – The device sends NetBIOS broadcasts to all ports within the NetBIOS protocol VLAN.
- **Other** – The device sends broadcasts for all protocol types other than those listed above to all ports within the VLAN.
Figure 72 shows an example of Layer 3 protocol VLANs configured within a Layer 2 port-based VLAN.

**FIGURE 72  Layer 3 protocol VLANs within a Layer 2 port-based VLAN**

**DEFAULT-VLAN**  
VLAN ID = 1  
Layer 2 Port-based VLAN  

User-configured port-based VLAN  

User-configured protocol VLAN, IP sub-net VLAN, IPX network VLAN, or AppleTalk cable VLAN  

You can add Layer 3 protocol VLANs or IP sub-net, IPX network, and AppleTalk cable VLANs to port-based VLANs.

Layer 3 VLANs cannot span Layer 2 port-based VLANs.

However, Layer 3 VLANs can overlap within a Layer 2 port-based VLAN.
Integrated Switch Routing (ISR)

The Brocade Integrated Switch Routing (ISR) feature enables VLANs configured on Layer 3 Switches to route Layer 3 traffic from one protocol VLAN or IP subnet, IPX network, or AppleTalk cable VLAN to another. Normally, to route traffic from one IP subnet, IPX network, or AppleTalk cable VLAN to another, you would need to forward the traffic to an external router. The VLANs provide Layer 3 broadcast domains for these protocols but do not in themselves provide routing services for these protocols. This is true even if the source and destination IP subnets, IPX networks, or AppleTalk cable ranges are on the same device.

ISR eliminates the need for an external router by allowing you to route between VLANs using virtual routing interfaces (vEs). A virtual routing interface is a logical port on which you can configure Layer 3 routing parameters. You configure a separate virtual routing interface on each VLAN that you want to be able to route from or to. For example, if you configure two IP subnet VLANs on a Layer 3 Switch, you can configure a virtual routing interface on each VLAN, then configure IP routing parameters for the subnets. Thus, the Layer 3 Switch forwards IP subnet broadcasts within each VLAN at Layer 2 but routes Layer 3 traffic between the VLANs using the virtual routing interfaces.

NOTE
The Layer 3 Switch uses the lowest MAC address on the device (the MAC address of port 1 or 1/1) as the MAC address for all ports within all virtual routing interfaces you configure on the device.

The routing parameters and the syntax for configuring them are the same as when you configure a physical interface for routing. The logical interface allows the Layer 3 Switch to internally route traffic between the protocol-based VLANs without using physical interfaces.

All the ports within a protocol-based VLAN must be in the same port-based VLAN. The protocol-based VLAN cannot have ports in multiple port-based VLANs, unless the ports in the port-based VLAN to which you add the protocol-based VLAN are 802.1Q tagged.

You can configure multiple protocol-based VLANs within the same port-based VLAN. In addition, a port within a port-based VLAN can belong to multiple protocol-based VLANs of the same type or different types. For example, if you have a port-based VLAN that contains ports 1 – 10, you can configure port 5 as a member of an AppleTalk protocol VLAN, an IP protocol VLAN, and an IPX protocol VLAN, and so on.

IP subnet, IPX network, and AppleTalk cable VLANs

The protocol-based VLANs described in the previous section provide separate protocol broadcast domains for specific protocols. For IP, IPX, and AppleTalk, you can provide more granular broadcast control by instead creating the following types of VLAN:

- **IP subnet VLAN** – An IP subnet broadcast domain for a specific IP subnet.
- **IPX network VLAN** – An IPX network broadcast domain for a specific IPX network.
- **AppleTalk cable VLAN** – An AppleTalk broadcast domain for a specific cable range.

You can configure these types of VLANs on Layer 3 Switches only. The Layer 3 Switch sends broadcasts for the IP subnet, IPX subnet, or AppleTalk cable range to all ports within the IP subnet, IPX network, or AppleTalk cable VLAN at Layer 2.

The Layer 3 Switch routes packets between VLANs at Layer 3. To configure an IP subnet, IPX network, or AppleTalk cable VLAN to route, you must add a virtual routing interface to the VLAN, then configure the appropriate routing parameters on the virtual routing interface.
**NOTE**
The Layer 3 Switch routes packets between VLANs of the same protocol. The Layer 3 Switch cannot route from one protocol to another.

**NOTE**
IP subnet VLANs are not the same thing as IP protocol VLANs. An IP protocol VLAN sends all IP broadcasts on the ports within the IP protocol VLAN. An IP subnet VLAN sends only the IP subnet broadcasts for the subnet of the VLAN. You cannot configure an IP protocol VLAN and an IP subnet VLAN within the same port-based VLAN.

This note also applies to IPX protocol VLANs and IPX network VLANs, and to AppleTalk protocol VLANs and AppleTalk cable VLANs.

**Default VLAN**

By default, all the ports on a FastIron and TurboIron device are in a single port-based VLAN. This VLAN is called the DEFAULT-VLAN and is VLAN number 1. FastIron devices do not contain any protocol VLANs or IP subnet, IPX network, or AppleTalk cable VLANs by default.

*Figure 73* shows an example of the default Layer 2 port-based VLAN.

**FIGURE 73** Default Layer 2 port-based VLAN

```
DEFAULT-VLAN
VLAN ID = 1
Layer 2 Port-based VLAN
```

By default, all ports belong to a single port-based VLAN, DEFAULT-VLAN. Thus, all ports belong to a single Layer 2 broadcast domain.
When you configure a port-based VLAN, one of the configuration items you provide is the ports that are in the VLAN. When you configure the VLAN, the Brocade device automatically removes the ports that you place in the VLAN from DEFAULT-VLAN. By removing the ports from the default VLAN, the Brocade device ensures that each port resides in only one Layer 2 broadcast domain.

**NOTE**
Information for the default VLAN is available only after you define another VLAN.

Some network configurations may require that a port be able to reside in two or more Layer 2 broadcast domains (port-based VLANs). In this case, you can enable a port to reside in multiple port-based VLANs by tagging the port. See the following section.

If your network requires that you use VLAN ID 1 for a user-configured VLAN, you can reassign the default VLAN to another valid VLAN ID. Refer to “Assigning a different VLAN ID to the default VLAN” on page 482.

### 802.1Q tagging

802.1Q tagging is an IEEE standard that allows a networking device to add information to a Layer 2 packet in order to identify the VLAN membership of the packet. Brocade devices tag a packet by adding a four-byte tag to the packet. The tag contains the tag value, which identifies the data as a tag, and also contains the VLAN ID of the VLAN from which the packet is sent.

- The default tag value is 8100 (hexadecimal). This value comes from the 802.1Q specification. You can change this tag value on a global basis on Brocade devices if needed to be compatible with other vendors’ equipment.
- The VLAN ID is determined by the VLAN on which the packet is being forwarded.

**Figure 74** shows the format of packets with and without the 802.1Q tag. The tag format is vendor-specific. To use the tag for VLANs configured across multiple devices, make sure all the devices support the same tag format.

**FIGURE 74** Packet containing a Brocade 802.1Q VLAN tag
If you configure a VLAN that spans multiple devices, you need to use tagging only if a port connecting one of the devices to the other is a member of more than one port-based VLAN. If a port connecting one device to the other is a member of only a single port-based VLAN, tagging is not required.

If you use tagging on multiple devices, each device must be configured for tagging and must use the same tag value. In addition, the implementation of tagging must be compatible on the devices. The tagging on all Brocade devices is compatible with other Brocade devices.

**Figure 75** shows an example of two devices that have the same Layer 2 port-based VLANs configured across them. Notice that only one of the VLANs requires tagging.

**FIGURE 75** VLANs configured across multiple devices
Support for 802.1Q-in-Q tagging

Brocade devices provide finer granularity for configuring 802.1Q tagging, enabling you to configure 802.1Q tag-types on a group of ports, thereby enabling the creation of two identical 802.1Q tags (802.1Q-in-Q tagging) on a single device. This enhancement improves SAV interoperability between Brocade devices and other vendors’ devices that support the 802.1Q tag-types, but are not very flexible with the tag-types they accept.

For example applications and configuration details, refer to “Configuring 802.1Q-in-Q tagging” on page 523.

802.1 Q-in-Q tagging for stack devices

Platform Support:

• FGS-STK and FLS-STK devices running software release 05.0.00 and later
• FGS, FLS, and FWS devices running software release 04.3.01 and later
• FCX-S devices running software release 06.0.00 and later

The following enhancements allow FGS-STK and FLS-STK, and FCX devices in an IronStack to use Q-in-Q and SAV, by allowing the changing of a tag profile for ports:

• In addition to the default tag type 0x8100, you can now configure one additional global tag profile with a number from 0xffffff.
• Tag profiles on a single port, or a group of ports can be configured to point to the global tag profile.

To configure a global tag profile, enter the following command in the configuration mode.

FGS624P Switch(config)# tag-profile 9500

Syntax: [no] tag-profile <tag-no>

<tag-no> - the number of the tag, can be 0x8100 (default), or 0xffffff
To direct individual ports or on a range of ports to this tag profile, enter commands similar to the following.

FGS648P Switch(config)# interface ethernet 1/1/1
FGS648P Switch(config-if-e1000-1/1/1)# tag-profile enable
FGS648P Switch(config-mif-1/1/1,1/2/1)# tag-profile enable

**Configuration notes for stackable devices**

- One global tag profile with a number between 0 and ffff can be configured on stackable devices.
- On individual ports, the `tag-profile` is enabled, it points to the global tag profile
- `Tag-profile` can also be enabled for provisional ports
- `Tag-type` and `tag-profile` cannot be configured at the same time. You will see the message “un-configure the tag-type to set the tag-profile.” If `tag-type` is already configured, you will need to unconfigure it and then add the `tag-profile`.

**Spanning Tree Protocol (STP)**

The default state of STP depends on the device type:

- STP is disabled by default on Brocade Layer 3 Switches.
- STP is enabled by default on Brocade Layer 2 Switches.

Also by default, each port-based VLAN has a separate instance of STP. Thus, when STP is globally enabled, each port-based VLAN on the device runs a separate spanning tree.

You can enable or disable STP on the following levels:

- **Globally** – Affects all ports on the device.

  **NOTE**
  
  If you configure a port-based VLAN on the device, the VLAN has the same STP state as the default STP state on the device. Thus, on Layer 2 Switches, new VLANs have STP enabled by default. On Layer 3 Switches, new VLANs have STP disabled by default. You can enable or disable STP in each VLAN separately. In addition, you can enable or disable STP on individual ports.

- **Port-based VLAN** – Affects all ports within the specified port-based VLAN.

STP is a Layer 2 protocol. Thus, you cannot enable or disable STP for individual protocol VLANs or for IP subnet, IPX network, or AppleTalk cable VLANs. The STP state of a port-based VLAN containing these other types of VLANs determines the STP state for all the Layer 2 broadcasts within the port-based VLAN. This is true even though Layer 3 protocol broadcasts are sent on Layer 2 within the VLAN.

It is possible that STP will block one or more ports in a protocol VLAN that uses a virtual routing interface to route to other VLANs. For IP protocol and IP subnet VLANs, even though some of the physical ports of the virtual routing interface are blocked, the virtual routing interface can still route so long as at least one port in the virtual routing interface protocol VLAN is not blocked by STP.

If you enable Single STP (SSTP) on the device, the ports in all VLANs on which STP is enabled become members of a single spanning tree. The ports in VLANs on which STP is disabled are excluded from the single spanning tree.
For more information, refer to Chapter 9, “Configuring Spanning Tree Protocol (STP) Related Features”.

Virtual routing interfaces

**NOTE**
On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

A virtual routing interface is a logical routing interface that Brocade Layer 3 Switches use to route Layer 3 protocol traffic between protocol VLANs.

Brocade devices send Layer 3 traffic at Layer 2 within a protocol VLAN. However, Layer 3 traffic from one protocol VLAN to another must be routed.

If you want the device to be able to send Layer 3 traffic from one protocol VLAN to another, you must configure a virtual routing interface on each protocol VLAN, then configure routing parameters on the virtual routing interfaces. For example, to enable a Layer 3 Switch to route IP traffic from one IP subnet VLAN to another, you must configure a virtual routing interface on each IP subnet VLAN, then configure the appropriate IP routing parameters on each of the virtual routing interfaces.

Figure 76 shows an example of Layer 3 protocol VLANs that use virtual routing interfaces for routing.

**Figure 76** Use virtual routing interfaces for routing between Layer 3 protocol VLANs
Brocade FastIron devices and TurboIron devices support the configuration of VLAN groups. To simplify configuration, you can configure VLAN groups and virtual routing interface groups. When you create a VLAN group, the VLAN parameters you configure for the group apply to all the VLANs within the group. Additionally, you can easily associate the same IP subnet interface with all the VLANs in a group by configuring a virtual routing interface group with the same ID as the VLAN group.

For configuration information, refer to "Configuring VLAN groups and virtual routing interface groups" on page 511.
Dynamic, static, and excluded port membership

When you add ports to a protocol VLAN, IP subnet VLAN, IPX network VLAN, or AppleTalk cable VLAN, you can add them dynamically or statically:

- Dynamic ports
- Static ports

You also can explicitly exclude ports.

**Dynamic ports**

Dynamic ports are added to a VLAN when you create the VLAN. However, if a dynamically added port does not receive any traffic for the VLAN protocol within ten minutes, the port is removed from the VLAN. However, the port remains a candidate for port membership. Thus, if the port receives traffic for the VLAN protocol, the device adds the port back to the VLAN.

After the port is added back to the VLAN, the port can remain an active member of the VLAN up to 20 minutes without receiving traffic for the VLAN protocol. If the port ages out, it remains a candidate for VLAN membership and is added back to the VLAN when the VLAN receives protocol traffic. At this point, the port can remain in the VLAN up to 20 minutes without receiving traffic for the VLAN protocol, and so on.

Unless you explicitly add a port statically or exclude a port, the port is a dynamic port and thus can be an active member of the VLAN, depending on the traffic it receives.

**NOTE**

You cannot configure dynamic ports in an AppleTalk cable VLAN. The ports in an AppleTalk cable VLAN must be static. However, ports in an AppleTalk protocol VLAN can be dynamic or static.

Figure 77 shows an example of a VLAN with dynamic ports. Dynamic ports not only join and leave the VLAN according to traffic, but also allow some broadcast packets of the specific protocol to “leak” through the VLAN. Refer to “Broadcast leaks” on page 479.

**FIGURE 77** VLAN with dynamic ports—all ports are active when you create the VLAN
A = active port

C = candidate port

When you add ports dynamically, all the ports are added when you add the VLAN.

SUBNET Ports in a new protocol VLAN that do not receive traffic for the VLAN protocol age out after 10 minutes and become candidate ports. Figure 78 shows what happens if a candidate port receives traffic for the VLAN protocol.

**FIGURE 78** VLAN with dynamic ports—candidate ports become active again if they receive protocol traffic

Ports that time out remain candidates for membership in the VLAN and become active again if they receive traffic for the VLAN's protocol, IP sub-net, IPX network, or AppleTalk cable range.

When a candidate port rejoins a VLAN, the timeout for that port becomes 20 minutes. Thus, the port remains an active member of the VLAN even if it does not receive traffic for 20 minutes. After that, the port becomes a candidate port again.
**Static ports**

Static ports are permanent members of the protocol VLAN. The ports remain active members of the VLAN regardless of whether the ports receive traffic for the VLAN protocol. You must explicitly identify the port as a static port when you add it to the VLAN. Otherwise, the port is dynamic and is subject to aging out.

**Excluded ports**

If you want to prevent a port in a port-based VLAN from ever becoming a member of a protocol, IP subnet, IPX network, or AppleTalk cable VLAN configured in the port-based VLAN, you can explicitly exclude the port. You exclude the port when you configure the protocol, IP subnet, IPX network, or AppleTalk cable VLAN.

Excluded ports do not leak broadcast packets. Refer to “Broadcast leaks” on page 479.

**Broadcast leaks**

A dynamic port becomes a member of a Layer 3 protocol VLAN when traffic from the VLAN's protocol is received on the port. After this point, the port remains an active member of the protocol VLAN, unless the port does not receive traffic from the VLAN's protocol for 20 minutes. If the port does not receive traffic for the VLAN's protocol for 20 minutes, the port ages out and is no longer an active member of the VLAN.

To enable a host that has been silent for awhile to send and receive packets, the dynamic ports that are currently members of the Layer 3 protocol VLAN "leak" Layer 3 broadcast packets to the ports that have aged out. When a host connected to one of the aged out ports responds to a leaked broadcast, the port is added to the protocol VLAN again.

To "leak" Layer 3 broadcast traffic, an active port sends 1/8th of the Layer 3 broadcast traffic to the inactive (aged out) ports.

Static ports do not age out and do not leak broadcast packets.

**Super aggregated VLANs**

**NOTE**

On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

You can aggregate multiple VLANs within another VLAN. This feature allows you to construct Layer 2 paths and channels. This feature is particularly useful for Virtual Private Network (VPN) applications in which you need to provide a private, dedicated Ethernet connection for an individual client to transparently reach its subnet across multiple networks.

For an application example and configuration information, refer to “Configuring super aggregated VLANs” on page 515.

**Trunk group ports and VLAN membership**

A trunk group is a set of physical ports that are configured to act as a single physical interface. Each trunk group port configuration is based on the configuration of the lead port, which is the lowest numbered port in the group.
If you add a trunk group lead port to a VLAN, all of the ports in the trunk group become members of that VLAN.

**Summary of VLAN configuration rules**

**NOTE**
This section does not apply to TurboIron X Series devices.

A hierarchy of VLANs exists between the Layer 2 and Layer 3 protocol-based VLANs:

- Port-based VLANs are at the lowest level of the hierarchy.
- Layer 3 protocol-based VLANs, IP, IPv6, IPX, AppleTalk, Decnet, and NetBIOS are at the middle level of the hierarchy.
- IP subnet, IPX network, and AppleTalk cable VLANs are at the top of the hierarchy.

**NOTE**
You cannot have a protocol-based VLAN and a subnet or network VLAN of the same protocol type in the same port-based VLAN. For example, you can have an IPX protocol VLAN and IP subnet VLAN in the same port-based VLAN, but you cannot have an IP protocol VLAN and an IP subnet VLAN in the same port-based VLAN, nor can you have an IP protocol VLAN and an IP network VLAN in the same port-based VLAN.

As a Brocade device receives packets, the VLAN classification starts from the highest level VLAN first. Therefore, if an interface is configured as a member of both a port-based VLAN and an IP protocol VLAN, IP packets coming into the interface are classified as members of the IP protocol VLAN because that VLAN is higher in the VLAN hierarchy.

**Multiple VLAN membership rules**

- A port can belong to multiple, unique, overlapping Layer 3 protocol-based VLANs without VLAN tagging.
- A port can belong to multiple, overlapping Layer 2 port-based VLANs only if the port is a tagged port. Packets sent out of a tagged port use an 802.1Q-tagged frame.
- When both port and protocol-based VLANs are configured on a given device, all protocol VLANs must be strictly contained within a port-based VLAN. A protocol VLAN cannot include ports from multiple port-based VLANs. This rule is required to ensure that port-based VLANs remain loop-free Layer 2 broadcast domains.
- IP protocol VLANs and IP subnet VLANs cannot operate concurrently on the system or within the same port-based VLAN.
- IPX protocol VLANs and IPX network VLANs cannot operate concurrently on the system or within the same port-based VLAN.
- If you first configure IP and IPX protocol VLANs before deciding to partition the network by IP subnet and IPX network VLANs, then you need to delete those VLANs before creating the IP subnet and IPX network VLANs.
- One of each type of protocol VLAN is configurable within each port-based VLAN on the Layer 2 Switch.
- Multiple IP subnet and IPX network VLANs are configurable within each port-based VLAN on the Layer 2 Switch.
Routing between VLANs

Brocade Layer 3 Switches can locally route IP, IPX, and Appletalk between VLANs defined within a single router. All other routable protocols or protocol VLANs (for example, DecNet) must be routed by another external router capable of routing the protocol.

Virtual routing interfaces (Layer 3 Switches only)

You need to configure virtual routing interfaces if an IP, IPX, or Appletalk protocol VLAN, IP subnet VLAN, AppleTalk cable VLAN, or IPX network VLAN needs to route protocols to another port-based VLAN on the same router. A virtual routing interface can be associated with the ports in only a single port-based VLAN. Virtual router interfaces must be defined at the highest level of the VLAN hierarchy.

If you do not need to further partition the port-based VLAN by defining separate Layer 3 VLANs, you can define a single virtual routing interface at the port-based VLAN level and enable IP, IPX, and Appletalk routing on a single virtual routing interface.

Some configurations may require simultaneous switching and routing of the same single protocol across different sets of ports on the same router. When IP, IPX, or Appletalk routing is enabled on a Brocade Layer 3 Switch, you can route these protocols on specific interfaces while bridging them on other interfaces. In this scenario, you can create two separate backbones for the same protocol, one bridged and one routed.

To bridge IP, IPX, or Appletalk at the same time these protocols are being routed, you need to configure an IP protocol, IP subnet, IPX protocol, IPX network, or Appletalk protocol VLAN and not assign a virtual routing interface to the VLAN. Packets for these protocols are bridged or switched at Layer 2 across ports on the router that are included in the Layer 3 VLAN. If these VLANs are built within port-based VLANs, they can be tagged across a single set of backbone fibers to create separate Layer 2 switched and Layer 3 routed backbones for the same protocol on a single physical backbone.

Routing between VLANs using virtual routing interfaces (Layer 3 Switches only)

Brocade calls the ability to route between VLANs with virtual routing interfaces Integrated Switch Routing (ISR). There are some important concepts to understand before designing an ISR backbone.

Virtual router interfaces can be defined on port-based, IP protocol, IP subnet, IPX protocol, IPX network, AppleTalk protocol, and AppleTalk cable VLANs.

To create any type of VLAN on a Brocade Layer 3 Switch, Layer 2 forwarding must be enabled. When Layer 2 forwarding is enabled, the Layer 3 Switch becomes a Switch on all ports for all non-routable protocols.
If the router interfaces for IP, IPX, or AppleTalk are configured on physical ports, then routing occurs independent of the Spanning Tree Protocol (STP). However, if the router interfaces are defined for any type VLAN, they are virtual routing interfaces and are subject to the rules of STP.

If your backbone consists of virtual routing interfaces all within the same STP domain, it is a bridged backbone, not a routed one. This means that the set of backbone interfaces that are blocked by STP will be blocked for routed protocols as well. The routed protocols will be able to cross these paths only when the STP state of the link is FORWARDING. This problem is easily avoided by proper network design.

When designing an ISR network, pay attention to your use of virtual routing interfaces and the spanning-tree domain. If Layer 2 switching of your routed protocols (IP, IPX, AppleTalk) is not required across the backbone, then the use of virtual routing interfaces can be limited to edge switch ports within each router. Full backbone routing can be achieved by configuring routing on each physical interface that connects to the backbone. Routing is independent of STP when configured on a physical interface.

If your ISR design requires that you switch IP, IPX, or Appletalk at Layer 2 while simultaneously routing the same protocols over a single backbone, then create multiple port-based VLANs and use VLAN tagging on the backbone links to separate your Layer 2 switched and Layer 3 routed networks.

There is a separate STP domain for each port-based VLAN. Routing occurs independently across port-based VLANs or STP domains. You can define each end of each backbone link as a separate tagged port-based VLAN. Routing will occur independently across the port-based VLANs. Because each port-based VLAN STP domain is a single point-to-point backbone connection, you are guaranteed to never have an STP loop. STP will never block the virtual router interfaces within the tagged port-based VLAN, and you will have a fully routed backbone.

**Dynamic port assignment (Layer 2 Switches and Layer 3 Switches)**

All Switch ports are dynamically assigned to any Layer 3 VLAN on Brocade Layer 2 Switches and any non-routable VLAN on Brocade Layer 3 Switches. To maintain explicit control of the VLAN, you can explicitly exclude ports when configuring any Layer 3 VLAN on a Brocade Layer 2 Switch or any non-routable Layer 3 VLAN on a Brocade Layer 3 Switch.

If you do not want the ports to have dynamic membership, you can add them statically. This eliminates the need to explicitly exclude the ports that you do not want to participate in a particular Layer 3 VLAN.

**Assigning a different VLAN ID to the default VLAN**

When you enable port-based VLANs, all ports in the system are added to the default VLAN. By default, the default VLAN ID is “VLAN 1”. The default VLAN is not configurable. If you want to use the VLAN ID “VLAN 1” as a configurable VLAN, you can assign a different VLAN ID to the default VLAN.

To reassign the default VLAN to a different VLAN ID, enter the following command.

```plaintext
FastIron(config)# default-vlan-id 4095
```

Syntax: `[no] default-vlan-d <vlan-id>`
You must specify a valid VLAN ID that is not already in use. For example, if you have already defined VLAN 10, do not try to use “10” as the new VLAN ID for the default VLAN. Valid VLAN IDs are numbers from 1 – 4095.

**NOTE**
Changing the default VLAN name does not change the properties of the default VLAN. Changing the name allows you to use the VLAN ID “1” as a configurable VLAN.

### Assigning different VLAN IDs to reserved VLANs 4091 and 4092

**Platform Support:**
- FastIron X Series devices running software release 04.0.00 and later – L2, BL3, L3
- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later

In releases prior to those listed above, VLANs 4091 and 4092 are reserved for Brocade internal VLAN management and cannot be configured. Starting in the releases listed above, VLAN IDs 4087, 4090, and 4093 are reserved for Brocade internal use only. VLAN 4094 is reserved for use by Single STP. Starting in release 04.0.00, if you want to use VLANs 4091 and 4092 as configurable VLANs, you can assign them to different VLAN IDs.

For example, to reassign reserved VLAN 4091 to VLAN 10, enter the following commands.

```plaintext
FastIron(config)# reserved-vlan-map vlan 4091 new-vlan 10
Reload required. Please write memory and then reload or power cycle.
FastIron(config)# write mem
FastIron(config)# exit
FastIron# reload
```

**NOTE**
You must save the configuration (write mem) and reload the software to place the change into effect.

The above configuration changes the VLAN ID of 4091 to 10. After saving the configuration and reloading the software, you can configure VLAN 4091 as you would any other VLAN.

**Syntax:** 
```plaintext
[no] reserved-vlan-map vlan 4091 | 4092 new-vlan <vlan-id>
```

For `<vlan-id>`, enter a valid VLAN ID that is not already in use. For example, if you have already defined VLAN 20, do not try to use “20” as the new VLAN ID. Valid VLAN IDs are numbers from 1 – 4090, 4093, and 4095. VLAN ID 4094 is reserved for use by the Single Spanning Tree feature.

### Viewing reassigned VLAN IDs for reserved VLANs 4091 and 4092

To view the assigned VLAN IDs for reserved VLANs 4091 and 4092, use the `show reserved-vlan-map` command. The reassigned VLAN IDs also display in the output of the `show running-config` and `show config` commands.

The following shows example output for the `show reserved-vlan-map` command.
Routing between VLANs

Syntax: show reserved-vlan-map

The following table defines the fields in the output of the `show reserved-vlan-map` command.

<table>
<thead>
<tr>
<th>Reserved Purpose</th>
<th>Default</th>
<th>Re-assign</th>
<th>Current</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU VLAN</td>
<td>4091</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>All Ports VLAN</td>
<td>4092</td>
<td>33</td>
<td>33</td>
</tr>
</tbody>
</table>

1. If you reassign a reserved VLAN without saving the configuration and reloading the software, the reassigned VLAN ID will display in the `Re-assign` column. However, the previously configured or default VLAN ID will display in the `Current` column until the configuration is saved and the device reloaded.

Assigning trunk group ports

When a “lead” trunk group port is assigned to a VLAN, all other members of the trunk group are automatically added to that VLAN. A lead port is the first port of a trunk group port range; for example, “1” in 1 – 4 or “5” in 5 – 8. Refer to “Trunk group rules” on page 547 for more information.

Configuring port-based VLANs

Port-based VLANs allow you to provide separate spanning tree protocol (STP) domains or broadcast domains on a port-by-port basis.

This section describes how to perform the following tasks for port-based VLANs using the CLI:

- Create a VLAN
- Delete a VLAN
- Modify a VLAN
- Change a VLAN priority
- Enable or disable STP on the VLAN

Example 1

Figure 79 shows a simple port-based VLAN configuration using a single Brocade Layer 2 Switch. All ports within each VLAN are untagged. One untagged port within each VLAN is used to connect the Layer 2 Switch to a Layer 3 Switch (in this example, a FSX) for Layer 3 connectivity between the two port-based VLANs.

FIGURE 79 Port-based VLANs 222 and 333
To create the two port-based VLANs shown in Figure 79, enter the following commands.

```plaintext
FastIron(config)# vlan 222 by port
FastIron(config-vlan-222)# untag e 1 to 8
FastIron(config-vlan-222)# vlan 333 by port
FastIron(config-vlan-333)# untag e 9 to 16
```

**Syntax:** `vlan <vlan-id> by port`

**Syntax:** `untagged ethernet [portnum] [to portnum] | ethernet [portnum] [to portnum]`

**Example 2**

Figure 80 shows a more complex port-based VLAN configuration using multiple Layer 2 Switches and IEEE 802.1Q VLAN tagging. The backbone link connecting the three Layer 2 Switches is tagged. One untagged port within each port-based VLAN on FESX-A connects each separate network wide Layer 2 broadcast domain to the router for Layer 3 forwarding between broadcast domains. The STP priority is configured to force FESX-A to be the root bridge for VLANs RED and BLUE. The STP priority on FESX-B is configured so that FESX-B is the root bridge for VLANs GREEN and BROWN.

**FIGURE 80** More complex port-based VLAN
To configure the Port-based VLANs on the FESX Layer 2 Switches in Figure 80, use the following method.

**Configuring FESX-A**

Enter the following commands to configure FESX-A.

```
FastIron> enable
FastIron# configure terminal
FastIron(config)# hostname FESX-A
FastIron-A(config)# vlan 2 name BROWN
FastIron-A(config-vlan-2)# untag ethernet 1 to 4 ethernet 17
FastIron-A(config-vlan-2)# tag ethernet 25 to 26
FastIron-A(config-vlan-2)# spanning-tree
FastIron-A(config-vlan-2)# vlan 3 name GREEN
FastIron-A(config-vlan-3)# untag ethernet 5 to 8 ethernet 18
FastIron-A(config-vlan-3)# tag ethernet 25 to 26
FastIron-A(config-vlan-3)# spanning-tree
FastIron-A(config-vlan-3)# vlan 4 name BLUE
FastIron-A(config-vlan-4)# untag ethernet 9 to 12 ethernet 19
FastIron-A(config-vlan-4)# tag ethernet 25 to 26
FastIron-A(config-vlan-4)# spanning-tree
FastIron-A(config-vlan-4)# spanning-tree priority 500
FastIron-A(config-vlan-4)# vlan 5 name RED
FastIron-A(config-vlan-5)# untag ethernet 13 to 16 ethernet 20
FastIron-A(config-vlan-5)# tag ethernet 25 to 26
FastIron-A(config-vlan-5)# spanning-tree
FastIron-A(config-vlan-5)# spanning-tree priority 500
FastIron-A(config-vlan-5)# end
FastIron-A# write memory
```
**Configuring FESX-B**

Enter the following commands to configure FESX-B.

FastIron> en
FastIron# configure terminal
FastIron(config)# hostname FESX-B
FastIron-B(config)# vlan 2 name BROWN
FastIron-B(config-vlan-2)# untag ethernet 1 to 4
FastIron-B(config-vlan-2)# tag ethernet 25 to 26
FastIron-B(config-vlan-2)# spanning-tree
FastIron-B(config-vlan-2)# spanning-tree priority 500
FastIron-B(config-vlan-2)# vlan 3 name GREEN
FastIron-B(config-vlan-3)# untag ethernet 5 to 8
FastIron-B(config-vlan-3)# tag ethernet 25 to 26
FastIron-B(config-vlan-3)# spanning-tree
FastIron-B(config-vlan-3)# spanning-tree priority 500
FastIron-B(config-vlan-3)# vlan 4 name BLUE
FastIron-B(config-vlan-4)# untag ethernet 9 to 12
FastIron-B(config-vlan-4)# tag ethernet 25 to 26
FastIron-B(config-vlan-4)# vlan 5 name RED
FastIron-B(config-vlan-5)# untag ethernet 13 to 16
FastIron-B(config-vlan-5)# tag ethernet 25 to 26
FastIron-B(config-vlan-5)# end
FastIron-B# write memory

**Configuring FESX-C**

Enter the following commands to configure FESX-C.

FastIron> en
FastIron# configure terminal
FastIron(config)# hostname FESX-C
FastIron-C(config)# vlan 2 name BROWN
FastIron-C(config-vlan-2)# untag ethernet 1 to 4
FastIron-C(config-vlan-2)# tag ethernet 25 to 26
FastIron-C(config-vlan-2)# vlan 3 name GREEN
FastIron-C(config-vlan-3)# untag ethernet 5 to 8
FastIron-C(config-vlan-3)# tag ethernet 25 to 26
FastIron-C(config-vlan-3)# spanning-tree
FastIron-C(config-vlan-3)# spanning-tree priority 500
FastIron-C(config-vlan-3)# vlan 4 name BLUE
FastIron-C(config-vlan-4)# untag ethernet 9 to 12
FastIron-C(config-vlan-4)# tag ethernet 25 to 26
FastIron-C(config-vlan-4)# vlan 5 name RED
FastIron-C(config-vlan-5)# untag ethernet 13 to 16
FastIron-C(config-vlan-5)# tag ethernet 25 to 26
FastIron-C(config-vlan-5)# end
FastIron-C# write memory

**Syntax:**

- `vlan <vlan-id>` by port
- `untagged ethernet [<slotnum>/]<portnum>` [to [<slotnum>/]<portnum>] | ethernet [<slotnum>/]<portnum>
- `tagged ethernet [<slotnum>/]<portnum>` [to [<slotnum>/]<portnum>] | ethernet [<slotnum>/]<portnum>
- `[no] spanning-tree`
- `spanning-tree [ethernet [<slotnum>/]<portnum> path-cost <value> priority <value>]` forward-delay <value> hello-time <value> maximum-age <time> priority <value>
Modifying a port-based VLAN

You can make the following modifications to a port-based VLAN:

- Add or delete a VLAN port.
- Enable or disable STP.

Removing a port-based VLAN

Suppose you want to remove VLAN 5 from the example in Figure 80. To do so, use the following procedure.

1. Access the global CONFIG level of the CLI on FESX-A by entering the following commands.

   FastIron-A> enable
   No password has been assigned yet...
   FastIron-A# configure terminal
   FastIron-A(config)#

2. Enter the following command.

   FastIron-A(config)# no vlan 5
   FastIron-A(config)#

3. Enter the following commands to exit the CONFIG level and save the configuration to the system-config file on flash memory.

   FastIron-A(config)#
   FastIron-A(config)# end
   FastIron-A# write memory
   FastIron-A#

4. Repeat steps 1 – 3 on FESX-B.

Syntax: no vlan <vlan-id> by port

Removing a port from a VLAN

Suppose you want to remove port 11 from VLAN 4 on FESX-A shown in Figure 80. To do so, use the following procedure.

1. Access the global CONFIG level of the CLI on FESX-A by entering the following command.

   FastIron-A> enable
   No password has been assigned yet...
   FastIron-A# configure terminal
   FastIron-A(config)#

2. Access the level of the CLI for configuring port-based VLAN 4 by entering the following command.

   FastIron-A(config)#
   FastIron-A(config)# vlan 4
   FastIron-A(config-vlan-4)#

3. Enter the following commands.

   FastIron-A(config-vlan-4)#
   FastIron-A(config-vlan-4)# no untag ethernet 11
   deleted port eth 11 from port-vlan 4.
   FastIron-A(config-vlan-4)#
4. Enter the following commands to exit the VLAN CONFIG mode and save the configuration to the system-config file on flash memory.

```
FastIron-A(config-vlan-4)#
FastIron-A(config-vlan-4)# end
FastIron-A# write memory
```

You can remove all the ports from a port-based VLAN without losing the rest of the VLAN configuration. However, you cannot configure an IP address on a virtual routing interface unless the VLAN contains ports. If the VLAN has a virtual routing interface, the virtual routing interface IP address is deleted when the ports associated with the interface are deleted. The rest of the VLAN configuration is retained.

**Enable spanning tree on a VLAN**

The spanning tree bridge and port parameters are configurable using one CLI command set at the Global Configuration Level of each Port-based VLAN. Suppose you want to enable the IEEE 802.1D STP across VLAN 3. To do so, use the following method.

**NOTE**
When port-based VLANs are not operating on the system, STP is set on a system-wide level at the global CONFIG level of the CLI.

1. Access the global CONFIG level of the CLI on FESX-A by entering the following commands.

```
FastIron-A> enable
No password has been assigned yet...
FastIron-A# configure terminal
FastIron-A(config)#
```

2. Access the level of the CLI for configuring port-based VLAN 3 by entering the following command.

```
FastIron-A(config)# vlan 3
FastIron-A(config-vlan-3)#
```

3. From VLAN 3 configuration level of the CLI, enter the following command to enable STP on all tagged and untagged ports associated with VLAN 3.

```
FastIron-B(config-vlan-3)#
FastIron-B(config-vlan-3)# spanning-tree
FastIron-B(config-vlan-3)#
```

4. Enter the following commands to exit the VLAN CONFIG mode and save the configuration to the system-config file on flash memory.

```
FastIron-B(config-vlan-3)#
FastIron-B(config-vlan-3)# end
FastIron-B# write memory
FastIron-B#
```

5. Repeat steps 1 – 4 on FESX-B.

**NOTE**
You do not need to configure values for the STP parameters. All parameters have default values as noted below. Additionally, all values will be globally applied to all ports on the system or on the port-based VLAN for which they are defined.
To configure a specific path-cost or priority value for a given port, enter those values using the key words in the brackets [ ] shown in the syntax summary below. If you do not want to specify values for any given port, this portion of the command is not required.

**Syntax:** `vlan <vlan-id> by port`

**Syntax:** `[no] spanning-tree`

**Syntax:** `spanning-tree [ethernet [<slotnum>/<portnum>] path-cost <value> priority <value>] forward-delay <value> hello-time <value> maximum-age <time> priority <value>`

**Bridge STP parameters (applied to all ports within a VLAN):**
- **Forward Delay** – the period of time a bridge will wait (the listen and learn period) before forwarding data packets. Possible values: 4 – 30 seconds. Default is 15.
- **Maximum Age** – the interval a bridge will wait for receipt of a hello packet before initiating a topology change. Possible values: 6 – 40 seconds. Default is 20.
- **Hello Time** – the interval of time between each configuration BPDU sent by the root bridge. Possible values: 1 – 10 seconds. Default is 2.
- **Priority** – a parameter used to identify the root bridge in a network. The bridge with the lowest value has the highest priority and is the root. Possible values: 1 – 65,535. Default is 32,678.

**Port parameters (applied to a specified port within a VLAN):**
- **Path Cost** – a parameter used to assign a higher or lower path cost to a port. Possible values: 1 – 65535. Default is (1000/Port Speed) for Half-Duplex ports and is (1000/Port Speed)/2 for Full-Duplex ports.
- **Priority** – value determines when a port will be rerouted in relation to other ports. Possible values: 0 – 255. Default is 128.

---

**Configuring IP subnet, IPX network and protocol-based VLANs**

Protocol-based VLANs provide the ability to define separate broadcast domains for several unique Layer 3 protocols within a single Layer 2 broadcast domain. Some applications for this feature might include security between departments with unique protocol requirements. This feature enables you to limit the amount of broadcast traffic end-stations, servers, and routers need to accept.

**Configuration example**

Suppose you want to create five separate Layer 3 broadcast domains within a single Layer 2 STP broadcast domain:
- Three broadcast domains, one for each of three separate IP subnets
- One for IPX Network 1
- One for the AppleTalk protocol

Also suppose you want a single router interface to be present within all of these separate broadcast domains, without using IEEE 802.1Q VLAN tagging or any proprietary form of VLAN tagging.
Figure 81 shows this configuration.

FIGURE 81 Protocol-based (Layer 3) VLANs

To configure the VLANs shown in Figure 81, use the following procedure.

1. To permanently assign ports 1 – 8 and port 25 to IP subnet VLAN 1.1.1.0, enter the following commands.

   FastIron> en  
   No password has been assigned yet...  
   FastIron# config t  
   FastIron(config)#  
   FastIron(config)# ip-subnet 1.1.1.0/24 name Green  
   FastIron(config-ip-subnet)# no dynamic  
   FastIron(config-ip-subnet)# static ethernet 1 to 8 ethernet 25

2. To permanently assign ports 9 – 16 and port 25 to IP subnet VLAN 1.1.2.0, enter the following commands.

   FastIron(config-ip-subnet)# ip-subnet 1.1.2.0/24 name Yellow  
   FastIron(config-ip-subnet)# no dynamic  
   FastIron(config-ip-subnet)# static ethernet 9 to 16 ethernet 25

3. To permanently assign ports 17 – 25 to IP subnet VLAN 1.1.3.0, enter the following commands.

   FastIron(config-ip-subnet)# ip-subnet 1.1.3.0/24 name Brown  
   FastIron(config-ip-subnet)# no dynamic  
   FastIron(config-ip-subnet)# static ethernet 17 to 25

4. To permanently assign ports 1 – 12 and port 25 to IPX network 1 VLAN, enter the following commands.
13 Configuring IP subnet, IPX network, and protocol-based VLANs within port-based VLANs

```plaintext
FastIron(config-ip-subnet)# ipx-network 1 ethernet_802.3 name Blue
FastIron(config-ipx-network)# no dynamic
FastIron(config-ipx-network)# static ethernet 1 to 12 ethernet 25
FastIron(config-ipx-network)#
```

5. To permanently assign ports 12 –– 25 to Appletalk VLAN, enter the following commands.

```plaintext
FastIron(config-ipx-proto)# atalk-proto name Red
FastIron(config-atalk-proto)# no dynamic
FastIron(config-atalk-proto)# static ethernet 13 to 25
FastIron(config-atalk-proto)# end
FastIron# write memory
FastIron#
```

Syntax: ip-subnet <ip-addr> <ip-mask> [name <string>]
Syntax: ipx-network <ipx-network-number> <frame-encapsulation-type> netbios-allow |
        netbios-disallow
        [name <string>]
Syntax: ip-proto | ipx-proto | atalk-proto | decnet-proto | netbios-proto | other-proto static |
        exclude | dynamic ethernet [<slotnum>/]<portnum> [to [<slotnum>/]<portnum>] [name |
        <string>]

Configuring IP subnet, IPX network, and protocol-based VLANs within port-based VLANs

Platform Support:
- FCX-S devices running software release 06.0.00 and later

If you plan to use port-based VLANs in conjunction with protocol-based VLANs, you must create the port-based VLANs first. Once you create a port-based VLAN, then you can assign Layer 3 protocol VLANs within the boundaries of the port-based VLAN. Generally, you create port-based VLANs to allow multiple separate STP domains.

**Example**

Suppose you need to provide three separate STP domains across an enterprise campus backbone. The first STP domain (VLAN 2) requires a set of ports at each Layer 2 Switch location to be statically mapped to IP only. No other protocols can enter the switches on this set of ports.

A second set of ports within STP domain VLAN 2 will be restricted to only IPX traffic. The IP and IPX protocol VLANs will overlap on Port 1 of FESX-A to support both protocols on the same router interface. The IP subnets and IPX network that span the two protocol VLANs will be determined by the FastIron router configuration. The IP and IPX Protocol VLANs ensure that only the ports included in each Layer 3 protocol VLAN will see traffic from the FastIron router.

The second STP domain (VLAN 3) requires that half the ports in the domain are dedicated to IP subnet 1.1.1.0/24 and the other ports are dedicated to IPX network 1. Similar to VLAN 2, Port 9 from VLAN 3 will be used to carry this IP subnet and IPX network to the FastIron router. No other protocols will be allowed to enter the network on VLAN 3. Also, no IP packets with a source address on subnet 1.1.1.0/24 or IPX packets with a source address on network 1 will be allowed to enter the switches on VLAN 3.
There is no need to segment Layer 3 broadcast domains within the STP broadcast domain (VLAN 4). The FastIron router will dictate the IP subnets and IPX network that are on VLAN 4. There are no Layer 3 protocol restrictions on VLAN 4; however, the FastIron router is configured to only forward IP and IPX between STP domains.

**FIGURE 82**  More protocol-based VLANs

To configure the Layer 3 VLANs on the FESX Layer 2 Switches in Figure 82, use the following procedure.

**Configuring FESX-A**

Enter the following commands to configure FESX-A.

1. Create port-based VLAN 2 and assign the untagged and tagged ports that will participate in this VLAN.

   FastIron-A >en  
   FastIron-A# config t  
   FastIron-A(config)# vlan 2 name IP_IPX_Protocol  
   FastIron-A(config-vlan-2)# untag e1 to 8  
   FastIron-A(config-vlan-2)# tag e25 to 26

2. Enable STP and set the priority to force FESX-A to be the root bridge for VLAN 2.

   FastIron-A(config-vlan-2)# spanning-tree  
   FastIron-A(config-vlan-2)# spanning-tree priority 500  
   FastIron-A(config-vlan-2)#

3. Create the IP and IPX protocol-based VLANs and statically assign the ports within VLAN 2 that will be associated with each protocol-based VLAN.
Configuring IP subnet, IPX network, and protocol-based VLANs within port-based VLANs

4. To prevent machines with non-IP protocols from getting into the IP portion of VLAN 2, create another Layer 3 protocol VLAN to exclude all other protocols from the ports that contains the IP-protocol VLAN. To do so, enter the following commands.

```
FastIron-A(config-vlan-ipx-proto)# other-proto name Block_other_proto
FastIron-A(config-vlan-other-proto)# no dynamic
FastIron-A(config-vlan-other-proto)# exclude e1 to 8
FastIron-A(config-vlan-other-proto)#
```

5. Create port-based VLAN 3. Note that FESX-B will be the root for this STP domain, so you do not need to adjust the STP priority.

```
FastIron-A(config-vlan-other-proto)# vlan 3 name IP-Sub_IPX-Net_Vlans
FastIron-A(config-vlan-3)# untag e9 to 16
FastIron-A(config-vlan-3)# tag e25 to 26
FastIron-A(config-vlan-3)# spanning-tree
FastIron-A(config-vlan-3)#
```

6. Create IP subnet VLAN 1.1.1.0/24, IPX network 1, and other-protocol VLANs

```
FastIron-A(config-vlan-3)# ip-subnet 1.1.1.0/24 name Green
FastIron-A(config-vlan-ip-subnet)# no dynamic
FastIron-A(config-vlan-ip-subnet)# static e9 to 12 e25 to 26
FastIron-A(config-vlan-ip-subnet)# exclude e13 to 16
FastIron-A(config-vlan-ip-subnet)# ipx-net 1 ethernet_802.3 name Brown
FastIron-A(config-vlan-ipx-network)# no dynamic
FastIron-A(config-vlan-ipx-network)# static e9 e13 to 16 e25 to 26
FastIron-A(config-vlan-ipx-network)# exclude e10 to 12
FastIron-A(config-vlan-ipx-network)# other-proto name Block_other_proto
FastIron-A(config-vlan-other-proto)# no dynamic
FastIron-A(config-vlan-other-proto)# exclude e9 to 16
FastIron-A(config-vlan-other-proto)#
```

7. Configure the last port-based VLAN 4. You need to set the STP priority for this VLAN because FESX-A will be the root bridge for this VLAN. Since you do not need to partition this STP domain into multiple Layer 3 broadcast domains, this is the only configuration required for VLAN 4.

```
FastIron-A(config-vlan-other-proto)# vlan 4 name Purple_ALL-Protocols
FastIron-A(config-vlan-4)# untag e17 to 24
FastIron-A(config-vlan-4)# tag e25 to 26
FastIron-A(config-vlan-4)# spanning-tree
FastIron-A(config-vlan-4)# spanning-tree priority 500
FastIron-A(config-vlan-4)#
```

**Configuring FESX-B**

Enter the following commands to configure FESX-B.

```
FastIron# config t
FastIron(config)# host FastIron-B
FastIron-B(config)# vlan 2 name IP_IPX_Protocol
FastIron-B(config-vlan-2)# untag e1 to 8
FastIron-B(config-vlan-2)# tag e25 to 26
```
Configuring IP subnet, IPX network, and protocol-based VLANs within port-based VLANs

FastIron-B(config-vlan-2)# spanning-tree
FastIron-B(config-vlan-2)# ip-proto name Red
FastIron-B(config-vlan-ip-proto)# no dynamic
FastIron-B(config-vlan-ip-proto)# static e1 to 4 e25 to 26
FastIron-B(config-vlan-ip-proto)# exclude e5 to 8
FastIron-B(config-vlan-ip-proto)# ipx-proto name Blue
FastIron-B(config-vlan-ipx-proto)# no dynamic
FastIron-B(config-vlan-ipx-proto)# static e5 to 8 e25 to 26
FastIron-B(config-vlan-ipx-proto)# exclude e1 to 4
FastIron-B(config-vlan-other-proto)# vlan 3 name IP-Sub_IPX-Net_VLANs
FastIron-B(config-vlan-3)# untag e9 to 16
FastIron-B(config-vlan-3)# tag e25 to 26
FastIron-B(config-vlan-3)# spanning-tree
FastIron-B(config-vlan-3)# spanning-tree priority 500
FastIron-B(config-vlan-3)# ip-sub 1.1.1.0/24 name Green
FastIron-B(config-vlan-ip-subnet)# no dynamic
FastIron-B(config-vlan-ip-subnet)# static e9 to 12 e25 to 26
FastIron-B(config-vlan-ip-subnet)# exclude e13 to 16
FastIron-B(config-vlan-ip-subnet)# ipx-net 1 ethernet_802.3 name Brown
FastIron-B(config-vlan-ipx-network)# no dynamic
FastIron-B(config-vlan-ipx-network)# static e13 to 16 e25 to 26
FastIron-B(config-vlan-ipx-network)# exclude e9 to 12
FastIron-B(config-vlan-ipx-network)# vlan 4 name Purple_ALL-Protocols
FastIron-B(config-vlan-4)# untag e17 to 24
FastIron-B(config-vlan-4)# tag e25 to 26
FastIron-B(config-vlan-4)# spanning-tree

Configuring FESX-C

Enter the following commands to configure FESX-C.

FastIron# config t
FastIron(config)# host FastIron-C
FastIron-C(config)# vlan 2 name IP_IPX_Protocol
FastIron-C(config-vlan-2)# untag e1 to 8
FastIron-C(config-vlan-2)# tag e25 to 26
FastIron-C(config-vlan-2)# spanning-tree
FastIron-C(config-vlan-2)# ip-proto name Red
FastIron-C(config-vlan-ip-proto)# no dynamic
FastIron-C(config-vlan-ip-proto)# static e1 to 4 e25 to 26
FastIron-C(config-vlan-ip-proto)# exclude e5 to 8
FastIron-C(config-vlan-ip-proto)# ipx-proto name Blue
FastIron-C(config-vlan-ipx-proto)# no dynamic
FastIron-C(config-vlan-ipx-proto)# static e5 to 8 e25 to 26
FastIron-C(config-vlan-ipx-proto)# exclude e1 to 4
FastIron-C(config-vlan-other-proto)# vlan 3 name IP-Sub_IPX-Net_VLANs
FastIron-C(config-vlan-3)# untag e9 to 16
FastIron-C(config-vlan-3)# tag e25 to 26
FastIron-C(config-vlan-3)# spanning-tree
FastIron-C(config-vlan-3)# ip-sub 1.1.1.0/24 name Green
FastIron-C(config-vlan-ip-subnet)# no dynamic
FastIron-C(config-vlan-ip-subnet)# static e9 to 12 e25 to 26
FastIron-C(config-vlan-ip-subnet)# exclude e13 to 16
FastIron-C(config-vlan-ip-subnet)# ipx-net 1 ethernet_802.3 name Brown
FastIron-C(config-vlan-ipx-network)# no dynamic
FastIron-C(config-vlan-ipx-network)# static e13 to 16 e25 to 26
FastIron-C(config-vlan-ipx-network)# exclude e9 to 12
Configuring an IPv6 protocol VLAN

You can configure a protocol-based VLAN as a broadcast domain for IPv6 traffic. When the Layer 3 Switch receives an IPv6 multicast packet (a packet with 06 in the version field and 0xFF as the beginning of the destination address), the Layer 3 Switch forwards the packet to all other ports.

NOTE
The Layer 3 Switch forwards all IPv6 multicast packets to all ports except the port that received the packet, and does not distinguish among subnet directed multicasts.

You can add the VLAN ports as static ports or dynamic ports. A static port is always an active member of the VLAN. Dynamic ports within any protocol VLAN age out after 10 minutes if no member protocol traffic is received on a port within the VLAN. The aged out port, however, remains as a candidate dynamic port for that VLAN. The port becomes active in the VLAN again if member protocol traffic is received on that port.

Once a port is re-activated, the aging out period for the port is reset to 20 minutes. Each time a member protocol packet is received by a candidate dynamic port (aged out port) the port becomes active again and the aging out period is reset for 20 minutes.

NOTE
Starting in software release 02.5.00, you can disable VLAN membership aging of dynamically added ports. Refer to “Disabling membership aging of dynamic VLAN ports” on page 504.

To configure an IPv6 VLAN, enter commands such as the following.

```
FastIron(config)# vlan 2
FastIron(config-vlan-2)# untag ethernet 1/1 to 1/8
FastIron(config-vlan-2)# ipv6-proto name V6
FastIron(config-ipv6-subnet)# static ethernet 1/1 to 1/6
FastIron(config-ipv6-subnet)# dynamic
```

The first two commands configure a port-based VLAN and add ports 1/1 – 1/8 to the VLAN. The remaining commands configure an IPv6 VLAN within the port-based VLAN. The `static` command adds ports 1/1 – 1/6 as static ports, which do not age out. The `dynamic` command adds the remaining ports, 1/7 – 1/8, as dynamic ports. These ports are subject to aging as described above.

Syntax: `[no] ipv6-proto [name <string>]`
Routing between VLANs using virtual routing interfaces (Layer 3 Switches only)

Brocade Layer 3 Switches offer the ability to create a virtual routing interface within a Layer 2 STP port-based VLAN or within each Layer 3 protocol, IP subnet, or IPX network VLAN. This combination of multiple Layer 2 or Layer 3 broadcast domains, or both, and virtual routing interfaces are the basis for Brocade’s very powerful Integrated Switch Routing (ISR) technology. ISR is very flexible and can solve many networking problems. The following example is meant to provide ideas by demonstrating some of the concepts of ISR.

**Example**

Suppose you want to move routing out to each of three buildings in a network. Remember that the only protocols present on VLAN 2 and VLAN 3 are IP and IPX. Therefore, you can eliminate tagged ports 25 and 26 from both VLAN 2 and VLAN 3 and create new tagged port-based VLANs to support separate IP subnets and IPX networks for each backbone link.

You also need to create unique IP subnets and IPX networks within VLAN 2 and VLAN 3 at each building. This will create a fully routed IP and IPX backbone for VLAN 2 and VLAN 3. However, VLAN 4 has no protocol restrictions across the backbone. In fact there are requirements for NetBIOS and DecNet to be bridged among the three building locations. The IP subnet and IPX network that exists within VLAN 4 must remain a flat Layer 2 switched STP domain. You enable routing for IP and IPX on a virtual routing interface only on FESX-A. This will provide the flat IP and IPX segment with connectivity to the rest of the network. Within VLAN 4 IP and IPX will follow the STP topology. All other IP subnets and IPX networks will be fully routed and have use of all paths at all times during normal operation.

*Figure 83* shows the configuration described above.

*FIGURE 83  Routing between protocol-based VLANs*
Routing between VLANs using virtual routing interfaces (Layer 3 Switches only)

To configure the Layer 3 VLANs and virtual routing interfaces on the FESX Layer 3 Switch in Figure 83, use the following procedure.

**Configuring FESX-A**

Enter the following commands to configure FESX-A. The following commands enable OSPF or RIP routing.

```
FastIron>en
No password has been assigned yet...
FastIron# configure terminal
FastIron(config)# hostname FESX-A
FastIron-A(config)# router ospf
FastIron-A(config-ospf-router)# area 0.0.0.0 normal
Please save configuration to flash and reboot.
FastIron-A(config-ospf-router)#
```

The following commands create the port-based VLAN 2. In the previous example, an external FESX defined the router interfaces for VLAN 2. With ISR, routing for VLAN 2 is done locally within each FESX. Therefore, there are two ways you can solve this problem. One way is to create a unique IP subnet and IPX network VLAN, each with its own virtual routing interface and unique IP or IPX address within VLAN 2 on each FESX. In this example, this is the configuration used for VLAN 3. The second way is to split VLAN 2 into two separate port-based VLANs and create a virtual router interface within each port-based VLAN. Later in this example, this second option is used to create a port-based VLAN 8 to show that there are multiple ways to accomplish the same task with ISR.

You also need to create the Other-Protocol VLAN within port-based VLAN 2 and 8 to prevent unwanted protocols from being Layer 2 switched within port-based VLAN 2 or 8. Note that the only port-based VLAN that requires STP in this example is VLAN 4. You will need to configure the rest of the network to prevent the need to run STP.
Routing between VLANs using virtual routing interfaces (Layer 3 Switches only)

Once you have defined the port-based VLAN and created the virtual routing interface, you need to configure the virtual routing interface just as you would configure a physical interface.

FastIron-A(config-vlan-other-proto)# interface ve1
FastIron-A(config-vif-1)# ip address 1.1.2.1/24
FastIron-A(config-vif-1)# ip ospf area 0.0.0.0

Do the same thing for VLAN 8.

FastIron-A(config-vif-2)# vlan 8 name IPX_Network2
FastIron-A(config-vlan-8)# untag ethernet 5 to 8
FastIron-A(config-vlan-8)# no spanning-tree
FastIron-A(config-vlan-8)# router-interface ve 2
FastIron-A(config-vlan-8)# other-proto name block-other-protocols
FastIron-A(config-vlan-other-proto)# no dynamic
FastIron-A(config-vlan-other-proto)# exclude ethernet 5 to 8
FastIron-A(config-vlan-other-proto)# int ve2
FastIron-A(config-vif-2)# ipx network 2 ethernet_802.3
FastIron-A(config-vif-2)#

The next thing you need to do is create VLAN 3. This is very similar to the previous example with the addition of virtual routing interfaces to the IP subnet and IPX network VLANs. Also there is no need to exclude ports from the IP subnet and IPX network VLANs on the router.

FastIron-A(config-vif-2)# vlan 3 name IP_Sub_&_IPX_Net_VLAN
FastIron-A(config-vlan-3)# untag e 9 to 16
FastIron-A(config-vlan-3)# no spanning-tree
FastIron-A(config-vlan-3)# ip-subnet 1.1.1.0/24
FastIron-A(config-vlan-ip-subnet)# static e 9 to 12
FastIron-A(config-vlan-ip-subnet)# router-interface ve3
FastIron-A(config-vlan-ip-subnet)# ipx-network 1 ethernet_802.3
FastIron-A(config-vlan-ipx-network)# static e 13 to 16
FastIron-A(config-vlan-ipx-network)# router-interface ve4
FastIron-A(config-vlan-ipx-network)# other-proto name block-other-protocols
FastIron-A(config-vlan-other-proto)# no dynamic
FastIron-A(config-vlan-other-proto)# exclude e 9 to 16
FastIron-A(config-vlan-other-proto)# interface ve 3
FastIron-A(config-vif-3)# ip addr 1.1.1.1/24
FastIron-A(config-vif-3)# ip ospf area 0.0.0.0
FastIron-A(config-vif-3)# int ve4
FastIron-A(config-vif-4)# ipx network 1 ethernet_802.3
FastIron-A(config-vif-4)#

Now configure VLAN 4. Remember this is a flat segment that, in the previous example, obtained its IP default gateway and IPX router services from an external FESX. In this example, FESX-A will provide the routing services for VLAN 4. You also want to configure the STP priority for VLAN 4 to make FESX-A the root bridge for this VLAN.

FastIron-A(config-vif-4)# vlan 4 name Bridged_ALL_Protocols
FastIron-A(config-vlan-4)# untag ethernet 17 to 24
FastIron-A(config-vlan-4)# tag ethernet 25 to 26
FastIron-A(config-vlan-4)# spanning-tree
FastIron-A(config-vlan-4)# spanning-tree priority 500
Routing between VLANs using virtual routing interfaces (Layer 3 Switches only)

It is time to configure a separate port-based VLAN for each of the routed backbone ports (Ethernet 25 and 26).

If you do not create a separate tagged port-based VLAN for each point-to-point backbone link, you need to include tagged interfaces for Ethernet 25 and 26 within VLANs 2, 3, and 8. This type of configuration makes the entire backbone a single STP domain for each VLAN 2, 3, and 8. This is the configuration used in the example in “Configuring IP subnet, IPX network and protocol-based VLANs” on page 490. In this scenario, the virtual routing interfaces within port-based VLANs 2, 3, and 8 will be accessible using only one path through the network. The path that is blocked by STP is not available to the routing protocols until it is in the STP FORWARDING state.

This completes the configuration for FESX-A. The configuration for FESX-B and C is very similar except for a few issues which are as follows:

- IP subnets and IPX networks configured on FESX-B and FESX-C must be unique across the entire network, except for the backbone port-based VLANs 5, 6, and 7 where the subnet is the same but the IP address must change.
- There is no need to change the default priority of STP within VLAN 4.
- There is no need to include a virtual router interface within VLAN 4.
- The backbone VLAN between FESX-B and FESX-C must be the same at both ends and requires a new VLAN ID. The VLAN ID for this port-based VLAN is VLAN 7.

**Configuration for FESX-B**

Enter the following commands to configure FESX-B.

```
FastIron> en
No password has been assigned yet...
FastIron# config t
FastIron(config)# hostname FESX-B
FastIron-B(config)# router ospf
FastIron-B(config-ospf-router)# area 0.0.0.0 normal
FastIron-B(config-ospf-router)# router ipx
```

Routing between VLANs using virtual routing interfaces (Layer 3 Switches only)

FastIron-B(config-ospf-router)# vlan 2 name IP-Subnet_1.1.6.0/24
FastIron-B(config-vlan-2)# untag e 1 to 4
FastIron-B(config-vlan-2)# no spanning-tree

```
Configuring protocol VLANs with dynamic ports

**NOTE**
TurboIron X Series devices do not support dynamic VLAN ports.

The configuration examples for protocol VLANs in the sections above show how to configure the VLANs using static ports. You also can configure the following types of protocol VLANs with dynamic ports:

- AppleTalk protocol
- IP protocol
- IPX protocol
- IP subnet
- IPX network

**NOTE**
The software does not support dynamically adding ports to AppleTalk cable VLANs. Conceptually, an AppleTalk cable VLAN consists of a single network cable, connected to a single port. Therefore, dynamic addition and removal of ports is not applicable.

**NOTE**
You cannot route to or from protocol VLANs with dynamically added ports.

Aging of dynamic ports

Platform Support:

- FastIron X Series devices running software release 02.5.00 and later

When you add the ports to the VLAN, the software automatically adds them all to the VLAN. However, dynamically added ports age out. If the age time for a dynamic port expires, the software removes the port from the VLAN. If that port receives traffic for the IP subnet or IPX network, the software adds the port to the VLAN again and starts the aging timer over. Each time the port receives traffic for the VLAN's IP subnet or IPX network, the aging timer starts over.

**NOTE**
You can disable VLAN membership aging of dynamically added ports. Refer to “Disabling membership aging of dynamic VLAN ports” on page 504).
Dynamic ports within any protocol VLAN age out after 10 minutes, if no member protocol traffic is received on a port within the VLAN. The aged out port, however, remains as a candidate dynamic port for that VLAN. The port becomes active in the VLAN again if member protocol traffic is received on that port.

Once a port is re-activated, the aging out period for the port is reset to 20 minutes. Each time a member protocol packet is received by a candidate dynamic port (aged out port) the port becomes active again and the aging out period is reset for 20 minutes.

**Disabling membership aging of dynamic VLAN ports**

Platform Support:

- FastIron X Series devices running software release 02.5.00 and later

You can disable VLAN membership aging of ports that are dynamically assigned to protocol or subnet-based VLANs. This feature resolves the connectivity issue that may occur in certain configurations when protocol or subnet VLANs are configured with dynamic port membership.

**NOTE**

This issue does not occur with statically assigned VLAN memberships. Thus, enable this feature only if your configuration includes dynamically assigned VLAN memberships for protocol or subnet VLANs.

To enable this feature, enter commands such as the following.

```
FastIron(config)# vlan 10 by port
FastIron(config-vlan-10)# int e 1/1 to 1/5
FastIron(config-vlan-10)# ip-proto name IP_Prot_VLAN
FastIron(config-vlan-ip-proto)# no-dynamic-aging
FastIron(config-vlan-ip-proto)# write memory
```

These commands create an IP protocol VLAN and disable the VLAN membership aging of ports that are dynamically assigned to the protocol VLAN.

**Syntax:** `[no] no-dynamic-aging`

Enter the `no` form of the command to disable this feature after it has been enabled.

By default, VLAN membership of dynamically assigned ports will age out after a period of time if no packets belonging to that protocol or subnet VLAN are received by the CPU.

The output of the `show running-config` command indicates if the no-dynamic-aging feature is enabled for a specific protocol or subnet VLAN.

**Configuration guidelines**

- You cannot dynamically add a port to a protocol VLAN if the port has any routing configuration parameters. For example, the port cannot have a virtual routing interface, IP subnet address, IPX network address, or AppleTalk network address configured on it.
- Once you dynamically add a port to a protocol VLAN, you cannot configure routing parameters on the port.
- Dynamic VLAN ports are not required or supported on AppleTalk cable VLANs.
Configuring an IP, IPX, or AppleTalk Protocol VLAN with Dynamic Ports

To configure an IP, IPX, or AppleTalk protocol VLAN with dynamic ports, use the following method.

To configure port-based VLAN 10, then configure an IP protocol VLAN within the port-based VLAN with dynamic ports, enter the following commands such as the following.

```
FastIron(config)# vlan 10 by port
FastIron(config-vlan-10)# untag ethernet 1/1 to 1/6
added untagged port ethe 1/1 to 1/6 to port-vlan 30.
FastIron(config-vlan-10)# ip-proto name IP Prot_VLAN
dynamic
FastIron(config)# write memory
```

**Syntax:**
- `vlan <vlan-id> by port [name <string>]`
- `untagged ethernet [<slotnum>/]<portnum> to [<slotnum>/]<portnum>`
- `ip-proto [name <string>]`
- `ipx-proto [name <string>]`
- `appletalk-cable-vlan <num> [name <string>]`
- `dynamic`

**NOTE**
Use the first `untagged` command for adding a range of ports. Use the second command for adding separate ports (not in a range).

```
Syntax: ip-proto [name <string>]
Syntax: ipx-proto [name <string>]
Syntax: appletalk-cable-vlan <num> [name <string>]
Syntax: dynamic
```

The procedure is similar for IPX and AppleTalk protocol VLANs. Enter `ipx-proto` or `atalk-proto` instead of `ip-proto`.

**Configuring an IP subnet VLAN with dynamic ports**

To configure port-based VLAN 10, then configure an IP subnet VLAN within the port-based VLAN with dynamic ports, enter commands such as the following.

```
FastIron(config)# vlan 10 by port name IP_VLAN
FastIron(config-vlan-10)# untag ethernet 1/1 to 1/6
added untagged port ethe 1/1 to 1/6 to port-vlan 30.
FastIron(config-vlan-10)# ip-subnet 1.1.1.0/24 name Mktg-LAN
FastIron(config-vlan-10)# dynamic
FastIron(config)# write memory
```

These commands create a port-based VLAN on chassis ports 1/1 – 1/6 named “Mktg-LAN”, configure an IP subnet VLAN within the port-based VLAN, and then add ports from the port-based VLAN dynamically.

**Syntax:**
- `vlan <vlan-id> by port [name <string>]`
- `untagged ethernet [<slotnum>/]<portnum> to [<slotnum>/]<portnum>`

or
Configuring uplink ports within a port-based VLAN

Syntax: untagged ethernet [<slotnum>/]<portnum> ethernet [<slotnum>/]<portnum>

NOTE
Use the first untagged command for adding a range of ports. Use the second command for adding separate ports (not in a range).

Syntax: ip-subnet <ip-addr> <ip-mask> [name <string>]

or

Syntax: ip-subnet <ip-addr>/<mask-bits> [name <string>]

Syntax: dynamic

Configuring an IPX network VLAN with dynamic ports

To configure port-based VLAN 20, then configure an IPX network VLAN within the port-based VLAN with dynamic ports, enter commands such as the following.

FastIron(config)# vlan 20 by port name IPX_VLAN
FastIron(config-vlan-10)# untag ethernet 2/1 to 2/6
added untagged port eth 2/1 to 2/6 to port-vlan 20.
FastIron(config-vlan-10)# ipx-network abcd ethernet_ii name Eng-LAN
FastIron(config-vlan-10)# dynamic
FastIron(config)# write memory

These commands create a port-based VLAN on chassis ports 2/1 – 2/6 named “Eng-LAN”, configure an IPX network VLAN within the port-based VLAN, and then add ports from the port-based VLAN dynamically.

Syntax: vlan <vlan-id> by port [name <string>]

Syntax: untagged ethernet [<slotnum>/]<portnum> to [<slotnum>/]<portnum>

or

Syntax: untagged ethernet [<slotnum>/]<portnum> ethernet [<slotnum>/]<portnum>

NOTE
Use the first untagged command for adding a range of ports. Use the second command for adding separate ports (not in a range).

Syntax: ipx-network <network-addr> ethernet_ii | ethernet_802.2 | ethernet_802.3 | ethernet_snap
 [name <string>]

Syntax: dynamic

Configuring uplink ports within a port-based VLAN

Platform Support:

• FastIron X Series devices running software release 02.5.00 and later
• FWS devices running software release 04.3.00 and later
• FGS and FLS devices running software release
• FGS-STK and FLS-STK devices running software release 05.0.00 and later
• FCX-S devices running software release 06.0.00 and later
• TurboIron X Series devices running software release 04.2.00 and later

You can configure a subset of the ports in a port-based VLAN as uplink ports. When you configure uplink ports in a port-based VLAN, the device sends all broadcast and unknown-unicast traffic from a port in the VLAN to the uplink ports, but not to other ports within the VLAN. Thus, the uplink ports provide tighter broadcast control within the VLAN.

This uplink port feature behaves the same as the private VLAN feature, but with the ability to support tagged ports. This feature also supports two private VLAN modes: the Primary ports (uplink ports) and Isolated ports (host ports).

For example, if two ports within a port-based VLAN are Gbps ports attached to the network and the other ports are 10/100 ports attached to clients, you can configure the two ports attached to the network as uplink ports. In this configuration, broadcast and unknown-unicast traffic in the VLAN does not go to all ports. The traffic goes only to the uplink ports. The clients on the network do not receive broadcast and unknown-unicast traffic from other ports, including other clients.

**Configuration considerations**

• When uplink port feature is enabled on FastIron devices, flooded traffic (unknown unicast, unregistered multicast, and broadcast traffic) is software forwarded.
• On TurboIron devices, flooded traffic (unknown unicast, unregistered multicast, and broadcast traffic) is hardware forwarded.
• This feature should not be enabled with protocol VLANs or private VLANs in the same VLAN.

**Configuration syntax**

To configure a port-based VLAN containing uplink ports, enter commands such as the following.

FastIron(config)# vlan 10 by port
FastIron(config-vlan-10)# untag ethernet 1/1 to 1/24
FastIron(config-vlan-10)# untag ethernet 2/1 to 2/2
FastIron(config-vlan-10)# uplink-switch ethernet 2/1 to 2/2

Syntax: `[no] uplink-switch ethernet [<slotnum>/]<portnum> [to [<slotnum>/]<portnum> | ethernet [<slotnum>/]<portnum>`

In this example, 24 ports on a 10/100 module and two Gbps ports on a Gbps module are added to port-based VLAN 10. The two Gbps ports are then configured as uplink ports.

To configure a port-based VLAN containing uplink ports on TurboIron devices, enter the following commands.

TurboIron(config)# vlan 500
TurboIron(config-vlan-500)# tagged ethernet 11 to 21
TurboIron(config-vlan-500)# uplink-switch ethernet 20 to 21

Syntax: `[no] uplink-switch ethernet <portnum> to <portnum>`
Configuring the same IP subnet address on multiple port-based VLANs

For a Brocade device to route between port-based VLANs, you must add a virtual routing interface to each VLAN. Generally, you also configure a unique IP subnet address on each virtual routing interface. For example, if you have three port-based VLANs, you add a virtual routing interface to each VLAN, then add a separate IP subnet address to each virtual routing interface. The IP address on each of the virtual routing interfaces must be in a separate subnet. The Brocade device routes Layer 3 traffic between the subnets using the subnet addresses.

**NOTE**
This feature applies only to Layer 3 Switches.

**NOTE**
Before using the method described in this section, refer to “Configuring VLAN groups and virtual routing interface groups” on page 511. You might be able to achieve the results you want using the methods in that section instead.

Figure 84 shows an example of this type of configuration.

**FIGURE 84** Multiple port-based VLANs with separate protocol addresses

As shown in this example, each VLAN has a separate IP subnet address. If you need to conserve IP subnet addresses, you can configure multiple VLANs with the same IP subnet address, as shown in Figure 85.

**FIGURE 85** Multiple port-based VLANs with the same protocol address
Configuring the same IP subnet address on multiple port-based VLANs

Each VLAN still requires a separate virtual routing interface. However, all three VLANs now use the same IP subnet address.

In addition to conserving IP subnet addresses, this feature allows containment of Layer 2 broadcasts to segments within an IP subnet. For ISP environments where the same IP subnet is allocated to different customers, placing each customer in a separate VLAN allows all customers to share the IP subnet address, while at the same time isolating them from one another Layer 2 broadcasts.

**NOTE**
You can provide redundancy to an IP subnet address that contains multiple VLANs using a pair of Brocade Layer 3 Switches configured for Brocade VRRP (Virtual Router Redundancy Protocol).

The Brocade device performs proxy Address Resolution Protocol (ARP) for hosts that want to send IP traffic to hosts in other VLANs that are sharing the same IP subnet address. If the source and destination hosts are in the same VLAN, the Brocade device does not need to use ARP:

- If a host attached to one VLAN sends an ARP message for the MAC address of a host in one of the other VLANs using the same IP subnet address, the Brocade device performs a proxy ARP on behalf of the other host. The Brocade device then replies to the ARP by sending the virtual routing interface MAC address. The Brocade device uses the same MAC address for all virtual routing interfaces.

When the host that sent the ARP then sends a unicast packet addressed to the virtual routing interface MAC address, the device switches the packet on Layer 3 to the destination host on the VLAN.

**NOTE**
If the Brocade device ARP table does not contain the requested host, the Brocade device forwards the ARP request on Layer 2 to the same VLAN as the one that received the ARP request. Then the device sends an ARP for the destination to the other VLANs that are using the same IP subnet address.
Configuring the same IP subnet address on multiple port-based VLANs

- If the destination is in the same VLAN as the source, the Brocade device does not need to perform a proxy ARP.

To configure multiple VLANs to use the same IP subnet address:

- Configure each VLAN, including adding tagged or untagged ports.
- Configure a separate virtual routing interface for each VLAN, but do not add an IP subnet address to more than one of the virtual routing interfaces.
- Configure the virtual routing interfaces that do not have the IP subnet address to “follow” the virtual routing interface that does have the address.

To configure the VLANs shown in Figure 85, you could enter the following commands.

```
FastIron(config)# vlan 1 by port
FastIron(config-vlan-1)# untag ethernet 1/1
FastIron(config-vlan-1)# tag ethernet 1/8
FastIron(config-vlan-1)# router-interface ve 1
```

**Syntax:** `router-interface ve <number>`

The commands above configure port-based VLAN 1. The VLAN has one untagged port (1/1) and a tagged port (1/8). In this example, all three VLANs contain port 1/8 so the port must be tagged to allow the port to be in multiple VLANs. You can configure VLANs to share a Layer 3 protocol interface regardless of tagging. A combination of tagged and untagged ports is shown in this example to demonstrate that sharing the interface does not change other VLAN features.

Notice that each VLAN still requires a unique virtual routing interface.

The following commands configure port-based VLANs 2 and 3.

```
FastIron(config-vlan-1)# vlan 2 by port
FastIron(config-vlan-2)# untag ethernet 1/2
FastIron(config-vlan-2)# tag ethernet 1/8
FastIron(config-vlan-2)# router-interface ve 2
FastIron(config-vlan-2)# vlan 3 by port
FastIron(config-vlan-3)# untag ethernet 1/5 to 1/6
FastIron(config-vlan-3)# tag ethernet 1/8
FastIron(config-vlan-3)# router-interface ve 3
```

The following commands configure an IP subnet address on virtual routing interface 1.

```
FastIron(config-vlan-3)# interface ve 1
FastIron(config-vif-1)# ip address 10.0.0.1/24
```

The following commands configure virtual routing interfaces 2 and 3 to “follow” the IP subnet address configured on virtual routing interface 1.

```
FastIron(config-vif-1)# interface ve 2
FastIron(config-vif-2)# ip follow ve 1
FastIron(config-vif-2)# interface ve 3
FastIron(config-vif-3)# ip follow ve 1
```

**NOTE**
Since virtual routing interfaces 2 and 3 do not have their own IP subnet addresses but instead are “following” virtual routing interface a IP address, you still can configure an IPX or AppleTalk interface on virtual routing interfaces 2 and 3.
Configuring VLAN groups and virtual routing interface groups

NOTE
On TurboIron X Series devices, VLAN groups are supported on devices running software release 04.2.00 and later.

To simplify configuration when you have many VLANs with the same configuration, you can configure VLAN groups and virtual routing interface groups.

NOTE
VLAN groups are supported on Layer 3 Switches and Layer 2 Switches. Virtual routing interface groups are supported only on Layer 3 Switches.

When you create a VLAN group, the VLAN parameters you configure for the group apply to all the VLANs within the group. Additionally, you can easily associate the same IP subnet interface with all the VLANs in a group by configuring a virtual routing interface group with the same ID as the VLAN group.

- The VLAN group feature allows you to create multiple port-based VLANs with identical port members. Since the member ports are shared by all the VLANs within the group, you must add the ports as tagged ports. This feature not only simplifies VLAN configuration but also allows you to have a large number of identically configured VLANs in a startup-config file on the device flash memory module. Normally, a startup-config file with a large number of VLANs might not fit on the flash memory module. By grouping the identically configured VLANs, you can conserve space in the startup-config file so that it fits on the flash memory module.

- The virtual routing interface group feature is useful when you want to configure the same IP subnet address on all the port-based VLANs within a VLAN group. You can configure a virtual routing interface group only after you configure a VLAN group with the same ID. The virtual routing interface group automatically applies to the VLANs in the VLAN group that has the same ID and cannot be applied to other VLAN groups or to individual VLANs.

You can create up to 32 VLAN groups and 32 virtual routing interface groups. A virtual routing interface group always applies only to the VLANs in the VLAN group with the same ID.

NOTE
Depending on the size of the VLAN ID range you want to use for the VLAN group, you might need to allocate additional memory for VLANs. On Layer 3 Switches, if you allocate additional memory for VLANs, you also need to allocate the same amount of memory for virtual routing interfaces. This is true regardless of whether you use the virtual routing interface groups. To allocate additional memory, refer to “Allocating memory for more VLANs or virtual routing interfaces” on page 514.

Configuring a VLAN group

To configure a VLAN group, enter commands such as the following.

```
FastIron(config)# vlan-group 1 vlan 2 to 1000
FastIron(config-vlan-group-1)# tagged 1/1 to 1/2
```

The first command in this example begins configuration for VLAN group 1, and assigns VLANs 2 through 1000 to the group. The second command adds ports 1/1 and 1/2 as tagged ports. Since all the VLANs in the group share the ports, you must add the ports as tagged ports.

Syntax: `vlan-group <num> vlan <vlan-id> to <vlan-id>`
Configuring VLAN groups and virtual routing interface groups

Syntax: tagged ethernet [<slotnum>/<portnum>] [to [<slotnum>/<portnum>]] | ethernet [<slotnum>/<portnum>]

The <num> parameter with the `vlan-group` command specifies the VLAN group ID and can be from 1 – 32. The `vlan <vlan-id> to <vlan-id>` parameters specify a contiguous range (a range with no gaps) of individual VLAN IDs. Specify the low VLAN ID first and the high VLAN ID second. The command adds all the specified VLANs to the VLAN group.

**NOTE**
The device memory must be configured to contain at least the number of VLANs you specify for the higher end of the range. For example, if you specify 2048 as the VLAN ID at the high end of the range, you first must increase the memory allocation for VLANs to 2048 or higher. Additionally, on Layer 3 Switches, if you allocate additional memory for VLANs, you also need to allocate the same amount of memory for virtual routing interfaces, before you configure the VLAN groups. This is true regardless of whether you use the virtual routing interface groups. The memory allocation is required because the VLAN groups and virtual routing interface groups have a one-to-one mapping. Refer to “Allocating memory for more VLANs or virtual routing interfaces” on page 514.

If a VLAN within the range you specify is already configured, the CLI does not add the group but instead displays an error message. In this case, create the group by specifying a valid contiguous range. Then add more VLANs to the group after the CLI changes to the configuration level for the group. See the following example.

You can add and remove individual VLANs or VLAN ranges from at the VLAN group configuration level. For example, if you want to add VLANs 1001 and 1002 to VLAN group 1 and remove VLANs 900 through 1000, enter the following commands.

```
FastIron(config-vlan-group-1)# add-vlan 1001 to 1002
FastIron(config-vlan-group-1)# remove-vlan 900 to 1000
```

Syntax: add-vlan <vlan-id> [to <vlan-id>]
Syntax: remove-vlan <vlan-id> [to <vlan-id>]

**Displaying information about VLAN groups**

To display VLAN group configuration information for FastIron devices, use the `show vlan-group` command.

```
FastIron# show vlan-group
vlan-group 1 vlan 2 to 20
  tagged ethe 1/1 to 1/2
!
vlan-group 2 vlan 21 to 40
  tagged ethe 1/1 to 1/2
!
```

Syntax: show vlan-group [<group-id>]

To display VLAN group configuration information for TurboIron devices, enter the following command.

```
TurboIron# show vlan-group
vlan-group 1 vlan 2 to 500
  tagged ethe 2 ethe 5
```

Syntax: show vlan-group
The \texttt{<group-id>\texttt{\textgreater\textless}} specifies a VLAN group. If you do not use this parameter, the configuration information for all the configured VLAN groups is displayed.

**Configuring a virtual routing interface group**

A virtual routing interface group allows you to associate the same IP subnet interface with multiple port-based VLANs. For example, if you associate a virtual routing interface group with a VLAN group, all the VLANs in the group have the IP interface of the virtual routing interface group.

**Configuration notes and feature limitations**

- When you configure a virtual routing interface group, all members of the group have the same IP subnet address. This feature is useful in collocation environments where the device has many IP addresses and you want to conserve the IP address space.
- The \texttt{group-router-interface\texttt{\textgreater\textless}} command creates router interfaces for each VLAN in the VLAN group by using the VLAN IDs of each of the VLANs as the corresponding virtual interface number. Therefore, if a VLAN group contains VLAN IDs greater than the maximum virtual interface number allowed, the \texttt{group-router-interface\texttt{\textgreater\textless}} command will be rejected.

**CLI syntax**

To configure a virtual routing interface group, enter commands such as the following.

```
FastIron(config)# vlan-group 1
FastIron(config-vlan-group-1)# group-router-interface
FastIron(config-vlan-group-1)# exit
FastIron(config)# interface group-ve 1
FastIron(config-vif-group-1)# ip address 10.10.10.1/24
```

These commands enable VLAN group 1 to have a group virtual routing interface, then configure virtual routing interface group 1. The software always associates a virtual routing interface group only with the VLAN group that has the same ID. In this example, the VLAN group ID is 1, so the corresponding virtual routing interface group also must have ID 1.

Syntax: \texttt{group-router-interface\texttt{\textgreater\textless}}

Syntax: \texttt{interface group-ve \textless\textgreater num\texttt{\textgreater\textless}}

Syntax: \texttt{[no] ip address \textless\textgreater ip-addr\texttt{\textgreater\textless}} \texttt{ip-mask} \texttt{[secondary]} or

Syntax: \texttt{[no] ip address \textless\textgreater ip-addr\texttt{\textgreater\textless}} \texttt{mask-bits} \texttt{[secondary]}

The \texttt{router-interface-group\texttt{\textgreater\textless}} command enables a VLAN group to use a virtual routing interface group. Enter this command at the configuration level for the VLAN group. This command configures the VLAN group to use the virtual routing interface group that has the same ID as the VLAN group. You can enter this command when you configure the VLAN group for the first time or later, after you have added tagged ports to the VLAN and so on.

The \texttt{<num>\texttt{\textgreater\textless}} parameter in the \texttt{interface group-ve \textless\textgreater num\texttt{\textgreater\textless}} command specifies the ID of the VLAN group with which you want to associate this virtual routing interface group. The VLAN group must already be configured and enabled to use a virtual routing interface group. The software automatically associates the virtual routing interface group with the VLAN group that has the same ID. You can associate a virtual routing interface group only with the VLAN group that has the same ID.
NOTE
IPv6 is not supported with group-ve.

NOTE
FastIron CX devices do not support ACLs with group-ve.

NOTE
FastIron devices support group-ve with OSPF and VRRP protocols only.

The syntax and usage for the ip address command is the same as when you use the command at the interface level to add an IP interface.

Displaying the VLAN group and virtual routing interface group information

To verify configuration of VLAN groups and virtual routing interface groups, display the running-config file. If you have saved the configuration to the startup-config file, you also can verify the configuration by displaying the startup-config file. The following example shows the running-config information for the VLAN group and virtual routing interface group configured in the previous examples. The information appears in the same way in the startup-config file.

FastIron# show running-config
lines not related to the VLAN group omitted...

vlan-group 1 vlan 2 to 900
  add-vlan 1001 to 1002
  tagged ethe 1/1 to 1/2
  router-interface-group

lines not related to the virtual routing interface group omitted...

interface group-ve 1
  ip address 10.10.10.1 255.255.255.0

NOTE
If you have enabled display of subnet masks in CIDR notation, the IP address information is shown as follows: 10.10.10.1/24.

Allocating memory for more VLANs or virtual routing interfaces

Brocade Layer 2 and Layer 3 Switches support up to 4095 VLANs. In addition, Layer 3 switches support up to 512 virtual routing interfaces.

The number of VLANs and virtual routing interfaces supported on your product depends on the device and, for Chassis devices, the amount of DRAM on the management module. Table 91 lists the default and configurable maximum numbers of VLANs and virtual routing interfaces for Layer 2 and Layer 3 Switches. Unless otherwise noted, the values apply to both types of switches.
Configuring super aggregated VLANs

NOTE
On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

**NOTE**
If many of your VLANs will have an identical configuration, you might want to configure VLAN groups and virtual routing interface groups after you increase the system capacity for VLANs and virtual routing interfaces. Refer to “Configuring VLAN groups and virtual routing interface groups” on page 511.

### Increasing the number of VLANs you can configure

**NOTE**
Although you can specify up to 4095 VLANs, you can configure only 4094 VLANs. VLAN ID 4094 is reserved for use by the Single Spanning Tree feature.

To increase the maximum number of VLANs you can configure, enter commands such as the following at the global CONFIG level of the CLI.

```
FastIron(config)# system-max vlan 2048
FastIron(config)# write memory
FastIron(config)# end
FastIron# reload
```

**Syntax:** `system-max vlan <num>`

The `<num>` parameter indicates the maximum number of VLANs. The range of valid values depends on the device you are configuring. Refer to Table 91.

### Increasing the number of virtual routing interfaces you can configure

To increase the maximum number of virtual routing interfaces you can configure, enter commands such as the following at the global CONFIG level of the CLI.

```
FastIron(config)# system-max virtual-interface 512
FastIron(config)# write memory
FastIron(config)# end
FastIron# reload
```

**Syntax:** `system-max virtual-interface <num>`

The `<num>` parameter indicates the maximum number of virtual routing interfaces. The range of valid values depends on the device you are configuring. Refer to Table 91.

**TABLE 91** VLAN and virtual routing interface support

<table>
<thead>
<tr>
<th>VLANs</th>
<th>Virtual routing interfaces</th>

<tbody>
<tr>
<td>Default maximum</td>
<td>Configurable maximum</td>
</tr>
<tr>
<td>64</td>
<td>4094</td>
</tr>
</tbody>
</table>

**NOTE**
On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.
You can aggregate multiple VLANs within another VLAN. This feature allows you to construct Layer 2 paths and channels. This feature is particularly useful for Virtual Private Network (VPN) applications in which you need to provide a private, dedicated Ethernet connection for an individual client to transparently reach its subnet across multiple networks.

Conceptually, the paths and channels are similar to Asynchronous Transfer Mode (ATM) paths and channels. A path contains multiple channels, each of which is a dedicated circuit between two end points. The two devices at the end points of the channel appear to each other to be directly attached. The network that connects them is transparent to the two devices.

You can aggregate up to 4094 VLANs within another VLAN. This provides a total VLAN capacity on one Brocade device of 16,760,836 channels (4094 * 4094).

The devices connected through the channel are not visible to devices in other channels. Therefore, each client has a private link to the other side of the channel.

The feature allows point-to-point and point-to-multipoint connections.

**Figure 86** shows a conceptual picture of the service that aggregated VLANs provide. Aggregated VLANs provide a path for multiple client channels. The channels do not receive traffic from other channels. Thus, each channel is a private link.

**FIGURE 86 Conceptual model of the super aggregated VLAN application**

Each client connected to the edge device is in its own port-based VLAN, which is like an ATM channel. All the clients’ VLANs are aggregated by the edge device into a single VLAN for connection to the core. The single VLAN that aggregates the clients’ VLANs is like an ATM path.
The device that aggregates the VLANs forwards the aggregated VLAN traffic through the core. The core can consist of multiple devices that forward the aggregated VLAN traffic. The edge device at the other end of the core separates the aggregated VLANs into the individual client VLANs before forwarding the traffic. The edge devices forward the individual client traffic to the clients. For the clients' perspective, the channel is a direct point-to-point link.

Figure 87 shows an example application that uses aggregated VLANs. This configuration includes the client connections shown in Figure 86.

**FIGURE 87** Example of a super aggregated VLAN application

In this example, a collocation service provides private channels for multiple clients. Although the same devices are used for all the clients, the VLANs ensure that each client receives its own Layer 2 broadcast domain, separate from the broadcast domains of other clients. For example, client 1 cannot ping client 5.
The clients at each end of a channel appear to each other to be directly connected and thus can be on the same subnet and use network services that require connection to the same subnet. In this example, client 1 is in subnet 192.168.1.0/24 and so is the device at the other end of client 1 channel.

Since each VLAN configured on the core devices is an aggregate of multiple client VLANs, the aggregated VLANs greatly increase the number of clients a core device can accommodate.

This example shows a single link between the core devices. However, you can use a trunk group to add link-level redundancy.

Configuration note

- Super Aggregated VLANs and VSRP are not supported together on the same device.

Configuring aggregated VLANs

To configure aggregated VLANs, perform the following tasks:

- On each edge device, configure a separate port-based VLAN for each client connected to the edge device. In each client VLAN:
  - Add the port connected to the client as an untagged port.
  - Add the port connected to the core device (the device that will aggregate the VLANs) as a tagged port. This port must be tagged because all the client VLANs share the port as an uplink to the core device.

- On each core device:
  - Enable VLAN aggregation. This support allows the core device to add an additional tag to each Ethernet frame that contains a VLAN packet from the edge device. The additional tag identifies the aggregate VLAN (the path). However, the additional tag can cause the frame to be longer than the maximum supported frame size. The larger frame support allows Ethernet frames up to 1530 bytes long.
  - For FGS, FLS, and FWS devices, the frame size is limited to 1522, not 1530, bytes. To allow frames larger than 1522, you must enable jumbo frames. To globally enable jumbo support, enter commands such as the following.

```
FGS Switch(config)# jumbo
FGS Switch(config)# write memory
FGS Switch(config)# end
FGS Switch# reload
```

**NOTE**

Enable the VLAN aggregation option only on the core devices.

- Configure a VLAN tag type (tag ID) that is different than the tag type used on the edge devices. If you use the default tag type (8100) on the edge devices, set the tag type on the core devices to another value, such as 9100. The tag type must be the same on all the core devices. The edge devices also must have the same tag type but the type must be different from the tag type on the core devices.
NOTE
You can enable the Spanning Tree Protocol (STP) on the edge devices or the core devices, but not both. If you enable STP on the edge devices and the core devices, STP will prevent client traffic from travelling through the core to the other side.

**Configuring aggregated VLANs on an edge device**

To configure the aggregated VLANs on device A in Figure 87 on page 517, enter the following commands.

```bash
FastIron(config)# vlan 101 by port
FastIron(config-vlan-101)# tagged ethernet 2/1
FastIron(config-vlan-101)# untagged ethernet 1/1
FastIron(config-vlan-101)# exit
FastIron(config)# vlan 102 by port
FastIron(config-vlan-102)# tagged ethernet 2/1
FastIron(config-vlan-102)# untagged ethernet 1/2
FastIron(config-vlan-102)# exit
FastIron(config)# vlan 103 by port
FastIron(config-vlan-103)# tagged ethernet 2/1
FastIron(config-vlan-103)# untagged ethernet 1/3
FastIron(config-vlan-103)# exit
FastIron(config)# vlan 104 by port
FastIron(config-vlan-104)# tagged ethernet 2/1
FastIron(config-vlan-104)# untagged ethernet 1/4
FastIron(config-vlan-104)# exit
FastIron(config)# vlan 105 by port
FastIron(config-vlan-105)# tagged ethernet 2/1
FastIron(config-vlan-105)# untagged ethernet 1/5
FastIron(config-vlan-105)# exit
FastIron(config)# write memory
```

**Syntax:**

- `vlan <vlan-id> [by port]`
- `tagged ethernet [slotnum]/portnum] [to [slotnum]/portnum] | ethernet [slotnum]/portnum]`
- `untagged ethernet [slotnum]/portnum] [to [slotnum]/portnum] | ethernet [slotnum]/portnum]`

Use the `tagged` command to add the port that the device uses for the uplink to the core device. Use the `untagged` command to add the ports connected to the individual clients.

**Configuring aggregated VLANs on a core device**

To configure the aggregated VLANs on device C in Figure 87 on page 517, enter the following commands.

```bash
FastIron(config)# tag-type 9100
FastIron(config)# aggregated-vlan
FastIron(config)# vlan 101 by port
FastIron(config-vlan-101)# tagged ethernet 4/1
FastIron(config-vlan-101)# untagged ethernet 3/1
FastIron(config-vlan-101)# exit
FastIron(config)# vlan 102 by port
```

**Syntax:**

- `tag-type <tag-type>
- `aggregated-vlan`
- `vlan <vlan-id> [by port]`
Configuring super aggregated VLANS

```plaintext
FastIron(config-vlan-102)# tagged ethernet 4/1
FastIron(config-vlan-102)# untagged ethernet 3/2
FastIron(config-vlan-102)# exit
FastIron(config)# write memory
```

**Syntax:** `[no] tag-type <num>`

**Syntax:** `[no] aggregated-vlan`

The `<num>` parameter specifies the tag type can be a hexadecimal value from 0 – ffff. The default is 8100.

**Verifying the configuration**

You can verify the VLAN, VLAN aggregation option, and tag configuration by viewing the running-config. To display the running-config, enter the `show running-config` command from any CLI prompt. After you save the configuration changes to the startup-config, you also can display the settings in that file by entering the `show configuration` command from any CLI prompt.

**Complete CLI examples**

The following sections show all the Aggregated VLAN configuration commands on the devices in Figure 87 on page 517.

**NOTE**

In these examples, the configurations of the edge devices (A, B, E, and F) are identical. The configurations of the core devices (C and D) also are identical. The aggregated VLAN configurations of the edge and core devices on one side must be symmetrical (in fact, a mirror image) to the configurations of the devices on the other side. For simplicity, the example in Figure 87 on page 517 is symmetrical in terms of the port numbers. This allows the configurations for both sides of the link to be the same. If your configuration does not use symmetrically arranged port numbers, the configurations should not be identical but must use the correct port numbers.

**Commands for device A**

```plaintext
FastIronA(config)# vlan 101 by port
FastIronA(config-vlan-101)# tagged ethernet 2/1
FastIronA(config-vlan-101)# untagged ethernet 1/1
FastIronA(config-vlan-101)# exit
FastIronA(config)# vlan 102 by port
FastIronA(config-vlan-102)# tagged ethernet 2/1
FastIronA(config-vlan-102)# untagged ethernet 1/2
FastIronA(config-vlan-102)# exit
FastIronA(config)# vlan 103 by port
FastIronA(config-vlan-103)# tagged ethernet 2/1
FastIronA(config-vlan-103)# untagged ethernet 1/3
FastIronA(config-vlan-103)# exit
FastIronA(config)# vlan 104 by port
FastIronA(config-vlan-104)# tagged ethernet 2/1
FastIronA(config-vlan-104)# untagged ethernet 1/4
FastIronA(config-vlan-104)# exit
FastIronA(config)# vlan 105 by port
```
Configuring super aggregated VLANs

**Commands for device B**

The commands for configuring device B are identical to the commands for configuring device A. Notice that you can use the same channel VLAN numbers on each device. The devices that aggregate the VLANs into a path can distinguish between the identically named channel VLANs based on the ID of the path VLAN.

```
FastIronB(config)# vlan 101 by port
FastIronB(config-vlan-101)# tagged ethernet 2/1
FastIronB(config-vlan-101)# untagged ethernet 1/1
FastIronB(config)# vlan 102 by port
FastIronB(config-vlan-102)# tagged ethernet 2/1
FastIronB(config-vlan-102)# untagged ethernet 1/2
FastIronB(config)# vlan 103 by port
FastIronB(config-vlan-103)# tagged ethernet 2/1
FastIronB(config-vlan-103)# untagged ethernet 1/3
FastIronB(config)# vlan 104 by port
FastIronB(config-vlan-104)# tagged ethernet 2/1
FastIronB(config-vlan-104)# untagged ethernet 1/4
FastIronB(config)# vlan 105 by port
FastIronB(config-vlan-105)# tagged ethernet 2/1
FastIronB(config-vlan-105)# untagged ethernet 1/5
FastIronB(config)# write memory
```

**Commands for device C**

Since device C is aggregating channel VLANs from devices A and B into a single path, you need to change the tag type and enable VLAN aggregation.

```
FastIronC(config)# tag-type 9100
FastIronC(config)# aggregated-vlan
FastIronC(config)# vlan 101 by port
FastIronC(config-vlan-101)# tagged ethernet 4/1
FastIronC(config-vlan-101)# untagged ethernet 3/1
FastIronC(config)# vlan 102 by port
FastIronC(config-vlan-102)# tagged ethernet 4/1
FastIronC(config-vlan-102)# untagged ethernet 3/2
FastIronC(config)# write memory
```

**Commands for device D**

Device D is at the other end of path and separates the channels back into individual VLANs. The tag type must be the same as tag type configured on the other core device (Device C). In addition, VLAN aggregation also must be enabled.

```
FastIronD(config)# aggregated-vlan
```
FastIronD(config)# tag-type 9100
FastIronD(config)# aggregated-vlan
FastIronD(config)# vlan 101 by port
FastIronD(config-vlan-101)# tagged ethernet 4/1
FastIronD(config-vlan-101)# untagged ethernet 3/1
FastIronD(config-vlan-101)# exit
FastIronD(config)# vlan 102 by port
FastIronD(config-vlan-102)# tagged ethernet 4/1
FastIronD(config-vlan-102)# untagged ethernet 3/2
FastIronD(config-vlan-102)# exit
FastIronD(config)# write memory

**Commands for device E**

Since the configuration in Figure 87 on page 517 is symmetrical, the commands for configuring device E are identical to the commands for configuring device A.

FastIronE(config)# vlan 101 by port
FastIronE(config-vlan-101)# tagged ethernet 2/1
FastIronE(config-vlan-101)# untagged ethernet 1/1
FastIronE(config-vlan-101)# exit
FastIronE(config)# vlan 102 by port
FastIronE(config-vlan-102)# tagged ethernet 2/1
FastIronE(config-vlan-102)# untagged ethernet 1/2
FastIronE(config-vlan-102)# exit
FastIronE(config)# vlan 103 by port
FastIronE(config-vlan-103)# tagged ethernet 2/1
FastIronE(config-vlan-103)# untagged ethernet 1/3
FastIronE(config-vlan-103)# exit
FastIronE(config)# vlan 104 by port
FastIronE(config-vlan-104)# tagged ethernet 2/1
FastIronE(config-vlan-104)# untagged ethernet 1/4
FastIronE(config-vlan-104)# exit
FastIronE(config)# vlan 105 by port
FastIronE(config-vlan-105)# tagged ethernet 2/1
FastIronE(config-vlan-105)# untagged ethernet 1/5
FastIronE(config-vlan-105)# exit
FastIronE(config)# write memory

**Commands for device F**

The commands for configuring device F are identical to the commands for configuring device E. In this example, since the port numbers on each side of the configuration in Figure 87 on page 517 are symmetrical, the configuration of device F is also identical to the configuration of device A and device B.

FastIronF(config)# vlan 101 by port
FastIronF(config-vlan-101)# tagged ethernet 2/1
FastIronF(config-vlan-101)# untagged ethernet 1/1
FastIronF(config-vlan-101)# exit
FastIronF(config)# vlan 102 by port
FastIronF(config-vlan-102)# tagged ethernet 2/1
FastIronF(config-vlan-102)# untagged ethernet 1/2
FastIronF(config-vlan-102)# exit
FastIronF(config)# vlan 103 by port
FastIronF(config-vlan-103)# tagged ethernet 2/1
FastIronF(config-vlan-103)# untagged ethernet 1/3
FastIronF(config-vlan-103)# exit
FastIronF(config)# vlan 104 by port

FastIronF(config)# vlan 101 by port
FastIronF(config-vlan-101)# tagged ethernet 2/1
FastIronF(config-vlan-101)# untagged ethernet 1/1
FastIronF(config-vlan-101)# exit
FastIronF(config)# vlan 102 by port
FastIronF(config-vlan-102)# tagged ethernet 2/1
FastIronF(config-vlan-102)# untagged ethernet 1/2
FastIronF(config-vlan-102)# exit
FastIronF(config)# vlan 103 by port
FastIronF(config-vlan-103)# tagged ethernet 2/1
FastIronF(config-vlan-103)# untagged ethernet 1/3
FastIronF(config-vlan-103)# exit
FastIronF(config)# vlan 104 by port
Configuring 802.1Q-in-Q tagging

Platform Support:
- FESX devices running software version 01.1.00 and later
- All FSX and FWSX software releases
- FGS, FLS, and FWS devices running software release 04.3.01 and later
- TurboIron X Series devices running software release 04.2.00 and later

802.1Q-in-Q tagging provides finer granularity for configuring 802.1Q tagging, enabling you to configure 802.1Q tag-types on a group of ports. This feature allows you to create two identical 802.1Q tags (802.1Q-in-Q tagging) on a single device. This enhancement improves SAV interoperability between Brocade devices and other vendors’ devices that support the 802.1Q tag-types, but are not very flexible with the tag-types they accept.

NOTE
Brocade devices treat a double-tagged Ethernet frame as a Layer 2 only frame. The packets are not inspected for Layer 3 and Layer 4 information, and operations are not performed on the packet utilizing Layer 3 or Layer 4 information.

Figure 88 shows an example application with 802.1Q-in-Q tagging.

**FIGURE 88** 802.1Q-in-Q configuration example
In Figure 88, the untagged ports (to customer interfaces) accept frames that have any 802.1Q tag other than the configured tag-type 9100. These packets are considered untagged on this incoming port and are re-tagged when they are sent out of the uplink towards the provider. The 802.1Q tag-type on the uplink port is 8100, so the Brocade device will switch the frames to the uplink device with an additional 8100 tag, thereby supporting devices that only support this method of VLAN tagging.

Configuration rules

- Since the uplink (to the provider cloud) and the edge link (to the customer port) must have different 802.1Q tags, make sure the uplink and edge link are in different port regions. Refer to “About port regions” on page 361 for a list of valid port regions.
- If you configure a port with an 802.1Q tag-type, the Brocade device automatically applies the 802.1Q tag-type to all ports within the same port region. Likewise, if you remove the 802.1Q tag-type from a port, the Brocade device automatically removes the 802.1Q tag-type from all ports within the same port region.
- FastIron X Series devices support one configured tag-type per device along with the default tag-type of 8100. For example, if you configure an 802.1Q tag of 9100 on ports 1 – 12, then later configure an 802.1Q tag of 5100 on port 15, the device automatically applies the 5100 tag to all ports in the same port region as port 15, and also changes the 802.1Q tag-type on ports 1 – 12 to 5100.
- TurboIron X Series devices support one configured tag-type per port along with the default tag-type of 8100. TurboIron devices do not have the port region concept and do not support tag-profile.
- 802.1Q-in-Q tagging and VSRP are not supported together on the same device.

Enabling 802.1Q-in-Q tagging

To enable 802.1Q-in-Q tagging, configure an 802.1Q tag on the untagged edge links (the customer ports) to any value other than the 802.1Q tag for incoming traffic. For example, in Figure 89, the 802.1Q tag on the untagged edge links (ports 11 and 12) is 9100, whereas, the 802.1Q tag for incoming traffic is 8100.

To configure 802.1 Q-in-Q tagging as shown in Figure 89, enter commands such as the following on the untagged edge links of devices C and D.

FastIron(config)# tag-type 9100 e 11 to 12
FastIron(config)# aggregated-vlan

Note that since ports 11 and 12 belong to the port region 1 – 12, the 802.1Q tag actually applies to ports 1 – 12.

Syntax: [no] tag-type <num> [ethernet [slotnum]<port number> to <port number>]]

The <num> parameter specifies the tag-type number and can be a hexadecimal value from 0 - ffff. The default is 8100.

The <slotnum> parameter is required on chassis devices.

The ethernet <port number> to <port number> parameter specifies the ports that will use the defined 802.1Q tag. This parameter operates with the following rules:
• If you specify a single port number, the 802.1Q tag applies to all ports within the port region. For example, if you enter the command `tag-type 9100 e 1`, the Brocade device automatically applies the 802.1Q tag to ports 1 – 12 since all of these ports are in the same port region. You can use the `show running-config` command to view how the command has been applied.

• If you do not specify a port or range of ports, the 802.1Q tag applies to all Ethernet ports on the device.

Example configuration

Figure 89 shows an example 802.1Q-in-Q configuration.

FIGURE 89  Example 802.1Q-in-Q configuration
Configuring 802.1Q-in-Q tag profiles

The 802.1Q-in-Q tagging feature supports a tag profile command that allows you to add a tag profile with a value of 0 to 0xffff in addition to the default tag-type 0x8100. This enhancement also allows you to add a tag profile for a single port, or to direct a group of ports to a globally-configured tag profile.

**CLI commands**

Syntax: `[no] tag-profile <tag-no>` (in the configuration mode)
Syntax: [no] tag-profile enable (in the single port/multi port interface configuration mode)

**Configuration notes**

- One tag profile of any number between 0 to 0xffff can be configured globally
- On individual ports, if tag-profile is enabled, the tag profile will point to the global tag profile
- Tag profile can also be enabled for provisional ports
- If a port has already been configured with a tag type, you must remove the tag-type before you add the tag profile

**Example**

To add a global tag-profile enter the following command.

```
FGS 648P Switch(config)# tag-profile 9500
```

This command adds a profile in addition to the default profile of 0x8100. To enable the new profile on individual ports, enter commands similar to the following.

```
FGS 648P Switch(config)# interface ethernet 1/1/1
FGS 648P Switch(config-if-e1000-1/1/1)# tag-profile enable
FGS 648P Switch(config-mif-1/1/1,1/2/1)# tag-profile enable
```

**NOTE**

Do not use the tag-type command in conjunction with the tag-profile command. If a tag-type has already been configured and you try to use the tag-profile command, you will see an error message telling you to remove the tag-type before you add the tag-profile.

**Configuring Q-in-Q tagging for stack devices**

**Platform Support:**

- FGS-STK and FLS-STK devices running software version 05.0.00 and later

For devices operating in an IronStack topology, when a tag-type for a port is changed, the tag-type for all of the ports on a stack unit also changes. Because of this limitation, SAV and Q-in-Q cannot be used at the same time on stacking devices.

The tag-profile command supports one extra tag profile in addition to the default tag-profile (0x8100). This additional tag profile can be configured specifically on only those ports where it is required.

**CLI commands**

Syntax: [no] tag-profile <tag-no> (in the configuration mode)

Syntax: [no] tag-profile enable (in the single port/multi port interface configuration mode)

**Example**

To configure one more global tag profile (in addition to the default tag profile) enter the following command.

```
FGS 648P Switch(config)# tag-profile 9100
```
To enable the new profile on individual ports or on a range of ports, enter commands similar to the following.

FGS 648P Switch(config)# interface ethernet 1/1/1
FGS 648P Switch(config-if-e1000-1/1/1)# tag-profile enable
FGS 648P Switch(config-mif-1/1/1,1/2/1)# tag-profile enable

**Configuration notes for stackable devices**

- One tag profile of any number between 0 to 0xffff can be configured globally
- On individual ports, if tag-profile is enabled, it points to the new additional global tag profile
- Tag profile can also be enabled for reserved ports
- Do not use the tag-type command in conjunction with the tag-profile command. If a tag-type has already been configured and you try to use the tag-profile command, you will see the following error message: “un-configure the tag-type to add the tag-profile.” You must remove the tag type before you add the tag profile.

### Configuring private VLANs

**Platform Support:**

- FastIron X Series devices running software release 02.4.00 and later
- FGS and FLS devices running software release
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 and later
- TurboIron X Series devices running software release 04.2.00 and later

**NOTE**

Software releases 02.4.00 and later support private VLANs on untagged ports. You cannot configure isolated, community, or primary VLANs on 802.1Q tagged ports.
A private VLAN is a VLAN that has the properties of standard Layer 2 port-based VLANs but also provides additional control over flooding packets on a VLAN. Figure 90 shows an example of an application using a private VLAN.

**FIGURE 90** Private VLAN used to secure communication between a workstation and servers

![Diagram of private VLAN](image)

This example uses a private VLAN to secure traffic between hosts and the rest of the network through a firewall. Five ports in this example are members of a private VLAN. The first port (port 3/2) is attached to a firewall. The next four ports (ports 3/5, 3/6, 3/9, and 3/10) are attached to hosts that rely on the firewall to secure traffic between the hosts and the rest of the network. In this example, two of the hosts (on ports 3/5 and 3/6) are in a community private VLAN, and thus can communicate with one another as well as through the firewall. The other two hosts (on ports 3/9 and 3/10), are in an isolated VLAN and thus can communicate only through the firewall. The two hosts are secured from communicating with one another even though they are in the same VLAN.

By default, the private VLAN does not forward broadcast or unknown-unicast packets from outside sources into the private VLAN. If needed, you can override this behavior for broadcast packets, unknown-unicast packets, or both. (Refer to “Enabling broadcast or unknown unicast traffic to the private VLAN” on page 534.)

You can configure a combination of the following types of private VLANs:

- **Primary** – The primary private VLAN ports are “promiscuous”. They can communicate with all the isolated private VLAN ports and community private VLAN ports in the isolated and community VLANS that are mapped to the promiscuous port.
• Secondary – The secondary private VLAN are secure VLANs that are separated from the rest of the network by the primary private VLAN. Every secondary private VLAN is associated with a primary private VLAN. The two types of secondary private VLANs are isolated private VLAN and community private VLAN.

• Isolated – Broadcasts and unknown-unicasts packet received on isolated ports are sent only to the primary port. They are not flooded to other ports in the isolated VLAN.

On TurboIron X Series devices running software release 04.2.00 and later the broadcasts, unknown-unicasts, and unregistered-multicast packets received on isolated ports are sent to the primary port. They are not flooded to other ports in the isolated VLAN.

• Community – Broadcasts and unknown unicasts received on community ports are sent to the primary port and also are flooded to the other ports in the community VLAN.

On TurboIron X Series devices running software release 04.2.00 and later the broadcasts, unknown unicasts, and unregistered multicast received on community ports are sent to the primary port and are flooded to the other ports in the community VLAN.

Each private VLAN must have a primary VLAN. The primary VLAN is the interface between the secured ports and the rest of the network. The private VLAN can have any combination of community and isolated VLANs. The community VLAN and isolated VLAN cannot forward traffic to each other. You cannot forwarding traffic between different private VLANs.

Table 92 list the differences between private VLANs and standard VLANs.

**TABLE 92** Comparison of private VLANs and standard port-based VLANs

<table>
<thead>
<tr>
<th>Forwarding behavior</th>
<th>Private VLANs</th>
<th>Standard VLANs</th>
</tr>
</thead>
<tbody>
<tr>
<td>All ports within a VLAN constitute a common Layer broadcast domain</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Broadcasts and unknown unicsats are forwarded to all the VLAN ports by default</td>
<td>No (isolated VLAN)</td>
<td>Yes (community VLAN)</td>
</tr>
</tbody>
</table>

Configuration notes

• Private VLANs are supported in releases 02.4.00 and later on untagged ports only. You cannot configure isolated, community, or primary VLANs on 802.1Q tagged ports.

**NOTE**
TurboIron X Series devices running software release 04.2.00 support 802.1Q tagged ports on private VLAN. Private VLAN is a hardware-based feature. Private VLANs on the TurboIron device forwards unknown-unicast, unregistered multicast, and broadcast in hardware.

• Normally, in any port-based VLAN, the Brocade device floods unknown unicast, unregistered multicast, and broadcast packets in hardware, although selective packets, such as IGMP, may be sent to only the CPU for analysis, based on the IGMP snooping configuration. When Protocol or Subnet VLANs are enabled, or if private VLAN mappings are enabled, the Brocade device will flood unknown unicast, unregistered multicast, and broadcast packets in software.
• There is currently no support for IGMP snooping within private VLANs. In order for clients in private VLANs to receive multicast traffic, IGMP snooping must be disabled so that all multicast packets are treated as unregistered packets and are flooded in software to all the ports.

• FastIron X Series devices and TurboIron X Series forward all known unicast traffic in hardware. This differs from the way the BigIron implements private VLANs, in that the BigIron uses the CPU to forward packets on the primary VLAN "promiscuous" port. In addition, on the BigIron, support for the hardware forwarding in this feature sometimes results in multiple MAC address entries for the same MAC address in the device MAC address table. On the FastIron X Series devices and TurboIron X Series devices, multiple MAC entries do not appear in the MAC address table because the FastIron X Series and TurboIron X Series transparently manages multiple MAC entries in hardware.

• You can configure private VLANs and dual-mode VLAN ports on the same device. However, the dual-mode VLAN ports cannot be members of private VLANs.

• A primary VLAN can have multiple ports. All these ports are active, but the ports that will be used depends on the private VLAN mappings. Also, secondary VLANs (isolated and community VLANs) can be mapped to multiple primary VLAN ports.

  Example
  
  pvlan mapping 901 ethernet 1
  pvlan mapping 901 ethernet 2
  pvlan mapping 901 ethernet 3

• Trunks are not supported on FastIron X Series devices when the ports are part of a private VLAN.

---

**Configuration notes and limitations for TurboIron devices**

Consider the following statements when configuring a private VLAN on a TurboIron X Series device running software release 04.2.00 and later:

• Each private VLAN can have multiple isolated VLANs or community VLANs. You can use any combination of isolated or community VLANs with the primary VLAN.

• You cannot configure a common port in any pair of primary, isolated, and community VLANs.

• You cannot configure the default VLAN (VLAN 1) as a private VLAN.

• You can configure Virtual interface (VE) on primary VLAN. The VE configuration in secondary private VLAN is not supported.

• A secondary VLAN can have only one primary VLAN associated with it.

• You can configure static trunk or dynamic trunk in both primary and secondary private VLAN.

• Spanning tree protocol is automatically disabled on private VLAN.

• You cannot enable Metro Ring Protocol (MRP), Virtual Switch Redundancy Protocol (VSRP), and Virtual Router Redundancy Protocol (VRRP) on private VLAN.

• You cannot enable single span on a private VLAN configured system and you cannot configure private VLAN on a single span enabled system.

• You cannot configure private VLAN through VLAN group.

• ICMP redirect is automatically disabled for private VLAN.

• To enhance private VLAN security, unique VLAN ID is used to identify the primary VLAN for different private VLANs. The known unicast among isolated VLAN and known unicast across different isolated or community VLAN is restricted.
Configuring private VLANs

- To enhance private VLAN flexibility, tagged, untagged, and dual mode ports are supported.
- All ports in the primary VLAN are promiscuous. You cannot configure an individual port in the primary to secondary private VLAN mapping. Traffic is forwarded to all ports in the primary private vlan when received from a secondary VLAN.

Command syntax

To configure a private VLAN, configure each of the component VLANs (isolated, community, and primary) as a separate port-based VLAN:

- Use standard VLAN configuration commands to create the VLAN and add ports.
- Identify the private VLAN type (isolated, community, or primary)
- For the primary VLAN, map the other private VLANs to the ports in the primary VLAN

**Configuring an isolated or community private VLAN**

To configure a community private VLAN, enter commands such as the following.

```
FastIron(config)# vlan 901
FastIron(config-vlan-901)# untagged ethernet 3/5 to 3/6
FastIron(config-vlan-901)# pvlan type community
```

These commands create port-based VLAN 901, add ports 3/5 and 3/6 to the VLAN as untagged ports, then specify that the VLAN is a community private VLAN.

Syntax: `untagged ethernet [slotnum]/portnum [to slotnum]/portnum | ethernet slotnum/portnum`  
Syntax: `[no] pvlan type community | isolated | primary`

The **untagged** command adds the ports to the VLAN.  
The **pvlan type** command specifies that this port-based VLAN is a private VLAN:

- **community** – Broadcasts and unknown unicast received on community ports are sent to the primary port and also are flooded to the other ports in the community VLAN.
- **isolated** – Broadcasts and unknown unicast received on isolated ports are sent only to the primary port. They are not flooded to other ports in the isolated VLAN.
- **primary** – The primary private VLAN ports are “promiscuous”. They can communicate with all the isolated private VLAN ports and community private VLAN ports in the isolated and community VLANs that are mapped to the promiscuous port.

To configure a community private VLAN on a TurboIron X Series device running software release 04.2.00 and later, enter the following commands.

```
TurboIron(config)# vlan 901
TurboIron(config-vlan-901)# untagged ethernet 5 to 6
TurboIron(config-vlan-901)# pvlan type community
```

These commands create port-based VLAN 901, add ports 5 and 6 to the VLAN as untagged ports, and then specify that the VLAN is a community private VLAN.

To configure an isolated private VLAN on a TurboIron X Series device running software release 04.2.00 and later, enter the following commands.

```
TurboIron(config)# vlan 902
TurboIron(config-vlan-902)# tagged ethernet 9 to 10
```
Configuring private VLANs

TurboIron(config-vlan-902)# pvlan type isolated

**Configuring the primary VLAN**

**NOTE**
The primary private VLAN has only one active port. If you configure the VLAN to have more than one port, the lowest-numbered port is the active one. The additional ports provide redundancy. If the active port becomes unavailable, the lowest-numbered available port becomes the active port for the VLAN.

**NOTE**
In TurboIron X Series devices, all the ports in the primary private VLAN are active.

To configure a primary private VLAN, enter commands such as the following.

FastIron(config)# vlan 7
FastIron(config-vlan-7)# untagged ethernet 3/2
FastIron(config-vlan-7)# pvlan type primary
FastIron(config-vlan-7)# pvlan mapping 901 ethernet 3/2

These commands create port-based VLAN 7, add port 3/2 as an untagged port, identify the VLAN as the primary VLAN in a private VLAN, and map the other private VLANs to the ports in this VLAN.

**Syntax:**
- `untagged ethernet [slotnum]portnum`
- `pvlan type community | isolated | primary`
- `pvlan mapping <vlan-id> ethernet [slotnum]portnum`

The `untagged` command adds the ports to the VLAN.

The `pvlan type` command specifies that this port-based VLAN is a private VLAN. Specify `primary` as the type.

The `pvlan mapping` command identifies the other private VLANs for which this VLAN is the primary. The command also specifies the primary VLAN ports to which you are mapping the other private VLANs. The parameters of the `pvlan mapping` command are as follows:

- The `<vlan-id>` parameter specifies another private VLAN. The other private VLAN you want to specify must already be configured.
- The `ethernet <portnum>` parameter specifies the primary VLAN port to which you are mapping all the ports in the other private VLAN (the one specified by `<vlan-id>`).

To configure a primary private VLAN, on TurboIron X Series device running software release 04.2.00 and later enter the following commands:

TurboIron(config)# vlan 7
TurboIron(config-vlan-7)# untagged ethernet 2
TurboIron(config-vlan-7)# pvlan type primary
TurboIron(config-vlan-7)# pvlan mapping 901

These commands create port-based VLAN 7, add port 2 as an untagged port, identify the VLAN as the primary VLAN in a private VLAN, and map the secondary private VLANs to the primary VLAN.

**NOTE**
For TurboIron devices, you do not have to specify the port in the primary vlan mapping.
Enabling broadcast or unknown unicast traffic to the private VLAN

To enhance private VLAN security, the primary private VLAN does not forward broadcast or unknown unicast packets to its community and isolated VLANs. For example, if port 3/2 in Figure 90 on page 529 receives a broadcast packet from the firewall, the port does not forward the packet to the other private VLAN ports (3/5, 3/6, 3/9, and 3/10).

This forwarding restriction does not apply to traffic from the private VLAN. The primary port does forward broadcast and unknown unicast packets that are received from the isolated and community VLANs. For example, if the host on port 3/9 sends an unknown unicast packet, port 3/2 forwards the packet to the firewall.

If you want to remove the forwarding restriction, you can enable the primary port to forward broadcast or unknown unicast traffic, if desired, using the following CLI method. You can enable or disable forwarding of broadcast or unknown unicast packets separately.

**NOTE**
On Layer 2 Switches and Layer 3 Switches, you also can use MAC address filters to control the traffic forwarded into and out of the private VLAN. In addition, if you are using a Layer 2 Switch, you also can use ACLs.

**NOTE**
FastIron CX devices do not support ACLs on interface groups.

**Command syntax**

To configure the ports in the primary VLAN to forward broadcast or unknown unicast and multicast traffic received from sources outside the private VLAN, enter the following commands at the global CONFIG level of the CLI.

```
FastIron(config)# pvlan-preference broadcast flood
FastIron(config)# pvlan-preference unknown-unicast flood
```

These commands enable forwarding of broadcast and unknown-unicast packets to ports within the private VLAN. To again disable forwarding, enter a command such as the following.

```
FastIron(config)# no pvlan-preference broadcast flood
```

This command disables forwarding of broadcast packets within the private VLAN.

**Syntax:** `[no] pvlan-preference broadcast | unknown-unicast flood`

**CLI example for Figure 90**

To configure the private VLANs shown in Figure 90 on page 529, enter the following commands.

```
FastIron(config)# vlan 901
FastIron(config-vlan-901)# untagged ethernet 3/5 to 3/6
FastIron(config-vlan-901)# pvlan type community
FastIron(config-vlan-901)# exit
FastIron(config)# vlan 902
FastIron(config-vlan-902)# untagged ethernet 3/9 to 3/10
FastIron(config-vlan-902)# pvlan type isolated
FastIron(config-vlan-902)# exit
FastIron(config)# vlan 903
```
FastIron(config-vlan-903)# untagged ethernet 3/7 to 3/8
FastIron(config-vlan-903)# pvlan type community
FastIron(config-vlan-903)# exit
FastIron(config)# vlan 7
FastIron(config-vlan-7)# untagged ethernet 3/2
FastIron(config-vlan-7)# pvlan type primary
FastIron(config-vlan-7)# pvlan mapping 901 ethernet 3/2
FastIron(config-vlan-7)# pvlan mapping 902 ethernet 3/2
FastIron(config-vlan-7)# pvlan mapping 903 ethernet 3/2

Enabling broadcast, unregistered multicast or unknown unicast traffic to the private VLAN on TurboIron device

To configure the ports in primary VLAN to forward broadcast, unregistered multicast, or unknown unicast, enter the following commands:

TurboIron(config-vlan-7)# pvlan preference unknown-unicast flood
TurboIron(config-vlan-7)# pvlan preference broadcast flood

Syntax: [no] pvlan preference broadcast | unknown-unicast

These commands enable forwarding of broadcast, unregistered multicast flood, and unknown-unicast packets to ports within the private VLAN.

Dual-mode VLAN ports

Platform Support:
- FastIron X Series devices
- FCX-S devices running software release 06.0.00 and later
- TurboIron X Series devices running software release 04.1.00 and later.

Configuring a tagged port as a dual-mode port allows it to accept and transmit both tagged traffic and untagged traffic at the same time. A dual-mode port accepts and transmits frames belonging to VLANs configured for the port, as well as frames belonging to the default VLAN (that is, untagged traffic).

For example, in Figure 91, port 2/11 is a dual-mode port belonging to VLAN 20. Traffic for VLAN 20, as well as traffic for the default VLAN, flows from a hub to this port. The dual-mode feature allows traffic for VLAN 20 and untagged traffic to go through the port at the same time.

FIGURE 91 Dual-mode VLAN port example
To enable the dual-mode feature on port 2/11 in Figure 91, enter the following commands.

FastIron(config)# vlan 20
FastIron(config-vlan-20)# tagged e 2/11
FastIron(config-vlan-20)# tagged e 2/9
FastIron(config-vlan-20)# int e 2/11
FastIron(config-if-e1000-2/11)# dual-mode
FastIron(config-if-e1000-2/11)# exit

Syntax: [no] dual-mode

You can configure a dual-mode port to transmit traffic for a specified VLAN (other than the DEFAULT-VLAN) as untagged, while transmitting traffic for other VLANs as tagged. Figure 92 illustrates this enhancement.

FIGURE 92  Specifying a default VLAN ID for a dual-mode port
In Figure 92, tagged port 2/11 is a dual-mode port belonging to VLANs 10 and 20. The default VLAN assigned to this dual-mode port is 10. This means that the port transmits tagged traffic on VLAN 20 (and all other VLANs to which the port belongs) and transmits untagged traffic on VLAN 10.

The dual-mode feature allows tagged traffic for VLAN 20 and untagged traffic for VLAN 10 to go through port 2/11 at the same time. A dual-mode port transmits only untagged traffic on its default VLAN (that is, either VLAN 1, or a user-specified VLAN ID), and only tagged traffic on all other VLANs.

The following commands configure VLANs 10 and 20 in Figure 92. Tagged port 2/11 is added to VLANs 10 and 20, then designated a dual-mode port whose specified default VLAN is 10. In this configuration, port 2/11 transmits only untagged traffic on VLAN 10 and only tagged traffic on VLAN 20.

```
FastIron(config)# vlan 10 by port
FastIron(config-vlan-10)# untagged e 2/10
FastIron(config-vlan-10)# tagged e 2/11
FastIron(config-vlan-10)# exit
FastIron(config)# vlan 20 by port
FastIron(config-vlan-20)# tagged e 2/9
FastIron(config-vlan-20)# tagged e 2/11
FastIron(config-vlan-20)# exit
FastIron(config)# int e 2/11
FastIron(config-if-e1000-2/11)# dual-mode 10
FastIron(config-if-e1000-2/11)# exit
```

Syntax: `[no] dual-mode [<vlan-id>]`

Notes:
- If you do not specify a `<vlan-id>` in the `dual-mode` command, the port default VLAN is set to 1. The port transmits untagged traffic on the DEFAULT-VLAN.
- The dual-mode feature is disabled by default. Only tagged ports can be configured as dual-mode ports.
- In trunk group, either all of the ports must be dual-mode, or none of them can be.

The `show vlan` command displays a separate row for dual-mode ports on each VLAN.
Example

FastIron# show vlan
Total PORT-VLAN entries: 3
Maximum PORT-VLAN entries: 16

legend: [S=Slot]

PORT-VLAN 1, Name DEFAULT-VLAN, Priority level0, Spanning tree Off
  Untagged Ports: (S1) 1 2 3 4 5 6 7 8
  Untagged Ports: (S2) 1 2 3 4 5 6 7 8 12 13 14 15 16 17 18 19
  Untagged Ports: (S2) 20 21 22 23 24
  Tagged Ports: None
  Uplink Ports: None
  DualMode Ports: None

PORT-VLAN 10, Name [None], Priority level0, Spanning tree Off
  Untagged Ports: (S2) 10
  Tagged Ports: None
  Uplink Ports: None
  DualMode Ports: (S2) 11

PORT-VLAN 20, Name [None], Priority level0, Spanning tree Off
  Untagged Ports: None
  Tagged Ports: (S2) 9
  Uplink Ports: None
  DualMode Ports: (S2) 11

Displaying VLAN information

After you configure the VLANs, you can verify the configuration using the `show` commands described in this section.

**NOTE**
If a VLAN name begins with "GVRP_VLAN_", the VLAN was created by the GARP VLAN Registration Protocol (GVRP). If a VLAN name begins with "STATIC_VLAN_", the VLAN was created by GVRP and then was converted into a statically configured VLAN.

Displaying VLANs in alphanumeric order

**Platform Support:**
- FastIron X Series devices running software release 03.0.00 and later
- Turbolon X Series devices running software release 04.1.00 and later

In releases prior to 03.0.00 for the FastIron X Series devices, the output of some show commands list VLANs in the order that they were configured. Starting with release 03.0.00, by default, the VLANs are displayed in alphanumeric order.

For example, in releases prior to 03.0.00, if you configure VLANs in the order VLAN 10, VLAN 100, then VLAN 2, the `show run` command output displays.
Starting with release 03.0.00, VLANs are displayed in alphanumeric order, as shown in the following example.

FastIron# show run
...
vlan 10 by port
...
vlan 100 by port
...
vlan 2 by port
...

Displaying system-wide VLAN information

Use the `show vlans` command to display VLAN information for all the VLANs configured on the device.

The following example shows the display output for a TurboIron X Series device.

TurboIron 24X# show vlans
Total PORT-VLAN entries: 2
Maximum PORT-VLAN entries: 8
legend: [S=Slot]

PORT-VLAN 1, Name DEFAULT-VLAN, Priority level0, Spanning tree Off
Untagged Ports: (S2) 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
Untagged Ports: (S2) 17 18 19 20 21 22 23 24
Untagged Ports: (S4) 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
Untagged Ports: (S4) 17 18 19 20 21 22 23 24
Tagged Ports: None

PORT-VLAN 10, Name IP_VLAN, Priority level0, Spanning tree Off
Untagged Ports: (S1) 1 2 3 4 5 6
Tagged Ports: None

The following example shows the display for the IP subnet and IPX network VLANs configured in the examples in “Configuring an IP subnet VLAN with dynamic ports” on page 505 and “Configuring an IPX network VLAN with dynamic ports” on page 506.
Displaying VLAN information

FastIron# show vlans
Total PORT-VLAN entries: 2
Maximum PORT-VLAN entries: 8
legend: [S=Slot]

PORT-VLAN 1, Name DEFAULT-VLAN, Priority level0, Spanning tree Off
Untagged Ports: (S2) 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
Untagged Ports: (S4) 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
Tagged Ports: None

PORT-VLAN 10, Name IP_VLAN, Priority level0, Spanning tree Off
Untagged Ports: (S1) 1 2 3 4 5 6
Tagged Ports: None

IP-subnet VLAN 1.1.1.0 255.255.255.0, Dynamic port enabled
Name: Mktg-LAN
Static ports: None
Exclude ports: None
Dynamic ports: (S1) 1 2 3 4 5 6

PORT-VLAN 20, Name IP_VLAN, Priority level0, Spanning tree Off
Untagged Ports: (S2) 1 2 3 4 5 6
Tagged Ports: None

IPX-network VLAN 0000ABCD, frame type ethernet_ii, Dynamic port enabled
Name: Eng-LAN
Static ports: None
Exclude ports: None
Dynamic ports: (S2) 1 2 3 4 5 6

The output of the show vlans command was enhanced in software release FSX 04.2.00. Ports that are tagged but are not dual-mode ports are listed as tagged ports. In the following example display output, ports 7 and 8 are dual-mode ports in port-based VLAN 4. Ports 7 and 8 also belong to port-based VLAN 3, but they are tagged ports only in VLAN 3 and are not configured as dual-mode ports.

FastIron# show vlan 4
Total PORT-VLAN entries: 5
Maximum PORT-VLAN entries: 3210
PORT-VLAN 4, Name [None], Priority level0, Spanning tree Off
Untagged Ports: None
Tagged Ports: 6 9 10 11
Uplink Ports: None
DualMode Ports: 7 8

ESX624FE+2XG Router# show vlan 3
Total PORT-VLAN entries: 5
Maximum PORT-VLAN entries: 3210
PORT-VLAN 3, Name [None], Priority level0, Spanning tree Off
Untagged Ports: None
Tagged Ports: 6 7 8 9 10
Uplink Ports: None
DualMode Ports: None

Syntax: show vlans [<vlan-id> | ethernet [<slotnum>/]<portnum>]
The <vlan-id> parameter specifies a VLAN for which you want to display the configuration information.
The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter specifies a port. If you use this parameter, the command lists all the VLAN memberships for the port.

### Displaying global VLAN information

**Platform Support:**
- FastIron X Series devices running software release FSX 04.2.00 and later

New in software release FSX 04.2.00, the `show vlan brief` command displays the following information:

- The system-max VLAN values (maximum, default, and current )
- The default VLAN ID number
- The total number of VLANs configured on the device
- The VLAN ID numbers of the VLANs configured on the device

The following shows example output.

```
FastIron# show vlan brief
System-max vlan Params: Max(4095) Default(64) Current(3210)
Default vlan Id :1
Total Number of Vlan Configured :5
VLANs Configured :1 to 4 10
```

**Syntax:** `show vlan brief`

### Displaying VLAN information for specific ports

Use one of the following methods to display VLAN information for specific ports.

To display VLAN information for all the VLANs of which port 7/1 is a member, enter the following command.

```
FastIron# show vlans e 7/1
Total PORT-VLAN entries: 3
Maximum PORT-VLAN entries: 8
legend: [S=Slot]

PORT-VLAN 100, Name [None], Priority level0, Spanning tree Off
  Untagged Ports: (S7)  1  2  3  4
  Tagged Ports: None
```

**Syntax:** `show vlans [<vlan-id>] | ethernet [<slotnum>/]<portnum>`

The `<vlan-id>` parameter specifies a VLAN for which you want to display the configuration information.

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter specifies a port. If you use this parameter, the command lists all the VLAN memberships for the port.
Displaying a port VLAN membership

Platform Support:

- FastIron X Series devices running software release FSX 04.2.00 and later

To display VLAN membership for a specific port on the device, enter a command such as the following.

```
FastIron# show vlan brief ethernet 7
Port 7 is a member of 3 VLANs
VLANs 3 to 4 10
```

Syntax: `show vlan brief ethernet [<slotnum>]/<portnum>`
The `<slotnum>` parameter is required on chassis devices.

Displaying a port dual-mode VLAN membership

Platform Support:

- FastIron X Series devices running software release FSX 04.2.00 and later

Starting in software release FSX 04.2.00, the output of the `show interfaces` command lists dual-mode configuration and corresponding VLAN numbers. In releases prior to FSX 04.2.00, tagged and untagged configurations were listed, but not dual-mode configurations. The following shows an example output.

```
FastIron# show interfaces ethernet e7
GigabitEthernet7 is down, line protocol is down
  Hardware is GigabitEthernet, address is 0012.f2a8.4706 (bia 0012.f2a8.4706)
  Configured speed auto, actual unknown, configured duplex fdx, actual unknown
  Configured mdi mode AUTO, actual unknown
  Member of 3 L2 VLANs, port is dual mode in Vlan 4, port state is BLOCKING
```

Syntax: `show interfaces ethernet [<slotnum>]/<portnum> [to [<slotnum>]/<portnum> [ethernet [<slotnum>]/<portnum>...]]`
The `<slotnum>` parameter is required on chassis devices.

Displaying port default VLAN IDs (PVIDs)

Platform Support:

- FastIron X Series devices running software release FSX 04.2.00 and later

Starting in software release FSX 04.2.00, the output of the `show interfaces brief` command lists the port default VLAN IDs (PVIDs) for each port. PVIDs are displayed as follows:

- For untagged ports, the PVID is the VLAN ID number.
- For dual-mode ports, the PVID is the dual-mode VLAN ID number.
- For tagged ports without dual-mode, the PVID is always Not Applicable (NA).
Displaying VLAN information

Syntax: `show interfaces brief [ethernet [slotnum]/]<portnum> [to [slotnum]/]<portnum> [ethernet [slotnum]/]<portnum>...]`

The `<slotnum>` parameter is required on chassis devices.

Displaying VLAN information
Trunk group overview

The Trunk group feature allows you to manually configure multiple high-speed load-sharing links between two Brocade Layer 2 Switches or Layer 3 Switches or between a Brocade Layer 2 Switch and Layer 3 Switch and a server.

In addition to enabling load sharing of traffic, trunk groups provide redundant, alternate paths for traffic if any of the segments fail.

- **Trunk groups** are manually-configured aggregate links containing multiple ports.
- **802.3ad link aggregation** is a protocol that dynamically creates and manages trunk groups.

**NOTE**
You can use both types of trunking on the same device. However, you can use only one type of trunking for a given port. For example, you can configure port 1/1 as a member of a static trunk group or you can enable 802.3ad link aggregation on the port, but you cannot do both.

*Figure 93* shows an example of a configuration that uses trunk groups.
The ports in a trunk group make a single logical link. Therefore, all the ports in a trunk group must be connected to the same device at the other end.

**Trunk group connectivity to a server**

To support termination of a trunk group, the server must have either multiple network interface cards (NICs) or either a dual or quad interface card installed. The trunk server is designated as a server with multiple adapters or a single adapter with multiple ports that share the same MAC and IP address.

*Figure 94* shows an example of a trunk group between a server and a Brocade device.
FIGURE 94  Trunk group between a server and a Brocade compact Layer 2 Switch or Layer 3 Switch

Multi-homing adapter has the same IP and MAC address

Trunk group rules

Table 93 lists the maximum number of trunk groups you can configure on a Brocade device and the valid number of ports in a trunk group. The table applies to static and LACP trunk ports.

TABLE 93  Trunk group support

</table>
• You cannot configure a port as a member of a trunk group if 802.3ad link aggregation is enabled on the port.

• Unlike the FES and other Brocade devices, trunk groups on devices listed in Table 93 are not classified as switch trunk groups or server trunk groups.

• For FastIron WS devices, mixed speed LACP trunks, (i.e. trunks with member ports that are a mix of 1Gbps and 10/100Mbps), are not allowed and if configured will not come up.

• The following rules apply to multi-slot trunk groups on FastIron X Series devices:
  
  • Multi-slot trunk groups are supported on GbE ports on FastIron X Series devices, and on 10-GbE ports starting in software release FSX 03.2.00.

  • Support for multi-slot trunk groups with one port per module was added in software release FSX 04.0.00. Previous releases support a minimum of two ports per module. The syntax is the same as for regular multi-slot trunks, except that the port range for each slot is a single port. Refer to “Example 3: Configuring a multi-slot trunk group with one port per module” on page 558.

  • Table 94 shows multi-slot trunk group support on FastIron X Series devices:

</tbody>
</table>
- On Turbolron X Series devices, port assignment on a module need not be consecutive. The port range can contain gaps. For example, you can configure ports 1, 3, and 4 (excluding 2). Refer to “Flexible trunk group membership” on page 551.
- Port assignment on a module need not be consecutive. The port range can contain gaps. For example, you can configure ports 1, 3, and 4 (excluding 2). Refer to “Flexible trunk group membership” on page 551.
- For FGS devices, trunking is supported on the 1-port 10-GbE module (port 0/3/1).
- Although the FastIron devices have port ranges, they do not apply to trunk groups.
- You can select any port to be the primary port of the trunk group.
- You cannot combine Gbps and 10-Gbps ports in the same trunk group.
- Make sure the device on the other end of the trunk link can support the same number of ports in the link. For example, if you configure a three-port trunk group on the FESX and the other end is a different type of switch, make sure the other switch can support a three-port trunk group.
- All the ports must be connected to the same device at the other end.
- All trunk group member properties must match the lead port of the trunk group with respect to the following parameters:
  - port tag type (untagged or tagged port)
  - statically configured port speed and duplex
  - QoS priority
- To change port parameters, you must change them on the primary port. The software automatically applies the changes to the other ports in the trunk group.
- The following restrictions apply to FWS 624 and FWS 648 products:
  - In FWS 624 and 648 devices, the first four ports are 1 Gbps, the remaining ports are 10/100 Mbps. For these devices, with both static and dynamic (LACP) trunking, all members of the trunk should be either the 1 Gbps ports or the 10/100 Mbps ports.

**Trunk group configuration examples**

Figure 95 shows some examples of valid 2-port trunk group links between devices. The trunk groups in this example are switch trunk groups between two Brocade devices. Ports in a valid 2-port trunk group on one device are connected to two ports in a valid 2-port trunk group on another device. The same rules apply to 3-port, 4-port, etc., trunk groups.
FIGURE 95 Examples of 2-port and 3-port trunk groups

Figure 96 shows examples of two Chassis devices connected by multi-slot trunk groups.
Flexible trunk group membership

This section describes flexible trunk group membership on FastIron devices and Turbolron X Series devices.
FastIron X Series and Turbolron X Series devices

Trunking is supported on non-consecutive ports in a module. For example, you can configure ports 2/4, 2/6, and 2/7 (excluding 2/5) together on a module as a trunk group. In releases prior to the above, the ports in a trunk group must be consecutive. This feature is supported on static and LACP trunk ports, as well as GbE and 10-GbE ports.

Flexible trunk ports follow the same rules as listed in “Trunk group rules” on page 547.

Configuration example
To configure a 4-port trunk with non-consecutive ports, enter a command such as the following.

```
FastIron(config)#trunk ethe 1/7 ethe 1/9 ethe 1/11 ethe 1/21
```

This creates a 4-port trunk group with the following members.

1/7, 1/9, 1/11, 1/21

Syntax: `[no] trunk ethernet [<slotnum>/]<portnum> ethernet [<slotnum>/]<portnum> | to ethernet [<slotnum>/]<portnum>...

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

You can list all of the ports individually, use the keyword to to specify ranges of ports, or a combination of both.

FGS, FWS, and FLS, FGS-STK, FLS-STK and FCX compact switches

These devices support flexible trunk group membership. This feature eliminates the requirement for port membership to be consecutive, and allows the trunking of ports on non-consecutive interfaces. It also allows port 0/3/1 on the FGS624XGP models to be added to a trunk group. This feature is supported on static and LACP trunk ports, as well as GbE and 10-GbE ports.

**NOTE**

Gbps and 10 Gbps ports cannot be grouped together.

Configuration examples
To configure a 4-port trunk on a FastIron GS device, enter the following command.

```
FGS624 Switch(config)#trunk ethe 0/1/7 ethe 0/1/9 ethe 0/1/11 ethe 0/1/21
```

This creates a 4-port trunk group with the following members.

0/1/7, 0/1/9, 0/1/11, 0/1/21

Syntax: `[no] trunk ethernet <port-list>

For `<port-list>`, specify the ports in the format `<stack-unit/slotnum/portnum>`

You can list all of the ports individually, use the keyword to to specify ranges of ports, or a combination of both.

You can configure up to 8 ports in a trunk group (each trunk group should have a minimum of 2 ports). Any number of members between 2 and 8 is supported for 1 Gbps port trunk groups, and a maximum of 2 members for 10 Gbps trunk groups.

The FLS supports the following 10 Gbps trunk groups:
- The FLS624 supports trunks 0/2/1-0/3/1, 0/3/1-0/4/1, or 0/2/1 - 0/4/1
- The FLS648 supports trunks 0/2/1 - 0/3/1

FGS devices support the following 10 Gbps trunk groups:
- The FGS624P supports trunks 0/2/1 - 0/2/2
- The FGS624XGP supports trunks 0/2/1 - 0/2/2, 0/2/1 - 0/3/1, 0/2/2 - 0/3/1
- The FGS648P supports trunks 0/2/1 - 0/2/2

FGS-STK and FLS-STK devices can support a large number of trunk groups across an IronStack.

FWS devices support the following 10 Gbps trunk groups:
- The FWS624 supports trunks 0/2/1-0/3/1, 0/3/1-0/4/1, or 0/2/1 - 0/4/1
- The FWS648 supports trunks 0/2/1 - 0/3/1

**Viewing the first and last ports in a trunk group**

Output for many of the `show` commands will show the first and last port in a trunk as `FirstPort-LastPort`, if the ports are consecutive, and `FirstPort*LastPort` if the ports are not consecutive.

With the configuration above, output from the `show mac` command resembles the following, which shows the first and last ports.

```
FastIron#show mac
Total active entries from all ports = 1
MAC-Address Port Type Index
0007.e910.c201 0/1/7-0/1/21 Dynamic 2920
```

For a trunk group with members 0/1/7 to 0/1/9, the output from the `show mac` command resembles the following.

```
FastIron#show mac
Total active entries from all ports = 1
MAC-Address Port Type Index
0007.e910.c201 0/1/7-0/1/9 Dynamic 2920
```

**Trunk group load sharing**

Unlike other Brocade devices, trunk groups on the FastIron devices and TurboIron X Series devices are not classified as switch trunk groups or server trunk groups.

Brocade devices load-share across the ports in the trunk group. The method used for the load sharing depends on the following:
- Device type – Chassis device or Stackable device
- Traffic type – Layer 2 or Layer 3
- Software version your device is running

**NOTE**
Layer 2 and Layer 3 AppleTalk traffic is not load-balanced. Layer 3 routed IP or IPX traffic also is not load balanced. These traffic types will however still be forwarded on the trunk ports.
**Note regarding IPv6**

Brocade devices that support IPv6 take the IPv6 address for a packet into account when sharing traffic across a trunk group. The load sharing is performed in the same way it is for IPv4 addresses; that is; trunk types for which traffic load is shared based on IPv4 address information can now use IPv6 addresses to make the load sharing decision.

Load sharing occurs as described in Table 95 or Table 96.

**Load sharing for unknown unicast, multicast, and broadcast traffic**

Brocade devices load balance unknown unicast, multicast, and broadcast traffic based on the source port and VLAN ID and not on any source or destination information in the packet.

For example, when the switch receives unknown unicast, multicast, and broadcast packets, and the packets are from the same source port, the packets are forwarded to the same port of the trunk group. Conversely, when the switch receives unknown unicast, multicast, and broadcast packets, and the packets are from different source ports, the packets are load-balanced across all the ports of the trunk group.

Note that this does not apply to known unicast traffic, which is always load balanced across all the ports of a trunk group based on the traffic's Layer 2 and Layer 3 source and destination parameters.

**How trunk load sharing works**

Load balancing procedures differ depending on the software version your device is running. In earlier releases, the Brocade device load balances all bridged traffic based on source and destination MAC addresses. In subsequent releases, the load balancing method for bridged traffic varies depending on the traffic type.

**NOTE**

There is no change in load balancing for routed traffic, which is always based on the source and destination IP addresses and protocol field (not applicable for FastIron GS and FastIron LS).

**NOTE**

Table 95 through Table 99 show how the different Brocade devices load balance traffic.

Table 95 shows how the FastIron X Series devices load balance traffic across the ports in a trunk group, if the device is running FESX/FWSX software release 02.2.00 or later or FSX software release 02.1.00 or later.

**NOTE**

Table 95 does not include unknown unicast, multicast, and broadcast traffic. Refer to “Load sharing for unknown unicast, multicast, and broadcast traffic”
Table 95 shows how the FESX and FSX load balance traffic across the ports in a trunk group, if the device is running a FESX/FWSX software release prior to 02.2.00 or a FSX software release prior to 02.1.00.

**Note**
Table 96 does not include unknown unicast, multicast, and broadcast traffic. Refer to “Load sharing for unknown unicast, multicast, and broadcast traffic”

Table 96 shows how the FESX and FSX load balance traffic across the ports in a trunk group, if the device is running a FESX/FWSX software release prior to 02.2.00 or a FSX software release prior to 02.1.00.

Table 98 describes how the TurboIron X Series devices load balance traffic.
Configuring a trunk group

1. Disconnect the cables from those ports on both systems that will be connected by the trunk group. Do not configure the trunk groups with the cables connected.

**NOTE**
If you connect the cables before configuring the trunk groups and then reboot, the traffic on the ports can create a spanning tree loop.

2. Configure the trunk group on one of the two Layer 2 Switches or Layer 3 Switches involved in the configuration.

**NOTE**
Downtime is incurred when adding a new port to a trunk group. It is suggested that you schedule the addition of ports to a trunk group to minimize downtime and its impact to the production network.

3. Save the configuration changes to the startup-config file.

## Adding Layer 2 information to trunk hash output

FastIron devices support the option to include Layer 2 information in the trunk hash calculation for IP packets. Use the following new CLI command.

**Syntax:** [no] trunk hash-options include-layer2

This command adds Layer 2 information (text in bold) to the following load-balancing parameters.

1. Non-IP: Source MAC, Destination MAC
2. IPv4 TCP/UDP: Source IP, Destination IP, Source TCP/UDP Port, Destination TCP/UDP Port, **Source MAC, Destination MAC**
3. IPv4 Non-TCP/UDP: Source IP, Destination IP, **Source MAC, Destination MAC**
4. IPv6 TCP/UDP: Source IP, Destination IP, Flow Label, Source TCP/UDP Port, Destination TCP/UDP Port, **Source MAC, Destination MAC**
5. IPv6 Non-TCP/UDP: Source IP, Destination IP, Flow Label, **Source MAC, Destination MAC**

## Configuring a trunk group

Follow the steps given below to configure a trunk group.

1. Disconnect the cables from those ports on both systems that will be connected by the trunk group. Do not configure the trunk groups with the cables connected.

**NOTE**
If you connect the cables before configuring the trunk groups and then reboot, the traffic on the ports can create a spanning tree loop.

2. Configure the trunk group on one of the two Layer 2 Switches or Layer 3 Switches involved in the configuration.

**NOTE**
Downtime is incurred when adding a new port to a trunk group. It is suggested that you schedule the addition of ports to a trunk group to minimize downtime and its impact to the production network.

3. Save the configuration changes to the startup-config file.
4. Dynamically place the new trunk configuration into effect by entering the **trunk deploy** command at the global CONFIG level of the CLI.

5. If the device at the other end of the trunk group is another Layer 2 Switch or Layer 3 Switch, repeat Steps 2 – 4 for the other device.

6. When the trunk groups on both devices are operational, reconnect the cables to those ports that are now configured as trunk groups, starting with the first port (lead port) of each trunk group.

7. To verify the link is operational, use the **show trunk** command.

### CLI syntax

The following is the CLI syntax for creating a trunk group. Configuration examples are shown in later sections of this chapter.

**Syntax:**

```
[no] trunk ethernet [stack-unit]/[slotnum]/primary-portnum to [slotnum]/portnum [ethernet stack-unit]/[slotnum]/primary-portnum to [stack-unit]/[slotnum]/portnum
```

**Syntax:** **trunk deploy**

Each **ethernet** parameter introduces a port group. Enter the slot number (if applicable) and the port number of the Ethernet port.

The **<stack-unit>** parameter is required on FGS and FLS devices running software release 03.0.00 and later, FWS devices running software release 04.3.00 and later and FGS and FLS stackable devices. Refer to “Configuring trunk groups for FastIron stackable devices” on page 559.

The **<slotnum>** parameter is required on chassis devices.

The **<primary-portnum> to <portnum>** parameters specify a port group. Notice that each port group must begin with a primary port. After you enter this command, the primary port of the first port group specified (which must be the group with the lower port numbers) becomes the primary port for the entire trunk group.

To configure a trunk group consisting of two groups of two ports each, enter commands such as the following.

```
FastIron(config)#trunk ethernet 1/1 to 1/2 ethernet 3/3 to 3/4
Trunk will be created in next trunk deploy
FastIron(config)#write memory
FastIron(config)#trunk deploy
```

**Example 1: Configuring the trunk groups shown in Figure 93**

To configure the trunk groups shown in **Figure 93**, enter the following commands. Notice that the commands are entered on multiple devices.

To configure the trunk group link between FSX1 and the FESX, enter the following commands.

---

**NOTE**

The text shown in italics in the CLI example below shows messages echoed to the screen in answer to the CLI commands entered.
Configuring a trunk group

Example 2: Configuring a trunk group that spans two Gbps Ethernet modules in a chassis device

This section shows how to configure a trunk group that spans two modules in a chassis device.

Multi-slot trunk groups are supported on 1-GbE ports, 10-GbE ports (starting in software release FSX 03.2.00), as well as on static and LACP trunk ports. For multi-slot trunk group rules, refer to Table 94 on page 548.

To configure a trunk group consisting of two groups of ports, 1/1 – 1/2 on module 1 and 4/5 – 4/6 on module 4, enter the following commands.

```
FastIron(config)#trunk ethernet 1/1 to 1/2 ethernet 4/5 to 4/6
Trunk will be created in next trunk deploy
FastIron(config)#write memory
FastIron(config)#trunk deploy
```

**NOTE**
The `trunk deploy` command dynamically places trunk configuration changes into effect, without a software reload.

Example 3: Configuring a multi-slot trunk group with one port per module

You can select one port per module in a multi-slot trunk group. Software releases prior to 04.0.00 support a minimum of two ports per module in a multi-slot trunk group.

This feature is supported on GbE and 10-GbE ports, as well as on static and LACP trunk ports. For multi-slot trunk group rules, refer to Table 94 on page 548.

To configure a two-port multi-slot trunk group consisting of ports 1/1 on module 1 and 2/1 on module 2, enter the following commands.

```
FastIron(config)#trunk e 1/5 to 1/8
Trunk will be created in next trunk deploy
FastIron(config)#write memory
FastIron(config)#trunk deploy
```

To configure the trunk group link between FSX2 and the server, enter the following commands.

```
FastIron(config)#trunk e 1/2 to 1/4
Trunk will be created in next trunk deploy
FastIron(config)#write memory
FastIron(config)#trunk deploy
```

You then configure the trunk group on the FESX.

```
FastIron(config)#trunk ethernet 17 to 18
Trunk will be created in next trunk deploy
FastIron(config)#write memory
FastIron(config)#trunk deploy
```

**NOTE**
The `trunk deploy` command dynamically places trunk configuration changes into effect, without a software reload.
Configuring a trunk group

Example 4: Configuring a trunk group of 10 Gbps Ethernet ports

You can configure 10 Gbps Ethernet ports together in a trunk group.

To configure a trunk group containing two 10 Gbps Ethernet ports, enter commands such as the following.

```plaintext
FastIron(config)#trunk ethernet 1/1 to 2/1
Trunk will be created in next trunk deploy
FastIron(config)#write memory
FastIron(config)#trunk deploy
```

Notice that the groups of ports meet the criteria for a multi-slot trunk group. Each group contains the same number of ports (two) and begins on a primary port (1/1 and 3/3).

Syntax: 
```
```

Syntax: trunk deploy

The <stack-unit> parameter is required on FGS and FLS devices running software release 03.0.00 and later, FWS devices running software release 04.3.00 and later and FGS and FLS stackable devices. Refer to “Configuring trunk groups for FastIron stackable devices” on page 559.

The <primary-portnum> parameter specifies the trunk group primary port.

The <secondary-portnum> parameter specifies the secondary port in the trunk group.

NOTE
Two-port trunk groups are supported for 10 Gbps Ethernet. You cannot specify more than two ports.

To display configuration information and load-sharing statistics for the trunk group, enter the show trunk command. Refer to “Displaying trunk group configuration information” on page 565.

Configuring trunk groups for FastIron stackable devices

In a Brocade IronStack system, a trunk group may have port members distributed across multiple stack units. Both static and dynamic trunking are supported.

NOTE
Cascaded trunks between stack units are not currently supported.

CLI syntax for IronStack devices

Syntax: 
```
```

FastIron and TurboIron 24X Configuration Guide
53-1001719-01
Configuring a trunk group

- `<stack-unit>` - the number of the stack unit (1-8)
- `<slotnum>` - a specific slot number for the stack unit
- `<primary-portnum>` to `<portnum>` - These parameters specify a port group. Each port group must begin with a primary port. The primary port of the first port group specified in the command (the group with the lowest port numbers) becomes the primary port for the entire trunk. The `<stack-unit>` and `<slotnum>` parameters are required for members of an IronStack.

IronStack static trunk group configuration notes

These notes apply to FGS-STK, FLS-STK, and FCX devices.

- If a stack unit fails, or is removed from the stack its static trunk configuration becomes a reserved configuration on the Active Controller. Any remaining ports of the static trunk in the IronStack continue to function.
- When a new stack unit is added to an IronStack, the new unit receives running configuration and trunk-related information, including a list of ports that are up and are members of a trunk, from the Active Controller.
- Before merging two IronStacks, make sure that there are no static trunks configured between them. This can result in self-looped ports.
- When an IronStack with static trunks partitions into multiple IronStacks, loops and forwarding errors may occur. In these cases, user intervention is required to remove the loops.
- 10 Gbps links support up to eight ports in a trunk for stackable units.

Static trunk group configuration for an IronStack

The following example shows how to configure a static trunk group for units in an IronStack.

```
STK1(config)#trunk ethe 1/1/1 ethe 2/1/4 ethe 3/1/7 ethe 4/1/2 ethe 5/1/5 ethe 6/1/7 ethe 7/1/2 ethe 7/1/5
Trunk will be created in next trunk deploy.
STK1(config)#trunk deploy
STK1(config)#show trunk
```

Configured trunks:

Link_Status   active  active  active  active  active  active  active  active
port_state    Forward Forward Forward Forward Forward Forward Forward Forward

**Additional trunking options**

The following trunking options can be performed on ports in deployed trunks. These options are supported on static trunk ports. Except where noted, these options are also supported on dynamic (LACP) trunk ports on FastIron X Series devices starting in release FSX 04.3.00. Note that these options are not supported on LACP trunk ports on Turbolron Series devices.

The additional trunking options are as follows:

- Naming a trunk port
- Disabling or re-enabling a trunk port
- Deleting a static trunk group (applies to static trunks only)
- Specifying the minimum number of ports in a trunk group (applies to static trunks only)
- Monitoring a trunk port
- Configuring outbound rate shaping on a trunk port
- Enabling sFlow forwarding on an individual port in a trunk
- Setting the sFlow sampling rate on an individual port in a trunk

**NOTE**

Depending on the operational state of LACP-enabled ports, at any time, these ports may join a trunk group, change trunk group membership, exit a trunk group, or possibly never join a trunk group. Therefore, before configuring trunking options on LACP-enabled ports (e.g., naming the port, disabling the port, etc.), verify the actual trunk group port membership using the `show trunk` command. To view the status of LACP, use the `show link-aggregate` command.

**Naming a trunk port**

To name an individual port in a trunk group, enter a command such as the following at the trunk group configuration level.

```
FastIron(config)#trunk e 4/1 to 4/4
FastIron(config-trunk-4/1-4/4)#port-name customer1 ethernet 4/2
```

This command assigns the name “customer1” to port 4/2 in the trunk group consisting of ports 4/1 – 4/4.

**Syntax:** `[no] port-name <ASCII string> ethernet [stack-unit]/[slotnum]/portnum

The `<ASCII string>` parameter specifies the port name. The name can be up to 49 characters long. The `<stack-unit>` parameter is required for FGS, FLS, FGS-STK and FLS-STK, and FCX devices. The `<slotnum>` parameter is required for chassis devices.
The `<portnum>` parameter is a valid port in the trunk group.

**Disabling or re-enabling a trunk port**

This feature is supported on individual ports of a static trunk group.

You can disable or re-enable individual ports in a trunk group. To disable an individual port in a trunk group, enter commands such as the following at the trunk group configuration level.

```
FastIron(config)#trunk e 4/1 to 4/4
FastIron(config-trunk-4/1-4/4)#config-trunk-ind
FastIron(config-trunk-4/1-4/4)#disable ethernet 4/2
```

**Syntax:** `[no] config-trunk-ind

**Syntax:** `[no] disable ethernet [<stack-unit>/<slotnum>/<portnum>]

The `<stack-unit>` parameter is required for FGS, FLS, FGS-STK and FLS-STK, and FCX devices.

The `config-trunk-ind` command enables configuration of individual ports in the trunk group. If you do not use this command, the `disable` and `enable` commands will be valid only for the primary port in the trunk group and will disable or enable all ports in the trunk group. You need to enter the `config-trunk-ind` command only once in a trunk group. After you enter the command, all applicable port configuration commands apply to individual ports only.

**NOTE**

If you enter `no config-trunk-ind`, all port configuration commands are removed from the individual ports and the configuration of the primary port is applied to all the ports. Also, once you enter the `no config-trunk-ind` command, the `enable`, `disable`, and `monitor` commands are valid only on the primary port and apply to the entire trunk group.

The `disable` command disables the port. The states of other ports in the trunk group are not affected.

If you have configured a name for the trunk port, you can specify the port name, as shown in the following example.

```
FastIron(config-trunk-4/1-4/4)#config-trunk-ind
FastIron(config-trunk-4/1-4/4)#disable customer1
```

**Syntax:** disable `<portname>`

To enable an individual port in a trunk group, enter commands such as the following at the trunk group configuration level.

```
FastIron(config-trunk-4/1-4/4)#config-trunk-ind
FastIron(config-trunk-4/1-4/4)#enable ethernet 4/2
```

**Syntax:** enable ethernet [<stack-unit>/<slotnum>/<portnum>]

The `<stack-unit>` parameter is required for FGS, FLS, FGS-STK and FLS-STK, and FCX devices.

**Syntax:** enable `<portname>`

**Disabling or re-enabling a range or list of trunk ports**

To disable a range of ports in a trunk group, enter commands such as the following:

```
FastIron(config)#trunk ethernet 2/1 to 2/4
FastIron(config-trunk-2/1-2/4)#config-trunk-ind
FastIron(config-trunk-2/1-2/4)#disable ethernet 2/3 to 2/4
```
This command disables ports 2/3 – 2/4 in trunk group 2/1 – 2/4.

To disable a list of ports, enter a command such as the following.

```
FastIron(config-trunk-2/1-2/4)#disable ethernet 2/1 ethernet 2/3 ethernet 2/4
```

This command disables ports 2/1, 2/3, and 2/4 in the trunk group.

You can specify a range and a list on the same command line. For example, to re-enable some trunk ports, enter a command such as the following.

```
FastIron(config-trunk-2/1-2/4)#enable ethernet 2/1 to 2/2 ethernet 2/4
```

Syntax: 
```
[no] config-trunk-ind
```

Syntax: 
```
[no] disable ethernet [<stack-unit>]/<slotnum>/| ethernet [<slotnum>] <portnum>
```

Syntax: 
```
[no] enable ethernet [<stack-unit>]/<slotnum>/| ethernet [<slotnum>] <portnum>
```

The `<stack-unit>` parameter is required for FGS, FLS, FGS-STK and FLS-STK, and FCX devices.

The `<slotnum>` parameter is required on chassis devices.

The to `<portnum>` parameter indicates that you are specifying a range. Specify the lower port number in the range first, then to, then the higher port number in the range.

The `<portnum>` parameter specifies an individual port. You can enter this parameter multiple times to specify a list, as shown in the examples above.

### Modifying Trunk Group Membership

You can change port membership by removing individual ports from the trunk group. To remove a port from a trunk group, use one of the following methods.

**NOTE**
Removing individual trunk ports is supported only on the ServerIron.

**USING THE CLI**

To remove ports 1/3 and 1/4 from the trunk group, enter the following command:

```
FESX Router(config)# no trunk ethernet 1/3 to 1/4
```

Syntax: 
```
no trunk ethernet | pos <portnum> [to <portnum>]
```

The `<portnum>` parameter indicates the port you are removing.

**NOTE**
Make sure you enter the lower port in the range before the “to” and the higher port in the range after the “to”.

As a shortcut, you also can enter just the lower port in the range. The software automatically removes all higher ports in addition to the specified port. For example, to remove ports 1/3 and 1/4, you can enter the following command:

```
FESX Router(config)# no trunk ethernet 1/3
```

The rules regarding trunk group membership are the same as in earlier software releases.

Therefore, for trunk group 1/1 – 1/4, the following commands are not valid:

```
FESX Router(config)# no trunk ethernet 1/2
```
Or

FESX Router(config)# no trunk ethernet 1/2 to 1/4
These commands are invalid because the trunk group cannot contain only a single port. These commands, if the software allowed them, would result in a trunk group consisting only of port 1/1.

On most devices, trunk groups can contain two ports or four ports but cannot contain only three ports. Therefore, the following command also is invalid for trunk group 1/1 – 1/4:

FESX Router(config)# no trunk ethernet 1/4
This command is invalid because it would result in a trunk group containing three ports, 1/1 – 1/3.

Deleting a static trunk group

Use the no trunk ethernet command to delete a static trunk group.

NOTE
To delete an LACP trunk group, use the CLI command no link-aggregate active | passive.

To delete a trunk group, use no in front of the command you used to create the trunk group. For example, to remove one of the trunk groups configured in the examples above, enter the following command.

FastIron(config)# no trunk ethernet 1/1 to 1/2 ethernet 3/3 to 3/4
Syntax: no trunk ethernet | pos [<stack-unit>[/<slotnum>[/]<portnum> to </stack-unit>[/<slotnum>[/]<portnum>]

The <stack-unit> parameter is required for FGS, FLS, FGS-STK and FLS-STK, and FCX devices.

The <slotnum> parameter is required on chassis devices.

Specifying the minimum number of ports in a static trunk group

You can configure Brocade devices to disable all of the ports in a trunk group when the number of active member ports drops below a specified threshold value. For example, if a trunk group has 4 ports, and the threshold for the trunk group is 3, then the trunk group is disabled if the number of available ports in the trunk group drops below 3. If the trunk group is disabled, then traffic is forwarded over a different link or trunk group.

For example, the following commands establish a trunk group consisting of 4 ports, then establish a threshold for this trunk group of three ports.

FastIron(config)# trunk e 3/31 to 3/34
FastIron(config-trunk-3/31-3/34)# threshold 3

In this example, if the number of active ports drops below three, then all the ports in the trunk group are disabled.

Syntax: [no] threshold <number>

• <number> - Specify a threshold number from 2 (default) up to the number of ports in a trunk group. The total number of threshold ports must be greater than 1.

NOTE
When using the no threshold command, it is not necessary to enter a number.
Configuration notes:

- This feature is supported on static trunk groups only. It is not supported on LACP trunk groups.
- When UDLD is enabled on a trunk port, trunk threshold is not supported.
- The disable module command can be used to disable the ports on a module. However, on 10 Gbps modules, the disable module command does not cause the remote connection to be dropped. If a trunk group consists of 10 Gbps ports, and you use the disable module command to disable ports in the trunk group, which then causes the number of active ports in the trunk group to drop below the threshold value, the trunk group is not disabled.
- If you establish a threshold for a trunk used in conjunction with Metro Ring Protocol (MRP) on 10 Gbps interfaces, then you must also enable Link Fault Signaling (LFS).
- If you specify a threshold for a trunk group, the other end of the trunk group must also have the same threshold configuration.

Monitoring a trunk port

You can monitor the traffic on an individual port of a static trunk group. For configuration details, refer to “Monitoring an individual trunk port” on page 726.

Configuring outbound rate shaping for a trunk port

You can configure the maximum rate at which outbound traffic is sent out on a static trunk port. For configuration details, refer to “Configuring outbound rate shaping for a trunk port” on page 760.

Enabling sFlow forwarding on a trunk port

You can enable sFlow forwarding on individual ports of a static trunk group. For configuration details, refer to “Enabling sFlow forwarding on individual trunk ports” on page 1752.

Setting the sFlow sampling rate on a trunk port

You can configure an individual trunk port to use a different sampling rate than the global default sampling rate. This feature is supported on static trunk ports. For configuration details, refer to “Changing the sampling rate for a trunk port” on page 1751.

Displaying trunk group configuration information

To display configuration information for the trunk groups, use the show trunk command. This command displays information for configured trunk groups and operational trunk groups. A configured trunk group is one that has been configured in the software but has not been placed into operation by a reset or reboot. An operational trunk group is one that has been placed into operation by a reset or reboot.

Enter the show trunk command at any CLI level.

Syntax: show trunk [ethernet | pos [<stack-unit>/<slotnum>/]<portnum> to [<slotnum>/]<portnum>]

The <stack-unit> parameter is required for FGS, FLS, FGS-STK and FLS-STK, and FCX devices.

The <slotnum> applies to chassis devices only.
NOTE
The `show trunk` command does not display any form of trunk when links are up.

FastIron#show trunk

Dynamic link aggregation

Brocade software supports the IEEE 802.3ad standard for link aggregation. This standard describes the Link Aggregation Control Protocol (LACP), a mechanism for allowing ports on both sides of a redundant link to form a trunk link (aggregate link), without the need for manual configuration of the ports into trunk groups.

When you enable link aggregation on a group of Brocade ports, the Brocade ports can negotiate with the ports at the remote ends of the links to establish trunk groups.

The link aggregation feature automates trunk configuration but can coexist with the Brocade trunk group feature. Link aggregation parameters do not interfere with trunk group parameters.

NOTE
Use the link aggregation feature only if the device at the other end of the link you want to aggregate also supports IEEE 802.3ad link aggregation. Otherwise, you need to manually configure the trunk links.

Link aggregation support is disabled by default. You can enable the feature on an individual port basis, in active or passive mode:

- **Active mode** – When you enable a port for active link aggregation, the Brocade port can exchange standard LACP Protocol Data Unit (LACPDU) messages to negotiate trunk group configuration with the port on the other side of the link. In addition, the Brocade port actively sends LACPDU messages on the link to search for a link aggregation partner at the other end of the link, and can initiate an LACPDU exchange to negotiate link aggregation parameters with an appropriately configured remote port.

- **Passive mode** – When you enable a port for passive link aggregation, the Brocade port can exchange LACPDU messages with the port at the remote end of the link, but the Brocade port cannot search for a link aggregation port or initiate negotiation of an aggregate link. Thus, the port at the remote end of the link must initiate the LACPDU exchange.

</tr>
</tbody>
</table>
NOTE
Brocade recommends that you disable or remove the cables from the ports you plan to enable for dynamic link aggregation. Doing so prevents the possibility that LACP will use a partial configuration to talk to the other side of a link. A partial configuration does not cause errors, but does sometimes require LACP to be disabled and re-enabled on both sides of the link to ensure that a full configuration is used. It's easier to disable a port or remove its cable first. This applies both for active link aggregation and passive link aggregation.

FGS-STK and FLS-STK devices support LACP. The following rules apply to units in an IronStack:

- With LACP trunk configurations, the LACP system id is the MAC address of the Active Controller. If the LACP system id changes, the entire trunk flaps and an STP re-convergence occurs.
- Link aggregation can be used to form multi-slot aggregate links on stack units, but the link aggregation keys must match for the port groups on each stack unit. For example, to configure an aggregate link containing ports 1/1/1 through 1/1/4, and 3/1/5 through 3/1/8, you must change the link aggregation key on one or both port groups so that the key is the same for all 8 ports. See the following example.

IronStack LACP trunk group configuration example

To configure a trunk group consisting of two groups of two ports each on an IronStack, enter commands similar to the following.

FGS648 Switch(config)#interface ethernet 1/1/1 to 1/1/4
FGS648 Switch(config-mif-1/1/1-1/1/4)#link-aggregate off
FGS648 Switch(config-mif-1/1/1-1/1/4)#link-aggregate configure key 10000
FGS648 Switch(config-mif-1/1/1-1/1/4)#link-aggregate active
FGS648 Switch(config-mif-1/1/1-1/1/4)#interface ethernet 3/1/5 to 3/1/8
FGS648 Switch(config-mif-3/1/5-3/1/8)#link-aggregate off
FGS648 Switch(config-mif-3/1/5-3/1/8)#link-aggregate configure key 10000
FGS648 Switch(config-mif-3/1/5-3/1/8)#link-aggregate active

This command sequence changes the key for ports 1/1/1-1/1/4 and 3/1/5-3/1/8 to 10000. Since all ports in an aggregate link must have the same key, this example forms a multi-slot aggregate link for ports 1/1/1-1/1/4 and 3/1/5-3/1/8.

Examples of valid LACP trunk groups

Brocade ports follow the same configuration rules for dynamically created aggregate links as they do for statically configured trunk groups. Refer to “Trunk group rules” on page 547 and “Trunk group load sharing” on page 553.

Figure 98 on page 569 shows some examples of valid aggregate links.
In this example, assume that link aggregation is enabled on all of the links between the Brocade device on the left and the device on the right (which can be either a Brocade device or another vendor device). The ports that are members of aggregate links in this example are following the configuration rules for trunk links on Brocade devices.

The Brocade rules apply to a Brocade device even if the device at the other end is from another vendor and uses different rules. Refer to “Trunk group rules” on page 547.

**Configuration notes and limitations**

This section lists the configuration considerations and limitations for dynamic link aggregation.
**FastIron GS, FastIron LS, and FastIron CX devices**

The following notes and feature limitations apply to the FGS, and FLS, FGS-STK and FLS-STK, and FCX devices:

- The dynamic link aggregation (802.3ad) implementation allows any number of ports up to eight to be aggregated into a link.

- The default key assigned to an aggregate link is based on the port type (1 Gbps port or 10 Gbps port). The FastIron GS assigns different keys to 10 Gbps ports than on 1 Gbps ports so that ports with different physical capabilities will not be able to form a trunk.

**NOTE**
The trunks that will be formed by link aggregation will strictly adhere to the static trunking rules on the FGS, FLS, FGS-STK, FLS-STK and FCX devices. Be careful in selecting keys if you are manually configuring link aggregation keys. Make sure that the possible trunks that you expect to be formed conform to the static trunking rules.

- When you enable link aggregation (LACP) on a group of Brocade ports, you must also assign a unique key (other than the default key) to all of the ports in the aggregate link.

- 10 Gbps links only support two port trunks.

**NOTE**
It is recommended to disable the link aggregation on ports before you disable link aggregation.

**IronStack dynamic trunk group (LACP trunk) notes**

- If a stack unit fails, or is removed from the stack, its LACP configuration becomes a reserved configuration on the Active Controller. Any remaining ports of the dynamic trunk in the IronStack continue to function.

- Merging two IronStacks with a dynamic trunk configured between them results in self-looped ports, which are detected and corrected by the Spanning Tree Protocol (STP). LACP configuration on the winning Active Controller is not affected by the LACP configuration on the losing Active Controller is lost after the merge.

- When an IronStack with dynamic trunks partitions into multiple IronStacks, the protocol will take care of splitting the dynamic trunk in the partner. No user intervention is required.

**FastIron X Series devices**

The following notes and feature limitations apply to the FastIron X Series devices:

- You cannot use 802.3ad link aggregation on a port configured as a member of a static trunk group.

- The dynamic link aggregation (802.3ad) implementation on FastIron X Series devices allows different numbers of ports to be aggregated in a link, depending on the hardware type (IPv6 or IPv4) and the software version running on the device. For details, refer to Table 93 on page 547.

- The default key assigned to an aggregate link is based on the port type (1 Gbps port or 10 Gbps port). The Brocade device assigns different keys to 10 Gbps ports than on 1 Gbps ports so that ports with different physical capabilities will not be able to form a trunk.
**NOTE**
The trunks that will be formed by link aggregation will strictly adhere to the static trunking rules on the Brocade device. Be careful in selecting keys if you are manually configuring link aggregation keys. Make sure that the possible trunks that you expect to be formed conform to the static trunking rules.

- When the feature dynamically adds or changes a trunk group, the `show trunk` command displays the trunk as both configured and active. However, the `show running-config` or `write terminal` command does not contain a trunk command defining the new or changed trunk group.
- If the feature places a port into a trunk group as a secondary port, all configuration information except information related to link aggregation is removed from the port. For example, if port 1/3 has an IP interface, and the link aggregation feature places port 1/3 into a trunk group consisting of ports 1/1 – 1/4, the IP interface is removed from the port.
- If you use this feature on a Layer 3 Switch that is running OSPF or BGP4, the feature causes these protocols to reset when a dynamic link change occurs. The reset includes ending and restarting neighbor sessions with OSPF and BGP4 peers, and clearing and relearning dynamic route entries and forwarding cache entries. Although the reset causes a brief interruption, the protocols automatically resume normal operation.
- Starting with software release FSX 02.4.00, you can enable link aggregation on 802.1Q tagged ports (ports that belong to more than one port-based VLAN). In releases prior to 02.4.00, link aggregation works with untagged ports only.

**NOTE**
It is recommended to disable the link aggregation on ports before you disable link aggregation.

**TurboIron X Series devices**
The following notes and feature limitations apply to the TurboIron X Series devices:

- You cannot use 802.3ad link aggregation on a port configured as a member of a static trunk group.
- The dynamic link aggregation (802.3ad) implementation on TurboIron X Series devices allows any number or ports up to eight to be aggregated into a link.
- The default key assigned to an aggregate link is based on the port type (1 Gbps port or 10 Gbps port). The Brocade device assigns different keys to 10 Gbps ports than on 1 Gbps ports so that ports with different physical capabilities will not be able to form a trunk.

**NOTE**
The trunks that will be formed by link aggregation will strictly adhere to the static trunking rules on the Brocade device. Be careful in selecting keys if you are manually configuring link aggregation keys. Make sure that the possible trunks that you expect to be formed conform to the static trunking rules.

- When the feature dynamically adds or changes a trunk group, the `show trunk` command displays the trunk as both configured and active. However, the `show running-config` or `write terminal` command does not contain a trunk command defining the new or changed trunk group.
• If the feature places a port into a trunk group as a secondary port, all configuration information except information related to link aggregation is removed from the port. For example, if port 3 has an IP interface, and the link aggregation feature places port 3 into a trunk group consisting of ports 1 – 4, the IP interface is removed from the port.

**NOTE**
Unique Key should be configured for each group of ports that have differing VLAN membership, regardless of being tagged or untagged.

• If you use this feature on a Layer 3 Switch that is running OSPF or BGP4, the feature causes these protocols to reset when a dynamic link change occurs. The reset includes ending and restarting neighbor sessions with OSPF and BGP4 peers, and clearing and relearning dynamic route entries and forwarding cache entries. Although the reset causes a brief interruption, the protocols automatically resume normal operation.

• You can enable link aggregation on 802.1Q tagged ports (ports that belong to more than one port-based VLAN).

**NOTE**
It is recommended to disable the link aggregation on ports before you disable link aggregation.

### Adaptation to trunk disappearance

The Brocade device will tear down an aggregate link if the device at the other end of the link reboots or brings all the links down. Tearing the aggregate link down prevents a mismatch if the other device has a different trunk configuration following the reboot or re-establishment of the links. Once the other device recovers, 802.3 can renegotiate the link without a mismatch.

### Flexible trunk eligibility

The criteria for trunk port eligibility in an aggregate link are flexible. A range of ports can contain down ports and still be eligible to become an aggregate link.

Software release 07.6.01b also increases the tolerance for down ports during link negotiation. In previous releases, all the ports in a valid trunk configuration (2-port, 4-port, or 8-port trunk starting on a valid primary port number) need to be up. Thus, in previous releases, if you enable link aggregation on four ports but one of the ports is down, the device will negotiate based only on a valid two-port trunk group consisting of two of the up ports. For example, if you enable link aggregation on ports 1/1 - 1/4 and port 1/3 is down, 802.3ad will negotiate only for a two-port link consisting of ports 1/1 and 1/2.

In release 07.6.01b and later, the device places the ports into 2-port groups by default, consisting of an odd-numbered port and the next even-numbered port. For example, ports 1/1 and 1/2 are a two-port group, as are ports 1/3 and 1/4, 9/1 and 9/2, and so on. If either of the ports in a two-port group is up, the device considers both ports to be eligible to be in an aggregate link.

**Figure 99** shows an example of 2-port groups in a range of four ports on which link aggregation is enabled. Based on the states of the ports, some or all of them will be eligible to be used in an aggregate link.
Table 100 shows examples of the ports from Figure 99 that will be eligible for an aggregate link based on individual port states.

</tbody>
</table>

As shown in these examples, all or a subset of the ports within a port range will be eligible for formation into an aggregate link based on port states. Notice that the sets of ports that are eligible for the aggregate link must be valid static trunk configurations.

**Enabling dynamic link aggregation**

By default, link aggregation is disabled on all ports. To enable link aggregation on a set of ports, enter commands such as the following at the Interface configuration level of the CLI.
NOTE
Configuration commands for link aggregation differ depending on whether you are using the default link aggregation key automatically assigned by the software, or if you are assigning a different, unique key. Follow the commands below, according to the type of key you are using. For more information about keys, refer to “Key” on page 577.

**Using the default key assigned by the software**

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-e1000-1/1)#link-aggregate active
FastIron(config)#interface ethernet 1/2
FastIron(config-if-e1000-1/2)#link-aggregate active
```

The commands in this example enable the active mode of link aggregation on ports 1/1 and 1/2. The ports can send and receive LACPDU messages. Note that these ports will use the default key, since one has not been explicitly configured.

**NOTE**
In conformance with the 802.3ad specification, the default key assigned to an aggregate link is based on the port type (1 Gbps port or 10 Gbps port). The Brocade device assigns different keys to 10 Gbps ports than 1 Gbps ports, so that ports with different physical capabilities will not be able to form a trunk.

**Assigning a unique key**

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-e1000-1/1)#link-aggregate configure key 10000
FastIron(config-if-e1000-1/1)#link-aggregate active
FastIron(config)#interface ethernet 1/2
FastIron(config-if-e1000-1/2)#link-aggregate configure key 10000
FastIron(config-if-e1000-1/2)#link-aggregate active
```

The commands in this example assign the key 10000 and enable the active mode of link aggregation on ports 1/1 and 1/2. The ports can send and receive LACPDU messages.

**NOTE**
As shown in this example, when configuring a key, it is pertinent that you assign the key prior to enabling link aggregation.

The following commands enable passive link aggregation on ports 1/5 – 1/8.

```
FastIron(config)#interface ethernet 1/5 to 1/8
FastIron(config-mif-1/5-1/8)#link-aggregate passive
```

The commands in this example enable the passive mode of link aggregation on ports 1/5 – 1/8. These ports wait for the other end of the link to contact them. After this occurs, the ports can send and receive LACPDU messages.

To disable link aggregation on a port, enter a command such as the following.

```
FastIron(config-if-e1000-1/8)# link-aggregate
Syntax: [no] link-aggregate <active | passive>
```

**Syntax:**

- `[no] link-aggregate <active | passive>`
- `[no] link-aggregate configure [system-priority <num>] | [port-priority <num>] | [key <num>]`
NOTE
For more information about keys, including details about the syntax shown above, refer to “Key” on page 577.

Dynamic Operation of Allocation Keys
Starting with software release 07.7.00, the Brocade device dynamically changes a port key based on changes to the port VLAN membership.

When you change a port VLAN membership, the device searches through existing key groups for a port with matching port properties. Specifically, it searches for a match on all three of the following properties:

- VLAN ID
- default key
- port tag type (tagged or untagged)

If it finds a match, the port (whose VLAN membership you are changing) gets the matching port key. If it does not find a match, the port gets a new key.

NOTE
For multi-slot trunk groups, you must manually configure the keys in the trunk group(s) to match. For instructions on configuring keys manually, see “Configuring keys for ports with link aggregation enabled” on page 580.

How changing the VLAN membership of a port affects trunk groups and dynamic keys

When you change a port VLAN membership and the port is currently a member of a trunk group, the following changes occur to the trunk group:

- The Brocade device tears down the existing trunk group.
- All ports in the trunk group get a new key.
- The new key group aggregates into a new trunk group.

When you change a port VLAN membership, and the port is not a member of a trunk group, the following changes occur:

- The port gets a new key depending on changes to the port VLAN tag type, as follows:
  - Tagged to Tagged VLAN – The primary port of the trunk group gets a new key.
  - Tagged to Untagged VLAN – The port gets the default key for untagged ports.
  - Untagged to Tagged VLAN – If the Brocade device finds a port with matching port properties, the port gets that port key. If it does not find one, the port gets a new key.
  - Untagged to Untagged VLAN – The port gets a new key depending on whether it is in the default VLAN or not. If there is a trunk group associated with the key, it is not affected.
- All other ports keep their existing key.
- The new key groups try to aggregate into trunk groups.
**Additional trunking options for LACP trunk ports**

**NOTE**
This feature is not supported on TurboIron X Series devices.

Additional trunking options are supported on individual ports that are part of an 802.3ad aggregate link. Previous releases allow you to configure trunking options on individual ports that are part of a manually-created trunk group only. Refer to “Additional trunking options” on page 561.

**Link aggregation parameters**

You can change the settings on individual ports for the following link aggregation parameters:

- System priority
- Port priority
- Timeout
- Key

**System priority**

The system priority parameter specifies the link aggregation priority on the Brocade device, relative to the devices at the other ends of the links on which link aggregation is enabled. A higher value indicates a lower priority. You can specify a priority from 0 – 65535. The default is 1.

System Priority does not take effect until you toggle the `link-aggregate <active| passive>` command.

**NOTE**
If you are connecting the Brocade device to another vendor device and the link aggregation feature is not working, set the system priority on the Brocade device to a lower priority (a higher priority value). In some cases, this change allows the link aggregation feature to operate successfully between the two devices.

**Port priority**

The port priority parameter determines the active and standby links. When a group of ports is negotiating with a group of ports on another device to establish a trunk group, the Brocade port with the highest priority becomes the default active port. The other ports (with lower priorities) become standby ports in the trunk group. You can specify a priority from 0 – 65535. A higher value indicates a lower priority. The default is 1.

**NOTE**
This parameter is not supported in the current software release. The primary port in the port group becomes the default active port. The primary port is the lowest-numbered port in a valid trunk-port group.
**Link type**

The link type parameter specifies whether the trunk is connecting to a server (server link) or to another networking device (switch link). The default link type is switch.

**Timeout**

You can specify a timeout mode, which determines how fast ports are removed from a trunk. You can specify a short timeout mode.

**Key**

Every port that is 802.3ad-enabled has a key. The key identifies the group of potential trunk ports to which the port belongs. Ports with the same key are called a key group and are eligible to be in the same trunk group.

When you enable link-aggregation on an untagged port, the software assigns a default key to the port. For tagged ports, you must manually configure link-aggregation keys. Refer to “Configuring keys for ports with link aggregation enabled” on page 580.

All ports within an aggregate link must have the same key. However, if the device has ports that are connected to two different devices, and the port groups allow the ports to form into separate aggregate links with the two devices, then each group of ports can have the same key while belonging to separate aggregate links with different devices. Figure 100 on page 578 shows an example.

**NOTE**

It is recommended to configure a unique key if ports are tagged or untagged in a VLAN.
Notice that the keys between one device and another do not need to match. The only requirement for key matching is that all the ports within an aggregate link on a given device must have the same key.

Devices that support multi-slot trunk groups can form multi-slot aggregate links using link aggregation. However, the link aggregation keys for the groups of ports on each module must match. For example, if you want to allow link aggregation to form an aggregate link containing ports 1/1 – 1/4 and 3/5 – 3/8, you must change the link aggregation key on one or both groups of ports so that the key is the same on all eight ports. Figure 101 on page 579 shows an example.
By default, the device ports are divided into 4-port groups. The software dynamically assigns a unique key to each 4-port group. If you need to divide a 4-port group into two 2-port groups, change the key in one of the groups so that the two 2-port groups have different keys. For example, if you plan to use ports 1/1 and 1/2 in VLAN 1, and ports 1/3 and 1/4 in VLAN 2, change the key for ports 1/3 and 1/4.

**NOTE**

If you change the key for a port group, Brocade recommends that you use the value 10000 or higher, to avoid potential conflicts with dynamically created keys.

### Viewing keys for tagged ports

To display link aggregation information, including the key for a specific port, enter a command such as the following at any level of the CLI.

```
FastIron# show link-aggregation ethernet 1/1
```

The command in this example shows the key and other link aggregation information for port 1/1.

To display link aggregation information, including the key for all ports on which link aggregation is enabled, enter the following command at any level of the CLI.

```
FastIron# show link-aggregation
```

![Multi-slot aggregate link](image)
Dynamic link aggregation

Syntax:  show link-aggregation [ethernet [\(<stack-unit>/\)<slotnum>/\)]<portnum>\]

The \(<stack-unit>\) parameter is required for FGS, FLS, and FGS-STK and FLS-STK devices.

Possible values: N/A

Default value: N/A

**Configuring link aggregation parameters**

You can configure one or more parameters on the same command line, and in any order.

**NOTE**
For key configuration only, configuration commands differ depending on whether or not link aggregation is enabled on the ports. Follow the appropriate set of commands below, according to your system configuration.

**Configuring a port group key if link aggregation is disabled**

Use this command sequence to change the key for ports that do not have link aggregation enabled, and for all other link aggregation parameters (i.e., system priority, port priority).

For example, to change the software-assigned key for a port group to another value, enter commands similar to the following.

```
FastIron(config)#interface ethernet 1/1 to 1/4
FastIron(config-mif-1/1-1/4)#link-aggregate configure key 10000
FastIron(config-mif-1/1-1/4)#interface ethernet 3/5 to 3/8
FastIron(config-mif-3/5-3/8)#link-aggregate configure key 10000
```

**Configuring keys for ports with link aggregation enabled**

As shown in this command sequence, to change the key on ports that already have link aggregation enabled, you must first turn OFF link aggregation, configure the new key, then re-enable link aggregation.

```
FastIron(config)# interface ethernet 1/1 to 1/4
FastIron(config-mif-1/1-1/4)# link-aggregate
FastIron(config-mif-1/1-1/4)# link-aggregate configure key 10000
FastIron(config-mif-1/1-1/4)# link-aggregate active
FastIron(config-mif-3/5-3/8)# link-aggregate
FastIron(config-mif-3/5-3/8)# link-aggregate configure key 10000
FastIron(config-mif-3/5-3/8)# link-aggregate active
```

These commands change the key for ports 1/1 – 1/4 and 3/5 – 3/8 to 10000. Since all ports in an aggregate link must have the same key, the command in this example enables ports 1/1 – 1/4 and 3/5 – 3/8 to form a multi-slot aggregate link.

Syntax: \([\text{no}] \) link-aggregate configure \([\text{system-priority} <num>] \) \| \([\text{port-priority} <num>] \) \| \([\text{key} <num>] \)

The **system-priority** \(<num>\) parameter specifies the Brocade device link aggregation priority. A higher value indicates a lower priority. You can specify a priority from 0 – 65535. The default is 1.
The `port-priority <num>` parameter specifies an individual port priority within the port group. A higher value indicates a lower priority. You can specify a priority from 0 – 65535. The default is 1.

The `key <num>` parameter identifies the group of ports that are eligible to be aggregated into a trunk group. The software automatically assigns a key to each group of ports. The software assigns the keys in ascending numerical order, beginning with 0. You can change a port group key to a value from 10000 – 65535.

**NOTE**
If you change the key for a port group, Brocade recommends that you use the value 10000 or higher, to avoid potential conflicts with dynamically created keys.

**Configuring port timeout**
You can control the time it takes to remove ports from a trunk with link aggregation enabled by configuring the link aggregated port with a “short” timeout mode. Once a port is configured with a timeout mode, it will remain in that timeout mode whether it is up or down or whether or not it is part of a trunk.

All ports in a trunk should have the same timeout mode, which is checked when link aggregation is enabled on ports.

To configure a port with a short timeout mode, enter a command such as the following.

```
FastIron(config)# interface ethernet8/1
FastIron(config-if-e1000-8/1)# link-aggregation configure timeout short
```

**Syntax:** `[no] link-aggregate configure timeout [short]`

If the timeout mode is not configured for a port and link aggregation is enabled, the port starts with a short timeout mode. Once a trunk is formed, the timeout mode is changed to the long timeout mode. The value for “long” and “short” is displayed in the output for the `show link-aggregate` command.

**NOTE**
LACP short timeout mode is not supported on FESX combo copper ports. If these ports are configured with a short timeout, the ports will flap and will not be aggregated into a trunk group.

**Displaying and determining the status of aggregate links**

The `show link-aggregation` command provides the ability to view the status of dynamic links. You can determine the status of ports that are members of an aggregate link, and whether LACPDU messages are being transmitted between the ports.

The following section provides details about the events that can affect the status of ports in an aggregate link and the status of LACP messages exchanged between the ports. Later sections provide instructions for viewing these status reports.
Displaying and determining the status of aggregate links

Events that affect the status of ports in an aggregate link

Brocade devices can block traffic on a port or shut down a port that is part of a trunk group or aggregate link, when a port joins a trunk group and the port on the other end of the link shuts down or stops transmitting LACP packets. Depending on the timeout value set on the port, the link aggregation information expires. If this occurs, the Brocade device shuts down the port and notifies all the upper layer protocols that the port is down.

Brocade devices can also block traffic on a port that is initially configured with link aggregation. The port is blocked until it joins a trunk group. In this case, traffic is blocked, but the port is still operational.

A port remains blocked until one of the following events occurs:

- Both ports in the aggregate link have the same key
- LACP brings the port back up
- The port joins a trunk group

Displaying link aggregation and port status information

Use the `show link-aggregation` command to determine the operational status of ports associated with aggregate links.

To display the link aggregation information for a specific port, enter a command such as the following at any level of the CLI.

```
FastIron# show link-aggregation ethernet 1/1
```

```
System ID: 00e0.52a9.bb00
Port [Sys P] [Port P] [ Key ] [Act][Tio][Agg][Syn][Col][Dis][Def][Exp] [Ope]
1/1 0 0 No L No No No No No Ope
```

The command in this example shows the link aggregation information for port 1/1.

To display the link aggregation information for all ports on which link aggregation is enabled, enter the following command at any level of the CLI.

```
FastIron# show link-aggregation
```

```
System ID: 00e0.52a9.bb00
Long timeout: 120, default: 120 Short timeout: 3, default: 3
Port [Sys P] [Port P] [ Key ] [Act][Tio][Agg][Syn][Col][Dis][Def][Exp] [Ope]
1/1 1 1 0 No L Agg Syn No No Def Exp Ope
1/2 1 1 0 No L Agg Syn No No Def Exp Ina
1/3 1 1 0 No L Agg Syn No No Def Exp Ina
1/4 1 1 0 No L Agg Syn No No Def Exp Blo
1/5 1 1 1 No L Agg No No Def Exp Ope
1/6 1 1 1 No L Agg No No Def Exp Ope
1/7 1 1 1 No L Agg No No Def Exp Dwn
1/8 1 1 1 No L Agg No No Def Exp Dwn
```

Syntax: `show link-aggregation [ethernet [<stack-id>/]<slotnum>]/<portnum>]`

The `<stack-id>` parameter is required on FGS, FLS, FGS-STK and FLS-STK devices.

The `<slotnum>` parameter is required on chassis devices.

Use `ethernet <portnum>` to display link-aggregation information for a specific port.
NOTE
Ports that are configured as part of an aggregate link must also have the same key. For more information about assigning keys, refer to the section “Link aggregation parameters” on page 576.

The show link aggregation command output is described in “CLI display of link aggregation information” on page 583.

TABLE 101  CLI display of link aggregation information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>System ID</td>
<td>Lists the base MAC address of the device. This is also the MAC address of port 1 (or 1/1).</td>
</tr>
<tr>
<td>Short timeout</td>
<td>Supported on systems running FSX software release 03.2.00.</td>
</tr>
<tr>
<td>Port</td>
<td>Lists the port number.</td>
</tr>
<tr>
<td>Sys P</td>
<td>Lists the system priority configured for this port.</td>
</tr>
<tr>
<td>Port P</td>
<td>Lists the port link aggregation priority.</td>
</tr>
<tr>
<td>Key</td>
<td>Lists the link aggregation key. On devices running FSX software release 03.2.00, this column displays “singleton” if the port is configured with a Single Instance of LACP. (Refer to “Configuring single link LACP” on page 585 for more details.</td>
</tr>
<tr>
<td>Act</td>
<td>Indicates the link aggregation mode, which can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• No – The mode is passive or link aggregation is disabled (off) on the port.</td>
</tr>
<tr>
<td></td>
<td>If link aggregation is enabled (and the mode is passive), the port can send and receive LACPDU messages to participate in negotiation of an aggregate link initiated by another port, but cannot search for a link aggregation port or initiate negotiation of an aggregate link.</td>
</tr>
<tr>
<td></td>
<td>• Yes – The mode is active. The port can send and receive LACPDU messages.</td>
</tr>
<tr>
<td>Tio</td>
<td>Indicates the timeout value of the port. The timeout value can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• L – Long. The trunk group has already been formed and the port is therefore using a longer message timeout for the LACPDU messages exchanged with the remote port. Typically, these messages are used as confirmation of the health of the aggregate link.</td>
</tr>
<tr>
<td></td>
<td>• S – Short. The port has just started the LACPDU message exchange process with the port at the other end of the link. The S timeout value also can mean that the link aggregation information received from the remote port has expired and the ports are starting a new information exchange.</td>
</tr>
<tr>
<td>Agg</td>
<td>Indicates the link aggregation state of the port. The state can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Agg – Link aggregation is enabled on the port.</td>
</tr>
<tr>
<td></td>
<td>• No – Link aggregation is disabled on the port.</td>
</tr>
<tr>
<td>Syn</td>
<td>Indicates the synchronization state of the port. The state can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• No – The port is out of sync with the remote port. The port does not understand the status of the LACPDU process and is not prepared to enter a trunk link.</td>
</tr>
<tr>
<td></td>
<td>• Syn – The port is in sync with the remote port. The port understands the status of the LACPDU message exchange process, and therefore knows the trunk group to which it belongs, the link aggregation state of the remote port, and so on.</td>
</tr>
<tr>
<td>Col</td>
<td>Indicates the collection state of the port, which determines whether the port is ready to send traffic over the trunk link.</td>
</tr>
<tr>
<td></td>
<td>• Col – The port is ready to send traffic over the trunk link.</td>
</tr>
<tr>
<td></td>
<td>• No – The port is not ready to send traffic over the trunk link.</td>
</tr>
</tbody>
</table>
Displaying and determining the status of aggregate links

**TABLE 101** CLI display of link aggregation information (Continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays...</th>
</tr>
</thead>
</table>
| Dis   | Indicates the distribution state of the port, which determines whether the port is ready to receive traffic over the trunk link.  
  - Dis – The port is ready to receive traffic over the trunk link.  
  - No – The port is not ready to receive traffic over the trunk link. |
| Def   | Indicates whether the port is using default link aggregation values. The port uses default values if it has not received link aggregation information through LACP from the port at the remote end of the link. This field can have one of the following values:  
  - Def – The port has not received link aggregation values from the port at the other end of the link and is therefore using its default link aggregation LACP settings.  
  - No – The port has received link aggregation information from the port at the other end of the link and is using the settings negotiated with that port. |
| Exp   | Indicates whether the negotiated link aggregation settings have expired. The settings expire if the port does not receive an LACPDU message from the port at the other end of the link before the message timer expires. This field can have one of the following values:  
  - Exp – The link aggregation settings this port negotiated with the port at the other end of the link have expired. The port is now using its default link aggregation settings.  
  - No – The link aggregation values that this port negotiated with the port at the other end of the link have not expired, so the port is still using the negotiated settings. |
| Ope   | Ope (operational) - The port is operating normally.  
  - Ina (inactive) - The port is inactive because the port on the other side of the link is down or has stopped transmitting LACP packets.  
  - Blo (blocked) - The port is blocked because the adjacent port is not configured with link aggregation or because it is not able to join a trunk group. To unblock the port and bring it to an operational state, enable link aggregation on the adjacent port and ensure that the ports have the same key.  
  - Dwn - <<Need definition.>> |

**Displaying link aggregation and port status information for stackable devices**

To display link aggregation information for devices in an IronStack, enter the `show link-aggregation` command. The output for an Ironstack resembles the following.

FGS624P-STK Router(config)#show link-aggregate  
System ID: 0012.f2e5.a200  
Long timeout: 120, default: 120  
Short timeout: 3, default: 3  
Port [Sys P] [Port P] [ Key ] [Act][Tio][Agg][Syn][Col][Dis][Def][Exp][Ope]  
1/1/1 1 1 13000 Yes L Agg Syn Col Dis No No Ope  
2/1/1 1 1 13000 Yes L Agg Syn Col Dis No No Ope  
3/1/1 1 1 13000 Yes L Agg Syn Col Dis No No Ope  
4/1/1 1 1 13000 Yes L Agg Syn Col Dis No No Ope

**Displaying LACP status information**

Use the `show trunk` command to determine the status of LACP. Refer to “Displaying trunk group configuration information” on page 565.
Clearing the negotiated aggregate links table

When a group of ports negotiates a trunk group configuration, the software stores the negotiated configuration in a table. You can clear the negotiated link aggregation configurations from the software. When you clear the information, the software does not remove link aggregation parameter settings you have configured. Only the configuration information negotiated using LACP is removed.

**NOTE**
The software automatically updates the link aggregation configuration based on LACPDU messages. However, clearing the link aggregation information can be useful if you are troubleshooting a configuration.

To clear the link aggregation information, enter the following command at the Privileged EXEC level of the CLI.

```
FastIron#clear link-aggregate
```

**Syntax:** clear link-aggregate

Configuring single link LACP

A single instance of link aggregation (or single link LACP) can be used for unidirectional link detection. Single link LACP is based on the 802.3ad LACP protocol; but allows you to form an aggregated link with only one Ethernet port. It is the preferred method for detecting unidirectional links across multi-vendor devices, instead of link-keepalive (UDLD), since it is based on a standard rather than on a proprietary solution.

**Configuration notes**

- This feature is supported on 1-GbE and 10-GbE ports.
- This feature is not supported on static trunk ports.
- This feature is not intended for the creation of trunk groups.
- The single link LACP timer is always short (3 seconds) and is not configurable. PDUs are sent out every three seconds.
- This feature is not supported on ports that have the `link-keepalive` command (UDLD) configured.

**CLI syntax**

To form a single link LACP, the port on both sides of the link must have LACP enabled. You can then define a single link LACP at the interface level of the device by entering the following command.

```
FastIron(config)#interface ethernet 8/1
FastIron(config-if-e1000-8/1)#link-aggregate configure singleton
Link-aggregation active
```

**Syntax:** `[no] link-aggregate configure singleton`

When single link LACP is configured, the `show link-aggregate` command displays the following information.
Configuring single link LACP

FastIron#show link-agg
System ID: 00e0.5200.0118
Long timeout: 120, default: 120 Short timeout: 3, default: 3
Port [Sys P] [Port P] [ Key ] [Act][Tio][Agg][Syn][Col][Dis][Def][Exp][Ope]
2/1 1 1 1 Yes S Agg Syn No No Def Exp Ina
2/2 1 1 1 Yes S Agg Syn No No Def Exp Ina
2/3 1 singleton Yes S Agg Syn No No Def Exp Ina
2/4 1 singleton Yes S Agg Syn No No Def Exp Dwn

If singleton is configured on the port, the “Key” column displays “singleton”. Refer to “CLI display of link aggregation information” on page 583 to interpret the information on the displayed output.

Also, when ports are logically brought up or down while singleton is configured on the port, the following Syslog messages are generated:

- Logical link on interface ethernet <slot#/port#> is up.
- Logical link on interface ethernet <slot#/port#> is down.
GVRP overview

GARP VLAN Registration Protocol (GVRP) is a Generic Attribute Registration Protocol (GARP) application that provides VLAN registration service by means of dynamic configuration (registration) and distribution of VLAN membership information.

A Brocade device enabled for GVRP can do the following:

- Learn about VLANs from other Brocade devices and configure those VLANs on the ports that learn about the VLANs. The device listens for GVRP Protocol Data Units (PDUs) from other devices, and implements the VLAN configuration information in the PDUs.
- Advertise VLANs configured on the device to other Brocade devices. The device sends GVRP PDUs advertising its VLANs to other devices. GVRP advertises statically configured VLANs and VLANs learned from other devices through GVRP.

GVRP enables a Brocade device to dynamically create 802.1Q-compliant VLANs on links with other devices that are running GVRP. GVRP reduces the chances for errors in VLAN configuration by automatically providing VLAN ID consistency across the network. You can use GVRP to propagate VLANs to other GVRP-aware devices automatically, without the need to manually configure the VLANs on each device. In addition, if the VLAN configuration on a device changes, GVRP automatically changes the VLAN configurations of the affected devices.

The Brocade implementation of GARP and GVRP is based on the following standards:

- IEEE draft P802.1w/D10, March 26, 2001
- IEEE draft P802.1u/D9, November 23, 2000
- IEEE draft P802.1t/D10, November 20, 2000

Application examples

Figure 102 shows an example of a network that uses GVRP. This section describes various ways you can use GVRP in a network such as this one. “CLI examples” on page 603 lists the CLI commands to implement the applications of GVRP described in this section.
In this example, a core device is attached to three edge devices. Each of the edge devices is attached to other edge devices or host stations (represented by the clouds).

The effects of GVRP in this network depend on which devices the feature is enabled on, and whether both learning and advertising are enabled. In this type of network (a core device and edge devices), you can have the following four combinations:

- Dynamic core and fixed edge
- Dynamic core and dynamic edge
- Fixed core and dynamic edge
- Fixed core and fixed edge

### Dynamic core and fixed edge

In this configuration, all ports on the core device are enabled to learn and advertise VLAN information. The edge devices are configured to advertise their VLAN configurations on the ports connected to the core device. GVRP learning is disabled on the edge devices.

<table>
<thead>
<tr>
<th>Core device</th>
<th>Edge device A</th>
<th>Edge device B</th>
<th>Edge device C</th>
</tr>
</thead>
<tbody>
<tr>
<td>- GVRP is enabled on all ports.</td>
<td>- GVRP is enabled on port 4/24. Learning is disabled.</td>
<td>- GVRP is enabled on port 4/1. Learning is disabled.</td>
<td>- GVRP is enabled on port 4/1. Learning is disabled.</td>
</tr>
<tr>
<td>- Both learning and advertising are enabled.</td>
<td>- VLAN 20</td>
<td>- VLAN 20</td>
<td>- VLAN 30</td>
</tr>
<tr>
<td>- Port 2/1 (untagged)</td>
<td>- Port 4/24 (tagged)</td>
<td>- Port 2/24 (untagged)</td>
<td>- Port 2/24 (untagged)</td>
</tr>
<tr>
<td>- VLAN 40</td>
<td>- Port 4/1 (tagged)</td>
<td>- VLAN 30</td>
<td>- VLAN 40</td>
</tr>
<tr>
<td>- Port 4/1 (untagged)</td>
<td>- Port 4/24 (tagged)</td>
<td>- Port 4/24 (untagged)</td>
<td>- Port 4/1 (tagged)</td>
</tr>
<tr>
<td>- Port 4/24 (tagged)</td>
<td>- Port 4/24 (tagged)</td>
<td>- Port 4/1 (tagged)</td>
<td>- Port 4/1 (tagged)</td>
</tr>
</tbody>
</table>

**NOTE:** Since learning is disabled on all the edge devices, advertising on the core device has no effect in this configuration.
In this configuration, the edge devices are statically (manually) configured with VLAN information. The core device dynamically configures itself to be a member of each of the edge device VLANs. The operation of GVRP on the core device results in the following VLAN configuration on the device:

- VLAN 20
  - 1/24 (tagged)
  - 6/24 (tagged)
- VLAN 30
  - 6/24 (tagged)
  - 8/17 (tagged)
- VLAN 40
  - 1/24 (tagged)
  - 8/17 (tagged)

VLAN 20 traffic can now travel through the core between edge devices A and B. Likewise, VLAN 30 traffic can travel between B and C and VLAN 40 traffic can travel between A and C. If an edge device is moved to a different core port or the VLAN configuration of an edge device is changed, the core device automatically reconfigures itself to accommodate the change.

Notice that each of the ports in the dynamically created VLANs is tagged. All GVRP VLAN ports configured by GVRP are tagged, to ensure that the port can be configured for additional VLANs.

---

**NOTE**
This example assumes that the core device has no static VLANs configured. However, you can have static VLANs on a device that is running GVRP. GVRP can dynamically add other ports to the statically configured VLANs but cannot delete statically configured ports from the VLANs.

---

**Dynamic core and dynamic edge**

GVRP is enabled on the core device and on the edge devices. This type of configuration is useful if the devices in the edge clouds are running GVRP and advertise their VLANs to the edge devices. The edge devices learn the VLANs and also advertise them to the core. In this configuration, you do not need to statically configure the VLANs on the edge or core devices, although you can have statically configured VLANs on the devices. The devices learn the VLANs from the devices in the edge clouds.

**Fixed core and dynamic edge**

GVRP learning is enabled on the edge devices. The VLANs on the core device are statically configured, and the core device is enabled to advertise its VLANs but not to learn VLANs. The edge devices learn the VLANs from the core.

**Fixed core and fixed edge**

The VLANs are statically configured on the core and edge devices. On each edge device, VLAN advertising is enabled but learning is disabled. GVRP is not enabled on the core device. This configuration enables the devices in the edge clouds to learn the VLANs configured on the edge devices.
VLAN names

The `show vlans` command lists VLANs created by GVRP as “GVRRP_VLAN_<vlan-id>”. VLAN names for statically configured VLANs are not affected. To distinguish between statically-configured VLANs that you add to the device and VLANs that you convert from GVRP-configured VLANs into statically-configured VLANs, the `show vlans` command displays a converted VLAN name as “STATIC_VLAN_<vlan-id>”.

Configuration notes

- If you disable GVRP, all GVRP configuration information is lost if you save the configuration change (write memory command) and then reload the software. However, if you reload the software without first saving the configuration change, the GVRP configuration is restored following a software reload.
- The maximum number of VLANs supported on a device enabled for GVRP is the same as the maximum number on a device that is not enabled for GVRP.
- To display the maximum number of VLANs allowed on your device, enter the `show default values` command. See the “vlan” row in the System Parameters section. Make sure you allow for the default VLAN (1), the GVRP base VLAN (4093), and the Single STP VLAN (4094). These VLANs are maintained as “Registration Forbidden” in the GVRP database. Registration Forbidden VLANs cannot be advertised or learned by GVRP.
- To increase the maximum number of VLANs supported on the device, enter the `system-max vlan <num>` command at the global CONFIG level of the CLI, then save the configuration and reload the software. The maximum number you can specify is listed in the Maximum column of the `show default values` display.
- The default VLAN (VLAN 1) is not advertised by the Brocade implementation of GVRP. The default VLAN contains all ports that are not members of statically configured VLANs or VLANs enabled for GVRP.

**NOTE**
The default VLAN has ID 1 by default. You can change the VLAN ID of the default VLAN, but only before GVRP is enabled. You cannot change the ID of the default VLAN after GVRP is enabled.

- Single STP must be enabled on the device. Brocade implementation of GVRP requires Single STP. If you do not have any statically configured VLANs on the device, you can enable Single STP as follows.
  ```
  FastIron(config)# vlan 1
  FastIron(config-vlan-1)# exit
  FastIron(config)# span
  FastIron(config)# span single
  ```
  These commands enable configuration of the default VLAN (VLAN 1), which contains all the device ports, and enable STP and Single STP.
- All VLANs that are learned dynamically through GVRP are added to the single spanning tree.
- All ports that are enabled for GVRP become tagged members of the GVRP base VLAN (4093). If you need to use this VLAN ID for another VLAN, you can change the GVRP VLAN ID. Refer to “Changing the GVRP base VLAN ID” on page 591. The software adds the GVRP base VLAN to the single spanning tree.
- All VLAN ports added by GVRP are tagged.
GVRP is supported only for tagged ports or for untagged ports that are members of the default VLAN. GVRP is not supported for ports that are untagged and are members of a VLAN other than the default VLAN.

To configure GVRP on a trunk group, enable the protocol on the primary port in the trunk group. The GVRP configuration of the primary port is automatically applied to the other ports in the trunk group.

You can use GVRP on a device even if the device has statically configured VLANs. GVRP does not remove any ports from the statically configured VLANs, although GVRP can add ports to the VLANS. GVRP advertises the statically configured VLANs. Ports added by GVRP do not appear in the running-config and will not appear in the startup-config file when you save the configuration. You can manually add a port to make the port a permanent member of the VLAN. After you manually add the port, the port will appear in the running-config and be saved to the startup-config file when you save the configuration.

VLANs created by GVRP do not support virtual routing interfaces or protocol-based VLANs. virtual routing interfaces and protocol-based VLANs are still supported on statically configured VLANs even if GVRP adds ports to those VLANs.

You cannot manually configure any parameters on a VLAN that is created by GVRP. For example, you cannot change STP parameters for the VLAN.

The GVRP timers (Join, Leave, and Leaveall) must be set to the same values on all the devices that are exchanging information using GVRP.

If the network has a large number of VLANs, the GVRP traffic can use a lot of CPU resources. If you notice high CPU utilization after enabling GVRP, set the GVRP timers to longer values. In particular, set the Leaveall timer to a longer value. Refer to “Changing the GVRP timers” on page 593.

The feature is supported only on Ethernet ports.

NOTE
If you plan to change the GVRP base VLAN ID (4093) or the maximum configurable value for the Leaveall timer (300000 ms by default), you must do so before you enable GVRP.

Configuring GVRP

To configure a device for GVRP, globally enable support for the feature, then enable the feature on specific ports. Optionally, you can disable VLAN learning or advertising on specific interfaces.

You can also change the protocol timers and the GVRP base VLAN ID.

Changing the GVRP base VLAN ID

By default, GVRP uses VLAN 4093 as a base VLAN for the protocol. All ports that are enabled for GVRP become tagged members of this VLAN. If you need to use VLAN ID 4093 for a statically configured VLAN, you can change the GVRP base VLAN ID.

NOTE
If you want to change the GVRP base VLAN ID, you must do so before enabling GVRP.

To change the GVRP base VLAN ID, enter a command such as the following at the global CONFIG level of the CLI.
Configuring GVRP

FastIron(config)# gvrp-base-vlan-id 1001
This command changes the GVRP VLAN ID from 4093 to 1001.

Syntax: [no] gvrp-base-vlan-id <vlan-id>
The <vlan-id> parameter specifies the new VLAN ID. You can specify a VLAN ID from 2 – 4092 or 4095.

Increasing the maximum configurable value of the Leaveall timer

By default, the highest value you can specify for the Leaveall timer is 300000 ms. You can increase the maximum configurable value of the Leaveall timer to 1000000 ms.

NOTE
You must enter this command before enabling GVRP. Once GVRP is enabled, you cannot change the maximum Leaveall timer value.

NOTE
This command does not change the default value of the Leaveall timer itself. The command only changes the maximum value to which you can set the Leaveall timer.

To increase the maximum value you can specify for the Leaveall timer, enter a command such as the following at the global CONFIG level of the CLI.

FastIron(config)# gvrp-max-leaveall-timer 1000000

Syntax: [no] gvrp-max-leaveall-timer <ms>
The <ms> parameter specifies the maximum number of ms to which you can set the Leaveall timer. You can specify from 300000 – 1000000 (one million) ms. The value must be a multiple of 100 ms. The default is 300000 ms.

Enabling GVRP

To enable GVRP, enter commands such as the following at the global CONFIG level of the CLI.

FastIron(config)# gvrp-enable
FastIron(config-gvrp)# enable all
The first command globally enables support for the feature and changes the CLI to the GVRP configuration level. The second command enables GVRP on all ports on the device.

The following command enables GVRP on ports 1/24, 2/24, and 4/17.

FastIron(config-gvrp)# enable ethernet 1/24 ethernet 2/24 ethernet 4/17

Syntax: [no] gvrp-enable
Syntax: [no] enable all | ethernet [<slotnum>/] <portnum> [ethernet [<slotnum>/] <portnum> | to [<slotnum>/] <portnum>]
The all parameter enables GVRP on all ports.
The ethernet [<slotnum>/] <portnum> [ethernet [<slotnum>/] <portnum> | to [<slotnum>/] <portnum>] parameter enables GVRP on the specified list or range of Ethernet ports.
Configuring GVRP

- To specify a list, enter each port as `ethernet <portnum>` followed by a space. Include the slot number if required. For example, to enable GVRP on three Ethernet ports on a FSX device, enter the following command: `enable ethernet 1/24 ethernet 6/24 ethernet 8/17`

- To specify a range, enter the first port in the range as `ethernet [<slotnum>/]<portnum>` followed by to followed by the last port in the range. For example, to add ports 1/1 – 1/8, enter the following command: `enable ethernet 1/1 to 1/8`.

You can combine lists and ranges in the same command. For example: `enable ethernet 1/1 to 1/8 ethernet 1/24 ethernet 6/24 ethernet 8/17`.

Disabling VLAN advertising

To disable VLAN advertising on a port enabled for GVRP, enter a command such as the following at the GVRP configuration level.

```
FastIron(config-gvrp)# block-applicant ethernet 1/24 ethernet 6/24 ethernet 8/17
```

This command disables advertising of VLAN information on ports 1/24, 6/24, and 8/17.

Syntax: `[no] block-applicant all | ethernet [<slotnum>/]<portnum> [ethernet [<slotnum>/]<portnum>]
<portnum> | to [<slotnum>/]<portnum>`

**NOTE**
Leaveall messages are still sent on the GVRP ports.

Disabling VLAN learning

To disable VLAN learning on a port enabled for GVRP, enter a command such as the following at the GVRP configuration level.

```
FastIron(config-gvrp)# block-learning ethernet 6/24
```

This command disables learning of VLAN information on port 6/24.

**NOTE**
The port still advertises VLAN information unless you also disable VLAN advertising.

Syntax: `[no] block-learning all | ethernet [<slotnum>/]<portnum> [ethernet [<slotnum>/]<portnum>]
<portnum> | to [<slotnum>/]<portnum>`

Changing the GVRP timers

GVRP uses the following timers:

- Join – The maximum number of milliseconds (ms) a device GVRP interfaces wait before sending VLAN advertisements on the interfaces. The actual interval between Join messages is randomly calculated to a value between 0 and the maximum number of milliseconds specified for Join messages. You can set the Join timer to a value from 200 – one third the value of the Leave timer. The default is 200 ms.
• Leave – The number of ms a GVRP interface waits after receiving a Leave message on the port to remove the port from the VLAN indicated in the Leave message. If the port receives a Join message before the Leave timer expires, GVRP keeps the port in the VLAN. Otherwise, the port is removed from the VLAN. When a port receives a Leave message, the port GVRP state is changed to Leaving. Once the Leave timer expires, the port GVRP state changes to Empty. You can set the Leave timer to a value from three times the Join timer – one fifth the value of the Leaveall timer. The default is 600 ms.

**NOTE**
When all ports in a dynamically created VLAN (one learned through GVRP) leave the VLAN, the VLAN is immediately deleted from the device's VLAN database. However, this empty VLAN is still maintained in the GVRP database for an amount of time equal to the following.

\[(\text{number-of-GVRP-enabled-up-ports}) \times (2 \times \text{join-timer})\]

While the empty VLAN is in the GVRP database, the VLAN does not appear in the `show vlans` display but does still appear in the `show gvrp vlan all` display.

• Leaveall – The minimum interval at which GVRP sends Leaveall messages on all GVRP interfaces. Leaveall messages ensure that the GVRP VLAN membership information is current by aging out stale VLAN information and adding information for new VLAN memberships, if the information is missing. A Leaveall message instructs the port to change the GVRP state for all its VLANs to Leaving, and remove them unless a Join message is received before the Leave timer expires. By default, you can set the Leaveall timer to a value from five times the Leave timer – maximum value allowed by software (configurable from 300000 – 1000000 ms). The default is 10000.

**NOTE**
The actual interval is a random value between the Leaveall interval and 1.5 * the Leaveall time or the maximum Leaveall time, whichever is lower.

**NOTE**
You can increase the maximum configurable value of the Leaveall timer from 300000 ms up to 1000000 ms using the `gvrp-max-leaveall-timer` command. (Refer to “Increasing the maximum configurable value of the Leaveall timer” on page 592.)

**Timer configuration requirements**
- All timer values must be in multiples of 100 ms.
- The Leave timer must be \( \geq 3 \times \) the Join timer.
- The Leaveall timer must be \( \geq 5 \times \) the Leave timer.
- The GVRP timers must be set to the same values on all the devices that are exchanging information using GVRP.

**Changing the Join, Leave, and Leaveall timers**
The same CLI command controls changes to the Join, Leave, and Leaveall timers. To change values to the timers, enter a command such as the following.

```
FastIron(config-gvrp)# join-timer 1000 leave-timer 3000 leaveall-timer 15000
```
This command changes the Join timer to 1000 ms, the Leave timer to 3000 ms, and the Leaveall timer to 15000.

**Syntax:**
```
[no] join-timer <ms> leave-timer <ms> leaveall-timer <ms>
```

**NOTE**
When you enter this command, all the running GVRP timers are canceled and restarted using the new times specified by the command.

**Resetting the timers to their defaults**

To reset the Join, Leave, and Leaveall timers to their default values, enter the following command.

```
FastIron(config-gvrp)# default-timers
```

**Syntax:**
```
default-timers
```

This command resets the timers to the following values:

- Join – 200 ms
- Leave – 600 ms
- Leaveall – 10000 ms

---

### Converting a VLAN created by GVRP into a statically-configured VLAN

You cannot configure VLAN parameters on VLANs created by GVRP. Moreover, VLANs and VLAN ports added by GVRP do not appear in the running-config and cannot be saved in the startup-config file.

To be able to configure and save VLANs or ports added by GVRP, you must convert the VLAN ports to statically-configured ports.

To convert a VLAN added by GVRP into a statically-configured VLAN, add the ports using commands such as the following.

```
FastIron(config)# vlan 22
FastIron(config-vlan-222)# tagged ethernet 1/1 to 1/8
```

These commands convert GVRP-created VLAN 22 containing ports 1/1 through 1/8 into statically-configured VLAN 22.

**Syntax:**
```
[no] vlan <vlan-id>
```

**Syntax:**
```
[no] tagged ethernet [<slotnum>/]<portnum> [to [<slotnum>/]<portnum> | ethernet [<slotnum>/]<portnum>]
```

Use the same commands to statically add ports that GVRP added to a VLAN.

**NOTE**
You cannot add the VLAN ports as untagged ports.
NOTE
After you convert the VLAN, the VLAN name changes from “GVRP_VLAN_<vlan-id>” to “STATIC_VLAN_<vlan-id>”.

Displaying GVRP information

You can display the following GVRP information:

- GVRP configuration information
- GVRP VLAN information
- GVRP statistics
- CPU utilization statistics
- GVRP diagnostic information

Displaying GVRP configuration information

To display GVRP configuration information, enter a command such as the following.

```
FastIron# show gvrp
GVRP is enabled on the system
GVRP BASE VLAN ID          : 4093
GVRP MAX Leaveall Timer    : 300000 ms
GVRP Join Timer            : 200 ms
GVRP Leave Timer           : 600 ms
GVRP Leave-all Timer       : 10000 ms
===========================================================================
Configuration that is being used:
  block-learning ethe 1/3
  block-applicant ethe 2/7 ethe 2/11
  enable ethe 1/1 to 1/7 ethe 2/1 ethe 2/7 ethe 2/11
===========================================================================
Spanning Tree: SINGLE SPANNING TREE
Dropped Packets Count: 0
===========================================================================
Number of VLANs in the GVRP Database: 15
Maximum Number of VLANs that can be present: 4095
===========================================================================
```

**Syntax:** `show gvrp [ethernet <port-num>]`

This display shows the following information.
To display detailed GVRP information for an individual port, enter a command such as the following.

```
TABLE 102  CLI display of summary GVRP information

</table>

To display detailed GVRP information for an individual port, enter a command such as the following.
Displaying GVRP information

This display shows the following information.

**TABLE 103** CLI display of detailed GVRP information for a port

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port number</td>
<td>The port for which information is being displayed.</td>
</tr>
<tr>
<td>GVRP Enabled</td>
<td>Whether GVRP is enabled on the port.</td>
</tr>
<tr>
<td>GVRP Learning</td>
<td>Whether the port can learn VLAN information from GVRP.</td>
</tr>
<tr>
<td>GVRP Applicant</td>
<td>Whether the port can advertise VLAN information into GVRP.</td>
</tr>
<tr>
<td>Port State</td>
<td>The port link state, which can be UP or DOWN.</td>
</tr>
<tr>
<td>Forwarding</td>
<td>Whether the port is in the GVRP Forwarding state:</td>
</tr>
<tr>
<td></td>
<td>• NO – The port is in the Blocking state.</td>
</tr>
<tr>
<td></td>
<td>• YES – The port is in the Forwarding state.</td>
</tr>
<tr>
<td>VLAN Membership</td>
<td>The VLANs of which the port is a member. For each VLAN, the following information is shown:</td>
</tr>
<tr>
<td></td>
<td>• VLAN ID – The VLAN ID.</td>
</tr>
<tr>
<td></td>
<td>• Mode – The type of VLAN, which can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• FIXED – The port will always be a member of this VLAN and the VLAN will always be advertised on this port by GVRP. A port becomes FIXED when you configure the port as a tagged member of a statically configured VLAN.</td>
</tr>
<tr>
<td></td>
<td>• FORBIDDEN – The VLAN is one of the special VLANs that is not advertised or learned by GVRP. In the current release, the following VLANs are forbidden: the default VLAN (1), the GVRP base VLAN (4093), or the Single STP VLAN (4094).</td>
</tr>
<tr>
<td></td>
<td>• NORMAL – The port became a member of this VLAN after learning about the VLAN through GVRP. The port membership in the VLAN depends on GVRP. If the VLAN is removed from the ports that send GVRP advertisements to this device, then the port will stop being a member of the VLAN.</td>
</tr>
</tbody>
</table>

Displaying GVRP VLAN information

To display information about all the VLANs on the device, enter the following command.

```
FastIron# show gvrp ethernet 2/1
Port 2/1 -
GVRP Enabled : YES

<td>Whether this is the default VLAN.</td>
</tr>
<tr>
<td>BASE-VLAN</td>
<td>Whether this is the base VLAN for GVRP.</td>
</tr>
<tr>
<td>Timer to Delete Entry Running</td>
<td>Whether all ports have left the VLAN and the timer to delete the VLAN itself is running. The timer is described in the note for the Leave timer in “Changing the GVRP timers” on page 593.</td>
</tr>
</tbody>
</table>

**Legend**
The meanings of the letter codes used in other parts of the display.

**Forbidden Members**
The ports that cannot become members of a VLAN advertised or leaned by GVRP.

**Fixed Members**
The ports that are statically configured members of the VLAN. GVRP cannot remove these ports.

**Normal(Dynamic) Members**
The ports that were added by GVRP. These ports also can be removed by GVRP.

**MODE**
The type of VLAN, which can be one of the following:
- **STATIC** – The VLAN is statically configured and cannot be removed by GVRP. This includes VLANs you have configured as well as the default VLAN (1), base GVRP VLAN (4093), and Single STP VLAN (4094).
- **DYNAMIC** – The VLAN was learned through GVRP.

To display detailed information for all VLANs, enter the `show gvrp vlan all` command.

### Displaying GVRP statistics

To display GVRP statistics for a port, enter a command such as the following.

```
FastIron# show gvrp statistics ethernet 2/1
```

**PORT 2/1 Statistics:**

- Leave All Received : 147
- Join Empty Received : 4193
- Join In Received : 599
- Leave Empty Received : 0
- Leave In Received : 0
- Empty Received : 588
- Leave All Transmitted : 157
- Join Empty Transmitted : 1794
- Join In Transmitted : 598
- Leave Empty Transmitted : 0
- Leave In Transmitted : 0
- Empty Transmitted : 1248
- Invalid Messages/Attributes Skipped : 0
- Failed Registrations : 0

**Syntax:** `show gvrp statistics all | ethernet [<slotnum>/] <port-num>`

This display shows the following information for the port.
To display GVRP statistics for all ports, enter the `show gvrp statistics all` command.

### Displaying CPU utilization statistics

You can display CPU utilization statistics for GVRP.

To display CPU utilization statistics for GVRP for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI:
If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. An example is given below.

```
FastIron# show process cpu
The system has only been up for 6 seconds.
```

To display utilization statistics for a specific number of seconds, enter a command such as the following.

```
FastIron# show process cpu 2
Statistics for last 1 sec and 80 ms
```

When you specify how many seconds’ worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

**Syntax: show process cpu [<num>]**

The `<num>` parameter specifies the number of seconds and can be from 1 – 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.
Clearing GVRP statistics

To clear the GVRP statistics counters, enter a command such as the following.

FastIron# clear gvrp statistics all

This command clears the counters for all ports. To clear the counters for a specific port only, enter a command such as the following.

FastIron# clear gvrp statistics ethernet 2/1

Syntax: clear gvrp statistics all | ethernet [slotnum/]portnum>

CLI examples

The following sections show the CLI commands for implementing the applications of GVRP described in "Application examples" on page 587.

NOTE
Although some of the devices in these configuration examples do not have statically configured VLANs, this is not a requirement. You always can have statically configured VLANs on a device that is running GVRP.

Displaying GVRP diagnostic information

To display diagnostic information, enter the following command.

FastIron# debug gvrp packets

```
GVRP:  Packets debugging is on
GVRP:  0x2095ced4:  01 80 c2 00 00 21 00 e0 52 ab 87 40 00 3a 42 42

GVRP:  0x207651d8:  04 01 00 0b 00 00
```

Syntax: debug gvrp packets
Dynamic core and fixed edge

In this configuration, the edge devices advertise their statically configured VLANs to the core device. The core device does not have any statically configured VLANs but learns the VLANs from the edge devices.

Enter the following commands on the core device.

```
FastIron> enable
FastIron# configure terminal
FastIron(config)# gvrp-enable
FastIron(config-gvrp)# enable all
```

These commands globally enable GVRP support and enable the protocol on all ports.

Enter the following commands on edge device A.

```
FastIron> enable
FastIron# configure terminal
FastIron(config)# vlan 20
FastIron(config-vlan-20)# untag ethernet 2/1
FastIron(config-vlan-20)# tag ethernet 4/24
FastIron(config-vlan-20)# vlan 40
FastIron(config-vlan-40)# untag ethernet 2/1
FastIron(config-vlan-40)# tag ethernet 4/24
FastIron(config-vlan-40)# exit
FastIron(config)# gvrp-enable
FastIron(config-gvrp)# enable ethernet 4/24
FastIron(config-gvrp)# block-learning ethernet 4/24
```

These commands statically configure two port-based VLANs, enable GVRP on port 4/24, and block GVRP learning on the port. The device will advertise the VLANs but will not learn VLANs from other devices.

Enter the following commands on edge device B.

```
FastIron> enable
FastIron# configure terminal
FastIron(config)# vlan 20
FastIron(config-vlan-20)# untag ethernet 2/24
FastIron(config-vlan-20)# tag ethernet 4/1
FastIron(config-vlan-20)# vlan 30
FastIron(config-vlan-30)# untag ethernet 4/24
FastIron(config-vlan-30)# tag ethernet 4/1
FastIron(config-vlan-30)# exit
FastIron(config)# gvrp-enable
FastIron(config-gvrp)# enable ethernet 4/1
FastIron(config-gvrp)# block-learning ethernet 4/1
```

Enter the following commands on edge device C.

```
FastIron> enable
FastIron# configure terminal
FastIron(config)# vlan 30
FastIron(config-vlan-30)# untag ethernet 2/24
FastIron(config-vlan-30)# tag ethernet 4/1
FastIron(config-vlan-20)# vlan 40
FastIron(config-vlan-40)# untag ethernet 4/24
FastIron(config-vlan-40)# tag ethernet 4/1
```
FastIron(config-vlan-40)# exit
FastIron(config)# gvrp-enable
FastIron(config-gvrp)# enable ethernet 4/1
FastIron(config-gvrp)# block-learning ethernet 4/1

Dynamic core and dynamic edge

In this configuration, the core and edge devices have no statically configured VLANs and are enabled to learn and advertise VLANs. The edge and core devices learn the VLANs configured on the devices in the edge clouds. To enable GVRP on all the ports, enter the following command on each edge device and on the core device.

FastIron> enable
FastIron# configure terminal
FastIron(config)# gvrp-enable
FastIron(config-gvrp)# enable all

Fixed core and dynamic edge

In this configuration, GVRP learning is enabled on the edge devices. The VLANs on the core device are statically configured, and the core device is enabled to advertise its VLANs but not to learn VLANs. The edge devices learn the VLANs from the core.

Enter the following commands on the core device.

FastIron> enable
FastIron# configure terminal
FastIron(config)# vlan 20
FastIron(config-vlan-20)# tag ethernet 1/24
FastIron(config-vlan-20)# tag ethernet 6/24
FastIron(config-vlan-20)# vlan 30
FastIron(config-vlan-30)# tag ethernet 6/24
FastIron(config-vlan-30)# tag ethernet 8/17
FastIron(config-vlan-30)# vlan 40
FastIron(config-vlan-40)# tag ethernet 1/5
FastIron(config-vlan-40)# tag ethernet 8/17
FastIron(config-vlan-40)# vlan 50
FastIron(config-vlan-50)# untag ethernet 6/1
FastIron(config-vlan-50)# tag ethernet 1/11
FastIron(config-vlan-50)# exit
FastIron(config)# gvrp-enable
FastIron(config-gvrp)# enable ethernet 1/24 ethernet 6/24 ethernet 8/17
FastIron(config-gvrp)# block-learning ethernet 1/24 ethernet 6/24 ethernet 8/17

These VLAN commands configure VLANs 20, 30, 40, and 50. The GVRP commands enable the protocol on the ports that are connected to the edge devices, and disable VLAN learning on those ports. All the VLANs are advertised by GVRP.

Enter the following commands on edge devices A, B, and C.

FastIron> enable
FastIron# configure terminal
FastIron(config)# gvrp-enable
FastIron(config-gvrp)# enable all
FastIron(config-gvrp)# block-applicant all
Fixed core and fixed edge

The VLANs are statically configured on the core and edge devices. On each edge device, VLAN advertising is enabled but learning is disabled. GVRP is not configured on the core device. This configuration enables the devices in the edge clouds to learn the VLANs configured on the edge devices.

This configuration does not use any GVRP configuration on the core device.

The configuration on the edge device is the same as in “Dynamic core and fixed edge” on page 604.
Overview

Platform Support:
- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later

The MAC-based VLAN feature controls network access by authenticating a host source MAC address, and mapping the incoming packet source MAC to a VLAN. Mapping is based on the MAC address of the end station connected to the physical port. Users who relocate can remain on the same VLAN as long as they connect to any switch in the same domain, on a port which is permitted in the VLAN. The MAC-based VLAN feature may be enabled for two types of hosts: static and dynamic.

MAC-based VLAN activity is determined by authentication through a RADIUS server. Incoming traffic that originates from a specific MAC address is forwarded only if the source MAC address-to-VLAN mapping is successfully authenticated. While multi-device port authentication is in progress, all traffic from the new MAC address will be blocked or dropped until the authentication succeeds. Traffic is dropped if the authentication fails.

NOTE
FastIron devices do not support UDLD link-keepalives on ports with MAC-based VLAN enabled.

NOTE
FastIron devices do not support STP BPDU packets on ports with MAC-based VLAN enabled.

NOTE
MAC-based VLAN does not work in conjunction with ACLs or MAC filters.

Static and dynamic hosts

Static hosts are devices on the network that do not speak until spoken to. Static hosts may not initiate a request for authentication on their own. Such static hosts can be managed through a link up or link down notification.

Dynamic hosts are “chatty” devices that generate packets whenever they are in the link up state. Dynamic hosts must be authenticated before they can switch or forward traffic.

MAC-based VLAN feature structure

The MAC-based VLAN feature operates in two stages:
Dynamic MAC-based VLAN

- Source MAC Address Authentication
- Policy-Based Classification and Forwarding

### Source MAC address authentication

Source MAC address authentication is performed by a central RADIUS server when it receives a PAP request with a username and password that match the MAC address being authenticated. When the MAC address is successfully authenticated, the server must return the VLAN identifier, which is carried in the Tunnel-Type, Tunnel-Medium-Type, and Tunnel-Private-Group-ID attributes of the RADIUS packets. If the Tunnel-Type is tagged, the MAC address will be blocked or restricted. If the identified VLAN does not exist, then the authentication is considered a failure, and action is taken based on the configured failure options. (The default failure action is to drop the traffic.) The RADIUS server may also optionally return the QoS attribute for the authenticated MAC address. Refer to Table 108 on page 611 for more information about attributes.

### Policy-based classification and forwarding

Once the authentication stage is complete, incoming traffic is classified based on the response from the RADIUS server. There are three possible actions:

- Incoming traffic from a specific source MAC is dropped because authentication failed
- Incoming traffic from a specific source MAC is classified as untagged into a specific VLAN
- Incoming traffic from a specific source MAC is classified as untagged into a restricted VLAN

Traffic classification is performed by programming incoming traffic and RADIUS-returned attributes in the hardware. Incoming traffic attributes include the source MAC address and the port on which the feature is enabled. The RADIUS-returned attributes are the VLAN into which the traffic is to be classified, and the QoS priority.

**NOTE**

This feature drops any incoming tagged traffic on the port, and classifies and forwards untagged traffic into the appropriate VLANs.

This feature supports up to a maximum of 32 MAC addresses per physical port, with a default of 2. Once a client MAC address is successfully authenticated and registered, the MAC-to-VLAN association remains until the port connection is dropped, or the MAC entry expires.

### MAC-based VLAN and port up or down events

When the state of a port is changed to down, all authorized and unauthorized MAC addresses are removed from the MAC-to-VLAN mapping table, any pending authentication requests are cancelled.

**Dynamic MAC-based VLAN**

**Platform Support:**

- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later
When enabled, this feature allows the dynamic addition of mac-vlan-permit ports to the VLAN table only after successful RADIUS authentication. Ports that fail RADIUS authentication are not added to the VLAN table.

When this feature is not enabled, the physical port is statically added to the hardware table, regardless of the outcome of the authentication process. This feature prevents the addition of un-authenticated ports to the VLAN table. For information about how to configure Dynamic MAC-based VLAN, refer to “Configuring dynamic MAC-based VLAN” on page 614.

Configuring MAC-based VLANs

Configure MAC-based VLAN mapping on the switch statically for static hosts, or dynamically for non-static hosts, by directing the RADIUS server to authenticate the incoming packet.

To configure the a MAC-based VLAN, first perform the following tasks:

- In the VLANs, configure `mac-vlan-permit` for each port that will be participating in the MAC-based VLAN
- If a port has been MAC-based VLAN-enabled, but has not been added as `mac-vlan-permit` in any of the VLANs, any MAC addresses learned on this port will be blocked in the reserved VLAN. To prevent this, you must create all of the VLANs and add all ports as `mac-vlan-permit` before enabling MAC-based VLAN on any ports.
- Disable any multi-device port authentication on ports you will be using for MAC-to-VLAN mapping

**NOTE**
Do not configure MAC-based VLAN on ports that are tagged to any VLAN. Do not use ports on which MAC-based VLAN is configured as tagged ports.

**NOTE**
For FCX devices, MAC-based VLAN with 802.1x will not work on the same port if 802.1x has the RADIUS VLAN attribute defined as an untagged VLAN (for example U:1, U:2).

**NOTE**
MAC-based VLAN is not supported on trunk or LACP ports. Do not configure trunks on MAC-based VLAN-enabled ports.

Using MAC-based VLANs and 802.1X security on the same port

On Brocade devices, MAC-based VLANs and 802.1X security can be configured on the same port. When both of these features are enabled on the same port, MAC-based VLAN is performed prior to 802.1X authentication. If MAC-based VLAN is successful, 802.1X authentication may be performed, based on the configuration of a vendor-specific attribute (VSA) in the profile for the MAC address on the RADIUS server.
When both features are configured on a port, a device connected to the port is authenticated as follows.

1. MAC-based VLAN is performed on the device to authenticate the device MAC address.

2. If MAC-based VLAN is successful, the device then checks to see if the RADIUS server included the Foundry-802_1x-enable VSA (described in Table 108) in the Access-Accept message that authenticated the device.

3. If the Foundry-802_1x-enable VSA is not present in the Access-Accept message, or is present and set to 1, then 802.1X authentication is performed for the device.

4. If the Foundry-802_1x-enable VSA is present in the Access-Accept message, and is set to 0, then 802.1X authentication is skipped.

**Configuring generic and Brocade vendor-specific attributes on the RADIUS server**

If the RADIUS authentication process is successful, the RADIUS server sends an Access-Accept message to the Brocade device, authenticating the device. The Access-Accept message includes Vendor-Specific Attributes (VSAs) that specify additional information about the device.

Add Brocade vendor-specific attributes to your RADIUS server configuration, and configure the attributes in the individual or group profiles of the devices that will be authenticated. Brocade vendor-ID is 1991, vendor-type 1. Table 107 lists generic RADIUS attributes. Table 108 lists Brocade Vendor-Specific Attributes.

**TABLE 107** Generic RADIUS attributes

Aging for MAC-based VLAN

The aging process for MAC-based VLAN works as described below.

For permitted hosts
For permitted hosts, as long as the Brocade device is receiving traffic aging does not occur. The age column in the output of the `show table-mac-vlan` command displays Ena or S <num>. If the Brocade device stops receiving traffic, the entry first ages out from the MAC table (in the hardware) and then the aging cycle for MAC-based VLAN begins. Aging in the MAC-based VLAN continues for 2 minutes (the default is 120 seconds) after which the MAC-based VLAN session is flushed out.

For blocked hosts
For blocked hosts, as long as the Brocade device is receiving traffic, aging does not occur. In the output of the `show table-mac-vlan` command, the age column displays H0 to H70, S0, and H0 to H70, etc. Aging of the MAC-based VLAN MAC occurs in two phases: hardware aging and software aging. The hardware aging period can be configured using the `mac-authentication hw-deny-age` command in config mode. The default is 70 seconds. The software aging time for MAC-based VLAN MACs can be configured using the `mac-authentication max-age` command. When the Brocade device is no longer receiving traffic from a MAC-based VLAN MAC address, the hardware aging period begins and lasts for a fixed length of time (default or user-configured). When the hardware

<table>
<thead>

<td>6</td>
<td>integer</td>
<td>Optional</td>
<td>Specifies whether 802.1x authentication is performed when MAC-based VLAN is successful for a device. This attribute can be set to one of the following: 0 - Do not perform 802.1x authentication on a device that passes MAC-based VLAN. Set the attribute to zero (0) for devices that do not support 802.1x authentication. 1 - Perform 802.1x authentication when a device passes MAC-based VLAN. Set the attribute to one (1) for devices that support 802.1x authentication.</td>
</tr>
<tr>
<td>Foundry-802_1x-valid</td>
<td>7</td>
<td>integer</td>
<td>Optional</td>
<td>Specifies whether the RADIUS record is valid only for MAC-based VLAN, or for both MAC-based VLAN and 802.1x authentication. This attribute can be set to one of the following: 0 - The RADIUS record is valid only for MAC-based VLAN. Set this attribute to zero (0) to prevent a user from using their MAC address as username and password for 802.1x authentication 1 - The RADIUS record is valid for both MAC-based VLAN and 802.1x authentication.</td>
</tr>
</tbody>
</table>
aging period ends, the software aging period begins. The software aging period lasts for a configurable amount of time (the default is 120 seconds). After the software aging period ends, the MAC-based VLAN session is flushed, and the MAC address can be authenticated or denied if the Brocade device again receives traffic from that MAC address.

For MAC-based dynamic activation
If all of the sessions age out on a port, the port is dynamically removed from the VLAN table. When any new session is established, the port is dynamically added back to the VLAN table.

NOTE
If the Brocade device receives a packet from an authenticated MAC address, and the MAC-based VLAN software aging is still in progress (hardware aging has already occurred), a RADIUS message is NOT sent to the RADIUS server. Instead the MAC address is reentered in the hardware along with the parameters previously returned from the RADIUS server. A RADIUS message is sent only when the MAC-based VLAN session ages out from the software.

To change the length of the software aging period
To change the length of the software aging period for blocked MAC addresses, enter a command such as the following.

FGS648P Switch(config)#mac-authentication max-age 180

Syntax: [no] mac-authentication max-age <seconds>
You can specify from 1 – 65535 seconds. The default is 120 seconds.

Disabling aging for MAC-based VLAN sessions
MAC addresses that have been authenticated or denied by a RADIUS server are aged out if no traffic is received from the MAC address for a certain period of time.

You can optionally disable aging for MAC-based VLAN session subject to authentication, either for all MAC addresses or for those learned on a specified interface.

Globally disabling aging
On most devices, you can disable aging on all interfaces where MAC-based VLAN has been enabled, by entering the following command.

FGS648P Switch(config)#mac-authentication disable-aging

Syntax: mac-authentication disable-aging
Enter the command at the global or interface configuration level.

The denied-mac-only parameter prevents denied sessions from being aged out, but ages out permitted sessions.

The permitted-mac-only parameter prevents permitted (authenticated and restricted) sessions from being aged out and ages denied sessions.

Disabling the aging on interfaces
To disable aging on a specific interface where MAC-based VLAN has been enabled, enter the command at the interface level.
Configuring MAC-based VLANs

FGS648P Switch(config)#interface e 3/1
FGS648P Switch(config-if-e1000-3/1)#mac-authentication disable-aging

Syntax: [no] mac-authentication disable-aging

Configuring the maximum MAC addresses per port

To configure the maximum number of MAC addresses allowed per port, use the following commands:

```
FGS648P Switch(config)#interface e 0/1/1
FGS648P Switch(config-if-e1000-0/1/1)#mac-authentication mac-vlan
max-mac-entries 24
```

NOTE
32 MAC addresses maximum are allowed per port. This total includes both static and dynamic hosts. The default number of allowed MACs is 2.

NOTE
To change the maximum MAC addresses per port, you must first disable MAC-based VLAN on that port.

Configuring a MAC-based VLAN for a static host

Follow the steps given below to configure a MAC-based VLAN for a static host.

1. Enable multi-device port authentication globally using the following command.

```
FGS648P Switch(config)#mac-authentication enable
```

2. Add each port on which you want MAC-based VLAN enabled as mac-vlan-permit for a specific VLAN.

```
FGS648P Switch(config)#vlan 10 by port
FGS648P Switch(config-vlan-10)#mac-vlan-permit ethernet 0/1/1 to 0/1/6
added mac-vlan-permit ports ethe 0/1/1 to 0/1/6 to port-vlan 10.
```

3. Add the static MAC-based VLAN configuration on the port.

```
FGS648P Switch(config)#interface e 0/1/1
FGS648P Switch(config-if-e1000-0/1/1)#mac-authentication mac-vlan
0000.0010.0011 vlan 10 priority 5
```

4. To enable MAC-based VLAN on the port.

```
FGS648P Switch(config)#interface e 0/1/1
FGS648P Switch(config-if-e1000-0/1/1)#mac-authentication mac-vlan enable
```

5. To disable MAC-based VLAN on the port.

```
FGS648P Switch(config)#interface e 0/1/1
FGS648P Switch(interface-0/1/1)#mac-auth mac-vlan disable
```

6. To remove and disable the MAC-based VLAN configuration.

```
FGS648P Switch(config)#interface e 0/1/1
FGS648P Switch(config-if-e1000-0/1/1)#no mac-auth mac-vlan
```
Configuring MAC-based VLAN for a dynamic host

Follow the steps given below to configure MAC-based VLAN for a dynamic host.

1. Enable multi-device port authentication globally using the following command.
   
   FGS648P Switch(config)#mac-authentication enable

2. Add each port on which you want MAC-based VLAN enabled as `mac-vlan-permit` for a specific VLAN.
   
   FGS648P Switch(config)#vlan 10 by port
   FGS648P Switch(config-vlan-10)#mac-vlan-permit ethernet 0/1/1 to 0/1/6

3. Enable MAC-based VLAN on the port.
   
   FGS648P Switch(config)#interface e 0/1/1
   FGS648P Switch(config-if-e1000-0/1/1)#mac-authentication mac-vlan enable

4. Disable MAC-based VLAN on the port.
   
   FGS648P Switch(config)#interface e 0/1/1
   FGS648P Switch(config-if-e1000-0/1/1)#mac-auth mac-vlan disable

5. Remove and disable the MAC-based VLAN configuration.
   
   FGS648P Switch(config)#interface e 0/1/1
   FGS648P Switch(config-if-e1000-0/1/1)#no mac-auth mac-vlan

Configuring dynamic MAC-based VLAN

To globally enable MAC-based VLAN globally (for all MAC-based VLAN ports), enter the following commands.

   FGS648P Switch(config)#mac-authentication enable
   FGS648P Switch(config)#mac-authentication mac-vlan-dyn-activation

To configure Dynamic MAC-based VLAN to add a specific port to a specific VLAN, enter commands similar to the following.

   FGS648P Switch(config)#vlan 10
   FGS648P Switch(config-vlan-10)#mac-vlan-permit e 0/1/35

**Syntax:** `mac-vlan-permit < stack | slot | port>

To disable Dynamic MAC-based VLAN, enter the following command.

   FGS648P Switch(config)#no mac-authentication mac-vlan-dyn-activation

**NOTE**

If static Mac-Based VLAN is configured on a port, the port will be added only to the VLAN table for which the static MAC-based VLAN configuration exists.

**NOTE**

If the Dynamic MAC-based VLAN is enabled after any MAC-based VLAN sessions are established, all sessions are flushed and the mac-vlan-permit ports are removed from the VLAN. The ports are then added back to the VLAN dynamically after they successfully pass the RADIUS authentication process.
The following guidelines apply to MAC-based VLAN configurations:

- MAC-to-VLAN mapping must be associated with VLANs that exist on the switch. Create the VLANs before you configure the MAC-based VLAN feature.
- Ports participating in MAC-based VLANs must first be configured as `mac-vlan-permit` ports under the VLAN configuration.
- In the RADIUS server configuration file, a MAC address cannot be configured to associate with more than one VLAN.
- This feature does not currently support dynamic assignment of a port to a VLAN. Users must pre-configure VLANs and port membership before enabling the feature.
- Multi-device port authentication filters will not work with MAC-based VLANs on the same port.
- MAC-based VLAN is not currently supported for trunk ports and LACP.
- MAC-based VLAN is not supported for VLAN groups, topology groups and dual-mode configuration.

The following table describes the CLI commands used to configure MAC-based VLANs.

### TABLE 109 CLI commands for MAC-based VLANs

<table>
<thead>
<tr>
<th>CLI command</th>

Configuring MAC-based VLANs using SNMP

Platform Support:

- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later

Several MIB objects have been developed to allow the configuration of MAC-based VLANs using SNMP. For more information, refer to the IronWare MIB Reference, in the MAC-based VLAN chapter.

Displaying the MAC-VLAN table

Enter the following command to display the MAC-VLAN table for an FGS device.

FGS648P Switch#show table-mac-vlan

</table>

The output from this command differs slightly for FCX devices, and resembles the following.

FCX648S Switch(config)#show table-mac-vlan

<table>
<thead>
<tr>
<th>Port</th>
<th>Vlan</th>
<th>Accepted</th>
<th>Rejected</th>
<th>Attempted</th>
<th>Static</th>
<th>Static</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/1/1</td>
<td>N/A</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>10</td>
</tr>
</tbody>
</table>

Syntax:  show table-mac-vlan

The following table describes the information in this output.
Displaying the MAC-VLAN table for a specific MAC address

Enter the following command to display the MAC-VLAN table information for a specific MAC address on an FGS device.

```
FGS624#show table-mac-vlan 0030.4875.3f73
```

```
+----------------+----------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| MAC Address    | Port     | Vlan Authenticated  | Time Age            | CAM Index | MAC Type Pri | Dot1x Type Pri | Pri Index |
+----------------+----------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| 0030.4875.3f73 | 0/1/1    | 2                   | 01d00h04m27s S0     | 0001      | 3728 Ena     | Dyn              | 0                  |
+----------------+----------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
```

The following example shows output from the show table-mac-vlan command while authentication is in progress on an FGS device.

```
FGS624#show table-mac-vlan 0000.0200.001b
```

```
+----------------+----------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| MAC Address    | Port     | Vlan Authenticated  | Time Age            | CAM Index | MAC Type Pri | Dot1x Type Pri | Pri Index |
+----------------+----------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| 0000.0200.001b | 0/1/2    | 4092                | 00d00h04m27s S36    | N/A       | N/A Dis      | Dyn              | 0                  |
+----------------+----------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
```

The following output shows information for a specific MAC address on an FCX device:

```
FCX648S Switch(config)#show table-mac-vlan 0000.0010.1001
```

```
+----------------+----------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| MAC Address    | Port     | Vlan Authenticated  | Time Age            | dot1x               |

Sample application

Figure 103 illustrates a sample configuration that uses MAC-based VLAN on port e 0/1/1 on the Brocade device. In this configuration, three host PCs are connected to port e 0/1/1 through a hub.

Host A MAC address is statically configured on port e 0/1/1. The profile for Host B MAC address on the RADIUS server specifies that the PC should be assigned to VLAN 2. Host C profile does not exist in the RADIUS server, and will be put into a restricted VLAN.
Host A MAC address is statically mapped to VLAN 1 with priority 1 and is not subjected to RADIUS authentication. When Host B MAC address is authenticated, the Access-Accept message from the RADIUS server specifies that Host B MAC address be placed into VLAN 2. Since Host C MAC address is not present in the RADIUS server, Host C will be rejected by the server and its MAC address will be placed into a restricted VLAN.

Below is the configuration for this example.

```
module 1 fgs-48-port-management-module
module 2 fgs-xfp-1-cx4-1-port-10g-module
vlan 1 by port
  untagged ethe 0/1/10
  mac-vlan-permit ethe 0/1/1 to 0/1/2
  no spanning-tree
vlan 2 by port
  untagged ethe 0/1/30
  mac-vlan-permit ethe 0/1/1 to 0/1/2
  no spanning-tree
vlan 666 name mac_restricted by port
  untagged ethe 0/1/20
  mac-vlan-permit ethe 0/1/1 to 0/1/2
  no spanning-tree
vlan 4000 name DEFAULT-VLAN by port
  no spanning-tree
vlan 4004 by port
  mac-vlan-permit ethe 0/1/1
  default-vlan-id 4000
ip address 10.44.3.8 255.255.255.0
ip default-gateway 10.44.3.1
radius-server host 10.44.3.111
radius-server key 1 $-ndUno
mac-authentication enable
mac-authentication max-age 60
```
mac-authentication hw-deny-age 30
mac-authentication auth-passwd-format xxxx.xxxx.xxxx
interface ethernet 0/1/1
  mac-authentication mac-vlan max-mac-entries 5
  mac-authentication mac-vlan 0030.4888.b9fe vlan 1 priority 1
  mac-authentication mac-vlan enable
!
interface ethernet 0/1/2
  mac-authentication mac-vlan max-mac-entries 5
  mac-authentication mac-vlan enable
!
end

The `show table-mac-vlan` command returns the following results for all ports in this configuration.

```
FGS648P Switch#show table-mac-vlan
---------------------------------------------------------------
  Port  Vlan  Accepted  Rejected  Attempted  Static  Static  Max
        Macs      Macs       Macs    Conf    Macs
---------------------------------------------------------------
 0/1/1   N/A  2         1         0          1       1       5
 0/1/2   N/A  0         0         0          0       0       5
```

The `show table-mac-vlan e 0/1/1` command returns the following results for port 0/1/1 in this configuration.

```
FGS648P Switch#show table-mac-vlan e 0/1/1

```
Sample application
ACL overview

This chapter describes how Access Control Lists (ACLs) are implemented and configured in the FastIron and TurboIron X Series and FCX devices.

**NOTE**
For information about IPv6 ACLs, refer to Chapter 18, “Configuring IPv6 Access Control Lists (ACLs)”.

Brocade devices support **rule-based ACLs** (sometimes called hardware-based ACLs), where the decisions to permit or deny packets are processed in hardware and all permitted packets are switched or routed in hardware. All denied packets are also dropped in hardware. In addition, FCX, FastIron and TurboIron X Series devices support inbound ACLs only. Outbound ACLs are not supported.

**NOTE**
FCX, FastIron and TurboIron X Series devices support hardware-based ACLs only. These devices do not support flow-based ACLs. In contrast, FES devices support flow-based ACLs only.

Rule-based ACLs program the ACL entries you assign to an interface into Content Addressable Memory (CAM) space allocated for the ports. The ACLs are programmed into hardware at startup (or as new ACLs are entered and bound to ports). Devices that use rule-based ACLs program the ACLs into the CAM entries and use these entries to permit or deny packets in the hardware, without sending the packets to the CPU for processing.

Rule-based ACLs are supported on the following interface types:

- Gbps Ethernet ports
- 10 Gbps Ethernet ports
- Trunk groups
- Virtual routing interfaces

**Types of IP ACLs**

You can configure the following types of IP ACLs:

- **Standard** – Permits or denies packets based on source IP address. Valid standard ACL IDs are 1 – 99 or a character string.
- **Extended** – Permits or denies packets based on source and destination IP address and also based on IP protocol information. Valid extended ACL IDs are a number from 100 – 199 or a character string.

**ACL IDs and entries**

ACLs consist of ACL IDs and ACL entries:
- **ACL ID** – An ACL ID is a number from 1 – 99 (for a standard ACL) or 100 – 199 (for an extended ACL) or a character string. The ACL ID identifies a collection of individual ACL entries. When you apply ACL entries to an interface, you do so by applying the ACL ID that contains the ACL entries to the interface, instead of applying the individual entries to the interface. This makes applying large groups of access filters (ACL entries) to interfaces simple. Refer to “Numbered and named ACLs” on page 631.

**NOTE**
This is different from IP access policies. If you use IP access policies, you apply the individual policies to interfaces.

- **ACL entry** – Also called an **ACL rule**, this is a filter command associated with an ACL ID. The maximum number of ACL rules you can configure is a system-wide parameter and depends on the device you are configuring. You can configure up to the maximum number of entries in any combination in different ACLs. The total number of entries in all ACLs cannot exceed the system maximum, listed in Table 110.

**TABLE 110**  Maximum number of ACL entries

</table>

The following rules apply to the FastIron devices, except for TurboIron X Series, listed in Table 110:

- Each ACL group must contain one entry for the implicit deny all IP traffic clause. Also, each ACL group uses a multiple of 8 ACL entries. For example, if all ACL groups contain 5 ACL entries, you could add 127 ACL groups (1016/8) in that port region. If all your ACL groups contain 8 ACL entries, you could add 63 ACL groups, since you must account for the implicit deny entry.

The TurboIron X Series supports a maximum of 1015 ACL entries per ACL.

You configure ACLs on a global basis, then apply them to the incoming traffic on specific ports. The software applies the entries within an ACL in the order they appear in the ACL configuration. As soon as a match is found, the software takes the action specified in the ACL entry (permit or deny the packet) and stops further comparison for that packet.
Numbered and named ACLs

When you configure an ACL, you can refer to the ACL by a numeric ID or by an alphanumeric name. The commands to configure numbered ACLs are different from the commands for named ACLs.

- **Numbered ACL** – If you refer to the ACL by a numeric ID, you can use 1 – 99 for a standard ACL or 100 – 199 for an extended ACL.

- **Named ACL** – If you refer to the ACL by a name, you specify whether the ACL is a standard ACL or an extended ACL, then specify the name.

You can configure up to 99 standard numbered IP ACLs and 100 extended numbered IP ACLs. You also can configure up to 99 standard named ACLs and 100 extended named ACLs by number.

Default ACL action

The default action when no ACLs are configured on a device is to permit all traffic. However, once you configure an ACL and apply it to a port, the default action for that port is to deny all traffic that is not explicitly permitted on the port:

- If you want to tightly control access, configure ACLs consisting of permit entries for the access you want to permit. The ACLs implicitly deny all other access.

- If you want to secure access in environments with many users, you might want to configure ACLs that consist of explicit deny entries, then add an entry to permit all access to the end of each ACL. The software permits packets that are not denied by the deny entries.

How hardware-based ACLs work

When you bind an ACL to inbound traffic on an interface, the device programs the Layer 4 CAM with the ACL. Permit and deny rules are programmed. Most ACL rules require one Layer 4 CAM entry. However, ACL rules that match on more than one TCP or UDP application port may require several CAM entries. The Layer 4 CAM entries for ACLs do not age out. They remain in the CAM until you remove the ACL:

- If a packet received on the interface matches an ACL rule in the Layer 4 CAM, the device permits or denies the packet according to the ACL.

- If a packet does not match an ACL rule, the packet is dropped, since the default action on an interface that has ACLs is to deny the packet.

How fragmented packets are processed

The descriptions above apply to non-fragmented packets. The default processing of fragments by hardware-based ACLs is as follows:

- The first fragment of a packet is permitted or denied using the ACLs. The first fragment is handled the same way as non-fragmented packets, since the first fragment contains the Layer 4 source and destination application port numbers. The device uses the Layer 4 CAM entry if one is programmed, or applies the interface's ACL entries to the packet and permits or denies the packet according to the first matching ACL.

- For other fragments of the same packet, they are subject to a rule only if there is no Layer 4 information in the rule or in any preceding rules.
The fragments are forwarded even if the first fragment, which contains the Layer 4 information, was denied. Generally, denying the first fragment of a packet is sufficient, since a transaction cannot be completed without the entire packet.

For tighter control, you can configure the port to drop all packet fragments. Refer to “Enabling strict control of ACL filtering of fragmented packets” on page 654.

**Hardware aging of Layer 4 CAM entries**

Rule-based ACLs use Layer 4 CAM entries. The device permanently programs rule-based ACLs into the CAM. The entries never age out.

### Configuration considerations

- FastIron and Turbolron X Series devices support inbound ACLs. Outbound ACL are not supported.
- Hardware-based ACLs are supported on:
  - GbE Ethernet ports
  - 10 Gbps Ethernet ports
  - Trunk groups
  - Virtual routing interfaces
- ACLs on the FastIron X Series and Turbolron X Series devices apply to all traffic, including management traffic.
- ACL logging is supported for denied packets and packets that are sent to the CPU to generate the log if logging is enabled on the port and the ACL that is applied to that port. ACL logging is not supported for packets that are processed in hardware (permitted packets).
- ACL logging is supported on FastIron CX devices for ACLs that are applied to network management access features such as Telnet, SSH, Web, SNMP.
- The number of ACL rules supported per device is listed in Table 110.
- Hardware-based ACLs support only one ACL per port. The ACL of course can contain multiple entries (rules). For example, hardware-based ACLs do not support ACLs 101 and 102 on port 1, but hardware-based ACLs do support ACL 101 containing multiple entries.
- ACLs on the FESX and FSX are affected by port regions. Multiple ACL groups share 1016 ACL rules per port region. Each ACL group must contain one entry for the implicit deny all IP traffic clause. Also, each ACL group uses a multiple of 8 ACL entries. For example, if all ACL groups contain 5 ACL entries, you could add 127ACL groups (1016/8) in that port region. If all your ACL groups contain 8 ACL entries, you could add 63 ACL groups, since you must account for the implicit deny entry.
- By default, the first fragment of a fragmented packet received by the Brocade device is permitted or denied using the ACLs, but subsequent fragments of the same packet are forwarded in hardware. Generally, denying the first fragment of a packet is sufficient, since a transaction cannot be completed without the entire packet.
• Starting in software release FSX 04.0.01, ACLs are supported on member ports of a VLAN on which DHCP snooping and Dynamic ARP Inspection (DAI) are enabled. Also new in release FSX 04.0.01, IP source guard and ACLs are supported together on the same port, as long as both features are configured at the port-level or per-port-per-VLAN level. Brocade ports do not support IP source guard and ACLs on the same port if one is configured at the port-level and the other is configured at the per-port-per-VLAN level.

• The following ACL features and options are not supported on the FastIron and TurboIron X Series devices:
  • Applying an ACL on a device that has Super Aggregated VLANs (SAVs) enabled.
  • ACL logging – ACL logging is supported for packets that are sent to the CPU for processing (denied packets). ACL logging is not supported for packets that are processed in hardware (permitted packets).
  • Flow-based ACLs
  • Layer 2 ACLs are not supported on FastIron devices.
  • TurboIron X Series devices support MAC filters instead of Layer 2 ACLs.
  • You can apply an ACL to a port that has TCP SYN protection or ICMP smurf protection, or both, enabled.

NOTE
TurboIron X Series and FastIron CX devices do not support ACLs on Group VEs, even though the CLI contains commands for this action.

Configuring standard numbered ACLs

This section describes how to configure standard numbered ACLs with numeric IDs and provides configuration examples.

Standard ACLs permit or deny packets based on source IP address. You can configure up to 99 standard numbered ACLs. There is no limit to the number of ACL entries an ACL can contain except for the system-wide limitation. For the number of ACL entries supported on a device, refer to “ACL IDs and entries” on page 629.

Standard numbered ACL syntax

Syntax: [no] access-list <ACL-num> deny | permit <source-ip> | <hostname> <wildcard> [log]

or

Syntax: [no] access-list <ACL-num> deny | permit <source-ip>/<mask-bits> | <hostname> [log]

Syntax: [no] access-list <ACL-num> deny | permit host <source-ip> | <hostname> [log]

Syntax: [no] access-list <ACL-num> deny | permit any [log]

Syntax: [no] ip access-group <ACL-num> in

The <ACL-num> parameter is the access list number from 1 – 99.

The deny | permit parameter indicates whether packets that match a policy in the access list are denied (dropped) or permitted (forwarded).
The `<source-ip>` parameter specifies the source IP address. Alternatively, you can specify the host name.

**NOTE**
To specify the host name instead of the IP address, the host name must be configured using the DNS resolver on the Brocade device. To configure the DNS resolver name, use the `ip dns server-address...` command at the global CONFIG level of the CLI.

The `<wildcard>` parameter specifies the mask value to compare against the host address specified by the `<source-ip>` parameter. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the `<source-ip>`. Ones mean any value matches. For example, the `<source-ip>` and `<wildcard>` values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in CIDR format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into ones. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/<mask-bits>” format. To enable the software to display the CIDR masks, enter the `ip show-subnet-length` command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

**NOTE**
If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the `show ip access-list` command.

The `host <source-ip> | <hostname>` parameter lets you specify a host IP address or name. When you use this parameter, you do not need to specify the mask. A mask of all zeros (0.0.0.0) is implied.

The `any` parameter configures the policy to match on all host addresses.

The `log` argument configures the device to generate Syslog entries and SNMP traps for packets that are denied by the access policy.

**NOTE**
You can enable logging on ACLs and filters that support logging even when the ACLs and filters are already in use. To do so, re-enter the ACL or filter command and add the `log` parameter to the end of the ACL or filter. The software replaces the ACL or filter command with the new one. The new ACL or filter, with logging enabled, takes effect immediately.

The `in` parameter applies the ACL to incoming traffic on the interface to which you apply the ACL. You can apply the ACL to an Ethernet port or virtual interface.
NOTE
If the ACL is for a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface.

Configuration example for standard numbered ACLs
To configure a standard ACL and apply it to incoming traffic on port 1/1, enter the following commands.

```plaintext
FastIron(config)# access-list 1 deny host 209.157.22.26 log
FastIron(config)# access-list 1 deny 209.157.29.12 log
FastIron(config)# access-list 1 deny host IPHost1 log
FastIron(config)# access-list 1 permit any
FastIron(config)# int eth 1/1
FastIron(config-if-1/1)# ip access-group 1 in
FastIron(config)# write memory
```

The commands in this example configure an ACL to deny packets from three source IP addresses from being received on port 1/1. The last ACL entry in this ACL permits all packets that are not explicitly denied by the first three ACL entries.

Configuring standard named ACLs

This section describes how to configure standard named ACLs with alphanumeric IDs. This section also provides configuration examples.

Standard ACLs permit or deny packets based on source IP address. You can configure up to 99 standard named ACLs. There is no limit to the number of ACL entries an ACL can contain except for the system-wide limitation. For the number of ACL entries supported on a device, refer to "ACL IDs and entries" on page 629.

The commands for configuring named ACL entries are different from the commands for configuring numbered ACL entries. The command to configure a numbered ACL is `access-list`. The command for configuring a named ACL is `ip access-list`. In addition, when you configure a numbered ACL entry, you specify all the command parameters on the same command. When you configure a named ACL, you specify the ACL type (standard or extended) and the ACL name with one command, which places you in the configuration level for that ACL. Once you enter the configuration level for the ACL, the command syntax is the same as the syntax for numbered ACLs.

Standard named ACL syntax

```plaintext
Syntax: [no] ip access-list standard <ACL-name> | <ACL-num>
Syntax: deny | permit <source-ip> | <hostname> <wildcard> [log]
  or
Syntax: deny | permit <source-ip>/<mask-bits> | <hostname> [log]
Syntax: deny | permit host <source-ip> | <hostname> [log]
Syntax: deny | permit any [log]
Syntax: [no] ip access-group <ACL-name> in
```
The `<ACL-name>` parameter is the access list name. You can specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name if you enclose the name in quotation marks (for example, “ACL for Net1”).

The `<ACL-num>` parameter allows you to specify an ACL number if you prefer. If you specify a number, you can specify from 1 – 99 for standard ACLs.

**NOTE**
For convenience, the software allows you to configure numbered ACLs using the syntax for named ACLs. The software also still supports the older syntax for numbered ACLs. Although the software allows both methods for configuring numbered ACLs, numbered ACLs are always formatted in the startup-config and running-config files in using the older syntax, as follows.

```
access-list 1 deny host 209.157.22.26 log
access-list 1 deny 209.157.22.0 0.0.0.255 log
access-list 1 permit any
access-list 101 deny tcp any any eq http log
```

The `deny | permit` parameter indicates whether packets that match a policy in the access list are denied (dropped) or permitted (forwarded).

The `<source-ip>` parameter specifies the source IP address. Alternatively, you can specify the host name.

**NOTE**
To specify the host name instead of the IP address, the host name must be configured using the DNS resolver on the Brocade device. To configure the DNS resolver name, use the `ip dns server-address...` command at the global CONFIG level of the CLI.

The `<wildcard>` parameter specifies the mask value to compare against the host address specified by the `<source-ip>` parameter. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the `<source-ip>`. Ones mean any value matches. For example, the `<source-ip>` and `<wildcard>` values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in CIDR format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into ones. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/<mask-bits>” format. To enable the software to display the CIDR masks, enter the `ip show-subnet-length` command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.
NOTE
If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the `show ip access-list` command.

The `host <source-ip> | <hostname>` parameter lets you specify a host IP address or name. When you use this parameter, you do not need to specify the mask. A mask of all zeros (0.0.0.0) is implied.

The `any` parameter configures the policy to match on all host addresses.

The `log` argument configures the device to generate Syslog entries and SNMP traps for packets that are denied by the access policy.

NOTE
You can enable logging on ACLs and filters that support logging even when the ACLs and filters are already in use. To do so, re-enter the ACL or filter command and add the `log` parameter to the end of the ACL or filter. The software replaces the ACL or filter command with the new one. The new ACL or filter, with logging enabled, takes effect immediately.

The `in` parameter applies the ACL to incoming traffic on the interface to which you apply the ACL. You can apply the ACL to an Ethernet port or virtual interface.

NOTE
If the ACL is bound to a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface.

Configuration example for standard named ACLs

To configure a standard named ACL, enter commands such as the following.

```
FastIron(config)#ip access-list standard Net1
FastIron(config-std-nACL)# deny host 209.157.22.26 log
FastIron(config-std-nACL)# deny 209.157.29.12 log
FastIron(config-std-nACL)# deny host IPHost1 log
FastIron(config-std-nACL)# permit any
FastIron(config-std-nACL)# exit
FastIron(config)#int eth 1/1
FastIron(config-if-e1000-1/1)# ip access-group Net1 in
```

The commands in this example configure a standard ACL named “Net1”. The entries in this ACL deny packets from three source IP addresses from being forwarded on port 1. Since the implicit action for an ACL is “deny”, the last ACL entry in this ACL permits all packets that are not explicitly denied by the first three ACL entries. For an example of how to configure the same entries in a numbered ACL, refer to “Configuring standard numbered ACLs” on page 633.

Notice that the command prompt changes after you enter the ACL type and name. The “std” in the command prompt indicates that you are configuring entries for a standard ACL. For an extended ACL, this part of the command prompt is “ext”. The “nACL” indicates that you are configuring a named ACL.
Configuring extended numbered ACLs

This section describes how to configure extended numbered ACLs.

Extended ACLs let you permit or deny packets based on the following information:

- IP protocol
- Source IP address or host name
- Destination IP address or host name
- Source TCP or UDP port (if the IP protocol is TCP or UDP)
- Destination TCP or UDP port (if the IP protocol is TCP or UDP)

The IP protocol can be one of the following well-known names or any IP protocol number from 0 – 255:

- Internet Control Message Protocol (ICMP)
- Internet Group Management Protocol (IGMP)
- Internet Gateway Routing Protocol (IGRP)
- Internet Protocol (IP)
- Open Shortest Path First (OSPF)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

For TCP and UDP, you also can specify a comparison operator and port name or number. For example, you can configure a policy to block web access to a specific website by denying all TCP port 80 (HTTP) packets from a specified source IP address to the website IP address.

**NOTE**

TurboIron X Series devices running software release 04.1.00 and later support extended ACLs.

Extended numbered ACL syntax

Syntax: `[no] access-list <ACL-num> deny | permit <ip-protocol> <source-ip> | <hostname>
         <wildcard> | <operator> <source-tcp/udp-port> | <destination-ip> | <hostname>
         | <icmp-num> | <icmp-type> | <wildcard> | <tcp/udp comparison operator>
         <destination-tcp/udp-port> | [dscp-cos-mapping] [dscp-marking <0-63>
         | [802.1p-priority-marking <0 – 7>... | dscp-cos-mapping]] [dscp-matching <0-63> | [log]
         [precedence <name> | <0 - 7> | [tos <0 - 63> | <name>]] [traffic policy <name>]

Syntax: `[no] access-list <ACL-num> deny | permit host <ip-protocol> any any

Syntax: `[no] ip access-group <ACL-num> in

The `<ACL-num>` parameter is the extended access list number. Specify a number from 100 – 199.

The `deny | permit` parameter indicates whether packets that match the policy are dropped or forwarded.

The `<ip-protocol>` parameter indicates the type of IP packet you are filtering. You can specify a well-known name for any protocol whose number is less than 255. For other protocols, you must enter the number. Enter “?” instead of a protocol to list the well-known names recognized by the CLI.
The `<source-ip> | <hostname>` parameter specifies the source IP host for the policy. If you want the policy to match on all source addresses, enter `any`.

The `<wildcard>` parameter specifies the portion of the source IP host address to match against. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example `0.0.0.255`. Zeros in the mask mean the packet source address must match the `<source-ip>`. Ones mean any value matches. For example, the `<source-ip>` and `<wildcard>` values `209.157.22.26 0.0.0.255` mean that all hosts in the Class C subnet `209.157.22.0` match the policy.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify `209.157.22.26/24` or `209.157.22.26 0.0.0.255`, then save the changes to the startup-config file, the value appears as `209.157.22.0/24` (if you have enabled display of subnet lengths) or `209.157.22.0 0.0.0.255` in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/<mask-bits>” format. To enable the software to display the CIDR masks, enter the `ip show-subnet-length` command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

**NOTE**
If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the `show ip access-list` command.

The `<destination-ip> | <hostname>` parameter specifies the destination IP host for the policy. If you want the policy to match on all destination addresses, enter `any`.

The `<icmp-type> | <icmp-num>` parameter specifies the ICMP protocol type:
- This parameter applies only if you specified `icmp` as the `<ip-protocol>` value.
- If you use this parameter, the ACL entry is sent to the CPU for processing.
- If you do not specify a message type, the ACL applies to all types of ICMP messages.

The `<icmp-num>` parameter can be a value from 0 - 255.

The `<icmp-type>` parameter can have one of the following values, depending on the software version the device is running:
- `any-icmp-type`
- `echo`
- `echo-reply`
- `information-request`
- `log`
- `mask-reply`
- `mask-request`
- `parameter-problem`
Configuring extended numbered ACLs

- redirect
- source-quench
- time-exceeded
- timestamp-reply
- timestamp-request
- traffic policy
- unreachable
- <num>

The `<tcp/udp comparison operator>` parameter specifies a comparison operator for the TCP or UDP port number. This parameter applies only when you specify `tcp` or `udp` as the IP protocol. For example, if you are configuring an entry for HTTP, specify `tcp eq http`. You can enter one of the following operators:

- **eq** – The policy applies to the TCP or UDP port name or number you enter after `eq`.
- **established** – This operator applies only to TCP packets. If you use this operator, the policy applies to TCP packets that have the ACK (Acknowledgment) or RST (Reset) bits set on (set to “1”) in the Control Bits field of the TCP packet header. Thus, the policy applies only to established TCP sessions, not to new sessions. Refer to Section 3.1, “Header Format”, in RFC 793 for information about this field.

**NOTE**
This operator applies only to destination TCP ports, not source TCP ports.

- **gt** – The policy applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after `gt`.
- **lt** – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after `lt`.
- **neq** – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after `neq`.
- **range** – The policy applies to all TCP or UDP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the `range` parameter. The `range` includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: range 23 53. The first port number in the `range` must be lower than the last number in the `range`.

The `<tcp/udp-port>` parameter specifies the TCP or UDP port number or well-known name. You can specify a well-known name for any application port whose number is less than 1024. For other application ports, you must enter the number. Enter “?” instead of a port to list the well-known names recognized by the CLI.

The `in` parameter specifies that the ACL applies to incoming traffic on the interface to which you apply the ACL. You can apply the ACL to an Ethernet port or a virtual interface.

**NOTE**
If the ACL is for a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface. Refer to “Configuring standard numbered ACLs” on page 633.
The **precedence** `<name> | <num>` parameter of the **ip access-list** command specifies the IP precedence. The precedence option for of an IP packet is set in a three-bit field following the four-bit header-length field of the packet header. You can specify one of the following:

- **critical** or 5 – The ACL matches packets that have the critical precedence. If you specify the option number instead of the name, specify number 5.
- **flash** or 3 – The ACL matches packets that have the flash precedence. If you specify the option number instead of the name, specify number 3.
- **flash-override** or 4 – The ACL matches packets that have the flash override precedence. If you specify the option number instead of the name, specify number 4.
- **immediate** or 2 – The ACL matches packets that have the immediate precedence. If you specify the option number instead of the name, specify number 2.
- **internet** or 6 – The ACL matches packets that have the internetwork control precedence. If you specify the option number instead of the name, specify number 6.
- **network** or 7 – The ACL matches packets that have the network control precedence. If you specify the option number instead of the name, specify number 7.
- **priority** or 1 – The ACL matches packets that have the priority precedence. If you specify the option number instead of the name, specify number 1.
- **routine** or 0 – The ACL matches packets that have the routine precedence. If you specify the option number instead of the name, specify number 0.

The **tos** `<name> | <num>` parameter of the **ip access-list** command specifies the IP ToS. You can specify one of the following:

- **max-reliability** or 2 – The ACL matches packets that have the maximum reliability ToS. The decimal value for this option is 2.
- **max-throughput** or 4 – The ACL matches packets that have the maximum throughput ToS. The decimal value for this option is 4.
- **min-delay** or 8 – The ACL matches packets that have the minimum delay ToS. The decimal value for this option is 8.
- **min-monetary-cost** or 1 – The ACL matches packets that have the minimum monetary cost ToS. The decimal value for this option is 1.

**NOTE**
This value is not supported on 10 Gbps Ethernet modules.

- **normal** or 0 – The ACL matches packets that have the normal ToS. The decimal value for this option is 0.
- `<num>` – A number from 0 – 15 that is the sum of the numeric values of the options you want. The ToS field is a four-bit field following the Precedence field in the IP header. You can specify one or more of the following. To select more than one option, enter the decimal value that is equivalent to the sum of the numeric values of all the ToS options you want to select. For example, to select the **max-reliability** and **min-delay** options, enter number 10. To select all options, select 15.

The **dscp-cos-mapping** option maps the DSCP value in incoming packets to a hardware table that provides mapping of each of the 0 – 63 DSCP values, and distributes them among eight traffic classes (internal priorities) and eight 802.1p priorities.

**NOTE**
The **dscp-cos-mapping** option overrides port-based priority settings.
NOTE
The `dscp-cos-mapping` option is **not** supported for TIX, FGS, FGS-STK, FLS and FLS-STK, or FCX devices.

The `dscp-marking` option enables you to configure an ACL that marks matching packets with a specified DSCP value. Enter a value from 0 – 63. Refer to “Using an IP ACL to mark DSCP values (DSCP marking)” on page 665.

The `dscp-matching` option matches on the packet DSCP value. Enter a value from 0 – 63. This option does not change the packet forwarding priority through the device or mark the packet. Refer to “DSCP matching” on page 668.

The `log` parameter enables SNMP traps and Syslog messages for packets denied by the ACL.

You can enable logging on ACLs and filters that support logging even when the ACLs and filters are already in use. To do so, re-enter the ACL or filter command and add the `log` parameter to the end of the ACL or filter. The software replaces the ACL or filter command with the new one. The new ACL or filter, with logging enabled, takes effect immediately.

The `traffic-policy` option enables the device to rate limit inbound traffic and to count the packets and bytes per packet to which ACL permit or deny clauses are applied. For configuration procedures and examples, refer to Chapter 25, “Configuring Traffic Policies”.

Configuration examples for extended numbered ACLs

To configure an extended access list that blocks all Telnet traffic received on port 1/1 from IP host 209.157.22.26, enter the following commands.

```
FastIron(config)#access-list 101 deny tcp host 209.157.22.26 any eq telnet log
FastIron(config)#access-list 101 permit ip any any
FastIron(config)#int eth 1/1
FastIron(config-if-e1000-1/1)#ip access-group 101 in
FastIron(config)#write memory
```

Here is another example of commands for configuring an extended ACL and applying it to an interface. These examples show many of the syntax choices. Notice that some of the entries are configured to generate log entries while other entries are not thus configured.

```
FastIron(config)# access-list 102 perm icmp 209.157.22.0/24 209.157.21.0/24
FastIron(config)# access-list 102 deny igmp host rkwong 209.157.21.0/24 log
FastIron(config)# access-list 102 deny igrp 209.157.21.0/24 host rkwong log
FastIron(config)# access-list 102 deny ip host 209.157.21.100 host 209.157.22.1 log
FastIron(config)# access-list 102 deny ospf any any log
FastIron(config)# access-list 102 permit ip any any
```

The first entry permits ICMP traffic from hosts in the 209.157.22.x network to hosts in the 209.157.21.x network.

The second entry denies IGMP traffic from the host device named “rkwong” to the 209.157.21.x network.

The third entry denies IGMP traffic from the 209.157.21.x network to the host device named “rkwong”.

```
The fourth entry denies all IP traffic from host 209.157.21.100 to host 209.157.22.1 and generates Syslog entries for packets that are denied by this entry.

The fifth entry denies all OSPF traffic and generates Syslog entries for denied traffic.

The sixth entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

The following commands apply ACL 102 to the incoming traffic on port 1/2 and to the incoming traffic on port 4/3.

```
FastIron(config)# int eth 1/2
FastIron(config-if-1/2)# ip access-group 102 in
FastIron(config-if-1/2)# exit
FastIron(config)# int eth 4/3
FastIron(config-if-4/3)# ip access-group 102 in
FastIron(config)# write memory
```

Here is another example of an extended ACL.

```
FastIron(config)# access-list 103 deny tcp 209.157.21.0/24 209.157.22.0/24
FastIron(config)# access-list 103 deny tcp 209.157.21.0/24 eq ftp 209.157.22.0/24
FastIron(config)# access-list 103 deny tcp 209.157.21.0/24 eq telnet neq 5
FastIron(config)# access-list 103 deny udp any range 5 6 209.157.22.0/24 range 7
```

The first entry in this ACL denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network.

The second entry denies all FTP traffic from the 209.157.21.x network to the 209.157.22.x network.

The third entry denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network, if the TCP port number of the traffic is less than the well-known TCP port number for Telnet (23), and if the TCP port is not equal to 5. Thus, TCP packets whose TCP port numbers are 5 or are greater than 23 are allowed.

The fourth entry denies UDP packets from any source to the 209.157.22.x network, if the UDP port number from the source network is 5 or 6 and the destination UDP port is 7 or 8.

The fifth entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

The following commands apply ACL 103 to the incoming traffic on ports 2/1 and 2/2.

```
FastIron(config)# int eth 2/1
FastIron(config-if-2/1)# ip access-group 103 in
FastIron(config-if-2/1)# exit
FastIron(config)# int eth 0/2/2
FastIron(config-if-2/2)# ip access-group 103 in
FastIron(config)# write memory
```
Configuring extended named ACLs

The commands for configuring named ACL entries are different from the commands for configuring numbered ACL entries. The command to configure a numbered ACL is `access-list`. The command for configuring a named ACL is `ip access-list`. In addition, when you configure a numbered ACL entry, you specify all the command parameters on the same command. When you configure a named ACL, you specify the ACL type (standard or extended) and the ACL number with one command, which places you in the configuration level for that ACL. Once you enter the configuration level for the ACL, the command syntax is the same as the syntax for numbered ACLs.

Extended ACLs let you permit or deny packets based on the following information:

- IP protocol
- Source IP address or host name
- Destination IP address or host name
- Source TCP or UDP port (if the IP protocol is TCP or UDP)
- Destination TCP or UDP port (if the IP protocol is TCP or UDP)

The IP protocol can be one of the following well-known names or any IP protocol number from 0 – 255:

- Internet Control Message Protocol (ICMP)
- Internet Group Management Protocol (IGMP)
- Internet Gateway Routing Protocol (IGRP)
- Internet Protocol (IP)
- Open Shortest Path First (OSPF)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

For TCP and UDP, you also can specify a comparison operator and port name or number. For example, you can configure a policy to block web access to a specific website by denying all TCP port 80 (HTTP) packets from a specified source IP address to the website’s IP address.

Extended named ACL syntax

Syntax: `[no] ip access-list extended <ACL-name> deny | permit <ip-protocol> <source-ip> | <hostname> <wildcard> [<operator> <source-tcp/udp-port>] <destination-ip> | <hostname> [<icmp-num> | <icmp-type> <wildcard> [<operator> <tcp/udp comparison operator> <destination-tcp/udp-port>]] [dscp-cos-mapping] [dscp-marking <0-63> [802.1p-priority-marking <0 – 7> ...] dscp-cos-mapping]] dscp-matching <0-63> [log] [precedence <name> | <0 – 7>] [tos <0 – 63> | <name>] [traffic policy <name>]

Syntax: `[no] access-list <num> deny | permit host <ip-protocol> any any

Syntax: `[no] ip access-group <num> in

The `<ACL-name>` parameter is the access list name. You can specify a string of up to 256 alphanumeric characters. You can use blanks in the ACL name if you enclose the name in quotation marks (for example, “ACL for Net1”).

The `deny` | `permit` parameter indicates whether packets that match the policy are dropped or forwarded.
The <ip-protocol> parameter indicates the type of IP packet you are filtering. You can specify a well-known name for any protocol whose number is less than 255. For other protocols, you must enter the number. Enter "?" instead of a protocol to list the well-known names recognized by the CLI.

The <source-ip> | <hostname> parameter specifies the source IP host for the policy. If you want the policy to match on all source addresses, enter any.

The < wildcard > parameter specifies the portion of the source IP host address to match against. The < wildcard > is a four-part value in dotted-decimal notation (IP address format) consisting of ones and zeros. Zeros in the mask mean the packet’s source address must match the <source-ip>. Ones mean any value matches. For example, the <source-ip> and < wildcard > values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/ <mask-bits>” format. To enable the software to display the CIDR masks, enter the ip show-subnet-length command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

NOTE
If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the show ip access-list command.

The < destination-ip > | < hostname > parameter specifies the destination IP host for the policy. If you want the policy to match on all destination addresses, enter any.

The <icmp-type> | <icmp-num> parameter specifies the ICMP protocol type:
- This parameter applies only if you specified icmp as the <ip-protocol> value.
- If you use this parameter, the ACL entry is sent to the CPU for processing.
- If you do not specify a message type, the ACL applies to all types of ICMP messages.

The <icmp-num> parameter can be a value from 0 – 255.

The <icmp-type> parameter can have one of the following values, depending on the software version the device is running:
- any-icmp-type
- echo
- echo-reply
- information-request
- log
- mask-reply
Configuring extended named ACLs

- mask-request
- parameter-problem
- redirect
- source-quench
- time-exceeded
- timestamp-reply
- timestamp-request
- traffic policy
- unreachable
- `<num>`

The `<tcp/udp comparison operator>` parameter specifies a comparison operator for the TCP or UDP port number. This parameter applies only when you specify `tcp` or `udp` as the IP protocol. For example, if you are configuring an entry for HTTP, specify `tcp eq http`. You can enter one of the following operators:

- `eq` – The policy applies to the TCP or UDP port name or number you enter after `eq`.
- `established` – This operator applies only to TCP packets. If you use this operator, the policy applies to TCP packets that have the ACK (Acknowledgment) or RST (Reset) bits set on (set to “1”) in the Control Bits field of the TCP packet header. Thus, the policy applies only to established TCP sessions, not to new sessions. Refer to Section 3.1, “Header Format”, in RFC 793 for information about this field.

**NOTE**
This operator applies only to destination TCP ports, not source TCP ports.

- `gt` – The policy applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after `gt`.
- `lt` – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after `lt`.
- `neq` – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after `neq`.
- `range` – The policy applies to all TCP or UDP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the range parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following: `range 23 53`. The first port number in the range must be lower than the last number in the range.

The `<tcp/udp-port>` parameter specifies the TCP or UDP port number or well-known name. You can specify a well-known name for any application port whose number is less than 1024. For other application ports, you must enter the number. Enter “?” instead of a port to list the well-known names recognized by the CLI.

The `in` parameter specifies that the ACL applies to incoming traffic on the interface to which you apply the ACL. You can apply the ACL to an Ethernet port or a virtual interface.

**NOTE**
If the ACL is for a virtual routing interface, you also can specify a subset of ports within the VLAN containing that interface when assigning an ACL to the interface. Refer to “Configuring standard numbered ACLs” on page 633.
The **precedence** `<name> | <num>` parameter of the `ip access-list` command specifies the IP precedence. The precedence option for of an IP packet is set in a three-bit field following the four-bit header-length field of the packet’s header. You can specify one of the following:

- **critical** or **5** – The ACL matches packets that have the critical precedence. If you specify the option number instead of the name, specify number 5.
- **flash** or **3** – The ACL matches packets that have the flash precedence. If you specify the option number instead of the name, specify number 3.
- **flash-override** or **4** – The ACL matches packets that have the flash override precedence. If you specify the option number instead of the name, specify number 4.
- **immediate** or **2** – The ACL matches packets that have the immediate precedence. If you specify the option number instead of the name, specify number 2.
- **internet** or **6** – The ACL matches packets that have the internetwork control precedence. If you specify the option number instead of the name, specify number 6.
- **network** or **7** – The ACL matches packets that have the network control precedence. If you specify the option number instead of the name, specify number 7.
- **priority** or **1** – The ACL matches packets that have the priority precedence. If you specify the option number instead of the name, specify number 1.
- **routine** or **0** – The ACL matches packets that have the routine precedence. If you specify the option number instead of the name, specify number 0.

The **tos** `<name> | <num>` parameter of the `ip access-list` command specifies the IP ToS. You can specify one of the following:

- **max-reliability** or **2** – The ACL matches packets that have the maximum reliability ToS. The decimal value for this option is 2.
- **max-throughput** or **4** – The ACL matches packets that have the maximum throughput ToS. The decimal value for this option is 4.
- **min-delay** or **8** – The ACL matches packets that have the minimum delay ToS. The decimal value for this option is 8.
- **min-monetary-cost** or **1** – The ACL matches packets that have the minimum monetary cost ToS. The decimal value for this option is 1.

**NOTE**
This value is not supported on 10 Gigabit Ethernet modules.

- **normal** or **0** – The ACL matches packets that have the normal ToS. The decimal value for this option is 0.
- `<num>` – A number from 0 – 15 that is the sum of the numeric values of the options you want. The ToS field is a four-bit field following the Precedence field in the IP header. You can specify one or more of the following. To select more than one option, enter the decimal value that is equivalent to the sum of the numeric values of all the ToS options you want to select. For example, to select the max-reliability and min-delay options, enter number 10. To select all options, select 15.
- The **dscp-cos-mapping** option maps the DSCP value in incoming packets to a hardware table that provides mapping of each of the 0 – 63 DSCP values, and distributes them among eight traffic classes (internal priorities) and eight 802.1p priorities.

**NOTE**
The **dscp-cos-mapping** option overrides port-based priority settings.
Preserving user input for ACL TCP/UDP port numbers

Prior to release 03.1.00 for the FastIron X Series, ACL implementations automatically display the TCP/UDP port name instead of the port number, regardless of user preference. This feature preserves the user input (name or number) and now displays either the port name or the number.

A new command has been added to enable this feature.

**Syntax:** `ip preserve-ACL-user-input-format`

The following example shows how this feature works for a TCP port (this feature works the same way for UDP ports). In this example, the user identifies the TCP port by number (80) when configuring ACL group 140. However, `show ip access-list 140` reverts back to the port name for the TCP port (http in this example). After the user issues the new `ip preserve-ACL-user-input-format` command, `show ip access-list 140` displays either the TCP port number or name, depending on how it was configured by the user.

```
FastIron(config)# access-list 140 permit tcp any any eq 80
FastIron(config)# access-list 140 permit tcp any any eq ftp
FastIron# show ip access-lists 140
```
Managing ACL comment text

ACL comment text describes entries in an ACL. The comment text appears in the output of `show` commands that display ACL information.

This section describes how to add, delete, and view ACL comments.

Adding a comment to an entry in a numbered ACL

To add comments to entries in a numbered ACL, enter commands such as the following.

```
FastIron(config)#access-list 100 remark The following line permits TCP packets
FastIron(config)#access-list 100 permit tcp 192.168.4.40/24 2.2.2.2/24
FastIron(config)#access-list 100 remark The following permits UDP packets
FastIron(config)#access-list 100 permit udp 192.168.2.52/24 2.2.2.2/24
FastIron(config)#access-list 100 deny ip any any
```

Starting in software release FSX 04.2.00, you can add comments to entries in a numbered ACL using the syntax for named ACLs. For example, using the same example configuration above, you could instead enter the following commands.

```
FastIron(config)#ip access-list extended 100
FastIron(config-ext-nACL)#remark The following line permits TCP packets
FastIron(config-ext-nACL)#permit tcp 192.168.4.40/24 2.2.2.2/24
FastIron(config-ext-nACL)#remark The following permits UDP packets
FastIron(config-ext-nACL)#permit udp 192.168.2.52/24 2.2.2.2/24
FastIron(config-ext-nACL)#deny ip any any
```

Syntax: `[no] access-list <ACL-num> remark <comment-text>`

or

Syntax: `[no] ip access-list standard | extended <ACL-num>`

Syntax: `remark <comment-text>`

For `<ACL-num>`, enter the number of the ACL.

The `<comment-text>` can be up to 128 characters in length. The comment must be entered separately from the actual ACL entry; that is, you cannot enter the ACL entry and the ACL comment with the same `access-list` or `ip access-list` command. Also, in order for the remark to be displayed correctly in the output of `show` commands, the comment must be entered immediately before the ACL entry it describes. Note that an ACL comment is tied to the ACL entry immediately following the comment. Therefore, if the ACL entry is removed, the ACL comment is also removed.

The `standard | extended` parameter indicates the ACL type.
Adding a comment to an entry in a named ACL

Platform Support:
- FastIron X Series devices running software release 04.2.00 and later – L2, BL3, L3

To add comments to entries in a named ACL, enter commands such as the following.

```
FastIron(config)# ip access-list extended TCP/UDP
FastIron(config-ext-nACL)# remark The following line permits TCP packets
FastIron(config-ext-nACL)# permit tcp 192.168.4.40/24 2.2.2.2/24
FastIron(config-ext-nACL)# remark The following permits UDP packets
FastIron(config-ext-nACL)# permit udp 192.168.2.52/24 2.2.2.2/24
FastIron(config-ext-nACL)# deny ip any any
```

Syntax: `[no] access-list standard | extended <ACL-name>`

Syntax: `remark <comment-text>`

The `standard | extended` parameter indicates the ACL type.

For `<ACL-name>`, enter the name of the ACL.

The `<comment-text>` can be up to 128 characters in length. The comment must be entered separately from the actual ACL entry; that is, you cannot enter the ACL entry and the ACL comment with the same `ip access-list` command. Also, in order for the remark to be displayed correctly in the output of show commands, the comment must be entered immediately before the ACL entry it describes. Note that an ACL comment is tied to the ACL entry immediately following the comment. Therefore, if the ACL entry is removed, the ACL comment is also removed.

Deleting a comment from an ACL entry

Platform Support:
- FastIron X Series devices running software release 04.2.00 and later – L2, BL3, L3

To delete a comment from an ACL entry, enter commands such as the following.

```
FastIron(config)# ip access-list standard 99
FastIron(config)# no remark The following line permits TCP packets
```

Syntax: `no remark <comment-text>`

Viewing comments in an ACL

You can use the following commands to display comments for ACL entries:

- `show running-config`
- `show access-list`
- `show ip access-list`

The following shows the comment text for a numbered ACL, ACL 100, in a `show running-config` display.
Applying an ACL to a virtual interface in a protocol- or subnet-based VLAN

By default, when you apply an ACL to a virtual interface in a protocol-based or subnet-based VLAN, the ACL takes effect on all protocol or subnet VLANs to which the untagged port belongs. To prevent the Brocade device from denying packets on other virtual interfaces that do not have an ACL applied, configure an ACL that permits packets in the IP subnet of the virtual interface in all protocol-based or subnet-based VLANs to which the untagged port belongs. The following is an example configuration.

```
FastIron# conf t
FastIron(config)# vlan 1 name DEFAULT-VLAN by port
FastIron(config-vlan-1)# ip-subnet 192.168.10.0 255.255.255.0
FastIron(config-vlan-ip-subnet)# static ethe 1
FastIron(config-vlan-ip-subnet)# router-interface ve 10
FastIron(config-vlan-ip-subnet)# ip-subnet 10.15.1.0 255.255.255.0
FastIron(config-vlan-ip-subnet)# static ethe 1
FastIron(config-vlan-ip-subnet)# router-interface ve 20
FastIron(config-vlan-ip-subnet)# logging console
FastIron(config-vlan-ip-subnet)# exit
FastIron(config-vlan-1)# no vlan-dynamic-discovery
Vlan dynamic discovery is disabled
FastIron(config-vlan-1)# int e 2
FastIron(config-if-e1000-2)# disable
FastIron(config-if-e1000-2)# interface ve 10
FastIron(config-vif-10)# ip address 192.168.10.254 255.255.255.0
```

Applying an ACL to a virtual interface in a protocol- or subnet-based VLAN

```
FastIron# show running-config
...
access-list 100 remark The following line permits TCP packets
access-list 100 permit tcp 192.168.4.40/24 2.2.2.2/24
access-list 100 remark The following line permits UDP packets
access-list 100 permit udp 192.168.2.52/24 2.2.2.2/24
access-list 100 deny ip any any

Syntax: show running-config

The following example shows the comment text for an ACL in a show access-list display. The output is identical in a show ip access-list display.

FastIron# show access-list
IP access list rate-limit 100 aaaa.bbbb.cccc
Extended IP access list TCP/UDP (Total flows: N/A, Total packets: N/A)
ACL Remark: The following line permits TCP packets
permit tcp 0.0.0.40 255.255.255.0 0.0.0.2 255.255.255.0 (Flows: N/A, Packets: N/A)
ACL Remark: The following line permits UDP packets
permit udp 0.0.0.52 255.255.255.0 0.0.0.2 255.255.255.0 (Flows: N/A, Packets: N/A)
deny ip any any (Flows: N/A, Packets: N/A)

Syntax: show access-list <ACL-num> | <ACL-name> | all
or
Syntax: show ip access-list <ACL-num> | <ACL-name> | all
```
Enabling ACL logging

You may want the software to log entries in the Syslog for packets that are denied by ACL filters. ACL logging is disabled by default; it must be explicitly enabled on a port.

When you enable logging for ACL entries, statistics for packets that match the deny conditions of the ACL entries are logged. For example, if you configure a standard ACL entry to deny all packets from source address 209.157.22.26, statistics for packets that are explicitly denied by the ACL entry are logged in the Syslog buffer and in SNMP traps sent by the Brocade device.

The first time an ACL entry denies a packet, the software immediately generates a Syslog entry and an SNMP trap. The software also starts a five-minute timer. The timer keeps track of all packets explicitly denied by the ACL entries. After five minutes, the software generates a single Syslog entry for each ACL entry that denied a packet. The Syslog entry (message) indicates the number of packets denied by the ACL entry during the previous five minutes. Note however that packet count may be inaccurate if the packet rate is high and exceeds the CPU processing rate.

If no ACL entries explicitly deny packets during an entire five-minute timer interval, the timer stops. The timer restarts when an ACL entry explicitly denies a packet.

**NOTE**
The timer for logging packets denied by Layer 2 filters is a different timer than the ACL logging timer.

**Configuration notes**

Note the following before configuring ACL logging:

- You can enable ACL logging on physical and virtual interfaces.
- ACL logging logs denied packets only.
- When ACL logging is disabled, packets that match the ACL rule are forwarded or dropped in hardware. When ACL logging is enabled, all packets that match the ACL deny rule are sent to the CPU. When ACL logging is enabled, Brocade recommends that you configure a traffic conditioner, then link the ACL to the traffic conditioner to prevent CPU overload. For example:
  ```
  FastIron(config)# traffic-policy TPD1 rate-limit fixed 100 exceed-action drop
  FastIron(config)# access-list 101 deny ip host 210.10.12.2 any traffic-policy TPD1 log
  ```
  **NOTE**
  Adding a rate limit to the ACL will not prevent a CPU overload on FCX devices.

- ACL logging is intended for debugging purpose. Brocade recommends that you disable ACL logging after the debug session is over.
**Configuration Tasks**

To enable ACL logging, complete the following steps:

1. Create ACL entries with the log option
2. Enable ACL logging on individual ports

**NOTE**

The command syntax for enabling ACL logging is different on IPv4 devices than on IPv6 devices. See the configuration examples in the next section.

3. Bind the ACLs to the ports on which ACL logging is enabled

**Example Configuration**

The following shows an example configuration on an IPv4 device.

```
FastIron(config)# access-list 1 deny host 209.157.22.26 log
FastIron(config)# access-list 1 deny 209.157.29.12 log
FastIron(config)# access-list 1 deny host IPHost1 log
FastIron(config)# access-list 1 permit any
FastIron(config)# interface e 1/4
FastIron(config-if-e1000-1/4)# ACL-logging
FastIron(config-if-e1000-1/4)# ip access-group 1 in
```

The above commands create ACL entries that include the log option, enable ACL logging on interface e 1/4, then bind the ACL to interface e 1/4. Statistics for packets that match the deny statements will be logged.

**NOTE**

The `ACL-logging` command shown above is not required for FGS, FWS, and FLS devices.

**Syntax:** ACL-logging

The `ACL-logging` command applies to IPv4 devices only. For IPv6 devices, use the `logging-enable` command as shown in the following example.

The following shows an example configuration on an IPv6 device.

```
FastIron(config)# ipv6 acc ACL_log_v6
FastIron(config-ipv6-access-list ACL_log_v6)# logging-enable
FastIron(config-ipv6-access-list ACL_log_v6)# deny ipv6 host 2001::1 any log
FastIron(config-ipv6-access-list ACL_log_v6)# inter e 9/12
FastIron(config-if-e1000-9/12)# ipv6 traffic-filter ACL_log_v6 in
```

The above commands create ACL entries that include the log option, then bind the ACL to interface e 9/12. Statistics for packets that match the deny statement will be logged.

**Syntax:** logging-enable

**NOTE**

The `logging-enabled` command applies to IPv6 devices only. For IPv4 devices, use the `ACL-logging` command as shown in the previous example.
Enabling strict control of ACL filtering of fragmented packets

**Displaying ACL Log Entries**

The first time an entry in an ACL permits or denies a packet and logging is enabled for that entry, the software generates a Syslog message and an SNMP trap. Messages for packets permitted or denied by ACLs are at the warning level of the Syslog.

When the first Syslog entry for a packet permitted or denied by an ACL is generated, the software starts an ACL timer. After this, the software sends Syslog messages every five minutes. If an ACL entry does not permit or deny any packets during the timer interval, the software does not generate a Syslog entry for that ACL entry.

**NOTE**
For an ACL entry to be eligible to generate a Syslog entry for denied packets, logging must be enabled for the entry. The Syslog contains entries only for the ACL entries that deny packets and have logging enabled.

To display Syslog entries, enter the following command from any CLI prompt:

```
FastIron#show log
```

Syslog logging: enabled (0 messages dropped, 2 flushes, 0 overruns)
Buffer logging: level ACDMEINW, 9 messages logged
  level code: A=alert C=critical D=debugging M=emergency E=error
  I=informational N=notification W=warning

Dynamic Log Buffer (50 lines):
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.6(0)(Ethernet 4 0000.0804.01 20.20.18.6(0), 1 event(s)
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.2(0)(Ethernet 4 0000.0804.01 20.20.18.2(0), 1 event(s)
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.4(0)(Ethernet 4 0000.0804.01 20.20.18.4(0), 1 event(s)
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.3(0)(Ethernet 4 0000.0804.01 20.20.18.3(0), 1 event(s)
0d00h12m18s:W:ACL: ACL: List 122 denied tcp 20.20.15.5(0)(Ethernet 4 0000.0804.01 20.20.18.5(0), 1 event(s)
0d00h12m18s:I:ACL: 122 applied to port 4 by  from console session
0d00h10m12s:I:ACL: 122 removed from port 4 by  from console session
0d00h09m56s:I:ACL: 122 removed from port 4 by  from console session
0d00h09m38s:I:ACL: 122 removed from port 4 by  from console session

**Syntax:** show log

Enabling strict control of ACL filtering of fragmented packets

**NOTE**
This feature is not supported on the FastIron GS.

The default processing of fragments by hardware-based ACLs is as follows:
Enabling ACL support for switched traffic in the router image

Platform Support:

- FastIron X Series devices running software release 02.5.00 and later
- FCX-S devices running software release 06.0.00 and later (enabled by default)
- TurboIron X Series devices running software release 04.2.00 and later

By default, when an ACL is applied to a physical or virtual routing interface, the Brocade Layer 3 device filters routed traffic only. It does not filter traffic that is switched from one port to another within the same VLAN or virtual routing interface, even if an ACL is applied to the interface.

You can enable the device to filter switched traffic within a VLAN or virtual routing interface. When filtering is enabled, the device uses the ACLs applied to inbound traffic to filter traffic received by a port from another port in the same virtual routing interface.

To enable this feature, enter a command such as the following.

```
FastIron(config)# access-list 101 bridged-routed
```

Applying the ACL rule above to an interface, enables filtering of traffic switched within a VLAN or virtual routing interface.

Syntax: `[no] ip access-list <ACL-ID> bridged-routed`

The `<ACL-ID>` parameter specifies a standard or extended numbered or named ACL.

You can use this feature in conjunction with `enable ACL-per-port-per-vlan`, to assign an ACL to a single port within a virtual interface. In this case, all of the Layer 3 traffic (bridged and routed) are filtered by the ACL.
Enabling ACL filtering based on VLAN membership or VE port membership

Platform Support:
- FastIron X Series devices running software release 02.4.00 and later
- TurboIron X Series devices running software release 04.1.00 and later

NOTE
This section applies to IPv4 ACLs only. IPv6 ACLs do not support ACL filtering based on VLAN membership or VE port membership.

You can apply an inbound IPv4 ACL to specific VLAN members on a port (Layer 2 devices only) or to specific ports on a virtual interface (VE) (Layer 3 Devices only).

By default, this feature support is disabled. To enable it, enter the following commands at the Global CONFIG level of the CLI.

FastIron (config)# enable ACL-per-port-per-vlan
FastIron (config)# write memory
FastIron (config)# exit
FastIron# reload

NOTE
On FastIron X Series devices, you must save the configuration and reload the software to place the change into effect. On TurboIron X Series devices, the write memory and reload commands are not necessary.

After entering the above commands, you can do the following:
- Apply an IPv4 ACL to specific VLAN members on a port – refer to “Applying an IPv4 ACL to specific VLAN members on a port (Layer 2 devices only)” on page 657
- Apply an IPv4 ACL to a subset of ports on a VE – refer to “Applying an IPv4 ACL to a subset of ports on a virtual interface (Layer 3 devices only)” on page 658

Syntax: [no] enable ACL-per-port-per-vlan
Enter the no form of the command to disable this feature.

Configuration notes

- Before enabling this feature on an IPv4 device, make sure the VLAN numbers are contiguous. For example, the VLAN numbers can be 201, 202, 203, and 204, but not 300, 401, 600, and 900.
Enabling ACL filtering based on VLAN membership or VE port membership

- Brocade devices running software release 04.0.01 and later do not support a globally-configured PBR policy together with per-port-per-VLAN ACLs.
- IPv4 ACLs that filter based on VLAN membership or VE port membership (ACL-per-port-per-VLAN), are supported together with IPv6 ACLs on the same device, as long as they are not bound to the same port or virtual interface.

Applying an IPv4 ACL to specific VLAN members on a port (Layer 2 devices only)

Platform Support:
- FastIron X Series devices running software release 02.3.03 and later
- TurboIron X Series devices running software release 04.1.00 and later

NOTE
This section applies to IPv4 ACLs only. IPv6 ACLs do not support ACL filtering based on VLAN membership.

When you bind an IPv4 ACL to a port, the port filters all inbound traffic on the port. However, on a tagged port, there may be a need to treat packets for one VLAN differently from packets for another VLAN. Starting with release 02.3.03, you can configure a tagged port on a Layer 2 device to filter packets based on the packets’ VLAN membership.

NOTE
Before you can bind an ACL to specific VLAN members on a port, you must first enable support for this feature. If this feature is not already enabled on your device, enable it as instructed in the section “Enabling ACL filtering based on VLAN membership or VE port membership” on page 656.

To apply an IPv4 ACL to a specific VLAN on a port, enter commands such as the following on a tagged port.

```
FastIron(config)# vlan 12 name vlan12
FastIron(config-vlan-12)# untag ethernet 5 to 8
FastIron(config-vlan-12)# tag ethernet 23 to 24
FastIron(config-vlan-12)# exit
FastIron(config)# access-list 10 deny host 209.157.22.26 log
FastIron(config)# access-list 10 deny 209.157.29.12 log
FastIron(config)# access-list 10 deny host IPHost1 log
FastIron(config)# access-list 10 permit
FastIron(config)# int e 1/23
FastIron(config-if-e1000-1/23))# per-vlan 12
FastIron(config-if-e1000-1/23-vlan-12))# ip access-group 10 in
```

The commands in this example configure port-based VLAN 12, and add ports e 5 – 8 as untagged ports and ports e 23 – 24 as tagged ports to the VLAN. The commands following the VLAN configuration commands configure ACL 10. Finally, the last three commands apply ACL 10 on VLAN 12 for which port e 23 is a member.

Syntax: `per-vlan <VLAN ID>`

Syntax: `[no] ip access-group <ACL ID>`

The `<VLAN ID>` parameter specifies the VLAN name or number to which you will bind the ACL.
The `<ACL ID>` parameter is the access list name or number.
Applying an IPv4 ACL to a subset of ports on a virtual interface (Layer 3 devices only)

Platform Support:

- FastIron X Series devices running software release 02.4.00 and later
- TurboIron X Series devices running software release 04.2.00 and later

**NOTE**
This section applies to IPv4 ACLs only. IPv6 ACLs do not support ACL filtering based on VE port membership.

You can apply an IPv4 ACL to a virtual routing interface. The virtual interface is used for routing between VLANs and contains all the ports within the VLAN. The IPv4 ACL applies to all the ports on the virtual routing interface. Starting with release 02.3.03, you also can specify a subset of ports within the VLAN containing a specified virtual interface when assigning an ACL to that virtual interface.

Use this feature when you do not want the IPv4 ACLs to apply to all the ports in the virtual interface VLAN or when you want to streamline IPv4 ACL performance for the VLAN.

**NOTE**
Before you can bind an IPv4 ACL to specific ports on a virtual interface, you must first enable support for this feature. If this feature is not already enabled on your device, enable it as instructed in the section "Enabling ACL filtering based on VLAN membership or VE port membership" on page 656.

To apply an ACL to a subset of ports within a virtual interface, enter commands such as the following.

```
FastIron(config)# vlan 10 name IP-subnet-vlan
FastIron(config-vlan-10)# untag ethernet 1/1 to 2/12
FastIron(config-vlan-10)# router-interface ve 1
FastIron(config-vlan-10)# exit
FastIron(config)# access-list 1 deny host 209.157.22.26 log
FastIron(config)# access-list 1 deny 209.157.29.12 log
FastIron(config)# access-list 1 deny host IPHost1 log
FastIron(config)# access-list 1 permit any
FastIron(config)# interface ve 1/1
FastIron(config-vif-1/1)# ip access-group 1 in ethernet 1/1 ethernet 1/3 ethernet 2/1 to 2/4
```

The commands in this example configure port-based VLAN 10, add ports 1/1 – 2/12 to the VLAN, and add virtual routing interface 1 to the VLAN. The commands following the VLAN configuration commands configure ACL 1. Finally, the last two commands apply ACL 1 to a subset of the ports associated with virtual interface 1.

**Syntax:**
```
[no] ip access-group <ACL ID> in ethernet <stack-unit>/<slotnum>/<portnum>
[to<stack-unit>/<slotnum>/<portnum>]
```

The `<ACL ID>` parameter is the access list name or number.

The `<slotnum>` parameter applies on chassis devices only. It does not apply on FESX devices.
Using ACLs to filter ARP packets

NOTE
This feature is not supported on TurboIron 24X Series devices.

You can use ACLs to filter ARP packets. Without this feature, ACLs cannot be used to permit or deny incoming ARP packets. Although an ARP packet contains an IP address just as an IP packet does, an ARP packet is not an IP packet; therefore, it is not subject to normal filtering provided by ACLs.

When a Brocade device receives an ARP request, the source MAC and IP addresses are stored in the device ARP table. A new record in the ARP table overwrites existing records that contain the same IP address. This behavior can cause a condition called "ARP hijacking", when two hosts with the same IP address try to send an ARP request to the Brocade device.

Normally ARP hijacking is not a problem because IP assignments are done dynamically; however, in some cases, ARP hijacking can occur, such as when a configuration allows a router interface to share the IP address of another router interface. Since multiple VLANs and the router interfaces that are associated with each of the VLANs share the same IP segment, it is possible for two hosts in two different VLANs to fight for the same IP address in that segment. ARP filtering using ACLs protects an IP host record in the ARP table from being overwritten by a hijacking host. Using ACLs to filter ARP requests checks the source IP address in the received ARP packet. Only packets with the permitted IP address will be allowed to be written in the ARP table; others are dropped.

Configuration considerations

- This feature is available on all devices running Layer 3 code. This filtering occurs on the management processor.
- The feature is available on physical interfaces and virtual routing interfaces. It is supported on the following physical interface types Ethernet and trunks.
- ACLs used to filter ARP packets on a virtual routing interface can be inherited from a previous interface if the virtual routing interface is defined as a follower virtual routing interface.

Configuring ACLs for ARP filtering

To implement the ACL ARP filtering feature, enter commands such as the following.

FastIron(config)# access-list 101 permit ip host 192.168.2.2 any
FastIron(config)# access-list 102 permit ip host 192.168.2.3 any
FastIron(config)# access-list 103 permit ip host 192.168.2.4 any
FastIron(config)# vlan 2
FastIron(config-vlan-2)# tag ethe 1/1 to 1/2
FastIron(config-vlan-2)# router-interface ve 2
FastIron(config-vlan-2)# vlan 3
FastIron(config-vlan-3)# tag ethe 1/1 to 1/2
FastIron(config-vlan-3)# router-int ve 3
FastIron(config-vlan-3)# vlan 4
FastIron(config-vlan-4)# tag ethe 1/1 to 1/2
FastIron(config-vlan-4)# router-int ve 4
FastIron(config-vlan-4)# interface ve 2
FastIron(config-ve-2)# ip access-group 101 in
FastIron(config-ve-2)# ip address 192.168.2.1/24
FastIron(config-ve-2)# ip use-ACL-on-arp 103
FastIron(config-ve-2)# exit
Using ACLs to filter ARP packets

FastIron(config)# interface ve 3
FastIron(config-ve-3)# ip access-group 102 in
FastIron(config-ve-3)# ip follow ve 2
FastIron(config-ve-3)# ip use-ACL-on-arp
FastIron(config-ve-3)# exit
FastIron(config-vlan-4)# interface ve 4
FastIron(config-ve-4)# ip follow ve 2
FastIron(config-ve-4)# ip use-ACL-on-arp
FastIron(config-ve-4)# exit

Syntax: \[no\] ip use-ACL-on-arp \[<access-list-number>\]

When the use-ACL-on-arp command is configured, the ARP module checks the source IP address of the ARP request packets received on the interface. It then applies the specified ACL policies to the packet. Only the packet with the IP address that the ACL permits will be allowed to be written in the ARP table; those that are not permitted will be dropped.

The <access-list-number> parameter identifies the ID of the standard ACL that will be used to filter the packet. Only the source and destination IP addresses will be used to filter the ARP packet. You can do one of the following for <access-list-number>:

- Enter an ACL ID to explicitly specify the ACL to be used for filtering. In the example above, the line FastIron(config-ve-2)# ip use-ACL-on-arp 103 specifies ACL 103 to be used as the filter.

- Allow the ACL ID to be inherited from the IP ACLs that have been defined for the device. In the example above, the line FastIron(config-ve-4)# ip use-ACL-on-arp allows the ACL to be inherited from IP ACL 101 because of the ip follow relationship between virtual routing interface 2 and virtual routing interface 4. Virtual routing interface 2 is configured with IP ACL 101; thus virtual routing interface 4 inherits IP ACL 101.

ARP requests will not be filtered by ACLs if one of the following conditions occur:

- If the ACL is to be inherited from an IP ACL, but there is no IP ACL defined.
- An ACL ID is specified for the use-ACL-on-arp command, but no IP address or “any any” filtering criteria have been defined under the ACL ID.

Displaying ACL filters for ARP

To determine which ACLs have been configured to filter ARP requests, enter a command such as the following.

FastIron(config)# show ACL-on-arp
Port ACL ID Filter Count
2 103 10
3 102 23
4 101 12

Syntax: show ACL-on-arp \[ ethernet \[<slotnum>/<portnum>\] \] | loopback \[<num>\] | ve \[<num>\] ]

If the slot number (chassis devices only) and interface number is not specified, all ports on the device that use ACLs for ARP filtering will be included in the display.

The Filter Count column shows how many ARP packets have been dropped on the interface since the last time the count was cleared.
Clearing the filter count

To clear the filter count for all interfaces on the device, enter a command such as the following.

```
FastIron(config)# clear ACL-on-arp
```

The above command resets the filter count on all interfaces in a device back to zero.

Syntax: clear ACL-on-arp

Filtering on IP precedence and ToS values

To configure an extended IP ACL that matches based on IP precedence, enter commands such as the following.

```
FastIron(config)#access-list 103 deny tcp 209.157.21.0/24 209.157.22.0/24 precedence internet
FastIron(config)#access-list 103 deny tcp 209.157.21.0/24 eq ftp 209.157.22.0/24 precedence 6
FastIron(config)#access-list 103 permit ip any any
```

The first entry in this ACL denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network, if the traffic has the IP precedence option “internet” (equivalent to “6”).

The second entry denies all FTP traffic from the 209.157.21.x network to the 209.157.22.x network, if the traffic has the IP precedence value “6” (equivalent to “internet”).

The third entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

To configure an IP ACL that matches based on ToS, enter commands such as the following.

```
FastIron(config)#access-list 104 deny tcp 209.157.21.0/24 209.157.22.0/24 tos normal
FastIron(config)#access-list 104 deny tcp 209.157.21.0/24 eq ftp 209.157.22.0/24 tos 13
FastIron(config)#access-list 104 permit ip any any
```

The first entry in this IP ACL denies TCP traffic from the 209.157.21.x network to the 209.157.22.x network, if the traffic has the IP ToS option “normal” (equivalent to “0”).

The second entry denies all FTP traffic from the 209.157.21.x network to the 209.157.22.x network, if the traffic has the IP ToS value “13” (equivalent to “max-throughput”, “min-delay”, and “min-monetary-cost”).

The third entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming or outgoing IP traffic on the ports to which you assign the ACL.

TCP flags - edge port security

Platform Support:
- FGS and FLS devices running software release 02.6.00 and later
- FWS devices running software release 04.3.00 or later
This release supports edge port security on FastIron GS and FastIron LS devices. This feature works in combination with IP ACL rules, and supports all 6 TCP flags present in the offset 13 of the TCP header:

- +|- urg = Urgent
- +|- ack = Acknowledge
- +|- psh = Push
- +|- rst = Reset
- +|- syn = Synchronize
- +|- fin = Finish

TCP flags can be combined with other ACL functions (such as dscp-marking and traffic policies), giving you greater flexibility when designing ACLs.

The TCP flags feature offers two options, match-all and match-any:

- **Match-any** - Indicates that incoming TCP traffic must be matched against any of the TCP flags configured as part of the match-any ACL rule. In CAM hardware, the number of ACL rules will match the number of configured flags.

- **Match-all** - Indicates that incoming TCP traffic must be matched against all of the TCP flags configured as part of the match-all ACL rule. In CAM hardware, there will be only one ACL rule for all configured flags.

**Example**

```
FastIron(config-ext-nACL)# permit tcp 1.1.1.1 0.0.0.255 eq 100 2.2.2.2 0.0.0.255 eq 300 match-all +urg +ack +syn -rst
```

This command configures a single rule in CAM hardware. This rule will contain all of the configured TCP flags (urg, ack, syn, and rst).

**Using TCP flags in combination with other ACL features**

The TCP Flags feature has the added capability of being combined with other ACL features.

**Example**

```
FastIron(config-ext-nACL)# permit tcp any any match-all +urg +ack +syn -rst traffic-policy test
```

This command configures the ACL to match incoming traffic with the TCP Flags urg, ack, and syn and also to apply the traffic policy (rate, limit, etc.) to the matched traffic.

```
FastIron(config-ext-nACL)# permit tcp any any match-all +urg +ack +syn -rst tos normal
```

This command configures the ACL to match incoming traffic with the flags urg, ack, and syn, and also sets the tos bit to normal when the traffic exits the device.

**NOTE**

TCP Flags combines the functionality of older features such as TCP Syn Attack and TCP Establish. Avoid configuring these older features on a port where you have configured TCP Flags. TCP Flags can perform all of the functions of TCP Syn Attack and TCP Establish, and more. However, if TCP Syn Attack is configured on a port along with TCP Flags, TCP Syn Attack will take precedence.
NOTE
If an ACL clause with match-any exists, and the system runs out of CAM, if the total number of TCP rules to TCP Flags will not fit within 1021 entries (the maximum rules allowed per device), then none of the TCP Flag rules will be programmed into the CAM hardware.

NOTE
If a range option and match-any TCP-flags are combined in the same ACL, the total number of rules will be calculated as Total number of rules in CAM hardware = (number of rules for range) * (number of rules for match-any TCP-flags).

QoS options for IP ACLs

Quality of Service (QoS) options enable you to perform QoS for packets that match the ACLs. Using an ACL to perform QoS is an alternative to directly setting the internal forwarding priority based on incoming port, VLAN membership, and so on. (This method is described in “Assigning QoS priorities to traffic” on page 742.)

The following QoS ACL options are supported:

- **dscp-cos-mapping** – This option is similar to the dscp-matching command (described below). This option maps the DSCP value in incoming packets to a hardware table that provides mapping of each of the 0 – 63 DSCP values, and distributes them among eight traffic classes (internal priorities) and eight 802.1p priorities.
  
  By default, the Brocade device does the 802.1p to CoS mapping. If you want to change the priority mapping to DSCP to CoS mapping, you must enter the following ACL statement.
  
  `permit ip any any dscp-cos-mapping`

- **dscp-marking** – Marks the DSCP value in the outgoing packet with the value you specify.

- **internal-priority-marking** and **802.1p-priority-marking** – Supported on FastIron devices only with the DSCP marking option, these commands assign traffic that matches the ACL to a hardware forwarding queue (internal-priority-marking), and re-mark the packets that match the ACL with the 802.1p priority (802.1p-priority-marking).

- **802.1p-and internal-marking** – Supported on Turbolron devices only with the DSCP marking option, this command assigns traffic that matches the ACL to a hardware forwarding queue and re-marks the packets that match the ACL with the 802.1p priority.

- **dscp-matching** – Matches on the packet DSCP value. This option does not change the packet forwarding priority through the device or mark the packet.

Configuration notes for FGS, FLS, FGS-STK, FLS-STK and FCX devices

- These devices do not support marking and prioritization simultaneously with the same rule. To achieve this, you need to create two separate rules. In other words, you can mark a rule with DSCP or 802.1p information, or you can prioritize a rule based on DSCP or 802.1p information. You can enable only one of the following ACL options per rule:
  
  - 802.1p-priority-marking
  - dscp-marking
QoS options for IP ACLs

- internal-priority-marking

For example, any one of the following commands is supported.

FastIron(config)# access-list 101 permit ip any any dscp-marking 43

or

FastIron(config)# access-list 101 permit ip any any 802.1p-priority-marking

or

FastIron(config)# access-list 101 permit ip any any internal-priority-marking

6

The following command is not supported.

FastIron(config)# access-list 101 permit ip any any dscp-marking 43
802.1p-priority-marking 4 internal-priority-marking 6

Using an ACL to map the DSCP value (DSCP CoS mapping)

The `dscp-cos-mapping` option maps the DSCP value in incoming packets to a hardware table that provides mapping of each of the 0 – 63 DSCP values, and distributes them among eight traffic classes (internal priorities) and eight 802.1p priorities.

NOTE
The `dscp-cos-mapping` option overrides port-based priority settings.

NOTE
The `dscp-cos-mapping` option is not supported for TIX, FGS, FGS-STK, FLS, and FLS-STK devices.

By default, the Brocade device does the 802.1p to CoS mapping. If you want to change the priority mapping to DSCP to CoS mapping, you must enter the following ACL statement.

`permit ip any any dscp-cos-mapping`

The complete CLI syntax for this feature is shown in “Configuring extended numbered ACLs” on page 638 and “Configuring extended named ACLs” on page 644. The following shows the syntax specific to the DSCP Cos mapping feature.

Syntax: ... `[dscp-marking <dscp-value> dscp-cos-mapping]`

or

Syntax: ... `[dscp-cos-mapping]`

NOTE
The `dscp-cos-mapping` option should not be used when assigning an 802.1p priority. To assign an 802.1p priority to a specific DSCP (using `dscp-match`), re-assign the DSCP value as well. For example

FastIron(config)# access-list 100 permit ip any any dscp-match 0 dscp-marking 0 802.1p 0 internal 1

NOTE
The `dscp-cos-mapping` option is not supported for TIX, FGS, FGS-STK, FLS, FLS-STK and FCX devices.
Using an IP ACL to mark DSCP values (DSCP marking)

The dscp-marking option for extended ACLs allows you to configure an ACL that marks matching packets with a specified DSCP value. You also can use DSCP marking to assign traffic to a specific hardware forwarding queue (refer to “Using an ACL to change the forwarding queue for FastIron X Series devices” on page 666).

For example, the following commands configure an ACL that marks all IP packets with DSCP value 5. The ACL is then applied to incoming packets on interface 7. Consequently, all inbound packets on interface 7 are marked with the specified DSCP value.

```
FastIron(config)# access-list 120 permit ip any any dscp-marking 5
dscp-cos-mapping
FastIron(config)# interface 1/7
FastIron(config-if-e1000-1/7)# ip access-group 120 in
```

Syntax: ...
dscp-marking <dscp-value>

The dscp-marking <dscp-value> parameter maps a DSCP value to an internal forwarding priority. The DSCP value can be from 0 – 63.

**Combined ACL for 802.1p marking on FastIron X Series devices**

Platform Support:
- FastIron X Series devices running software release 03.1.00 and later

**NOTE**
This section applies to FastIron X Series devices. For feature support on TurboIron X Series devices, refer to “Combined ACL for 802.1p marking on TurboIron X Series devices” on page 667.

FastIron X Series devices support a simple method for assigning an 802.1p priority value to packets without affecting the actual packet or the DSCP. Prior to release 03.1.00, users were required to provide DSCP-marking and DSCP-matching information in order to assign 802.1p priority values, which required the deployment of a 64-line ACL to match all possible DSCP values. Users were also required to configure an internal priority marking value. This release allows users to easily specify 802.1p priority marking values directly, and changes internal priority marking from required to optional. If the user does not set a specific internal marking priority, the default value is the same as the 802.1p priority marking value. Priority values range from 0 to 7.

Two new ACL parameters support this feature, one required for priority marking and one optional for internal priority marking. These parameters apply to IP, TCP, and UDP.

**For IP**

```
FastIron(config)# acc 104 per ip any any 802.1p-priority-marking 1
```

or the following command, which also assigns an optional internal-priority-marking value.

```
FastIron(config)# acc 104 per ip any any 802.1p-priority-marking 1 internal-priority-marking 5
```

Syntax: access-list <num(100-199)> permit ip any any 802.1p-priority-marking <priority value (0-7)> [internal-priority-marking <value (0-7)>]

**For TCP**

```
FastIron(config)# acc 105 per tcp any any 802.1p-priority-marking 1
```

or the following command, which also assigns an optional internal-priority-marking value.

```
FastIron(config)# acc 105 per tcp any any 802.1p-priority-marking 1 internal-priority-marking 5
```
Using an ACL to change the forwarding queue for FastIron X Series devices

NOTE
This section applies to FastIron X Series devices. For feature support on TurboIron X Series devices, refer to “Using an ACL to change the forwarding queue for TurboIron X Series devices” on page 667.

The 802.1p-priority-marking <0 – 7> parameter re-marks the packets of the 802.1Q traffic that match the ACL with this new 802.1p priority, or marks the packets of the non-802.1Q traffic that match the ACL with this 802.1p priority, later at the outgoing 802.1Q interface.

The 802.1p priority mapping is shown in Table 111.

The internal-priority-marking <0 – 7> parameter assigns traffic that matches the ACL to a specific hardware forwarding queue (qosp0 – qosp7).

NOTE
The internal-priority-marking parameter overrides port-based priority settings.

In addition to changing the internal forwarding priority, if the outgoing interface is an 802.1Q interface, this parameter maps the specified priority to its equivalent 802.1p (CoS) priority and marks the packet with the new 802.1p priority. Table 111 lists the default mappings of hardware forwarding queues to 802.1p priorities on the FESX and FSX.

<table>
<thead>
<tr>
<th>Forwarding queue</th>
<th>qosp0</th>
<th>qosp1</th>
<th>qosp2</th>
<th>qosp3</th>
<th>qosp4</th>
<th>qosp5</th>
<th>qosp6</th>
<th>qosp7</th>
</tr>
</thead>
<tbody>
<tr>
<td>802.1p</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>7</td>
</tr>
</tbody>
</table>

The complete CLI syntax for 802.1p priority marking and internal priority marking is shown in “Configuring extended numbered ACLs” on page 638 and “Configuring extended named ACLs” on page 644. The following shows the syntax specific to these features.

Syntax: acc 105 per tcp any any 802.1p-priority-marking 1
internal-priority-marking 5

Syntax: access-list <num(100-199)> permit tcp any any 802.1p-priority-marking <priority value (0-7)> [internal-priority-marking <value (0-7)>]

For UDP

Syntax: access-list <num(100-199)> permit udp any any 802.1p-priority-marking <priority value (0-7)> [internal-priority-marking <value (0-7)>]
Combined ACL for 802.1p marking on TurboIron X Series devices

Platform Support:
- TurboIron X Series devices running software release 04.1.00 and later

**NOTE**
This section applies to TurboIron X Series devices. For feature support on FastIron X Series devices, refer to “Combined ACL for 802.1p marking on FastIron X Series devices” on page 665.

TurboIron X Series devices support a simple method for assigning an 802.1p priority and internal marking priority to packets without affecting the actual packet or the DSCP marking. TurboIron X Series devices use the same configured value for both the internal marking priority and the 802.1p priority marking value. This differs from FastIron X Series devices, which support the configuration of different values for each priority marking type. The priority value ranges from 0 to 7.

This feature is enabled through the use of an ACL option. The option applies to IP, TCP, and UDP traffic.

For IP
FastIron(config)# acc 104 per ip any any 802.1p-and-internal-marking 1

Syntax: access-list <num(100-199)> permit ip any any 802.1p-and-internal-marking <priority value (0-7)>

For TCP
FastIron(config)# acc 105 per tcp any any 802.1p-and-internal-marking 1

Syntax: access-list <num(100-199)> permit tcp any any 802.1p-and-internal-marking <priority value (0-7)>

For UDP
FastIron(config)# acc 105 per udp any any 802.1p-and-internal-marking 1

Syntax: access-list <num(100-199)> permit udp any any 802.1p-and-internal-marking <priority value (0-7)>

In each of these examples, the 802.1p value and internal priority value were set to 1.

Using an ACL to change the forwarding queue for TurboIron X Series devices

**NOTE**
This section applies to TurboIron X Series devices. For feature support on FastIron X Series devices, refer to “Using an ACL to change the forwarding queue for FastIron X Series devices” on page 666.

The 802.1p-and-internal-marking <0 – 7> parameter does the following:
- Re-marks the packets of the 802.1Q traffic that match the ACL with this new priority, or marks the packets of the non-802.1Q traffic that match the ACL with this priority, later at the outgoing 802.1Q interface.
- Assigns traffic that matches the ACL to the specific hardware forwarding queue (qosp0 – qosp7).

**NOTE**
The 802.1p-and-internal-marking option overrides port-based priority settings.
ACL-based rate limiting

Platform Support:

- FastIron X Series devices running software release 02.3.03 and later
- Turbolron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

ACL-based rate limiting provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs. This feature is available in the Layer 2 and Layer 3 code.

For more details, including configuration procedures, refer to Chapter 25, "Configuring Traffic Policies".

NOTE

For complete syntax information, refer to "Extended numbered ACL syntax" on page 638.

DSCP matching

The dscp-matching option matches on the packet DSCP value. This option does not change the packet forwarding priority through the device or mark the packet.

To configure an ACL that matches on a packet with DSCP value 29, enter a command such as the following.

```
FastIron(config)# access-list 112 permit ip 1.1.1.0 0.0.0.255 2.2.2.x 0.0.0.255
dscp-matching 29
```

The complete CLI syntax for this feature is shown in "Configuring extended numbered ACLs" on page 638 and "Configuring extended named ACLs" on page 644. The following shows the syntax specific to this feature.

Syntax: ...dscp-matching <0 – 63>

NOTE

For complete syntax information, refer to "Extended numbered ACL syntax" on page 638.

ACL-based rate limiting

Platform Support:

- FastIron X Series devices running software release 02.3.03 and later
- Turbolron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

ACL-based rate limiting provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs. This feature is available in the Layer 2 and Layer 3 code.

For more details, including configuration procedures, refer to Chapter 25, "Configuring Traffic Policies".

NOTE

For complete syntax information, refer to "Extended numbered ACL syntax" on page 638.

DSCP matching

The dscp-matching option matches on the packet DSCP value. This option does not change the packet forwarding priority through the device or mark the packet.

To configure an ACL that matches on a packet with DSCP value 29, enter a command such as the following.

```
FastIron(config)# access-list 112 permit ip 1.1.1.0 0.0.0.255 2.2.2.x 0.0.0.255
dscp-matching 29
```

The complete CLI syntax for this feature is shown in "Configuring extended numbered ACLs" on page 638 and "Configuring extended named ACLs" on page 644. The following shows the syntax specific to this feature.

Syntax: ...dscp-matching <0 – 63>

NOTE

For complete syntax information, refer to "Extended numbered ACL syntax" on page 638.
ACL statistics

Platform Support:
- FastIron X Series devices running software release 02.3.03 and later

ACL statistics is a mechanism for counting the number of packets and the number of bytes per packet to which ACL filters are applied.

To see the configuration procedures for ACL statistics, refer to Chapter 25, “Configuring Traffic Policies”.

NOTE
The terms ACL statistics and ACL counting are used interchangeably in this guide and mean the same thing.

Using ACLs to control multicast features

You can use ACLs to control the following multicast features:
- Limit the number of multicast groups that are covered by a static rendezvous point (RP)
- Control which multicast groups for which candidate RPs sends advertisement messages to bootstrap routers
- Identify which multicast group packets will be forwarded or blocked on an interface

For configuration procedures, refer to Chapter 28, “Configuring IP Multicast Protocols”.

Enabling and viewing hardware usage statistics for an ACL

The number of configured ACL rules can affect the rate at which hardware resources are used. You can use the `show access-list hw-usage on` command to enable hardware usage statistics, followed by the `show access-list <access-list-id>` command to determine the hardware usage for an ACL. To gain more hardware resources, you can modify the ACL rules so that it uses less hardware resource.

To enable and view hardware usage statistics, enter commands such as the following:

```
FastIron# show access-list hw-usage on
FastIron# show access-list 100
Extended IP access list 100 (hw usage : 2)
deny ip any any (hw usage : 1

Syntax:  show access-list hw-usage on
Syntax:  show access-list <access-list-id>
```

where <access-list-id> is a valid ACL name or number.

Compared to FastIron devices, the behavior of these commands differ slightly on the TurboIron. The differences on the TurboIron are as follows.
- When an ACL is not attached to any port, the `show access-list` command will display an estimate of the current TCAM usage, assuming it is attached to one port and one VLAN. Once the ACL is attached to a port, the `show access-list <access-list-id>` command will show the exact current TCAM usage by the ACL.
Displaying ACL information

To display the number of Layer 4 CAM entries used by each ACL, enter the following command.

FastIron#show access-list all

Extended IP access list 100 (Total flows: N/A, Total packets: N/A, Total rule cam use: 3)
permit udp host 192.168.2.169 any (Flows: N/A, Packets: N/A, Rule cam use: 1)
permit icmp any any (Flows: N/A, Packets: N/A, Rule cam use: 1)
deny ip any any (Flows: N/A, Packets: N/A, Rule cam use: 1)

Syntax: show access-list <ACL-num> | <ACL-name> | all

The Rule cam use field lists the number of CAM entries used by the ACL or entry. The number of CAM entries listed for the ACL itself is the total of the CAM entries used by the ACL entries.

For flow-based ACLs, the Total flows and Flows fields list the number of Layer 4 session table flows in use for the ACL.

The Total packets and Packets fields apply only to flow-based ACLs.

Troubleshooting ACLs

Use the following methods to troubleshoot ACLs:

- If the ACL contains filters with Layer 4 source or destination port ranges and the ACL is not attached to any port or VLAN, then the minimum and maximum number of estimated TCAM usage per filter is displayed in ‘x or y’ format where ‘x’ is the minimum number and ‘y’ is the maximum number of estimated TCAM entries.
- Whenever the ACL is attached to a different VLAN (on the same or another port), the TCAM usage count is incremented to reflect the current usage.

The following shows an example show access-list command output before an ACL is attached to a port. This example applies to the TurboIron only.

TurboIron 24X(config-if-e10000-2-vlan-2)#show access-list 111
Extended IP access list 111 (hw usage : 3 or up to 13)
permit tcp any range 10 40 any (hw usage : 1 or 5)
permit tcp any range 10 60 any (hw usage : 1 or 7)

The following shows an example show access-list command output after an ACL is attached to a port. This example applies to the TurboIron only.

TurboIron 24X(config-if-e10000-2)#show access-list 111
Extended IP access list 111 (hw usage : 3)
permit tcp any range 10 40 any (hw usage : 1)
permit tcp any range 10 60 any (hw usage : 1)
Policy-based routing (PBR)

Platform Support:

- FESX and FSX devices running software release 03.0.00 and later – L3

Policy-Based Routing (PBR) allows you to use ACLs and route maps to selectively modify and route IP packets in hardware. The ACLs classify the traffic. Route maps that match on the ACLs set routing attributes for the traffic.

A PBR policy specifies the next hop for traffic that matches the policy. Using standard ACLs with PBR, you can route IP packets based on their source IP address. With extended ACLs, you can route IP packets based on all of the clauses in the extended ACL.

You can configure the Brocade device to perform the following types of PBR based on a packet Layer 3 and Layer 4 information:

- Select the next-hop gateway.
- Send the packet to the null interface (null0).

When a PBR policy has multiple next hops to a destination, PBR selects the first live next hop specified in the policy that is up. If none of the policy's direct routes or next hops are available, the packet is routed in the normal way.

Configuration considerations

- Policy-Based Routing is not supported in the Base Layer 3 code.
- Global Policy-Based Routing is not supported when IP Follow is configured on an interface.
- Starting in software release FSX 04.0.01, global Policy-Based Routing is not supported with per-port-per-VLAN ACLs.
- A PBR policy on an interface takes precedence over a global PBR policy.
- You cannot apply PBR on a port if that port already has ACLs, ACL-based rate limiting, DSCP-based QoS, MAC filtering.
- The number of route maps that you can define is limited by the available system memory, which is determined by the system configuration and how much memory other features use. When a route map is used in a PBR policy, the PBR policy uses up to six instances of a route map, up to five ACLs in a matching policy of each route map instance, and up to six next hops in a set policy of each route map instance. Note that the CLI will allow you configure more than six next hops in a route map; however, the extra next hops will not be placed in the PBR database. The route map could be used by other features like BGP or OSPF, which may use more than six next hops.
- ACLs with the log option configured should not be used for PBR purposes.
• PBR ignores explicit or implicit `deny ip any any` ACL entries, to ensure that for route maps that use multiple ACLs, the traffic is compared to all the ACLs. PBR also ignores any deny clauses in an ACL. Traffic that matches a deny clause is routed normally using Layer 3 paths.

• PBR always selects the first next hop from the next hop list that is up. If a PBR policy's next hop goes down, the policy uses another next hop if available. If no next hops are available, the device routes the traffic in the normal way.

• PBR is not supported for fragmented packets. If the PBR ACL filters on Layer 4 information like TCP/UDP ports, fragmented packets are routed normally.

• You can change route maps or ACL definitions dynamically and do not need to rebind the PBR policy to an interface.

### Configuring a PBR policy

To configure PBR, you define the policies using IP ACLs and route maps, then enable PBR globally or on individual interfaces. The device programs the ACLs into the packet processor on the interfaces and routes traffic that matches the ACLs according to the instructions in the route maps.

To configure a PBR policy:

- Configure ACLs that contain the source IP addresses for the IP traffic you want to route using PBR.
- Configure a route map that matches on the ACLs and sets the route information.
- Apply the route map to an interface.

### Configure the ACLs

PBR uses route maps to change the routing attributes in IP traffic. This section shows an example of how to configure a standard ACL to identify the source subnet for IP traffic.

To configure a standard ACL to identify a source subnet, enter a command such as the following.

```
FastIron(config)# access-list 99 permit 209.157.23.0 0.0.0.255
```

The command in this example configures a standard ACL that permits traffic from subnet 209.157.23.0/24. After you configure a route map that matches based on this ACL, the software uses the route map to set route attributes for the traffic, thus enforcing PBR.

**NOTE**

Do not use an access group to apply the ACL to an interface. Instead, use a route map to apply the ACL globally or to individual interfaces for PBR, as shown in the following sections.

**Syntax:** `[no]access-list <num> deny | permit <source-ip> | <hostname> < wildcard>

or

**Syntax:** `[no]access-list <num> deny | permit <source-ip>/<mask-bits> | <hostname>

**Syntax:** `[no]access-list <num> deny | permit host <source-ip> | <hostname>

**Syntax:** `[no]access-list <num> deny | permit any

The `<num>` parameter is the access list number and can be from 1 – 99.

The `deny` | `permit` parameter indicates whether packets that match a policy in the access list are denied (dropped) or permitted (forwarded).
NOTE
If you are configuring the ACL for use in a route map, always specify permit. Otherwise, the Brocade device will ignore deny clauses and packets that match deny clauses are routed normally.

The <source-ip> parameter specifies the source IP address. Alternatively, you can specify the host name.

NOTE
To specify the host name instead of the IP address, the host name must be configured using the DNS resolver on the Brocade device. To configure the DNS resolver name, use the ip dns server-address... command at the global CONFIG level of the CLI.

The <wildcard> parameter specifies the mask value to compare against the host address specified by the <source-ip> parameter. The <wildcard> is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the <source-ip>. Ones mean any value matches. For example, the <source-ip> and <wildcard> values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in CIDR format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/mask-bits” format. To enable the software to display the CIDR masks, enter the ip show-subnet-length command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

NOTE
If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the show ip access-list command.

The host <source-ip> | <hostname> parameter lets you specify a host IP address or name. When you use this parameter, you do not need to specify the mask. A mask of all zeros (0.0.0.0) is implied.

The any parameter configures the policy to match on all host addresses.

NOTE
Do not use the log option in ACLs that will be used for PBR.

Configure the route map

After you configure the ACLs, you can configure a PBR route map that matches based on the ACLs and sets routing information in the IP traffic.
NOTE
The match and set statements described in this section are the only route-map statements supported for PBR. Other route-map statements described in the documentation apply only to the protocols with which they are described.

To configure a PBR route map, enter commands such as the following.

```plaintext
FastIron(config)# route-map test-route permit 99
FastIron(config-routemap test-route)# match ip address 99
FastIron(config-routemap test-route)# set ip next-hop 192.168.2.1
FastIron(config-routemap test-route)# exit
```

The commands in this example configure an entry in a route map named “test-route”. The match statement matches on IP information in ACL 99. The set statement changes the next-hop IP address for packets that match to 192.168.2.1.

**Syntax:** `[no]route-map <map-name> permit | deny <num>`

The `<map-name>` is a string of characters that names the map. Map names can be up to 32 characters in length. You can define an unlimited number of route maps on the Brocade device, as long as system memory is available.

The `permit | deny` parameter specifies the action the Brocade device will take if a route matches a match statement:

- If you specify `deny`, the Brocade device does not apply a PBR policy to packets that match the ACLs in a match clause. Those packets are routed normally,
- If you specify `permit`, the Brocade device applies the match and set statements associated with this route map instance.

The `<num>` parameter specifies the instance of the route map you are defining. Routes are compared to the instances in ascending numerical order. For example, a route is compared to instance 1, then instance 2, and so on.

PBR uses up to six route map instances for comparison and ignores the rest.

**Syntax:** `[no] match ip address <ACL-num-or-name>`

The `<ACL-num>` parameter specifies a standard or extended ACL number or name.

**Syntax:** `[no] set ip next hop <ip-addr>`

This command sets the next-hop IP address for traffic that matches a match statement in the route map.

**Syntax:** `[no] set interface null0`

This command sends the traffic to the null0 interface, which is the same as dropping the traffic.

**Enabling PBR**

After you configure the ACLs and route map entries, you can enable PBR globally, on individual interfaces, or both as described in this section. To enable PBR, you apply a route map you have configured for PBR globally or locally.

**Enabling PBR globally**

To enable PBR globally, enter a command such as the following at the global CONFIG level.

```plaintext
FastIron(config)# ip policy route-map test-route
```
This command applies a route map named “test-route” to all interfaces on the device for PBR.

**Syntax:** `ip policy route-map <map-name>`

**Enabling PBR locally**

To enable PBR locally, enter commands such as the following.

```
FastIron(config)# interface ve 1
FastIron(config-vif-1)# ip policy route-map test-route
```

The commands in this example change the CLI to the Interface level for virtual interface 1, then apply the “test-route” route map to the interface. You can apply a PBR route map to Ethernet ports or virtual interfaces.

**Syntax:** `ip policy route-map <map-name>`

Enter the name of the route map you want to use for the route-map `<map-name>` parameter.

**Configuration examples**

This section presents configuration examples for:

- “Basic example” on page 675
- “Setting the next hop” on page 676
- “Setting the output interface to the null interface” on page 677
- “Trunk formation” on page 677

**Basic example**

The following commands configure and apply a PBR policy that routes HTTP traffic received on virtual routing interface 1 from the 10.10.10.x/24 network to 5.5.5.x/24 through next-hop IP address 1.1.1.1/24 or, if 1.1.1.x is unavailable, through 2.2.2.1/24.

```
FastIron(config)#access-list 101 permit tcp 10.10.10.0 0.0.0.255 eq http 5.5.5.0 0.0.0.255
FastIron(config)#route-map net10web permit 101
FastIron(config-route-map net10web)#match ip address 101
FastIron(config-route-map net10web)#set ip next-hop 1.1.1.1
FastIron(config-route-map net10web)#set ip next-hop 2.2.2.2
FastIron(config-route-map net10web)#exit
FastIron(config)#vlan 10
FastIron(config-vlan-10)#tagged ethernet 1/1 to 1/4

FastIron(config-vlan-10)#router-interface ve 1
FastIron(config)#interface ve 1
FastIron(config-vif-1)#ip policy route-map net10web
```

**Syntax:** `[no] route-map <map-name> permit | deny <num>`

**Syntax:** `[no] set ip next hop <ip-addr>`

This command sets the next-hop IP address for traffic that matches a match statement in the route map.
Policy-based routing (PBR)

Setting the next hop

The following commands configure the Brocade device to apply PBR to traffic from IP subnets 209.157.23.x, 209.157.24.x, and 209.157.25.x. In this example, route maps specify the next-hop gateway for packets from each of these subnets:

- Packets from 209.157.23.x are sent to 192.168.2.1.
- Packets from 209.157.24.x are sent to 192.168.2.2.
- Packets from 209.157.25.x are sent to 192.168.2.3.

The following commands configure three standard ACLs. Each ACL contains one of the ACLs listed above. Make sure you specify permit instead of deny in the ACLs, so that the Brocade device permits the traffic that matches the ACLs to be further evaluated by the route map. If you specify deny, the traffic that matches the deny statements are routed normally. Notice that these ACLs specify any for the destination address.

```
FastIron(config)# access-list 50 permit 209.157.23.0 0.0.0.255
FastIron(config)# access-list 51 permit 209.157.24.0 0.0.0.255
FastIron(config)# access-list 52 permit 209.157.25.0 0.0.0.255
```

The following commands configure three entries in a route map called “test-route”. The first entry (permit 50) matches on the IP address information in ACL 50 above. For IP traffic from subnet 209.157.23.0/24, this route map entry sets the next-hop IP address to 192.168.2.1.

```
FastIron(config)# route-map test-route permit 50
FastIron(config-route-map test-route)# match ip address 50
FastIron(config-route-map test-route)# set ip next-hop 192.168.2.1
FastIron(config-route-map test-route)# exit
```

The following commands configure the second entry in the route map. This entry (permit 51) matches on the IP address information in ACL 51 above. For IP traffic from subnet 209.157.24.0/24, this route map entry sets the next-hop IP address to 192.168.2.2.

```
FastIron(config)# route-map test-route permit 51
FastIron(config-route-map test-route)# match ip address 51
FastIron(config-route-map test-route)# set ip next-hop 192.168.2.2
FastIron(config-route-map test-route)# exit
```

The following commands configure the third entry in the test-route route map. This entry (permit 52) matches on the IP address information in ACL 52 above. For IP traffic from subnet 209.157.25.0/24, this route map entry sets the next-hop IP address to 192.168.2.3.

```
FastIron(config)# route-map test-route permit 52
FastIron(config-route-map test-route)# match ip address 52
FastIron(config-route-map test-route)# set ip next-hop 192.168.2.3
FastIron(config-route-map test-route)# exit
```

The following command enables PBR by globally applying the test-route route map to all interfaces.

```
FastIron(config)# ip policy route-map test-route
```

Alternatively, you can enable PBR on specific interfaces, as shown in the following example. The commands in this example configure IP addresses in the three source subnets identified in ACLs 50, 51, and 52, then apply route map test-route to the interface.

```
FastIron(config)# interface ve 1
FastIron(config-vif-1)# ip address 209.157.23.1/24
FastIron(config-vif-1)# ip address 209.157.24.1/24
FastIron(config-vif-1)# ip address 209.157.25.1/24
FastIron(config-vif-1)# ip policy route-map test-route
```
**Setting the output interface to the null interface**

The following commands configure a PBR policy to send all traffic from 192.168.1.204/32 to the null interface, thus dropping the traffic instead of forwarding it.

```
FastIron(config)# access-list 56 permit 209.168.1.204 0.0.0.0
```

The following commands configure an entry in a route map called “file-13”. The first entry (permit 56) matches on the IP address information in ACL 56 above. For IP traffic from the host 209.168.1.204/32, this route map entry sends the traffic to the null interface instead of forwarding it, thus sparing the rest of the network the unwanted traffic.

```
FastIron(config)# route-map file-13 permit 56
FastIron(config-routemap file-13)# match ip address 56
FastIron(config-routemap file-13)# set interface null0
FastIron(config-routemap file-13)# exit
```

The following command enables PBR by globally applying the route map to all interfaces.

```
FastIron(config)# ip policy route-map file-13
```

Alternatively, you can enable PBR on specific interfaces, as shown in the following example. The commands in this example configure IP addresses in the source subnet identified in ACL 56, then apply route map file-13 to the interface.

```
FastIron(config)# interface ethernet 3/11
FastIron(config-if-e10000-3/11)# ip address 192.168.1.204/32
FastIron(config-if-e10000-3/11)# ip policy route-map file-13
```

**Trunk formation**

When a trunk is formed, the PBR policy on the primary port applies to all the secondary ports. If a different PBR policy exists on a secondary port at the time of a trunk formation, that policy is overridden by the PBR policy on the primary port. If the primary port does not have a PBR policy, then the secondary ports will not have a PBR policy.

When a trunk is removed, the PBR policy that was applied to the trunk interface is unbound (removed) from former secondary ports. If global PBR is configured, the secondary ports adhere to the global PBR; otherwise, no PBR policy is bound to former secondary ports.
Policy-based routing (PBR)
Configuring IPv6 Access Control Lists (ACLs)

ACL overview

This chapter describes how Access Control Lists (ACLs) are implemented and configured on a Brocade IPv6 Layer 3 Switch.

Platform Support:

- FESX and FSX IPv6 devices running software release 04.1.00 and later – L2, BL3, L3

Brocade supports IPv6 Access Control Lists (ACLs), which you can use for traffic filtering. You can configure up to 100 IPv6 ACLs.

An IPv6 ACL is composed of one or more conditional statements that pose an action (permit or deny) if a packet matches a specified source or destination prefix. There can be up to 1024 statements per device, including IPv6, IPv4, MAC filters, and default statements. When the maximum number of ACL rules are reached on the device, an error message will display on the console.

In ACLs with multiple statements, you can specify a priority for each statement. The specified priority determines the order in which the statement appears in the ACL. The last statement in each IPv6 ACL is an implicit deny statement for all packets that do not match the previous statements in the ACL.

You can configure an IPv6 ACL on a global basis, then apply it to the incoming IPv6 packets on specified interfaces. You can apply only one IPv6 ACL to an interface incoming traffic. When an interface receives an IPv6 packet, it applies the statements within the ACL in their order of appearance to the packet. As soon as a match occurs, the Brocade device takes the specified action (permit or deny the packet) and stops further comparison for that packet.

**NOTE**

IPv6 ACLs are supported on inbound traffic and are implemented in hardware, making it possible for the Brocade device to filter traffic at line-rate speed on 10 Gbps interfaces.

The Brocade implementation of IPv6 ACLs enable traffic filtering based on the following information:

- IPv6 protocol
- Source IPv6 address
- Destination IPv6 address
- IPv6 message type
- Source TCP or UDP port (if the IPv6 protocol is TCP or UDP)
- Destination TCP or UDP port (if the IPv6 protocol is TCP or UDP)

The IPv6 protocol can be one of the following well-known names or any IPv6 protocol number from 0 – 255:

- Authentication Header (AHP)
**Configuration notes**

- Encapsulating Security Payload (ESP)
- Internet Control Message Protocol (ICMP)
- Internet Protocol Version 6 (IPv6)
- Stream Control Transmission Protocol (SCTP)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)

**NOTE**
TCP and UDP filters will be matched only if they are listed as the first option in the extension header.

For TCP and UDP, you also can specify a comparison operator and port name or number. For example, you can configure a policy to block web access to a specific website by denying all TCP port 80 (HTTP) packets from a specified source IPv6 address to the website IPv6 address.

IPv6 ACLs also provide support for filtering packets based on DSCP.

This chapter contains the following sections:
- “Configuring an IPv6 ACL” on page 681
- “Applying an IPv6 ACL to an interface” on page 688
- “Adding a comment to an IPv6 ACL entry” on page 689
- “Displaying IPv6 ACLs” on page 690

IPv4 ACLs that filter based on VLAN membership or VE port membership (ACL-per-port-per-VLAN), are supported together with IPv6 ACLs on the same device, as long as they are not bound to the same port or virtual interface.

IPv4 source guard and IPv6 ACLs are supported together on the same device, as long as they are not configured on the same port or virtual interface.

IPv6 ACLs do not support ACL filtering based on VLAN membership or VE port membership.

If an IPv6 ACL has the implicit `deny` condition, make sure it also permits the IPv6 link-local address, in addition to the global unicast address. Otherwise, routing protocols such as OSPF will not work. To view the link-local address, use the `show ipv6 interface` command.

IPv6 must be enabled on the interface before an ACL can be applied to it. If IPv6 is not enabled on the interface, the system will display the following error message.

```
FastIron(config-if-e1000-7)# ipv6 traffic-filter netw in
Error: IPv6 is not enabled for interface 7
```

To enable IPv6 on an interface, enter `ipv6 enable` at the Interface level of the CLI, or assign an IPv6 address to the interface as described in “Configuring IPv6 on each router interface” on page 214.

You cannot disable IPv6 on an interface to which an ACL is bound. Attempting to do so will cause the system to return the following error message.

```
FastIron(config-if-e1000-7)# no ipv6 enable
Error: Port 7 has IPv6 ACL configured. Cannot disable IPv6
```

To disable IPv6, first remove the ACL from the interface.
Configuring an IPv6 ACL

Follow the steps given below to configure an IPv6 ACL.

1. Create the ACL
2. Enable IPv6 on the interface to which the ACL will be applied
3. Apply the ACL to the interface

Example configurations

To configure an access list that blocks all Telnet traffic received on port 1/1 from IPv6 host 2000:2382:e0bb::2, enter the following commands.

```bash
FastIron(config)# ipv6 access-list fdry
FastIron(config-ipv6-access-list-fdry)# deny tcp host 2000:2382:e0bb::2 any eq telnet
FastIron(config-ipv6-access-list-fdry)# permit ipv6 any any
FastIron(config-ipv6-access-list-fdry)# exit
FastIron(config)# int eth 1/1
FastIron(config-if-1/1)# ipv6 enable
FastIron(config-if-1/1)# ipv6 traffic-filter fdry in
FastIron(config)# write memory
```

Here is another example of commands for configuring an ACL and applying it to an interface.

```bash
FastIron(config)# ipv6 access-list netw
FastIron(config-ipv6-access-list-netw)# permit icmp 2000:2383:e0bb::/64 2001:3782::/64
FastIron(config-ipv6-access-list-netw)# deny ipv6 host 2000:2383:e0ac::2 host 2000:2383:e0aa:0::24
FastIron(config-ipv6-access-list-netw)# deny udp any any
FastIron(config-ipv6-access-list-netw)# permit ipv6 any any
```

The first condition permits ICMP traffic from hosts in the 2000:2383:e0bb::x network to hosts in the 2001:3782::x network.

The second condition denies all IPv6 traffic from host 2000:2383:e0ac::2 to host 2000:2383:e0aa:0::24.

The third condition denies all UDP traffic.

The fourth condition permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL would deny all incoming IPv6 traffic on the ports to which you assigned the ACL.

The following commands apply the ACL "netw" to the incoming traffic on port 1/2 and to the incoming traffic on port 4/3.

```bash
FastIron(config)# int eth 1/2
FastIron(config-if-1-1/2)# ipv6 enable
FastIron(config-if-1-1/2)# ipv6 traffic-filter netw in
FastIron(config-if-1-1/2)# exit
FastIron(config)# int eth 4/3
FastIron(config-if-4-3)# ipv6 enable
FastIron(config-if-4-3)# ipv6 traffic-filter netw in
FastIron(config)# write memory
```

Here is another example.
Configuring an IPv6 ACL

FastIron(config)# ipv6 access-list nextone
FastIron(config-ipv6-access-list rtr)# deny udp any range 5 6 2001:1570:22::/24
FastIron(config-ipv6-access-list rtr)# permit ipv6 any any
FastIron(config-ipv6-access-list rtr)# write memory

The first condition in this ACL denies TCP traffic from the 2001:1570:21::x network to the 2001:1570:22::x network.

The next condition denies UDP packets from any source with source UDP port in ranges 5 to 6 and whose destination is to the 2001:1570:22::/24 network.

The third condition permits all packets containing source and destination addresses that are not explicitly denied by the first two. Without this entry, the ACL would deny all incoming IPv6 traffic on the ports to which you assign the ACL.

A show running-config command displays the following.

FastIron(config)# show running-config
ipv6 access-list rtr
deny udp any range 5 6 2001:1570:22::/24
permit ipv6 any any

A show ipv6 access-list command displays the following.

FastIron(config)# sh ipv6 access-list rtr
ipv6 access-list rtr: 3 entries
20: deny udp any range rje 6 2001:1570:22::/24
30: permit ipv6 any any

The following commands apply the ACL “rtr” to the incoming traffic on ports 2/1 and 2/2.

FastIron(config)# int eth 2/1
FastIron(config-if-2/1)# ipv6 enable
FastIron(config-if-2/1)# ipv6 traffic-filter rtr in
FastIron(config-if-2/1)# exit
FastIron(config)# int eth 2/2
FastIron(config-if-2/2)# ipv6 enable
FastIron(config-if-2/2)# ipv6 traffic-filter rtr in
FastIron(config)# write memory

Default and implicit IPv6 ACL action

The default action when no IPv6 ACLs are configured on an interface is to permit all IPv6 traffic. However, once you configure an IPv6 ACL and apply it to an interface, the default action for that interface is to deny all IPv6 traffic that is not explicitly permitted on the interface.

- If you want to tightly control access, configure ACLs consisting of permit entries for the access you want to permit. The ACLs implicitly deny all other access.
- If you want to secure access in environments with many users, you might want to configure ACLs that consist of explicit deny entries, then add an entry to permit all access to the end of each ACL. The permit entry permits packets that are not denied by the deny entries.
Every IPv6 ACL has the following implicit conditions as its last match conditions.

1. `permit icmp any any nd-na` – Allows ICMP neighbor discovery acknowledgements.
2. `permit icmp any any nd-ns` – Allows ICMP neighbor discovery solicitations.
3. `deny ipv6 any any` – Denies IPv6 traffic. You must enter a `permit ipv6 any any` as the last statement in the access-list if you want to permit IPv6 traffic that were not denied by the previous statements.

**NOTE**
If an IPv6 ACL has the implicit `deny` condition, make sure it also permits the IPv6 link-local address, in addition to the global unicast address. Otherwise, routing protocols such as OSPF will not work. To view the link-local address, use the `show ipv6 interface` command.

The conditions are applied in the order shown above, with `deny ipv6 any any` as the last condition applied.

For example, if you want to deny ICMP neighbor discovery acknowledgement, then permit any remaining IPv6 traffic, enter commands such as the following:

```
FastIron(config)# ipv6 access-list netw
FastIron(config-ipv6-access-list-netw)# permit icmp 2000:2383:e0bb::/64 2001:3782::/64
FastIron(config-ipv6-access-list-netw)# deny icmp any any nd-na
FastIron(config-ipv6-access-list-netw)# permit ipv6 any any
```

The first permit statement permits ICMP traffic from hosts in the 2000:2383:e0bb:x network to hosts in the 2001:3782::x network.

The deny statement denies ICMP neighbor discovery acknowledgement.

The last entry permits all packets that are not explicitly denied by the other entries. Without this entry, the ACL will deny all incoming IPv6 traffic on the ports to which you assigned the ACL.

Furthermore, if you add the statement `deny icmp any any` in the access list, then all neighbor discovery messages will be denied. You must explicitly enter the `permit icmp any any nd-na` and `permit icmp any any nd-ns` statements just before the `deny icmp` statement if you want the ACLs to permit neighbor discovery as in the example below.

```
FastIron(config)# ipv6 access-list netw
FastIron(config-ipv6-access-list-netw)# permit icmp 2000:2383:e0bb::/64 2001:3782::/64
FastIron(config-ipv6-access-list-netw)# permit icmp any any nd-na
FastIron(config-ipv6-access-list-netw)# permit icmp any any nd-ns
FastIron(config-ipv6-access-list-netw)# deny icmp any any
FastIron(config-ipv6-access-list-netw)# permit ipv6 any any
```

**ACL syntax**

**NOTE**
The following features are not supported:

- `ipv6-operator flow-label`
For IPv6 and supported protocols other than ICMP, TCP, or UDP

Syntax: [no] ipv6 access-list <ACL name>

Syntax: permit | deny <protocol>
        <ipv6-source-prefix/prefix-length> | any | host <source-ipv6_address>
        <ipv6-destination-prefix/prefix-length> | any | host <ipv6-destination-address>
        [ipv6-operator [value]]
        [802.1p-priority-matching <number>]
        [dscp-marking <number> 802.1p-priority-marking <number> internal-priority-marking <number>]
        | [dscp-marking <dscp-value> dscp-cos-mapping] | [dscp-cos-mapping]

For ICMP

Syntax: [no] ipv6 access-list <ACL name>

Syntax: permit | deny icmp <ipv6-source-prefix/prefix-length> | any | host
        <source-ipv6_address>
        <ipv6-destination-prefix/prefix-length> | any | host <ipv6-destination-address>
        [ipv6-operator [value]]
        [ [icmp-type][icmp-code] ] | [icmp-message]
        [802.1p-priority-matching <number>]
        [dscp-marking <number> 802.1p-priority-marking <number> internal-priority-marking <number>]
        [dscp-marking <dscp-value> dscp-cos-mapping]
        [dscp-cos-mapping]

For TCP

Syntax: [no] ipv6 access-list <ACL name>

Syntax: permit | deny <tcp>
        <ipv6-source-prefix/prefix-length> | any | host <source-ipv6_address> [tcp-udp-operator]
        [source-port-number]]
        <ipv6-destination-prefix/prefix-length> | any | host <ipv6-destination-address>
        [tcp-udp-operator [destination-port-number]]
        [ipv6-operator [value]]
        [802.1p-priority-matching <number>]
        [dscp-marking <number> 802.1p-priority-marking <number> internal-priority-marking <number>]
        [dscp-marking <dscp-value> dscp-cos-mapping]
        [dscp-cos-mapping]
For UDP

Syntax: [no] ipv6 access-list <ACL name>

Syntax: permit | deny <udp>
   <ipv6-source-prefix/prefix-length> | any | host <ipv6-source-address> [tcp-udp-operator [source port number]]
   <ipv6-destination-prefix/prefix-length> | any | host <ipv6-destination-address> [tcp-udp-operator [destination port number]]
   [ipv6-operator [value]]
   [802.1p-priority-matching <number>]
   [dscp-marking <number> 802.1p-priority-marking <number> internal-priority-marking <number>]
   [dscp-marking <dscp-value> dscp-cos-mapping]
   [dscp-cos-mapping]

<td>&lt;ipv6-source-prefix&gt;/prefix-length</td>
<td>The &lt;ipv6-source-prefix&gt;/prefix-length parameter specify a source prefix and prefix length that a packet must match for the specified action (deny or permit) to occur. You must specify the &lt;ipv6-source-prefix&gt; parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the prefix-length parameter as a decimal value. A slash mark (/) must follow the &lt;ipv6-prefix&gt; parameter and precede the prefix-length parameter.</td>
</tr>
<tr>
<td>&lt;ipv6-destination-prefix&gt;/prefix-length</td>
<td>The &lt;ipv6-destination-prefix&gt;/prefix-length parameter specify a destination prefix and prefix length that a packet must match for the specified action (deny or permit) to occur. You must specify the &lt;ipv6-destination-prefix&gt; parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the prefix-length parameter as a decimal value. A slash mark (/) must follow the &lt;ipv6-prefix&gt; parameter and precede the prefix-length parameter.</td>
</tr>
<tr>
<td>any</td>
<td>When specified instead of the &lt;ipv6-source-prefix&gt;/prefix-length or &lt;ipv6-destination-prefix&gt;/prefix-length parameters, matches any IPv6 prefix and is equivalent to the IPv6 prefix::/0.</td>
</tr>
<tr>
<td>host</td>
<td>Allows you specify a host IPv6 address. When you use this parameter, you do not need to specify the prefix length. A prefix length of all128 is implied.</td>
</tr>
<tr>
<td>tcp-udp-operator</td>
<td>The &lt;tcp-udp-operator&gt; parameter can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• eq – The policy applies to the TCP or UDP port name or number you enter after eq.</td>
</tr>
<tr>
<td></td>
<td>• gt – The policy applies to TCP or UDP port numbers greater than the port number or the numeric equivalent of the port name you enter after gt. Enter &quot;?&quot; to list the port names.</td>
</tr>
<tr>
<td></td>
<td>• lt – The policy applies to TCP or UDP port numbers that are less than the port number or the numeric equivalent of the port name you enter after lt.</td>
</tr>
<tr>
<td></td>
<td>• neq – The policy applies to all TCP or UDP port numbers except the port number or port name you enter after neq.</td>
</tr>
<tr>
<td></td>
<td>• range – The policy applies to all TCP port numbers that are between the first TCP or UDP port name or number and the second one you enter following the range parameter. The range includes the port names or numbers you enter. For example, to apply the policy to all ports between and including 23 (Telnet) and 53 (DNS), enter the following range 23 53. The first port number in the range must be lower than the last number in the range.</td>
</tr>
</tbody>
</table>

The <source-port-number> and <destination-port-number> for the tcp-udp-operator is the number of the port.
TABLE 113 Syntax descriptions (Continued)

<table>
<thead>
<tr>
<th>Arguments...</th>
<th>Description...</th>
</tr>
</thead>
</table>
| ipv6-operator | Allows you to filter the packets further by using one of the following options:  
  • dscp – The policy applies to packets that match the traffic class value in the traffic class field of the IPv6 packet header. This operator allows you to filter traffic based on TOS or IP precedence. You can specify a value from 0 – 63.  
  • fragments – The policy applies to fragmented packets that contain a non-zero fragment offset. |

NOTE  
This option is not applicable to filtering based on source or destination port, TCP flags, and ICMP flags.

  • routing – The policy applies only to IPv6 source-routed packets.  
  • This option is not applicable to filtering based on source or destination port, TCP flags, and ICMP flags.

802.1p-priority-matching <number>  
If you want to match only those packets that have the same 802.1p priorities as specified in the ACL. Enter 0 – 7.

dscp-marking <number>  
Use the dscp-marking <number> parameter to specify a new QoS value to the packet. If a packet matches the filters in the ACL statement, this parameter assigns the DSCP value that you specify to the packet. Enter 0 – 63.

802.1p-priority-marking <number>  
Use the 802.1p-priority-marking <number> parameter to specify a new QoS value to the packet. If a packet matches the filters in the ACL statement, this parameter assigns the 802.1p priority that you specify to the packet. Enter 0 – 7.

internal-priority-marking <number>  
Use the internal-priority-marking <number> parameter to specify a new QoS value to the packet. If a packet matches the filters in the ACL statement, this parameter assigns the internal priority that you specify to the packet. Enter 0 – 7.

dscp-marking <number>  
Use the dscp-marking <number> parameter to specify a DSCP value and map that value to an internal QoS table to obtain the packet new QoS value. The following occurs when you use these parameters.  
  • You enter 0 – 63 for the dscp-marking <number> parameter.  
  • The dscp-cos-mapping parameter takes the DSCP value you specified and compares it to an internal QoS table, which is indexed by DSCP values. The corresponding 802.1p priority, internal forwarding priority, and DSCP value is assigned to the packet.

dscp-cos-mapping  
Use dscp-cos-mapping if you want to use the DSCP value in the packet header to alter its QoS value. When you enter dscp-cos-mapping, the DSCP value in the packet header is compared to a column in the internal QoS table. The 802.1p priority, internal forwarding priority, and DSCP value that are mapped to the matching column is assigned to the packet.

ICMP message configurations

If you want to specify an ICMP message, you can enter one of the following:  
  • beyond-scope  
  • destination-unreachable
Applying an IPv6 ACL to an interface

To apply an IPv6 ACL to an interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# ipv6 traffic-filter access1 in
```

This example applies the IPv6 ACL “access1” to incoming IPv6 packets on Ethernet interface 3/1. As a result, Ethernet interface 3/1 denies all incoming packets from the site-local prefix fec0:0:0:2::/64 and the global prefix 2001:100:1::/48 and permits all other incoming packets.

Syntax: `ipv6 traffic-filter <ipv6-ACL-name> in`

---

**NOTE**

If you do not specify a message type, the ACL applies to all types ICMP messages types.

- echo-reply
- echo-request
- header
- hop-limit
- mld-query
- mld-reduction
- mld-report
- nd-na
- nd-ns
- next-header
- no-admin
- no-route
- packet-too-big
- parameter-option
- parameter-problem
- port-unreachable
- reassembly-timeout
- renum-command
- renum-result
- renum-seq-number
- router-advertisement
- router-renumbering
- router-solicitation
- sequence
- time-exceeded
- unreachable
For the `<ipv6-ACL-name>` parameter, specify the name of an IPv6 ACL created using the `ipv6 access-list` command.

The `in` keyword applies the specified IPv6 ACL to incoming IPv6 packets on the interface.

## Adding a comment to an IPv6 ACL entry

**Platform Support:**
- FastIron X Series IPv6 devices running software release 04.2.00 and later – L2, BL3, L3

You can optionally add a comment to describe entries in an IPv6 ACL. The comment appears in the output of `show` commands that display ACL information.

You can add a comment by entering the `remark` command immediately preceding an ACL entry. For example, to enter comments preceding an ACL entry, enter commands such as the following.

```
FastIron(config)# ipv6 access-list rtr
FastIron(config-ipv6-access-list rtr)# remark This entry permits ipv6 packets from 3002::2 to any destination
FastIron(config-ipv6-access-list rtr)# permit ipv6 host 3000::2 any
FastIron(config-ipv6-access-list rtr)# remark This entry denies udp packets from any source to any destination
FastIron(config-ipv6-access-list rtr)# deny udp any any
FastIron(config-ipv6-access-list rtr)# remark This entry denies IPv6 packets from any source to any destination
FastIron(config-ipv6-access-list rtr)# deny ipv6 any any
FastIron(config-ipv6-access-list rtr)# write memory
```

**Syntax:** `remark <comment-text>`

The `<comment-text>` can be up to 256 characters in length.

The following shows the comment text for the ACL named “rtr” in a `show running-config` display.

```
FastIron# show running-config
ipv6 access-list rtr
  remark This entry permits ipv6 packets from 3002::2 to any destination
  permit ipv6 host 3000::2 any
  remark This entry denies udp packets from any source to any destination
  deny udp any any
  remark This entry denies IPv6 packets from any source to any destination
  deny ipv6 any any
```

**Syntax:** `show running-config`

## Deleting a comment from an IPv6 ACL entry

**Platform Support:**
- FastIron X Series IPv6 devices running software release 04.2.00 and later – L2, BL3, L3

To delete a comment from an IPv6 ACL entry, enter commands such as the following.

```
FastIron(config)# ipv6 access-list rtr
FastIron(config-ipv6-access-list rtr)# no remark This entry permits ipv6 packets from 3002::2 to any destination
```

**Syntax:** No specific syntax for deleting comments.
Enabling ACL logging

You may want the software to log entries in the Syslog for packets that are denied by ACL filters. ACL logging is disabled by default; it must be explicitly enabled on a port. Refer to “Enabling ACL logging” on page 652.

Displaying IPv6 ACLs

To display the IPv6 ACLs configured on a device, enter the `show ipv6 access-list` command. Here is an example.

```
FastIron# show ipv6 access-list
ipv6 access-list v6-ACL1: 1 entries
    deny ipv6 any any
ipv6 access-list v6-ACL2: 1 entries
    permit ipv6 any any
ipv6 access-list v6-ACL3: 2 entries
    deny ipv6 2001:aa:10::/64 any
    permit ipv6 any any
ipv6 access-list v6-ACL4: 2 entries
    deny ipv6 2002:aa::/64 any
    permit ipv6 any any
ipv6 access-list v6-ACL5: 8 entries
    permit tcp 2002:bb::/64 any
    permit ipv6 2001:aa:101::/64 any
    permit ipv6 2001:aa:10::/64 2001:aa:102::/64
dscp-marking 63 dscp-cos-mapping
    permit ipv6 any any dscp-matching 63 dscp-cos-mapping
    permit ipv6 any any fragments
```

Syntax: `show ipv6 access-list`

To display a specific IPv6 ACL configured on a device, enter the `show ipv6 access-list` command followed by the ACL name. The following example shows the ACL named "rtr".

```
FastIron# show ipv6 access-list rtr
ipv6 access-list rtr: 3 entries
    remark This entry permits ipv6 packets from 3002::2 to any destination
    permit ipv6 host 3000::2 any
    remark This entry denies udp packets from any source to any destination
    deny udp any any
    remark This entry denies IPv6 packets from any source to any destination
    deny ipv6 any any
```

Syntax: `show ipv6 access-list [<access-list-name>]`
For the `<access-list-name>` parameter, specify the name of an IPv6 ACL created using the `ipv6 access-list` command.
Power Over Ethernet overview

This section provides an overview of the requirements for delivering power over the LAN, as defined by the Institute of Electrical and Electronics Engineers Inc. (IEEE) in the 802.3af specification.

Brocade POE and POE+ devices provide Power over Ethernet, compliant with the standards described in the IEEE 802.3af specification for delivering in-line power. The 802.3af specification defines the standard for delivering power over existing network cabling infrastructure, enabling multicast-enabled full streaming audio and video applications for converged services, such as, Voice over IP (VoIP), WLAN access points, IP surveillance cameras, and other IP technology devices.

POE technology eliminates the need for an electrical outlet and dedicated UPS near IP powered devices. With power sourcing devices, such as Brocade FSX, power is consolidated and centralized in the wiring closets, improving the reliability and resiliency of the network. Because POE can provide power over Ethernet cable, power is continuous, even in the event of a power failure.

PoE Plus (PoE+) doubles the power available to powered devices. For the POE specifications for your device, see the appropriate hardware installation guide.

Terms used in this section

The following terms are introduced in this section:

- **Power sourcing device/equipment** - This is the source of the power, or the device that integrates the power onto the network. Power sourcing devices/equipment have embedded POE technology. In this case, the power sourcing device is Brocade POE or POE+ device.
- **IP powered device** or **Power consuming device** - This is the Ethernet device that requires power and is situated on the other end of the cable opposite the power sourcing equipment.

Methods for delivering POE and POE+

There are two methods for delivering power over the network, as defined in the 802.3af (POE) and 802.3at (POE+) specifications:

- **Endspan** - Power is supplied through the Ethernet ports on a power sourcing device. With the Endspan solution, power can be carried over the two data pairs (Alternative A) or the two spare pairs (Alternative B).
- **Midspan** - Power is supplied by an intermediate power sourcing device placed between the switch and the powered device. With the Midspan solution, power is carried over the two spare pairs (Alternative B).

With both methods, power is transferred over four conductors, between the two pairs. 802.3af- or 802.3at-compliant powered devices are able to accept power from either pairs.

Brocade POE and POE+ devices use the Endspan method, compliant with the 802.3af and 802.3at standards.
The Endspan and Midspan methods are described in more detail in the following sections.

**NOTE**
All 802.3af- and 802.3at-compliant power consuming devices are required to support both application methods defined in the specifications.

**Endspan**

The POE Endspan method uses the Ethernet switch ports on power sourcing equipment, such as Brocade FSX POE, which has embedded POE technology to deliver power over the network.

With the Endspan solution, there are two supported methods of delivering power. In Alternative A, four wires deliver data and power over the network. Specifically, power is carried over the live wire pairs that deliver data, as illustrated in Figure 104. In Alternative B, the four wires of the spare pairs are used to deliver power over the network. Brocade POE and POE+ devices support Alternative A.

The Endspan method is illustrated in Figure 104.

**FIGURE 104** POE Endspan delivery method

**Midspan**

The POE Midspan solution uses an intermediate device, usually a powered device, to inject power into the network. The intermediate device is positioned between the switch and the powered device and delivers power over the network using the spare pairs of wires (Alternative B). The intermediate device has multiple channels (typically 6 to 24), and each of the channels has data input and a data plus power RJ-45 output connector.

The Midspan method is illustrated in Figure 105.
POE Midspan Delivery Method

**Autodiscovery**

POE and POE+ autodiscovery is a detection mechanism that identifies whether or not an installed device is 802.3af- or 802.3at-compatible. When you plug a device into an Ethernet port that is capable of providing in-line power, the autodiscovery mechanism detects whether or not the device requires power and how much power is needed. The autodiscovery mechanism also has a disconnect protection mechanism that shuts down the power once a powered device has been disconnected from the network or when a faulty powered device has been detected. This feature enables safe installation and prevents high-voltage damage to equipment.

POE autodiscovery is achieved by periodically transmitting current or test voltages that can detect when a powered device is attached to the network. When an 802.3af- or 802.3at-compatible device is plugged into a POE port, the powered device reflects test voltage back to the power sourcing device (the Brocade device), ultimately causing the power to be switched ON. Non-compatible devices do not reflect test voltage back to the power sourcing device.

**Power class**

Different power classes determine the amount of power a POE powered device receives. When a valid powered device is detected, the Brocade POE device performs power classification by inducing a specific voltage and measuring the current consumption of the powered device. Depending on the measured current, the Brocade device assigns the appropriate class to the powered device. Powered devices that do not support classification are assigned a class of 0 (zero). Brocade supports POE+ for class 4 devices only. Table 115 shows the different power classes and their respective power consumption needs.
Power specifications

The actual implementation of the 802.3af standard limits power to 15.4W (44V to 57V) from the power sourcing device. This is in compliance with safety standards and existing wiring limitations. Though limited by the 802.3af standard, 15.4 watts of power is ample, as most powered devices consume an average of 5 to 12 watts of power. IP phones, wireless LAN access points, and network surveillance cameras each consume an average of 3.5 to 9 watts of power.

Brocade FastIron CX HPOE (POE+) class 4 devices support the implementation of the 802.3at standard, which nearly doubles the available power. For specification information, see the Brocade FastIron CX Switch Hardware Installation Guide.

The 48-volt power supply for FSX devices (part number SX-POE-AC-PWR) provides power to the POE daughter card, and ultimately to POE power-consuming devices. The number of POE power-consuming devices that one 48-volt power supply can support depends on the number of watts required by each power-consuming device. Each 48-volt power supply can provide 1080 watts of power, and each POE port supports a maximum of 15.4 watts of power per POE power-consuming device. For example, if each POE power-consuming device attached to the FSX consumes 10 watts of power, one 48-volt supply will power up to 108 POE ports. You can install a second 48-volt supply for additional POE power. Power supply specifications are covered in the Foundry FastIron X Series Chassis Hardware Installation Guide and in the Foundry FastIron Stackable Hardware Installation Guide.

**CAUTION**

The SX-POE-AC-PWR power supply is designed exclusively for use with the FSX POE devices. The power supply produces extensive power to support 802.3af applications. Installing the power supply in a device other than the FSX POE will cause extensive damage to your equipment.

Cabling requirements

The 802.3af standard currently supports POE on 10/100/1000 Mbps Ethernet ports operating over standard Category 5 unshielded twisted pair (UTP) cable or better. If your network uses cabling categories less than 5, you cannot implement POE without first upgrading your cables to CAT 5 UTP or better.

Supported powered devices

Brocade POE and POE+ devices support the following types of IP powered devices:
• Voice over IP (VoIP) phones
• Wireless LAN access points
• IP surveillance cameras

The following sections briefly describe these IP powered devices.

**VoIP**

Voice over IP (VoIP) is the convergence of traditional telephony networks with data networks, utilizing the existing data network infrastructure as the transport system for both services. Traditionally, voice is transported on a network that uses circuit-switching technology, whereas data networks are built on packet-switching technology. To achieve this convergence, technology has been developed to take a voice signal, which originates as an analog signal and transport it within a digital medium. This is done by devices, such as VoIP Telephones, which receive the originating tones and place them in UDP packets, the size and frequency of which is dependant on the Coding / Decoding (CODEC) technology that has been implemented in the VoIP Telephone / device. The VoIP control packets use the TCP/IP format.

**Wireless LAN access points**

Wireless LANs enable you to establish and maintain a wireless network connection within or between buildings, without the constraints of wires or cables as imposed by a wired LAN. Wireless LAN access points provide the link between the wired LAN and the wireless LAN.

Brocade IronPoint Access Point allows wireless clients to connect to your enterprise network. It is a full-featured access point that can be managed as a single device by IronView Network Manager, a network management tool that manages several Brocade devices in a network. For more information about Brocade IronPoint Access Point, refer to the IronPoint Wireless LAN Configuration Guide.

One of the main concerns with wireless LAN access points is the additional protection needed to secure the network. To help ensure continuous security against unauthorized Wireless LAN Access Points deployment, and deliver advanced security for entry-level WLAN Access Points, the Brocade POE and POE+ devices include IEEE 802.1x support for a flexible and dynamic security implementation. All switch ports can be configured as secured, requiring 802.1x authentication, or unsecured, requiring no authentication. For more information about this feature, refer to Chapter 42, “Configuring 802.1X Port Security”.

**IP surveillance cameras**

IP surveillance technology provides digital streaming of video over Ethernet, providing real-time, remote access to video feeds from cameras.

The main benefit of using IP surveillance cameras on the network is that you can view surveillance images from any computer on the network. If you have access to the Internet, you can securely connect from anywhere in the world to view a chosen facility or even a single camera from your surveillance system. By using a Virtual Private Network (VPN) or the company intranet, you can manage password-protected access to images from the surveillance system. Similar to secure payment over the Internet, images and information are kept secure and can be viewed only by approved personnel.
POE and CPU utilization

Depending on the number of POE-configured ports that have powered PDs, there may be a slight and noticeable increase of up to 15% in CPU utilization. In typical scenarios, this is normal behavior for PoE and does not affect the functionality of other features on the switch.

Enabling or disabling Power over Ethernet

To enable a port to receive in-line power for 802.3af-compliant and non-compliant power consuming devices, enter commands such as the following.

```
FastIron#config t
FastIron(config)#interface e 1/1
FastIron(config-if-e1000-1/1)#inline power
```

After entering the above commands, the console will display the following message.

```
FastIron(config-if-e1000-1/1)#PoE Info: Power enabled on port 1/1.
```

Syntax: `[no] inline power`

Use the `no` form of the command to disable the port from receiving in-line power.

**NOTE**

The FSX with POE can automatically detect whether or not a power consuming device is 802.3af-compliant. Therefore, the CLI command `inline power legacy-powerdevice`, which is used on FES POE devices to configure 802.3af non-compliant devices, does not apply on the FSX POE.

Disabling support for POE legacy power consuming devices

This feature is supported on FastIron X Series POE devices running software release 03.0.00 or later.

Brocade POE devices automatically support most legacy power consuming devices (non-802.3af compliant devices), as well as all 802.3af-compliant devices. In releases prior to 03.0.00, support for legacy devices is always enabled on Brocade POE devices and cannot be disabled. Starting with release 03.0.00, if desired, you can disable and re-enable support for legacy POE power consuming devices on a global basis (on the entire device) or on individual slots (chassis devices only). When you disable legacy support, 802.3af-compliant devices are not affected.

To disable support for legacy power consuming devices on a global basis, enter the following command at the Global CONFIG level of the CLI.

```
FastIron(config)#no legacy-inline-power
```

On chassis devices (FSX, FSX 800, and FSX 1600), you can disable support for legacy power consuming devices per slot. To disable support on a slot, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#no legacy-inline-power 2
```

The above command disables legacy support on all ports in slot 2.

Syntax: `[no] legacy-inline-power [<slotnum>]/`
To re-enable support for legacy power consuming devices after it has been disabled, enter the `legacy-inline-power` command (without the `no` parameter).

`<slotnum>` is required on chassis devices when disabling or re-enabling legacy support on a slot.

Use the `show run` command to view whether support for POE legacy power consuming devices is enabled or disabled.

### Enabling the detection of POE power requirements advertised through CDP

Many power consuming devices, such as Cisco VOIP phones and other vendors’ devices, use CDP to advertise their power requirements to power sourcing devices, such as Brocade POE devices. Brocade power consuming devices are compatible with Cisco and other vendors’ power consuming devices, in that they can detect and process power requirements for these devices automatically.

#### Configuration considerations

- This feature is supported in FSX POE devices running software release 02.2.00 or later
- If you configure a port with a maximum power level or a power class for a power consuming device, the power level or power class takes precedence over the CDP power requirement. Therefore, if you want the device to adhere to the CDP power requirement, do not configure a power level or power class on the port.
- The FSX POE will adjust a port power only if there are available power resources on the device.

#### Command syntax

To enable the Brocade device to detect CDP power requirements, enter the following commands.

```
FastIron#config t
FastIron(config)#cdp run
```

Syntax: `[no] cdp run`

Use the `no` form of the command to disable the detection of CDP power requirements.

### Setting the maximum power level for a POE power consuming device

When POE is enabled on a port to which a power consuming device is attached, by default, the Brocade POE device will supply 15.4 watts of power at the RJ45 jack, minus any power loss through the cables. For example, a POE port with a default maximum power level of 15.4 watts will receive a maximum of 12.95 watts of power after 2.45 watts of power loss through the cable. This is compliant with the IEEE 802.3af specification for delivering in-line power. Devices that are configured to receive less POE power, for example, 4.0 watts of power, will experience a lower rate of power loss through the cable.
If desired, you can manually configure the maximum amount of power that the Brocade POE device will supply at the RJ45 jack. You can specify from 1 to 15.4 watts of maximum power for each power consuming device connected to the switch.

**Configuration notes**

- This feature is supported for FSX POE devices running release 02.2.00 or later, FGS, FLS devices, and FWS devices running software release 04.3.01 and later, and FCX devices running software release 06.0.00 and later.
- There are two ways to configure the power level for a POE power consuming device. The first method is discussed in this section. The other method is provided in the section “Setting the power class for a POE power consuming device” on page 700. For each POE port, you can configure either a maximum power level or a power class. You cannot configure both. You can, however, configure a maximum power level on one port and a power class on another port.
- The CLI commands for this feature differ on the FSX POE compared to the FES POE. On the FES POE, there are separate CLI commands for 802.3af-compliant versus 802.3-af non-compliant power consuming devices. On the FSX, there is one command for all power consuming devices. The command syntax is also different on the FSX. To configure your device, refer to the appropriate section, below.

**Command syntax**

To configure the maximum power level for a power consuming device, enter commands such as the following.

```
FastIron#config t
FastIron(config)#interface e 1/1
FastIron(config-if-e1000-1/1)#inline power power-limit 14000
```

These commands enable in-line power on interface e 1 in slot 1 and set the POE power level to 14,000 milliwatts (14 watts).

**Syntax:**  `inline power power-limit <power level>`

where `<power level>` is the number of milliwatts, between 1000 and 15400. The default is 15400.

For information about resetting the maximum power level, refer to “Resetting POE parameters” on page 703.

---

**Setting the power class for a POE power consuming device**

A power class specifies the maximum amount of power that a Brocade POE device will supply to a power consuming device. **Table 115** shows the different power classes and their respective maximum power allocations.

<table>
<thead>
<tr>
<th>Class</th>
<th>Maximum power (Watts)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15.4 (default)</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>

---
Setting the power class for a POE power consuming device

By default, the power class for all power consuming devices is zero (0). As shown in Table 115, a power consuming device with a class of 0 receives 15.4 watts of power.

Configuration notes

- This feature is supported for FSX POE devices running release 02.2.00 or later. It is also supported for FGS, FLS devices, and FWS devices running software release 04.3.01 and later.
- The power class sets the maximum power level for a power consuming device. Alternatively, you can set the maximum power level as instructed in the section “Setting the maximum power level for a POE power consuming device” on page 699. For each POE port, you can configure either a power class or a maximum power level. You cannot configure both. You can, however, configure a power level on one port and power class on another port.
- The power class includes any power loss through the cables. For example, a POE port with a default power class of 0 (15.4 watts) will receive a maximum of 12.95 watts of power after 2.45 watts of power loss through the cable. This is compliant with the IEEE 802.3af specification for delivering in-line power. Devices that are configured to receive less POE power, for example, class 1 devices (4.0 watts), will experience a lower rate of power loss through the cable.
- The CLI commands for this feature differ on the FSX POE compared to the FES POE. On the FES POE, there are separate CLI commands for 802.3af-compliant versus 802.3-af non-compliant power consuming devices. On the FSX, there is one command for all power consuming devices. The command syntax is also different on the FSX.

Command syntax

To configure the power class for a POE power consuming device, enter commands such as the following.

```
FastIron(config-if-e1000-1/1)#inline power power-by-class 2
```

These commands enable in-line power on interface e 1 in slot 1 and set the power class to 2.

Syntax: `inline power power-by-class <class value>`

where `<class value>` is the power class. Enter a value from 0 – 3. Refer to Table 115 for the power classes and their respective maximum power allocations. The default is 0 (15.4 watts).

For information about resetting the power class, refer to “Resetting POE parameters” on page 703.
Setting the in-line power priority for a POE port

Each FSX POE (48V) power supply provides a maximum of 1080 watts of power, and each POE port receives a default maximum value of 15.4 watts of power, minus any power loss through the cable. The power capacity of one or two POE power supplies is shared among all POE power consuming devices attached to the FSX POE.

In a configuration where POE power consuming devices collectively have a greater demand for power than the POE power supply or supplies can provide, the FSX must place the POE ports that it cannot power in standby or denied mode (waiting for power) until the available power increases. The available power increases when one or more POE ports are powered down, or, if applicable, when an additional POE power supply is installed in the FSX.

When POE ports are in standby or denied mode (waiting for power) and the FSX receives additional power resources, by default, the FSX will allocate newly available power to the standby ports in ascending order, by slot number then by port number, provided enough power is available for the ports. For example, POE port 1/11 should receive power before POE port 2/1. However, if POE port 1/11 needs 12 watts of power and POE port 2/1 needs 10 watts of power, and 11 watts of power become available on the device, the FSX will allocate the power to port 2/1 since it does not have sufficient power for port 1/11.

You can configure an in-line power priority on POE ports, whereby ports with a higher in-line power priority will take precedence over ports with a low in-line power priority. For example, if a new POE port comes on-line and the port is configured with a high priority, if necessary (if power is already fully allocated to power consuming devices), the FSX will remove power from a POE port or ports that have a lower priority and allocate the power to the POE port that has the higher value.

Ports that are configured with the same in-line power priority are given precedence based on the slot number and port number in ascending order, provided enough power is available for the port. For example, if both POE port 1/2 and POE port 2/1 have a high in-line power priority value, POE port 1/2 will receive power before POE port 2/1. However, if POE port 1/2 needs 12 watts of power and POE port 2/1 needs 10 watts of power, and 11 watts of power become available on the device, the FSX will allocate the power to POE port 2/1 since it does not have sufficient power for port 1/2. By default, all ports are configured with a low in-line power priority.

Command syntax

To configure an in-line power priority for a POE port on a FSX, enter commands such as the following.

```
FastIron(config-if-e1000-1/1)#inline power priority 2
```

These commands enable in-line power on interface e 1 in slot 1 and set the in-line power priority level to high.

**Syntax:** `[no] inline power priority <priority num>

where **priority** <priority num> is the in-line power priority number. The default is 3 (low priority). You can specify one of the following values:

- 3 – low priority
- 2 – high priority
- 1 – critical priority
Use the **inline power** command (without a priority number) to reset a port priority to the default (low) priority.

Use the **no inline power** command to disable the port from receiving in-line power.

For information about resetting the in-line power priority, refer to "Resetting POE parameters" on page 703.

To view the in-line power priority for all POE ports, issue the **show inline power** command at the Privileged EXEC level of the CLI. Refer to “Displaying POE operational status” on page 703.

### Resetting POE parameters

**NOTE**
This feature applies to the FSX POE only.

To override or reset POE port parameters including power priority, power class, and maximum power level, you must specify each POE parameter in the CLI command line. This section provides some examples.

**Example**
To change a POE port power priority from high to low (the default value) and keep the current maximum configured power level of 3000, enter commands such as the following.

```
FastIron#config t
FastIron(config)#interface e 1/1
FastIron(config-if-e1000-1/1)#inline power priority 3 power-limit 3000
```

Note that you must specify both the inline power priority and the maximum power level (**power-limit** command), even though you are keeping the current configured maximum power level at 3000. If you do not specify the maximum power level, the device will apply the default value of 15400 (15.4 watts). Also, you must specify the inline power priority before specifying the power limit.

**Example**
To change a port power class from 2 (4 watts max) to 3 (7 watts max) and keep the current configured power priority of 2, enter commands such as the following.

```
FastIron#config t
FastIron(config)#interface e 1/1
FastIron(config-if-e1000-1/1)#inline power priority 2 power-by-class 3
```

Note that you must specify both the power class and the inline power priority, even though you are not changing the power priority. If you do not specify the power priority, the device will apply the default value of 3 (low priority). Also, you must specify the inline power priority before specifying the power class.

### Displaying power over Ethernet information

This section lists the CLI commands for viewing POE information.

**Displaying POE operational status**

The **show inline power** command displays operational information about Power over Ethernet.
You can view the POE operational status for the entire device, for a specific POE module only, or for a specific interface only. In addition you can use the `show inline power detail` command to display in depth information about POE power supplies.

The following shows an example of the `show inline power` display output on a FastIron POE device.

FastIron#show inline power

Power Capacity: Total is 2160000 mWatts. Current Free is 18800 mWatts.

Power Allocations: Requests Honored 769 times

Displaying power over Ethernet information
TCAM entries in FWS devices

The Layer 2 with Base Layer 3 software image contains all the system-level features in the Layer 2 images, along with the following:

- Static IP routes
- RIPv1 and RIPv2 (see note, below)
- Routing between directly connected subnets
- RIP advertisements of the directly connected subnets
- Virtual interfaces
- VRRP

NOTES:

- Layer 2 with Base Layer 3 images provide static RIP support. The device does not learn RIP routes from other Layer 3 devices. However, the device does advertise directly connected routes and can be configured to dynamically learn default routes. Brocade recommends that you deploy these devices only at the edge of your network, since incoming traffic can learn directly-connected routes advertised by the Brocade device, but outgoing traffic to other devices must use statically configured or default routes.
- The Base Layer 3 images do not support IP multicasting, OSPF, or BGP4.
- Base Layer 3 feature support has been added to FGS and FLS devices effective with release 04.0.00.
- The FWSX devices are Layer 2 switches only. They do not support Base Layer 3 and full Layer 3 features.
- The TurboIron X Series devices do not support Base Layer 3 images.

The size of the TCAM in FWS devices is limited to 1024 routing entries. When this limit is reached, the following warning message is displayed:

No free TCAM entry available. System will be unstable. Please reboot system.

At the same time, the following Syslog is generated:

System: No Free Tcam Entry available. System will be unstable.

You must reboot the device when you see these messages.

Adding a static IP route

Platform Support:

- FastIron X Series devices – all L3 software releases
Adding a static ARP entry

Static entries are useful in cases where you want to pre-configure an entry for a device that is not connected to the Brocade device, or you want to prevent a particular entry from aging out. The software removes a dynamic entry from the ARP cache if the ARP aging interval expires before the entry is refreshed. Static entries do not age out, regardless of whether the Brocade device receives an ARP request from the device that has the entry address. The software places a static ARP entry into the ARP cache as soon as you create the entry.

To add a static ARP entry, enter a command such as the following at the global CONFIG level of the CLI.

FastIron(config)# arp 1 209.157.22.3 aaaa.bbbb.cccc ethernet 3

This command adds a static ARP entry that maps IP address 209.157.22.3 to MAC address aaaa.bbbb.cccc. The entry is for a MAC address connected to FastIron port 3.

Syntax: y[no] arp <num> <ip-addr> <mac-addr> ethernet [<stack-unit>/]<slotnum>[/]<portnum>
The `<num>` parameter specifies the entry number. You can specify a number from 1 up to the maximum number of static entries allowed on the device. You can allocate more memory to increase this amount. To do so, enter the `system-max ip-static-arp <num>` command at the global CONFIG level of the CLI.

The `<ip-addr>` command specifies the IP address of the device that has the MAC address of the entry.

The `<mac-addr>` parameter specifies the MAC address of the entry.

The `<stack-unit>` parameter is required on FGS and FLS devices running software version 2.5 and later, and on FGS-STK and FLS-STK devices running software version 5.0 and later.

The `<portnum>` command specifies the port number attached to the device that has the MAC address of the entry. If you are configuring a chassis device, specify the slot number as well as the port number (`<slotnum>/<portnum>`).

**NOTE**
The `clear arp` command clears learned ARP entries but does not remove any static ARP entries.

### Modifying and displaying layer 3 system parameter limits

This section shows how to view and configure some of the Layer 3 system parameter limits.

#### Configuration notes

- Changing the system parameters reconfigures the device memory. Whenever you reconfigure the memory on a Brocade device, you must save the change to the startup-config file, then reload the software to place the change into effect.
- The Layer 3 system parameter limits for FastIron IPv6 models are automatically adjusted by the system and cannot be manually modified. Refer to “FastIron IPv6 models” on page 716.

#### FGS with base layer 3

**NOTE**
This section applies only to the FGS, FLS, FGS-STK and FLS-STK Base-L3 build. It does not apply to other platforms such as FESX or SuperX.

FGS Base-L3 uses TCAMs for IP routing, access list and MAC based vlan and some other features. The maximum value for TCAMs in FGS and FGS-STK devices is 1020, and 1019 for FWS devices.

You can set the number of TCAMs reserved for IP routing using the `system-max` command.

```
FGS(config)# system-max hw-ip-route-tcam ??
```

The range is from 64 to 1020 (1019 for FWS devices) and the default is 256.

The `show ip route` command displays the usage of TCAMs in routing.
Example

FGS# show ip route
Total number of IP routes: 29
Route TCAM: total 64, used 64, add HW route failure=34

<table>

... In this example "add HW route failure" shows the number of failures in installing routing TCAM.

FGS Base L3 installs routing TCAMs for the interface subnet and static routes. A packet is routed in hardware if its destination IP address matches the interface or stack route subnet, and the nexthop or destination ARP is resolved. The unknown unicast packets have destination IP addresses that do not match any static route or interface subnets.

The handling of unknown unicast packets differs depending on TCAM availability. For example, for a system that never encounters out-of-TCAM situation, If the default route is not configured or its next hop ARP is not resolved, all unknown unicast packets are handled based on the default L2 behavior. They are either dropped in hardware if "route-only" is configured, or VLAN-flooded in hardware.

NOTE
FGS Base-L3 does not allow "route-only" config.

If the default route is configured and its next hop ARP is resolved, unknown unicast packets are hardware-routed to the next hop, and not VLAN-flooded.

Once the FGS runs out of TCAM, it traps the unknown unicast packets to CPU for processing. If the default route is defined and its next hop ARP is resolved, the packets are routed by CPU. Otherwise, they follow the default L2 behavior. Because FGS Base L3 does not allow "route-only" configurations, these packets are VLAN-flooded.

The system does not change this CPU handling behavior back to hardware switching even when TCAMs again become available.

FastIron IPv4 models

You can configure the following Layer 3 system parameters on FastIron IPv4 models:
- Number of IP next hops and IP route entries
- Number of hardware logical interfaces (physical port and VLAN pairs)
- Number of multicast output interfaces (clients)

These parameters are automatically enabled with pre-defined default values. You can however, adjust these values to conform with your network topology.

To display the current settings for the Layer 3 system parameters, use the `show default value` command. Refer to “Displaying layer 3 system parameter limits” on page 716.

To modify the default settings for the Layer 3 system parameters, use the `system max` command at the Global CONFIG level of the CLI. Refer to “Modifying layer 3 system parameter limits on IPv4 models” on page 715.
Modifying layer 3 system parameter limits on IPv4 models

The Layer 3 system parameter limits share the same hardware memory space and, by default, consume all of the hardware memory allocated for these Layer 3 limits. Therefore, to increase the limit for one of the parameters, you must first decrease one or both of the other parameters’ limits. If you enter a value that exceeds the memory limit, the CLI will display an error message and the configuration will not take effect.

For example, if the network topology has a smaller number of IP next hops and routes, but has numerous multicast output interfaces, you could decrease the number of IP next hops and routes, then increase the number of multicast output interfaces. To do so, enter commands such as the following.

```
FastIron(config)# system-max hw-ip-next-hop 1024
FastIron(config)# system-max hw-ip-mcast-mll 2048
FastIron(config)# write mem
FastIron(config)# reload
```

Likewise, if the network topology does not have a large number of VLANs, and the VLANs configured on physical ports are not widely distributed, you could decrease the number of hardware logical interfaces, then increase the number of IP next hops and multicast output interfaces. To do so, enter commands such as the following.

```
FastIron(config)# system-max hw-logical-interface 2048
FastIron(config)# system-max hw-ip-next-hop 3072
FastIron(config)# system-max hw-ip-mcast-mll 2048
FastIron(config)# write mem
FastIron(config)# reload
```

Syntax: `system max hw-ip-next-hop <num>`
Syntax: `system max hw-logical-interface <num>`
Syntax: `system max hw-ip-mcast-mll <num>`

**NOTE**
The above commands are not supported on IPv6 devices. Refer to “FastIron IPv6 models” on page 716.

The `hw-ip-next-hop <num>` parameter specifies the maximum number of IP next hops and routes supported on the device. Note that the maximum number includes unicast next hops and multicast route entries. Enter a number from 100 to 6144. The default is 2048.

The `hw-logical-interface <num>` parameter specifies the number of hardware logical interface pairs (physical port and VLAN pairs) supported on the device. Enter a number from 0 to 4096. When this parameter is set to 4096 (the maximum), the limit is not enforced. If you enter a number less than 4096, the limit is the total number of physical port and VLAN pairs that are IP-enabled in the system. The default is 4096.

The `hw-ip-mcast-mll <num>` parameter specifies the maximum number of multicast output interfaces (clients) supported on the device. If a given source or group has clients in `n` tagged VLANs on the router, then `n + 1` mll entries are consumed for that source or group entry. Enter a number from 0 to 4096. The default is 1024.
FastIron IPv6 models

FastIron IPv6 models support the same Layer 3 system parameters that use hardware memory, as do FastIron IPv4 models. However, there are some configuration differences for IPv6 models versus IPv4 models. The differences are as follows:

- Number of IP next hops and IP route entries – 6144 maximum and default value. The system automatically calculates this value, based on the maximum number of VLANs supported system-wide.
- Number of hardware logical interfaces (physical port and VLAN pairs) – This value is the same as the maximum number of VLANs supported system-wide, so it is not configurable nor displayed in the `show default values` output in IPv6 models.
- Number of multicast output interfaces (clients) – 3072 maximum. This value is fixed in IPv6 models and cannot be modified. This system parameter occupies its own hardware memory space.

To display the current settings for the Layer 3 system parameters, use the `show default value` command. Refer to “Displaying layer 3 system parameter limits” on page 716.

Displaying layer 3 system parameter limits

To display the Layer 3 system parameter defaults, maximum values, and current values, enter the `show default value` command at any level of the CLI.

The following shows an example output on a FastIron X Series IPV4 device.

```
FastIron# show default value
sys log buffers:50         mac age time:300 sec       telnet sessions:5
ip arp age:10 min          bootp relay max hops:4     ip ttl:64 hops
ip addr per intf:24
igmp group memb.:140 sec   igmp query:60 sec
ospf dead:40 sec           ospf hello:10 sec          ospf retrans:5 sec
ospf transit delay:1 sec

System Parameters    Default    Maximum    Current
ip-arp               4000       64000      4000
ip-static-arp        512        1024       512
hw-ip-next-hop       2048       6144       2048
hw-logical-interface 4096       4096       4096
hw-ip-mcast-mll      1024       4096       1024
```

The following shows an example output on a FastIron X Series IPV6 device.
Configuring RIP

Platform Support:
- FastIron X Series devices running software release 02.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FGS and FLS devices running software release 05.0.00 and later
- FWS devices running software release 02.0.00 and later

**NOTE**
On TurboIron X Series devices, RIP version 2 is supported on devices running software release 04.2.00 and later.

RIP is disabled by default. If you want the Brocade device to use RIP, you must enable the protocol globally, then enable RIP on individual ports. When you enable RIP on a port, you also must specify the version (version 1 only, version 2 only, or version 1 compatible with version 2).

Optionally, you also can set or change the following parameters:
- Route redistribution – You can enable the software to redistribute static routes from the IP route table into RIP. Redistribution is disabled by default.
- Learning of default routes – The default is disabled.
- Loop prevention (split horizon or poison reverse) – The default is poison reverse.

**Enabling RIP**

RIP is disabled by default. To enable it, use the following CLI method. You must enable the protocol both globally and on the ports on which you want to use RIP.

```
FastIron# show default value
sys log buffers:50       mac age time:300 sec       telnet sessions:5
ip arp age:10 min        bootp relay max hops:4     ip ttl:64 hops
ip addr per intf:24
igmp group memb.:140 sec igmp query:60 sec
ospf dead:40 sec         ospf hello:10 sec         ospf retrans:5 sec
ospf transit delay:1 sec

System Parameters    Default    Maximum    Current
ip-arp               4000       64000      4000
ip-static-arp        512        1024       512

hw-ip-next-hop       6144       6144       6144
hw-ip-mcast-mll      1024       4096       1024
hw-traffic-condition  50        1024        50
```
To enable RIP globally, enter the following command.

```
FastIron(config)# router rip
```

Syntax: `[no] router rip`

To enable RIP on a port and specify the RIP version, enter commands such as the following.

```
FastIron(config-rip-router)# interface ethernet 1
FastIron(config-if-e1000-1)# ip rip v1-only
```

This command changes the CLI to the configuration level for port 1 and enables RIP version 1 on the interface. You must specify the version.

Syntax: `interface ethernet [<slotnum>/<portnum>]`

Syntax: `[no] ip rip v1-only | v1-compatible-v2 | v2-only`

**Enabling redistribution of IP static routes into RIP**

By default, the software does not redistribute the IP static routes in the route table into RIP. To configure redistribution, perform the following tasks:

- Configure redistribution filters (optional). You can configure filters to permit or deny redistribution for a route based on the route metric. You also can configure a filter to change the metric. You can configure up to 64 redistribution filters. The software uses the filters in ascending numerical order and immediately takes the action specified by the filter. Thus, if filter 1 denies redistribution of a given route, the software does not redistribute the route, regardless of whether a filter with a higher ID permits redistribution of that route.

**NOTE**
The default redistribution action is permit, even after you configure and apply a permit or deny filter. To deny redistribution of specific routes, you must configure a deny filter.

**NOTE**
The option to set the metric is not applicable to static routes.

- Enable redistribution.

**NOTE**
If you plan to configure redistribution filters, do not enable redistribution until you have configured the filters.

When you enable redistribution, all IP static routes are redistributed by default. If you want to deny certain routes from being redistributed into RIP, configure deny filters for those routes before you enable redistribution. You can configure up to 64 RIP redistribution filters. They are applied in ascending numerical order.

**NOTE**
The default redistribution action is still permit, even after you configure and apply redistribution filters to the port. If you want to tightly control redistribution, apply a filter to deny all routes as the last filter (filter ID 64), then apply filters with lower filter IDs to allow specific routes.

To configure a redistribution filter, enter a command such as the following.

```
FastIron(config-rip-router)# deny redistribute 1 static address 207.92.0.0 255.255.0.0
```
This command denies redistribution of all 207.92.x.x IP static routes.

**Syntax:**  
\[no\] permit | deny redistribute \(<filter-num>\) static address \(<ip-addr>\) \(<ip-mask>\)  
\[match-metric \(<value>\) | set-metric \(<value>\)\]

The \(<filter-num>\) specifies the redistribution filter ID. Specify a number from 1 – 64. The software uses the filters in ascending numerical order. Thus, if filter 1 denies a route from being redistributed, the software does not redistribute that route even if a filter with a higher ID permits redistribution of the route.

The address \(<ip-addr>\) \(<ip-mask>\) parameters apply redistribution to the specified network and subnet address. Use 0 to specify “any”. For example, “207.92.0.0 255.255.0.0” means “any 207.92.x.x subnet”. However, to specify any subnet (all subnets match the filter), enter “address 255.255.255.255 255.255.255.255”.

The match-metric \(<value>\) parameter applies redistribution to those routes with a specific metric value; possible values are from 1 – 15.

The set-metric \(<value>\) parameter sets the RIP metric value that will be applied to the routes imported into RIP.

**NOTE**  
The set-metric parameter does not apply to static routes.

The following command denies redistribution of a 207.92.x.x IP static route only if the route metric is 5.

FastIron(config-rip-router)# deny redistribute 2 static address 207.92.0.0 255.255.0.0 match-metric 5

The following commands deny redistribution of all routes except routes for 10.10.10.x and 20.20.20.x.

FastIron(config-rip-router)# deny redistribute 64 static address 255.255.255.255 255.255.255.255  
FastIron(config-rip-router)# permit redistribute 1 static address 10.10.10.0 255.255.255.0  
FastIron(config-rip-router)# permit redistribute 2 static address 20.20.20.0 255.255.255.0

**Enabling redistribution**

After you configure redistribution parameters, you need to enable redistribution.

To enable RIP redistribution, enter the following command.

FastIron(config-rip-router)# redistribution

**Syntax:**  
\[no\] redistribution

**Enabling learning of default routes**

By default, the software does not learn RIP default routes.

To enable learning of default RIP routes, enter commands such as the following.

FastIron(config)# interface ethernet 0/1/1  
FastIron(config-if-e1000-1)# ip rip learn-default
Syntax:  `interface ethernet [<stack-unit>]<slotnum>/]<portnum>`

Syntax: `[no] ip rip learn-default`

The `<stack-unit>` parameter is required on FGS and FLS devices, and on FGS-STK and FLS-STK devices running software release 05.0.00 and later.

The `<slotnum>`/ parameter applies to chassis devices only.

### Changing the route loop prevention method

RIP can use the following methods to prevent routing loops:

- Split horizon – The Brocade device does not advertise a route on the same interface as the one on which it learned the route.
- Poison reverse – The Brocade device assigns a cost of 16 (“infinite” or “unreachable”) to a route before advertising it on the same interface as the one on which it learned the route. This is the default.

**NOTE**

These methods are in addition to RIP maximum valid route cost of 15.

To enable split horizon, enter commands such as the following.

```
FastIron(config)# interface ethernet 0/1/1
FastIron(config-if-e1000-1)# no ip rip poison-reverse
```

Syntax: `[no] ip rip poison-reverse`

### Other layer 3 protocols

For information about other IP configuration commands in the Layer 2 with Base Layer 3 image that are not included in this chapter, refer to Chapter 30, “Configuring IP”.

For information about enabling or disabling Layer 3 routing protocols, refer to “Enabling or disabling routing protocols” on page 720. For complete configuration information about the routing protocols, refer to the other chapters in this book.

### Enabling or disabling routing protocols

This section describes how to enable or disable routing protocols. For complete configuration information about the routing protocols, refer to the other chapters in this book.

FESX and FSX devices running full Layer 3 code support the following protocols:

- BGP4
- IGMP
- IP
- IP multicast (DVMRP, PIM-SM, PIM-DM)
- OSPF
- RIPV1 and V2
Enabling or disabling layer 2 switching

By default, Brocade Layer 3 Switches support Layer 2 switching. These devices switch the routing protocols that are not supported on the devices. If you want to disable Layer 2 switching, you can do so globally or on individual ports, depending on the version of software your device is running.

Configuration notes

- Make sure you really want to disable all Layer 2 switching operations before you use this option. Consult your reseller or Brocade for information.
- This feature is supported in the following configurations:
  - The FESX running software release 01.1.00 or prior, supports disabling Layer 2 switching on a global basis only. Starting in release 02.1.01, the FESX supports disabling Layer 2 switching on an individual interface as well as on a global basis.
  - The FSX running software release 02.2.00 and later supports disabling Layer 2 switching on an individual interface as well as on a global basis.
  - The TurboIron X Series devices running software release 04.2.00 and later supports disabling Layer 2 switching on an individual interface as well as on a global basis.

Command syntax

To globally disable Layer 2 switching on a Layer 3 Switch, enter commands such as the following.

```
FastIron(config)# route-only
FastIron(config)# exit
FastIron# write memory
FastIron# reload
```

To re-enable Layer 2 switching on a Layer 3 Switch, enter the following.

```
FastIron(config)# no route-only
FastIron(config)# exit
FastIron# write memory
FastIron# reload
```

Syntax: [no] route-only
Enabling or disabling layer 2 switching

To disable Layer 2 switching only on a specific interface, go to the Interface configuration level for that interface, then disable the feature. The following commands show how to disable Layer 2 switching on port 2.

```
FastIron(config)# interface ethernet 2
FastIron(config-if-e1000-2)# route-only
```

**Syntax:** `[no] route-only`

To re-enable Layer 2 switching, enter the command with "no", as in the following example.

```
FastIron(config-if-e1000-2)# no route-only
```

**NOTE**
For TurboIron, `route-only` will not disable Layer 2 switching on ports within a VLAN that has a VE configured.
Mirroring support by platform

The procedures in this chapter describe how to configure port mirroring on Brocade devices. Port mirroring is a method of monitoring network traffic that forwards a copy of each incoming or outgoing packet from one port on a network switch to another port where the packet can be analyzed. Port mirroring may be used as a diagnostic tool or debugging feature, especially for preventing attacks. Port mirroring can be managed locally or remotely.

Configure port mirroring by assigning a port from which to copy all packets, and a “mirror” port where the copies of the packets are sent (also known as the monitor port). A packet received on, or issued from, the first port is forwarded to the second port as well. Attach a protocol analyzer on the mirror port to monitor each segment separately. The analyzer captures and evaluates the data without affecting the client on the original port.

The mirror port may be a port on the same switch with an attached RMON probe, a port on a different switch in the same hub, or the switch processor.

Table 118 lists which Brocade devices support the mirroring features discussed in this chapter.

Configuring port mirroring and monitoring

FastIron X Series devices support monitoring of both inbound and outbound traffic on individual ports (one mirror port per port region). FastIron GS and FLS, as well as Turbolron X Series devices support one mirror port per device. See the configuration notes in the next section for multi-stack mirroring for FGS-STK and FLS-STK, and FCX stacking devices.

To configure port monitoring, first specify the mirror port, then enable monitoring on the monitored port.

The mirror port is the port to which the monitored traffic is copied. Attach your protocol analyzer to the mirror port. The monitored port is the port whose traffic you want to monitor.
### Configuration notes

Refer to the following rules when configuring port mirroring and monitoring:

- **Port monitoring and sFlow support:**
  - FastIron X Series devices support sFlow and inbound port monitoring together on the same device, however, these devices do not support port monitoring and sFlow together within the same port region. Refer to the section “About port regions” on page 361 for a list of valid port ranges on these devices.
  - FastIron GS and LS devices support sFlow and port monitoring together on the same port.
  - TurboIron X Series devices support sFlow and port monitoring together on the same port.
  - FCX devices support sFlow and port monitoring together on the same port.
  - If you configure both ACL mirroring and ACL based rate limiting on the same port, then all packets that match are mirrored, including the packets that exceed the rate limit.
  - Table 119 lists the number of mirror and monitor ports supported on the Brocade devices.

#### TABLE 119  Number of mirror and monitored ports supported

<td>no limit</td>
</tr>
</tbody>
</table>

**NOTE**

FastIron X Series devices support multiple ingress and egress mirror ports. For 1 Gbps ports, ports in groups of 12 share one ingress mirror port and one egress mirror port. So ports 1 and 2 cannot have different mirror ports, but ports 1 and 13 can. Each 10 Gbps port can have one ingress mirror port and one egress mirror port.

**NOTE**

For devices other than the FastIron X Series, it is possible to configure more than 8 egress ports, although only the first 8 are operational. This is also true for mirrored VLANs - more than 8 can be configured, but only the first 8 are operational.

- You can configure a mirror port specifically as an ingress port, an egress port, or both.
- Mirror ports can run at any speed and are not related to the speed of the ingress or egress monitored ports.
- The same port cannot be both a monitored port and the mirror port.
- The same port can be monitored by one mirror port for ingress traffic and another mirror port for egress traffic.
- The mirror port cannot be a trunk port.
• The monitored port and its mirror port do not need to belong to the same port-based VLAN:
  • If the mirror port is in a different VLAN from the monitored port, the packets are tagged with the monitor port VLAN ID.
  • If the mirror port is in the same VLAN as the monitored port, the packets are tagged or untagged, depending on the mirror port configuration.

**NOTE**
FastIron GS and LS devices perform “as-is” mirroring. Mirrored packets are sent out of the mirror port in the VLAN tagged or untagged format in which they are received or sent on the monitor port. The VLAN tagged or untagged format is not changed.

• More than one monitored port can be assigned to the same mirror port.
• If the primary interface of a trunk is enabled for monitoring, the entire trunk will be monitored. You can also enable an individual trunk port for monitoring using the `config-trunk-ind` command.
• For stacked devices, if the ingress and egress analyzer ports are always network ports on the local device, each device may configure the ingress and egress analyzer port independently. However, if you need to mirror to a remote port, then only one ingress and one egress analyzer port are supported for the entire system.
• For ingress ACL mirroring, the previous ingress rule also applies. The analyzer port setting command `acl-mirror-port` must be specified for each port, even though the hardware only supports one port per device. This applies whether the analyzer port is on the local device or on a remote device. For example, when port mirroring is set to a remote device, any mirroring (ACL, MAC filter, or VLAN) enabled ports are globally set to a single analyzer port, as shown in the following example.

```
FCX648SHPOE Switch(config)# mirror ethernet 1/1/24
FCX648SHPOE Switch(config)# mirror ethernet 2/1/48
FCX648SHPOE Switch(config)# interface ethernet 1/1/1
FCX648SHPOE Switch(config)# interface ethernet 1/1/1)# monitor ethernet 2/1/48 both
```

The analyzer port (2/1/48) is set to all devices in the system

```
FCX648SHPOE Switch# interface ethernet 1/1/2
FCX648SHPOE Switch(interface ethernet 1/1/2)# ip access-group 101 in
FCX658SHPOE Switch# exit
FCX648SHPOE Switch# interface ethernet 1/1/1
FCX648SHPOE Switch(interface ethernet 1/1/1)# acl-mirror-port ethernet 2/1/48
```

The previous command is required even though the analyzer port is already set globally by the port mirroring command.

```
FCX648SHPOE Switch#interface ethernet 1/1/3
FCX648SHPOE Switch(interface ethernet 1/1/3)# ip access-group 101
FCX648SHPOE Switch(interface ethernet 1/1/3)# acl-mirror-port ethernet 2/1/48
FCX648SHPOE Switch(interface ethernet 1/1/3)# permit ip any any mirror
FCX648SHPOE Switch(interface ethernet 1/1/3)# ip access-group 102
FCX648SHPOE Switch(interface ethernet 1/1/3)# deny ip any any log
```

**Monitoring a port**

This section describes how to configure port mirroring and monitoring. To configure port monitoring on an individual port on a Brocade device, enter commands similar to the following.
Configuring port mirroring and monitoring

FastIron(config)#mirror-port ethernet 1/2/4
FastIron(config)#interface ethernet 1/2/11
FastIron(config-if-e1000-11)#monitor ethernet 1/2/4 both

Traffic on port e 1/2/11 will be monitored, and the monitored traffic will be copied to port e 1/2/4, the mirror port.

Syntax: [no] mirror-port ethernet [<stack-unit>/]<slotnum>/]<portnum> [input | output]
Syntax: [no] monitor ethernet [<stack-unit>/]<slotnum>/]<portnum> both | in | out

The <stack-unit> parameter is required on FastIron GS devices running software release 02.5.00 or later, and for FGS-STK and FLS-STK devices running software release 05.0.00 and later and acting as stack units in an IronStack.

The <slotnum> parameter is required on chassis devices and on FastIron GS devices running software release 02.5.00 or later.

The <portnum> parameter for mirror-port ethernet specifies the port to which the monitored traffic will be copied. The <portnum> parameter for monitor ethernet specifies the port on which traffic will be monitored.

The input and output parameters configure the mirror port exclusively for ingress or egress traffic. If you do not specify one, both types of traffic apply.

The both, in, and out parameters specify the traffic direction you want to monitor on the mirror port. There is no default.

To display the port monitoring configuration, enter the show monitor and show mirror commands.

Monitoring an individual trunk port

You can monitor the traffic on an individual port of a static trunk group. Monitoring an individual port of an LACP trunk group on FastIron X Series devices is supported starting in release FSX 04.3.00. Note that monitoring an LACP trunk port is not supported on TurboIron X Series devices.

By default, when you monitor the primary port in a trunk group, aggregated traffic for all the ports in the trunk group is copied to the mirror port. You can configure the device to monitor individual ports in a trunk group. You can monitor the primary port or a secondary port individually.

To configure port monitoring on an individual port in a trunk group, enter commands such as the following.

FastIron(config)#mirror-port ethernet 2/6
FastIron(config)#trunk e 2/2 to 2/5
FastIron(config-trunk-2/2-2/5)#config-trunk-ind
FastIron(config-trunk-2/2-2/5)#monitor ethernet 2/4 ethernet 2/6 in

Traffic on trunk port e 2/4 will be monitored, and the monitored traffic will be copied to port e 2/6, the mirror port.

Syntax: [no] mirror-port ethernet [<stack-unit>/]<slotnum>/]<portnum> [input | output]
Syntax: [no] config-trunk-ind

Syntect: [no] monitor ethernet [<slotnum>/]<portnum> both | in | out

The <stack-unit> parameter is required on FastIron GS devices running software release 02.5.00 or later, and for FGS-STK and FLS-STK devices running software release 05.0.00 and later and acting as stack units in an IronStack.
The `<slotnum>` parameter is required on chassis devices and on FastIron GS devices running software release 02.5.00 or later.

The `<portnum>` parameter for `mirror-port ethernet` specifies the port to which the monitored traffic will be copied. The `<portnum>` parameter for `monitor ethernet` specifies the port on which traffic will be monitored.

The `input` or `output` parameters configure the mirror port exclusively for ingress or egress traffic. If you do not specify one, both types of traffic apply.

The `config-trunk-ind` command enables configuration of individual ports in the trunk group. You enter the `config-trunk-ind` command only once in a trunk group. After you enter the command, all applicable port configuration commands apply to individual ports only.

**NOTE**
If you enter `no config-trunk-ind`, all port configuration commands are removed from the individual ports and the configuration of the primary port is applied to all the ports. Also, once you enter the `no config-trunk-ind` command, the enable, disable, and monitor commands are valid only on the primary port and apply to the entire trunk group.

The `both`, `in`, and `out` parameters specify the traffic direction you want to monitor on the mirror port. There is no default.

To display the port monitoring configuration, enter the `show monitor` and `show mirror` commands.

---

### Configuring mirroring on an IronStack

You can configure mirroring on a Brocade IronStack. An IronStack consists of up to 8 FGS-STK or FLS-STK devices. The stack operates as a chassis. The following examples show how to configure mirroring for ports that are on different members of a stack, and for ports that are on the same stack member as the mirror port.

**Configuration notes**

The following mirroring configuration information applies to FGS-STK and FLS-STK devices connected in an IronStack topology:

- The input or output mirroring port can be on different ports
- An IronStack can have one mirroring port that monitors multiple ports, but cannot have multiple mirror ports for one monitored port.
- If the mirror port and the monitored ports are on different stack units, only one active mirror port is allowed for the entire IronStack.
- If the mirror port and the monitored ports are on the same port region, multiple active mirror ports are allowed for the entire IronStack. FGS-STK and FLS-STK devices support 24 ports per port region.
- The maximum number of monitored VLANs on an IronStack is 8.
Example 1. Configuring mirroring for ports on different members in an IronStack

In this example, although 2 ports are configured as active ports, only one active mirror port (port 1/1/24) is allowed for the entire stack since the mirror ports and the monitored ports are on different stack members.

```
FLS624 Switch(config)#mirror-port ethernet 1/1/24
FLS624 Switch(config)#mirror-port ethernet 2/1/24
FLS624 Switch(config)#interface ethernet 1/1/1
FLS624 Switch(config-if-e1000-1/1/1)#monitor ethernet 1/1/24 both
FLS624 Switch(config)#interface ethernet 2/1/1
FLS624 Switch(config-if-e1000-2/1/1)#monitor ethernet 1/1/24 both
FLS624 Switch(config)#int ethernet 4/1/1
FLS624 Switch(config-if-e1000-4/1/1)#monitor ethernet 1/1/24 both
```

Example 2. Configuring mirroring for ports on the same stack member in an IronStack

```
FLS624 Switch(config)#mirror-port ethernet 1/1/24
FLS624 Switch(config)#mirror-port ethernet 2/1/24
FLS624 Switch(config)#mirror-port ethernet 3/1/24
FLS624 Switch(config)#mirror-port ethernet 4/1/24
FLS624 Switch(config)#interface ethernet 1/1/1
FLS624 Switch(config-if-e1000-1/1/1)#monitor ethernet 1/1/24 both
FLS624 Switch(config)#interface ethernet 2/1/1
FLS624 Switch(config-if-e1000-2/1/1)#monitor ethernet 2/1/24 both
FLS624 Switch(config)#int ethernet 4/1/1
FLS624 Switch(config-if-e1000-4/1/1)#monitor ethernet 4/1/24 both
```

ACL-based inbound mirroring

This section describes how to configure ACL-based inbound mirroring for FastIron devices.

Creating an ACL-based inbound mirror clause for FGS, FGS-STK, FLS, FLS-STK, and FWS devices

Unlike a mirror-port per device or port region on FESX and SuperX devices, FGS, FLS, FGS-STK, FLS-STK, and FWS devices only support one system-wide ingress and one system-wide egress port per system. In other words, these devices do not support the concept of an ACL-mirror-port.

For these devices, as soon as an ACL with a mirror clause is applied to a port, the traffic matching the flow is mirrored (both deny, which is not supported in FESX, and permit).

The following example shows how to configure an ACL-based inbound mirror clause for FGS, FLS, FGS-STK, FLS-STK, and FWS devices.

1. Configure the mirror port.

   ```
   FGS624P Switch(config)#mirror-port ethernet 1/1/2
   System-wide ingress mirror port set to port 1/1/2.
   System-wide egress mirror port set to port 1/1/2.
   ```

2. Configure the ACL inbound mirror clause.

   ```
   FGS624P Switch(config)#access-list 101 permit ip any any mirror
   ```
At this point not all IP traffic will be mirrored to port 1/1/2, since the ACL has not yet been applied to any port.

3. Apply the ACL inbound clause to the monitor port.

   FGS624P Switch(config)#int e 1/1/5
   FGS624P Switch(config-if-e1000-1/1/5)#ip access-group 101 in

To display ACL mirror settings, enter the `show access-list all` command.

   FGS624P Switch#show access-list all
   Extended IP access list 101
   permit ip any any mirror

The configuration process is now complete.

Creating an ACL-based inbound mirror clause for TurboIron X Series devices

The following example shows how to configure an ACL-based inbound mirror clause for TurboIron X Series devices.

1. Configure the mirror port.

   TurboIron 24X(config)#mirror-port ethernet 2

2. Configure the ACL inbound mirror clause.

   TurboIron 24X(config)#access-list 101 permit ip any any mirror

   At this point not all IP traffic will be mirrored to port 2, since the ACL has not yet been applied to any port.

3. Apply the ACL inbound clause to the monitor port.

   TurboIron 24X(config)#int e 5
   TurboIron 24X(config-if-e1000-5)#ip access-group 101 in

4. Configure the monitor port to use the mirror port.

   TurboIron 24X(config-if-e1000-5)#acl-mirror-port ethernet 2

To display ACL mirror settings, enter the `show access-list all` command.

   TurboIron 24X#show access-list all
   Extended IP access list 101
   permit ip any any mirror

Creating an ACL-based inbound mirror clause for FastIron X Series devices

The `mirror` keyword has been added for inclusion in ACL clauses to direct traffic that meets the clause to be sent to mirror another port. In the following example, the ACL is used to direct traffic to a mirror port.

   FastIron(config)#access-list 101 permit ip any any mirror
ACL-based inbound mirroring

The `mirror` parameter directs selected traffic to the mirrored port. Traffic to be mirrored can only be selected using the permit clause and is only supported on Layer-3 ACLs for FastIron X Series devices. Deny traffic is dropped and not mirrored.

**Specifying the destination mirror port**

You can specify physical ports or a trunk to mirror traffic from. If you complete the rest of the configuration but do not specify a destination mirror port, the port-mirroring ACL will be non-operational. This can be useful if you want to be able to mirror traffic by a set criteria on-demand. With this configuration, you just configure a destination mirror port whenever you want the port-mirroring ACL to become operational.

The following sections describe how to specify a destination port for a port or a trunk as well as the special considerations required when mirroring traffic from a virtual interface.

**Specifying the destination mirror port for physical ports**

When you want traffic that has been selected by ACL-based Inbound Mirroring to be mirrored, you must configure a destination mirror port. This configuration is performed at the Interface Configuration of the port whose traffic you are mirroring. The destination port must be the same for all ports in a port region as described in “Ports from a port region must be mirrored to the same destination mirror port” on page 730.

In the following example, ACL mirroring traffic from port 1/1 is mirrored to port 1/3.

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-e10000-1/1)#ACL-mirror-port ethernet 1/3
```

Syntax: `[no] ACL-mirror-port ethernet [<stack-unit>]/[<slotnum>]/<portnum>

The `[/<stack-unit>]/[<slotnum>]/<portnum>` variable specifies port to which ACL-mirror traffic from the configured interface will be mirrored.

The `<stack-unit>` parameter is required on FastIron GS and LS devices running software release 02.5.00 or later, and on FGS-STK and FLS-STK devices running software release 05.00 and later.

The `<slotnum>` parameter is required on chassis devices and on FastIron GS devices running software release 02.5.00 or later.

The `<portnum>` parameter specifies the mirror port to which the monitored port traffic will be copied.

**Ports from a port region must be mirrored to the same destination mirror port**

Port regions as described in “About port regions” on page 361 are important when defining a destination mirror port. This is because all traffic mirrored from any single port in a port region will be mirrored to the same destination mirror port as traffic mirrored from any other port in the same port region. For example, ports 1/1 to 1/12 are in the same port region. If you configure ports 1/1 and 1/2 to mirror their traffic, they should use the same destination mirror port as shown in the following configuration.

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-e10000-1/1)#ACL-mirror-port ethernet 2/3
FastIron(config)#interface ethernet 1/2
FastIron(config-if-e10000-1/2)#ACL-mirror-port ethernet 2/3
```

If ports within the same port region are mirrored to different destination ports, an error message will be generated as shown in the following example, and the configuration will be disallowed.
ACL-based inbound mirroring

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-e10000-1/1)#ACL-mirror-port ethernet 4/3
FastIron(config)#interface ethernet 1/2
FastIron(config-if-e10000-1/2)#ACL-mirror-port ethernet 4/7
```

Error - Inbound Mirror port 4/3 already configured for port region 1/1 - 1/12

When a destination port is configured for any port within a port region, traffic from any ACL with a mirroring clause assigned to any port in that port region will be mirrored to that destination port. This will occur even if a destination port is not explicitly configured for the port with the ACL configured. In the following example, an ACL with a mirroring clause (101) is applied to a port (1/1). Another port in the same region (1/3) has a destination port set (4/3). In this example, traffic generated from operation of ACL 101 is mirrored to port 4/3 even though a destination port has not explicitly been defined for traffic from port 1/1.

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-e10000-1/1)#ip access-group 101 in
FastIron(config)#interface ethernet 1/3
FastIron(config-if-e10000-1/3)#ACL-mirror-port ethernet 4/3
```

**NOTE**

If a destination mirror port is not configured for any ports within the port region where the port-mirroring ACL is configured, the ACL will not mirror the traffic but the ACL will be applied to traffic on the port.

**Specifying the destination mirror port for trunk ports**

You can mirror the traffic that has been selected by ACL-based Inbound Mirroring from a trunk by configuring a destination port for the primary port within the trunk configuration as shown.

```
FastIron(config)#trunk ethernet 1/1 to 1/4
FastIron(config)#interface ethernet 1/1
FastIron(config-if-e10000-1/1)#ACL-mirror-port ethernet 1/8
```

Using this configuration, all trunk traffic will be mirrored to port 1/8.

**Limitations when configuring ACL-based mirroring with trunks**

The `config-trunk-ind` option as described in "Disabling or re-enabling a trunk port" on page 562 cannot operate with ACL-Based Mirroring as described in the following:

- If a trunk is configured with the `config-trunk-ind` option, ACL-Based Mirroring will not be allowed.
- If the `config-trunk-ind` option is added to a trunk, any ports that are configured for ACL-based Mirroring will have monitoring removed and the following message will be displayed.

Trunk port monitoring, if any, has been removed.

If an individual port is configured for ACL-Based Mirroring, you cannot add it to a trunk. If you try to add a port that is configured for ACL-Based Mirroring to a trunk, the following message appears.

Note - ACL-mirror-port configuration is removed from port 2 in new trunk.

**NOTE**

If you want to add a port configured for ACL-Based Mirroring to a trunk, you must first remove the `ACL-mirror-port` from the port configuration. You can then add the port to a trunk that can then be configured for ACL-Based Trunk Mirroring.
ACL-based inbound mirroring

**Behavior of ACL-based mirroring when deleting trunks**

If you delete a trunk that has ACL-Based Mirroring configured, the ACL-Based Mirroring configuration will be configured on the individual ports that made up the trunk.

For example, if a trunk is configured as shown in the following example and is then deleted from the configuration as shown, each of the ports that previously were contained in the trunk will be configured for ACL-Based Mirroring.

```
FastIron(config)#trunk ethernet 4/1 to 4/2
FastIron(config)#trunk deploy
FastIron(config)#interface ethernet 4/1
FastIron(config-if-e10000)#ACL-mirror-port ethernet 5/3
```

To delete the trunk, enter the following command.

```
FastIron(config)#no trunk ethernet 4/1 to 4/2
```

Configuration for ACL-Based Mirroring on ports 4/1 and 4/2 that results from the trunk being deleted.

```
interface ethernet 4/1
  ACL-mirror-port ethernet 5/3
interface ethernet 4/2
  ACL-mirror-port ethernet 5/3
```

**Configuring ACL-based mirroring for ACLs bound to virtual interfaces**

For configurations that have an ACL configured for ACL-Based Mirroring bound to a virtual interface, you must configure the `ACL-mirror-port` command on a physical port that is a member of the same VLAN as the virtual interface. Additionally, only traffic that arrives at ports that belong to the same port group as the physical port where the `ACL-mirror-port` command is configured will be mirrored. This follows the same rules described in “Ports from a port region must be mirrored to the same destination mirror port” on page 730.

For example, in the following configuration ports 4/1, 4/2 and 5/2 are in VLAN 10 with ve 10. Ports 4/1 and 4/2 belong to the same port group while port 5/3 belongs to another port group.

```
FastIron(config)#vlan 10
FastIron(config-vlan-10)#tagged ethernet 4/1 to 4/2
FastIron(config-vlan-10)#tagged ethernet 5/3
FastIron(config-vlan-10)#router-interface ve 10

FastIron(config)#interface ethernet 4/1
FastIron(config-if-e10000-4/1)#ACL-mirror-port ethernet 5/1
FastIron(config)#interface ve 10
FastIron(config-vif-10)#ip address 10.10.10.254/24
FastIron(config-vif-10)#ip access-group 102 in
FastIron(config)#access-list 102 permit ip any any mirror
```

In this configuration, the `ACL-mirror-port` command is configured on port 4/1 which is a member of ve 10. Because of this, ACL-Based Mirroring will only apply to VLAN 10 traffic that arrives on ports 4/1 and 4/2. It will not apply to VLAN 10 traffic that arrives on port 5/3 because that port belongs to a different port group than ports 4/1 and 4/2. This is because if you apply ACL-Based Mirroring on an entire VE, and enable mirroring in only one port region, traffic that is in the same VE but on a port in a different port region will not be mirrored.

To make the configuration apply ACL-Based Mirroring to VLAN 10 traffic arriving on port 5/3, you must add the following command to the configuration.
MAC filter-based mirroring

This feature allows traffic entering an ingress port to be monitored from a mirror port connected to a data analyzer, based on specific source and destination MAC addresses. This feature supports mirroring of inbound traffic only. Outbound mirroring is not supported.

MAC-Filter-Based Mirroring allows a user to specify a particular stream of data for mirroring using a filter. This eliminates the need to analyze all incoming data to the monitored port. To configure MAC-Filter-Based Mirroring, the user must perform three steps:

• Define a mirror port
• Create a MAC filter with a mirroring clause
• Apply the MAC filter to an interface

The following sections describe these steps.

Configuring MAC filter-based mirroring on FGS, FLS, FWS, FGS-STK, and FLS-STK devices

1. Define a mirror port

To activate mirroring on a port, use the mirror command in the global configuration mode.

Example

FastIron(config)#mirror e 0/1/14

NOTE
If there is no input mirror port configured, MAC-Filter Based Mirroring does not take effect. It remains in the configuration, but is not activated.
FGS, FWS, and FLS devices support one ingress mirror and one egress mirror per system. These ports are shared by all mirroring features - Port-Based Mirroring, VLAN-Based Mirroring, ACL-Based Mirroring and MAC-Based Mirroring.

**NOTE**
Port-Based Mirroring, VLAN Mirroring, and MAC-Filter-Based Mirroring can be enabled on a port at the same time. In this case, the preference order is Port, VLAN, and MAC-Filter.

---

2. **Create a MAC filter with a mirroring clause**

The keyword `mirror` is added to MAC filter clauses to direct desired traffic to the mirror port. In the following examples, the MAC filter directs traffic to a mirror port.

```
FastIron(config)#mac filter 1 permit 0000.1111.2222.ffff.ffff.ffff
0000.2222.3333.ffff.ffff.fff mirror
```

In this example, any flow matching the SA (source address) 0000.1111.2222 and the DA (destination address) 0000.2222.3333 will be mirrored. Other flows will not be mirrored.

---

3. **Apply the MAC filter to an interface**

Apply the MAC filter to an interface using the `mac-filter-group` command, as shown.

```
FastIron(config)#interface ethernet 0/1/1
FastIron(config-if-e10000-0/1/1)#mac filter-group 1
```

**NOTE**
For the FLS-STK devices, an ACL-mirror-port is required.

---

### Configuring MAC filter-based mirroring on TurboIron X Series devices

The following example shows how to configure MAC filter-based mirroring on TurboIron X Series devices.

1. **Configure the mirror port.**

   TurboIron 24X(config)#mirror-port ethernet 2

2. **Configure the MAC filter inbound mirror clause.**

   TurboIron 24X(config)#mac filter 1 permit 0000.0000.0010 ffff.ffff.ffff any mirror

3. **Apply the MAC filter inbound mirror clause to the monitor port.**

   TurboIron 24X(config)#int e 5
   TurboIron 24X(config-if-e10000-5)#mac filter-group 1

4. **Configure the monitor port to use the mirror port.**

   TurboIron 24X(config-if-e10000-5)#acl-mirror-port ethernet 2

To display ACL mirror settings, enter the `show access-list all` command.
VLAN-based mirroring

Platform Support:
- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later

The VLAN-Based Mirroring feature allows users to monitor all incoming traffic in one or more VLANs by sending a mirror image of that traffic to a configured mirror port. This feature meets the requirements of CALEA (Communications Assistance for Law Enforcement Act of 1994).

**NOTE**
The maximum number of monitored VLANs for FGS-STK and FLS-STK devices is 8.

**Configuring VLAN-based mirroring**

Configure this feature using the `monitor` command, in VLAN configuration mode.

FastIron(config-VLAN-20)#monitor

**Syntax:** `[no] monitor

**Example**
To enable mirroring on VLANs 10 and 20, to mirror port e 0/1/21, enter the following commands.

FastIron(config)#mirror-port ethernet 1/1/21 input
FastIron(config)#vlan 10
FastIron(config-VLAN-10)#monitor ethernet 1/1/21
FastIron(config)#vlan 20
FastIron(config-VLAN-20)#monitor ethernet 1/1/21
FastIron(config-VLAN-20)#end

**NOTE**
For FGS-STK and FLS-STK devices, since it is possible to have multiple mirror ports, monitor ports must specify which mirror port they are monitoring.

To disable mirroring on VLAN 20, enter the following commands.

FastIron(config)#vlan 20
FastIron(config-VLAN-20)#no monitor
FastIron(config-VLAN-20)#end

**Displaying VLAN mirroring status**

The `show vlan` command displays the VLAN mirroring status.

FastIron#show vlans
Total PORT-VLAN entries: 4
Maximum PORT-VLAN entries: 4060
### VLAN-based mirroring

### Configuration notes

The following rules apply to VLAN-Based Mirroring configurations.

1. A VLAN must have at least one port member configured before “monitor” can be configured.

2. Multiple VLANs can have monitor enabled at the same time, and the maximum number of monitor-configured VLANs is 8.

3. FGS, FWS, and FLS and FGS-STK and FLS-STK devices support one ingress and one egress mirror per system. These mirror ports are shared by all mirroring features; Port-Based Mirroring, VLAN-Based Mirroring, ACL-Based Mirroring, and MAC-Filter-Based Mirroring.

4. The mirror port is subject to the same scheduling and bandwidth management as the other ports in the system. If the amount of traffic being sent to the mirror port exceeds the available bandwidth, some of that traffic may be dropped.

5. All incoming traffic (tagged and untagged) in the VLAN is mirrored. Mirroring is “as-is”, and is not affected by the configuration of the mirror port itself. Incoming tagged traffic is sent out tagged and incoming untagged traffic is sent out untagged, regardless of which VLANs the mirror port belongs to, and whether the mirror port is tagged or untagged.

This feature is supported on Layer 2 and Layer 3 images.
Classification

Quality of Service (QoS) features are used to prioritize the use of bandwidth in a switch. When QoS features are enabled, traffic is classified as it arrives at the switch, and processed through on the basis of configured priorities. Traffic can be dropped, prioritized for guaranteed delivery, or subject to limited delivery options as configured by a number of different mechanisms.

This chapter describes how QoS is implemented and configured in FastIron and TurboIron devices. Classification is the process of selecting packets on which to perform QoS, reading the QoS information and assigning a priority to the packets. The classification process assigns a priority to packets as they enter the switch. These priorities can be determined on the basis of information contained within the packet or assigned to the packet as it arrives at the switch. Once a packet or traffic flow is classified, it is mapped to a forwarding priority queue.

Packets on Brocade devices are classified in up to eight traffic classes with values between 0 and 7. Packets with higher priority classifications are given a precedence for forwarding.

Processing of classified traffic

The trust level in effect on an interface determines the type of QoS information the device uses for performing QoS. The Brocade device establishes the trust level based on the configuration of various features and if the traffic is switched or routed. The trust level can be one of the following:

- Ingress port default priority
- Static MAC address
- Layer 2 Class of Service (CoS) value – This is the 802.1p priority value in the Ethernet frame. It can be a value from 0 – 7. The 802.1p priority is also called the Class of Service.
- Layer 3 Differentiated Service codepoint (DSCP) – This is the value in the six most significant bits of the IP packet header 8-bit DSCP field. It can be a value from 0 – 63. These values are described in RFCs 2472 and 2475. The DSCP value is sometimes called the DiffServ value. The device automatically maps a packet's DSCP value to a hardware forwarding queue. Refer to “Viewing QoS settings” on page 752”.
- ACL keyword – An ACL can also prioritize traffic and mark it before sending it along to the next hop. This is described in the ACL chapter in the section “QoS options for IP ACLs” on page 663.

Given the variety of different criteria, there are multiple possibilities for traffic classification within a stream of network traffic. For this reason, the priority of packets must be resolved based on which criteria takes precedence. Precedence follows the scheme illustrated in Figure 106.
Determining the trust level of a packet

Figure 106 illustrates how the Brocade device determines the trust level of a packet.

**FIGURE 106** Determining a packet trust level

1. Packet received on ingress port
2. Does the packet match an ACL that defines a priority? Yes/No
   - Yes: Trust the DSCP-CoS-mapping or the DSCP-marking
   - No: Does the port have Trust DSCP enable? Yes/No
     - Yes: Trust the DSCP/ToS value
     - No: Is the packet tagged? Yes/No
       - Yes: Trust the 802.1p CoS value
       - No: Does the MAC address match a static entry? Yes/No
         - Yes: Trust the priority of the static MAC entry
         - No: Does the port have a default priority? Yes/No
           - Yes: Trust the port’s default priority
           - No: Use the default priority of 0
As shown in the figure, the first criteria considered is whether the packet matches on an ACL that defines a priority. If this is not the case and the packet is tagged, the packet is classified with the 802.1p CoS value. If neither of these are true, the packet is next classified based on the static MAC address, ingress port default priority, or the default priority of zero (0).

Once a packet is classified by one of the procedures mentioned, it is mapped to an internal forwarding queue. There are eight queues designated as 0 to 7. The internal forwarding priority maps to one of these eight queues as shown in Table 120 through Table 123. The mapping between the internal priority and the forwarding queue cannot be changed.

Table 120 through Table 123 show the default QoS mappings that are used if the trust level for CoS or DSCP is enabled.

</table>
Mapping between DSCP value and Forwarding Queue cannot be changed. However, mapping between DSCP values and the other properties can be changed as follows:

- **DSCP to internal forwarding priority mapping** – You can change the mapping between the DSCP value and the Internal Forwarding priority value from the default values shown in Table 120 through Table 123. This mapping is used for COS marking and determining the internal priority when the trust level is DSCP. Refer to “Changing the DSCP –> internal forwarding priority mappings” on page 746.

- **Internal forwarding priority to forwarding queue** – You can reassign an internal forwarding priority to a different hardware forwarding queue. Refer to “Changing the internal forwarding priority –> hardware forwarding queue mappings” on page 747.

### QoS for Brocade stackable devices

Brocade FGS-STK and FLS-STK devices support QoS. Units in a stack communicate the stack topology information and other proprietary control information through the stacking links. For more information about stacking links and IronStack technology, refer to Chapter 5, “Brocade Stackable Devices”.

In addition to control information, the stacking links also carry user network data packets. In an IronStack topology, the priority of stacking-specific control packets is elevated above that of data path packets, preventing loss of control packets, and timed retries that affect performance. This prioritization also prevents stack topology changes that may occur if enough stack topology information packets are lost.

IronStack technology reserves one QoS profile to provide a higher priority for stack topology and control traffic.

### Stacking QoS profile restrictions

In a stacking topology, since CoS level 7 is reserved for stacking, quality profiles for QP7 cannot be configured. If an attempt is made to configure a profile for Q7, the system ignores the configuration.

**NOTE**

This applies only when the device is operating in stacking mode. It does not apply to standalone devices.
QoS behavior for trusting layer 2 (802.1p) in an IronStack

By default, layer 2 Trust is turned on. Since priority 7 is reserved for stacking control packets, any ingress data traffic with priority 7 is mapped to internal hardware queue 6. All other priorities are mapped to their corresponding queues.

QoS behavior for trusting layer 3 (DSCP) in an IronStack

When trust dscp is enabled, packets arriving with DSCP values 56 to 63 are mapped to internal hardware queue 6. All other DSCP values are mapped to their corresponding internal hardware queues.

QoS behavior on port priority and VLAN priority in an IronStack

Port Priority and VLAN Priority has a higher precedence that the 802.1p priority examination. If Port Priority is set to 7, all incoming traffic is mapped to internal hardware queue 6.

When stacking is not enabled on a device, all priorities are mapped to their corresponding queues without restrictions.

QoS behavior for 802.1p marking in an IronStack

By default in stacking mode, 802.1p marking is not enabled. Outgoing tagged traffic is not marked with 802.1p in the VLAN tag based on the internal hardware queue into which ingress traffic was classified.

When stacking is disabled on a device, outgoing traffic is marked with 802.1p based on the internal hardware queue.

QoS queues

Brocade devices support the eight QoS queues (qosp0 – qosp7) listed in Table 124.

<table>
<thead>
<tr>
<th>QoS Priority Level</th>
<th>QoS Queue</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>qosp0 (lowest priority queue)</td>
</tr>
<tr>
<td>1</td>
<td>qosp1</td>
</tr>
<tr>
<td>2</td>
<td>qosp2</td>
</tr>
<tr>
<td>3</td>
<td>qosp3</td>
</tr>
<tr>
<td>4</td>
<td>qosp4</td>
</tr>
<tr>
<td>5</td>
<td>qosp5</td>
</tr>
<tr>
<td>6</td>
<td>qosp6</td>
</tr>
<tr>
<td>7</td>
<td>qosp7 (highest priority queue)</td>
</tr>
</tbody>
</table>
The queue names listed above are the default names. If desired, you can rename the queues as instructed in "Renaming the queues" on page 749.

Packets are classified and assigned to specific queues based on the criteria shown in Figure 106.

Assigning QoS priorities to traffic

By default, all traffic is in the best-effort queue (qosp0) and is honored on tagged ports on all FastIron and TurboIron switches. You can assign traffic to a higher queue based on the following:

- Incoming port (sometimes called the ingress port)
- Static MAC entry

The following sections describe how to change the priority for each of the items listed above.

Although it is possible for a packet to qualify for an adjusted QoS priority based on more than one of the criteria listed in the section above, the system always gives a packet the highest priority for which it qualifies. Thus, if a packet is entitled to the premium queue because of its IP source and destination addresses, but is entitled only to the high queue because of its incoming port, the system places the packet in the premium queue on the outgoing port.

When you apply a QoS priority to one of the items listed above, you specify a number from 0 – 7. The priority number specifies the IEEE 802.1 equivalent to one of the eight QoS queues on Brocade devices. The numbers correspond to the queues as shown in Table 120.

Changing a port priority

To change the QoS priority of port 1 to the premium queue (qosp7), enter the following commands.

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-e1000-1/1)#priority 7
```

The device will assign priority 7 to untagged switched traffic received on port 1.

Syntax: `[no] priority <num>`

The `<num>` parameter can be from 0 – 7 and specifies the IEEE 802.1 equivalent to one of eight QoS queues listed in Table 120.

Assigning static MAC entries to priority queues

By default, all MAC entries are in the best effort queue. When you configure a static MAC entry, you can assign the entry to a higher QoS level.

To configure a static MAC entry and assign the entry to the premium queue, enter commands such as the following.

```
FastIron(config)#vlan 9
FastIron(config-vlan-9)#static-mac-address 1145.1163.67FF ethernet 1/1 priority 7
FastIron(config-vlan-9)#write memory
```

Syntax: `[no] static-mac-address <mac-addr> ethernet [<stack-unit> | <slotnum>/]<portnum> [priority <num>] [host-type | router-type | fixed-host]`

The `<slotnum>` parameter applies to the FSX only.

The `priority <num>` parameter can be from 0 – 7 and specifies the IEEE 802.1 equivalent to one of the eight QoS queues.
NOTE
The location of the static-mac-address command in the CLI depends on whether you configure port-based VLANs on the device. If the device does not have more than one port-based VLAN (VLAN 1, which is the default VLAN containing all ports), the static-mac-address command is at the global CONFIG level of the CLI. If the device has more than one port-based VLAN, then the static-mac-address command is not available at the global CONFIG level. In this case, the command is available at the configuration level for each port-based VLAN.

Buffer allocation/threshold for QoS queues

By default, Brocade Ironware software allocates a certain number of buffers to the outbound transport queue for each port based on QoS priority. The buffers control the total number of packets permitted in the outbound queue for the port. If desired, you can increase or decrease the maximum number of outbound transmit buffers allocated to all QoS queues, or to specific QoS queues on a port or group of ports. On FastIron devices, this feature is called dynamic buffer allocation. For more information, refer to “Dynamic buffer allocation for QoS priorities for FastIron X Series devices” on page 386. On TurboIron X Series devices, this feature is called egress buffer threshold. For more information, refer to “Egress buffer thresholds for QoS priorities” on page 393.

NOTE
This feature is not supported for FCX devices.

Marking

Marking is the process of changing the packet QoS information (the 802.1p and DSCP information in a packet) for the next hop. For example, for traffic coming from a device that does not support DiffServ, you can change the packet IP Precedence value into a DSCP value before forwarding the packet.

You can mark a packet Layer 2 CoS value, its Layer 3 DSCP value, or both values. The Layer 2 CoS or DSCP value the device marks in the packet is the same value that results from mapping the packet QoS value into a Layer 2 CoS or DSCP value.

Marking is optional and is disabled by default. Marking is performed using ACLs. When marking is not used, the device still performs the mappings listed in “Classification” on page 737 for scheduling the packet, but leaves the packet QoS values unchanged when the device forwards the packet.

For configuration syntax, rules, and examples of QoS marking, refer to “QoS options for IP ACLs” on page 663.

Configuring DSCP-based QoS

Brocade IronWare releases support basic DSCP-based QoS (also called Type of Service (ToS) based QoS) as described in this chapter. However, the FastIron and TurboIron X Series family of switches do not support other advanced DSCP-based QoS features as described in the Foundry Enterprise Configuration and Management Guide.
Brocade IronWare releases also support marking of the DSCP value. The software can read Layer 3 Quality of Service (QoS) information in an IP packet and select a forwarding queue for the packet based on the information. The software interprets the value in the six most significant bits of the IP packet header 8-bit ToS field as a Diffserv Control Point (DSCP) value, and maps that value to an internal forwarding priority.

The internal forwarding priorities are mapped to one of the eight forwarding queues (qosp0 – qosp7) on the Brocade device. During a forwarding cycle, the device gives more preference to the higher numbered queues, so that more packets are forwarded from these queues. So for example, queue qosp7 receives the highest preference while queue qosp0, the best-effort queue, receives the lowest preference.

**Application notes**

- DSCP-based QoS is not automatically honored for routed and switched traffic. The default is 802.1p to CoS mapping. To honor DSCP-based QoS, you must change the priority mapping to DSCP to CoS mapping. Refer to “Using ACLs to honor DSCP-based QoS” on page 744.
- When DSCP marking is enabled, the device changes the contents of the inbound packet ToS field to match the DSCP-based QoS value. This differs from the BigIron, which marks the outbound packet ToS field.

**Using ACLs to honor DSCP-based QoS**

This section shows how to configure Brocade devices to honor DSCP-based QoS for routed and switched traffic.

**FGS, FLS, FWS, FGS-STK, FLS-STK, and TurboIron X Series Devices**

These devices support DSCP-based QoS on a per-port basis. DSCP-based QoS is not automatically honored for switched traffic. The default is 802.1p to CoS mapping. To honor DSCP-based QoS, enter the following command at the interface level of the CLI.

```
FastIron(config-if-e1000-11)trust dscp
```

When `trust dscp` is enabled, the interface honors the Layer 3 DSCP value. By default, the interface honors the Layer 2 CoS value.

**FastIron X Series devices**

FastIron X Series devices require the use of an ACL to honor DSCP-based QoS for routed traffic in the Layer 3 image, or for switched traffic in the Layer 2 image. To enable DSCP-based QoS on these devices, apply an ACL entry such as the following.

```
FastIron(config)#access-list 101 permit ip any any dscp-cos-mapping
```

**NOTE**

Use the `bridged-routed` keyword in the ACL to honor DSCP for switched traffic in the Layer 3 image. Refer to “Enabling ACL support for switched traffic in the router image” on page 655.
Configuring the QoS mappings

You can optionally change the following QoS mappings:

- DSCP \rightarrow{} internal forwarding priority
- Internal forwarding priority \rightarrow{} hardware forwarding queue

The mappings are globally configurable and apply to all interfaces.

Default DSCP \rightarrow{} Internal forwarding priority mappings

The DSCP values are described in RFCs 2474 and 2475. Table 125 list the default mappings of DSCP values to internal forwarding priority values.

**TABLE 125** Default DSCP to internal forwarding priority mappings

<table>
<thead>
<tr>
<th>Internal forwarding priority</th>
<th>DSCP value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (lowest priority queue)</td>
<td>0 – 7</td>
</tr>
<tr>
<td>1</td>
<td>8 – 15</td>
</tr>
<tr>
<td>2</td>
<td>16 – 23</td>
</tr>
<tr>
<td>3</td>
<td>24 – 31</td>
</tr>
<tr>
<td>4</td>
<td>32 – 39</td>
</tr>
<tr>
<td>5</td>
<td>40 – 47</td>
</tr>
<tr>
<td>6</td>
<td>48 – 55</td>
</tr>
<tr>
<td>7 (highest priority queue)</td>
<td>56 – 63</td>
</tr>
</tbody>
</table>

Notice that DSCP values range from 0 – 63, whereas the internal forwarding priority values range from 0 – 7. Any DSCP value within a given range is mapped to the same internal forwarding priority value. For example, any DSCP value from 8 – 15 maps to priority 1.

After performing this mapping, the device maps the internal forwarding priority value to one of the hardware forwarding queues.

**TABLE 126** Default mappings of internal forwarding priority values to the hardware forwarding queues.

<table>
<thead>
<tr>
<th>Internal forwarding priority</th>
<th>Forwarding queues</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (lowest priority queue)</td>
<td>qosp0</td>
</tr>
<tr>
<td>1</td>
<td>qosp1</td>
</tr>
<tr>
<td>2</td>
<td>qosp2</td>
</tr>
<tr>
<td>3</td>
<td>qosp3</td>
</tr>
<tr>
<td>4</td>
<td>qosp4</td>
</tr>
<tr>
<td>5</td>
<td>qosp5</td>
</tr>
<tr>
<td>6</td>
<td>qosp6</td>
</tr>
<tr>
<td>7 (highest priority queue)</td>
<td>qosp7</td>
</tr>
</tbody>
</table>
You can change the DSCP -> internal forwarding mappings. You also can change the internal forwarding priority-> hardware forwarding queue mappings.

### Changing the DSCP –> internal forwarding priority mappings

To change the DSCP –> internal forwarding priority mappings for all the DSCP ranges, enter commands such as the following at the global CONFIG level of the CLI.

```plaintext
FastIron(config)#qos-tos map dscp-priority 0 2 3 4 to 1
FastIron(config)#qos-tos map dscp-priority 8 to 5
FastIron(config)#qos-tos map dscp-priority 16 to 4
FastIron(config)#qos-tos map dscp-priority 32 to 0
FastIron(config)#qos-tos map dscp-priority 40 to 7
FastIron(config)#qos-tos map dscp-priority 48 to 3
FastIron(config)#qos-tos map dscp-priority 56 to 6
FastIron(config)#ip rebind-ACL all
```

The first command in the above example maps priority 1 to DSCP values 0, 2, 3, and 4.

These commands configure the mappings displayed in the DSCP to forwarding priority portion of the QoS information display. To read this part of the display, select the first part of the DSCP value from the d1 column and select the second part of the DSCP value from the d2 row. For example, to read the DSCP to forwarding priority mapping for DSCP value 24, select 2 from the d1 column and select 4 from the d2 row. The mappings that are changed by the command above are shown below in bold type.

```plaintext
FastIron#show qos-tos
...portions of table omitted for simplicity...
```

**DSCP-Priority map: (dscp = d1d2)**

<table>
<thead>

<td>7</td>
<td>7</td>
<td>7</td>
</tr>
</tbody>
</table>

**Syntax:** `[no] qos-tos map dscp-priority <dscp-value> [<dscp-value> ...] to <priority>`
The \texttt{<dscp-value> [<dscp-value> ...]} parameter specifies the DSCP value ranges you are remapping.

Starting with software releases FGS/FLS 04.1.00 and FSX 04.2.00, and on Turbolron X Series devices, you can specify up to eight DSCP values in the same command, to map to the same forwarding priority. For example FastIron(config)#qos-tos map dscp-priority 1 2 3 4 5 6 7 8 to 6. In releases prior to these, you can specify up to seven DSCP values in the same command.

The \texttt{<priority>} parameter specifies the internal forwarding priority.

**Changing the internal forwarding priority \rightarrow hardware forwarding queue mappings**

To reassign an internal forwarding priority to a different hardware forwarding queue, enter commands such as the following at the global CONFIG level of the CLI.

FastIron(config)#qos tagged-priority 2 qosp0

**Syntax:** \texttt{[no] qos tagged-priority <num> <queue>}

The \texttt{<num>} parameter can be from 0 – 7 and specifies the internal forwarding priority.

The \texttt{<queue>} parameter specifies the hardware forwarding queue to which you are reassigning the priority. The default queue names are as follows:

- qosp7
- qosp6
- qosp5
- qosp4
- qosp3
- qosp2
- qosp1
- qosp0

**Scheduling**

Scheduling is the process of mapping a packet to an internal forwarding queue based on its QoS information, and servicing the queues according to a mechanism.

This section describes the scheduling methods used on FastIron devices as well as on Turbolron X Series devices.

**QoS Queuing methods**

The following QoS queuing methods are supported in all IronWare releases for the FastIron and Turbolron devices:
• **Weighted round robin (WRR)** – WRR ensures that all queues are serviced during each cycle. A weighted fair queuing algorithm is used to rotate service among the eight queues on the FastIron and TurboIron devices. The rotation is based on the weights you assign to each queue. This method rotates service among the queues, forwarding a specific number of packets in one queue before moving on to the next one.

**NOTE**
In stacking mode QOSP7 queue is reserved as Strict Priority under weighted queuing. Attempts to change the QOSP7 setting will be ignored.

WRR is the default queuing method and uses a default set of queue weights. The number of packets serviced during each visit to a queue depends on the percentages you configure for the queues. The software automatically converts the percentages you specify into weights for the queues.

**NOTE**
Queue cycles on the FastIron and TurboIron devices are based on bytes. These devices service a given number of bytes (based on weight) in each queue cycle. FES and BI/FI queue cycles are based on packets. The bytes-based scheme is more accurate than a packets-based scheme if packets vary greatly in size.

• **Strict priority (SP)** – SP ensures service for high priority traffic. The software assigns the maximum weights to each queue, to cause the queuing mechanism to serve as many packets in one queue as possible before moving to a lower queue. This method biases the queuing mechanism to favor the higher queues over the lower queues.

For example, strict queuing processes as many packets as possible in qos3 before processing any packets in qos2, then processes as many packets as possible in qos2 before processing any packets in qos1, and so on.

• **Hybrid WRR and SP** – Starting with software release FSX 02.2.00, an additional configurable queuing mechanism combines both the strict priority and weighted round robin mechanisms. The combined method enables the Brocade device to give strict priority to delay-sensitive traffic such as VOIP traffic, and weighted round robin priority to other traffic types.

By default, when you select the combined SP and WRR queueing method, the Brocade device assigns strict priority to traffic in qos7 and qos6, and weighted round robin priority to traffic in qos0 through qos5. Thus, the Brocade device schedules traffic in queue 7 and queue 6 first, based on the strict priority queueing method. When there is no traffic in queue 7 and queue 6, the device schedules the other queues in round-robin fashion from the highest priority queue to the lowest priority queue.

**NOTE**
Brocade stack-capable devices that are operating as members of a stack reserve queue 6 and queue 7 for stacking functions. For more information, see <appropriate section>.

By default, when you specify the combined SP and WRR queueing method, the system balances the traffic among the queues as shown in Table 127. If desired, you can change the default bandwidth values as instructed in the section “Changing the bandwidth allocations of the hybrid WRR and SP queues” on page 751.
Selecting the QoS queuing method

By default, Brocade devices use the weighted fair queuing method of packet prioritization. To change the method to strict priority or back to weighted fair queuing, enter the following command at the Global CONFIG level of the CLI.

FastIron(config)#qos mechanism strict

To change the method back to weighted round robin, enter the following command.

FastIron(config)#qos mechanism weighted

Syntax: [no] qos mechanism strict | weighted

**NOTE**
The following combined method is supported in releases FSX 02.2.00 and later.

To change the queuing mechanism to the combined SP and WRR method, enter the following command at the Global CONFIG level of the CLI.

FastIron(config)#qos mechanism mixed-sp-wrr

Syntax: mechanism mixed-sp-wrr

Configuring the QoS queues

Each of the queues has the following configurable parameters:
- The queue name
- The minimum percentage of a port outbound bandwidth guaranteed to the queue

**Renaming the queues**

The default queue names are qos7, qos6, qos5, qos4, qos3, qos2, qos1, and qos0. You can change one or more of the names if desired.

To rename queue “qos3” to “92-octane”, enter the following command.

FastIron(config)#qos name qos3 92-octane

Syntax: qos name <old-name> <new-name>

---

**TABLE 127** Default bandwidth for combined SP and WRR queueing methods

<table>
<thead>
<tr>
<th>Queue</th>
<th>Default bandwidth</th>
</tr>
</thead>
<tbody>
<tr>
<td>qos7</td>
<td>Strict priority (highest priority)</td>
</tr>
<tr>
<td>qos6</td>
<td>Strict priority</td>
</tr>
<tr>
<td>qos5</td>
<td>25%</td>
</tr>
<tr>
<td>qos4</td>
<td>15%</td>
</tr>
<tr>
<td>qos3</td>
<td>15%</td>
</tr>
<tr>
<td>qos2</td>
<td>15%</td>
</tr>
<tr>
<td>qos1</td>
<td>15%</td>
</tr>
<tr>
<td>qos0</td>
<td>15% (lowest priority)</td>
</tr>
</tbody>
</table>
The `<old-name>` parameter specifies the name of the queue before the change.

The `<new-name>` parameter specifies the new name of the queue. You can specify an alphanumeric string up to 32 characters long.

### Changing the minimum bandwidth percentages of the WRR queues

If you are using the weighted round robin mechanism instead of the strict mechanism, you can change the weights for each queue by changing the minimum percentage of bandwidth you want each queue to guarantee for its traffic.

By default, the eight QoS queues on FastIron and TurboIron devices receive the following minimum guaranteed percentages of a port total bandwidth. Note that the defaults differ when jumbo frames are enabled.

<table>
<thead>
<tr>
<th>Queue</th>
<th>Default minimum percentage of bandwidth</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Without jumbo frames</td>
</tr>
<tr>
<td>qosp7</td>
<td>75%</td>
</tr>
<tr>
<td>qosp6</td>
<td>7%</td>
</tr>
<tr>
<td>qosp5</td>
<td>3%</td>
</tr>
<tr>
<td>qosp4</td>
<td>3%</td>
</tr>
<tr>
<td>qosp3</td>
<td>3%</td>
</tr>
<tr>
<td>qosp2</td>
<td>3%</td>
</tr>
<tr>
<td>qosp1</td>
<td>3%</td>
</tr>
<tr>
<td>qosp0</td>
<td>3%</td>
</tr>
</tbody>
</table>

When the queuing method is weighted round robin, the software internally translates the percentages into weights. The weight associated with each queue controls how many packets are processed for the queue at a given stage of a cycle through the weighted round robin algorithm.

**NOTE**
Queue cycles on the FastIron and TurboIron devices are based on bytes. These devices service a given number of bytes (based on the weight) in each queue cycle. FES and BI/FI queue cycles are based on packets. The bytes-based scheme is more accurate than a packets-based scheme if packets vary greatly in size.

The bandwidth allocated to each queue is based on the relative weights of the queues. You can change the bandwidth percentages allocated to the queues by changing the queue weights.

There is no minimum bandwidth requirement for a given queue. For example, queue qosp3 is not required to have at least 50% of the bandwidth.

### Command syntax
To change the bandwidth percentages for the queues, enter commands such as the following. Note that this example uses the default queue names.
Scheduling

Syntax: \[no\] qos profile \(<queue>\) \(<\text{percentage}>\) \(<queue>\) \(<\text{percentage}>\) \(<queue>\) \(<\text{percentage}>\) \(<queue>\) \(<\text{percentage}>\) \(<queue>\) \(<\text{percentage}>\) \(<queue>\) \(<\text{percentage}>\) \(<queue>\) \(<\text{percentage}>\)

Each \(<queue>\) parameter specifies the name of a queue. You can specify the queues in any order on the command line, but you must specify each queue.

The \(<\text{percentage}>\) parameter specifies a number for the percentage of the device outbound bandwidth that is allocated to the queue. Brocade QoS queues require a minimum bandwidth percentage of 3% for each priority. When jumbo frames are enabled, the minimum bandwidth requirement is 8%. If these minimum values are not met, QoS may not be accurate.

Configuration notes

- The total of the percentages you enter must equal 100.
- FastIron and TurboIron devices do not adjust the bandwidth percentages you enter. BigIron QoS does adjust the bandwidth percentages to ensure that each queue has at least its required minimum bandwidth percentage.

On the FGS, FLS, FWS, and FGS-STK and FLS-STK, and FCX devices you can use QoS queue 1 for priority traffic, even when sFlow is enabled on the port. This differs from the FastIron X Series and TurboIron X Series devices, which support seven priorities instead of eight when sFlow is enabled. QoS queue 1 is reserved for sFlow and not used by other packets. Any non-sFlow packets assigned to QoS queue 1 will be directed to QoS queue 0.

Changing the bandwidth allocations of the hybrid WRR and SP queues

Platform Support:

- FastIron X Series devices running software release 02.2.00 and later
- TurboIron X Series devices running software release 04.1.00 and later
- FGS and FLS devices running software release 04.2.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FCX-S devices running software release 06.0.00 and later

To change the default bandwidth percentages for the queues when the device is configured to use the combined SP and WRR queuing mechanism, enter commands such as the following. Note that this example uses the default queue names.

FastIron(config)#qos profile qosp7 sp qosp6 sp qosp5 20 qosp4 16 qosp3 16 qosp2 16 qosp1 16 qosp0 6

Syntax: \[no\] qos profile \(<queue>\) sp \(<queue>\) sp | \(<\text{percentage}>\) \(<queue>\) sp | \(<\text{percentage}>\) \(<queue>\) sp | \(<\text{percentage}>\) \(<queue>\) sp | \(<\text{percentage}>\) \(<queue>\) sp | \(<\text{percentage}>\) \(<queue>\) sp | \(<\text{percentage}>\) \(<queue>\) sp | \(<\text{percentage}>\)
Each `<queue x>` parameter specifies the name of a queue. You can specify the queues in any order on the command line, but you must specify each queue. Note that queue 7 supports strict priority only, queue 6 supports both strict priority and WRR queuing mechanisms, and queues 0 – 5 support the WRR queuing mechanism only.

**NOTE**
Brocade stack-capable devices that are operating as members of a stack reserve queue 6 and queue 7 for stacking functions.

The `sp` parameter configures strict priority as the queuing mechanism. Note that only queue 7 and queue 6 support this method.

The `<percentage>` parameter configures WRR as the queuing mechanism and specifies the percentage of the device outbound bandwidth allocated to the queue. The queues require a minimum bandwidth percentage of 3% for each priority. When jumbo frames are enabled, the minimum bandwidth requirement is 8%. If these minimum values are not met, QoS may not be accurate.

**NOTE**
The percentages must add up to 100. The Brocade device does not adjust the bandwidth percentages you enter. In contrast, the BigIron QoS does adjust the bandwidth percentages to ensure that each queue has at least its required minimum bandwidth percentage.

### Viewing QoS settings

To display the QoS settings for all of the queues, enter the `show qos-profiles` command.

The following shows an example display output on a FESX.

```
FastIron#show qos-profiles all
bandwidth scheduling mechanism: weighted priority
Profile qosp7     : Priority7   bandwidth requested  25% calculated  25%
Profile qosp6     : Priority6   bandwidth requested  15% calculated  15%
Profile qosp5     : Priority5   bandwidth requested  12% calculated  12%
Profile qosp4     : Priority4   bandwidth requested  12% calculated  12%
Profile qosp3     : Priority3   bandwidth requested  10% calculated  10%
Profile qosp2     : Priority2   bandwidth requested  10% calculated  10%
Profile qosp1     : Priority1   bandwidth requested  10% calculated  10%
Profile qosp0     : Priority0   bandwidth requested   6% calculated   6%
```

**Syntax:** `show qos-profiles all | <name>`

The `all` parameter displays the settings for all eight queues.

The `<name>` parameter displays the settings for the specified queue.

### Viewing DSCP-based QoS settings

To display configuration information for DSCP-based QoS, enter the following command at any level of the CLI.
FastIron#show qos-tos
DSCP-->Traffic-Class map: (DSCP = d1d2: 00, 01...63)

<table>
<thead>
<tr>
<th>d2</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>

Configuring Rate Limiting and Rate Shaping on the FastIron X Series, FCX Series, and TurboIron Series

Chapter 23

Configuring Rate Limiting and Rate Shaping on the FastIron X Series, FCX Series, and TurboIron Series

Rate limiting overview

This chapter describes how to configure rate limiting and rate shaping on Brocade TIX, FCX, FESX, FSX, and FWSX devices.

Rate limiting applies to inbound ports and rate shaping applies to outbound ports.

NOTE
To configure rate limiting on the FGS, FLS, FGS-STK, and FLS-STK, refer to Chapter 24, “Configuring Rate Limiting on FGS, FGS-STK, FLS, FLS-STK, and FWS Devices”.

Port-based fixed rate limiting is supported on inbound ports. This feature allows you to specify the maximum number of bytes a given port on a FastIron device can receive, or the maximum number of kilobits a given port on a TurboIron device can receive. The port drops bytes or kilobits that exceed the limit you specify. You can configure a Fixed Rate Limiting policy on a port inbound direction only. Fixed rate limiting applies to all traffic on the rate limited port.

Fixed rate limiting is at line rate and occurs in hardware. Refer to “Rate limiting in hardware” on page 755.

When you specify the maximum number of bytes or kilobits, you specify it in bits per second (bps). The Fixed Rate Limiting policy applies to one-second intervals and allows the port to receive the number of bytes or kilobits you specify in the policy, but drops additional bytes or kilobits. Unused bandwidth is not carried over from one interval to the next.

NOTE
Brocade recommends that you do not use Fixed Rate Limiting on ports that receive route control traffic or Spanning Tree Protocol (STP) control traffic. If the port drops control packets due to the Fixed Rate Limiting policy, routing or STP can be disrupted.

Rate limiting in hardware

Each Brocade device supports line-rate rate limiting in hardware. The device creates entries in Content Addressable Memory (CAM) for the rate limiting policies. The CAM entries enable the device to perform the rate limiting in hardware instead of sending the traffic to the CPU. The device sends the first packet in a given traffic flow to the CPU, which creates a CAM entry for the traffic flow. A CAM entry consists of the source and destination addresses of the traffic. The device uses the CAM entry for rate limiting all the traffic within the same flow. A rate limiting CAM entry remains in the CAM for two minutes before aging out.
How Fixed Rate Limiting works

Fixed Rate Limiting counts the number of bytes (FastIron devices) or kilobits (TurboIron devices) that a port receives, in one second intervals. If the number exceeds the maximum number you specify when you configure the rate, the port drops all further inbound packets for the duration of the one-second interval.

Once the one-second interval is complete, the port clears the counter and re-enables traffic.

Figure 107 shows an example of how Fixed Rate Limiting works. In this example, a Fixed Rate Limiting policy is applied to a port to limit the inbound traffic to 500000 bits (62500 bytes) a second. During the first two one-second intervals, the port receives less than 500000 bits in each interval. However, the port receives more than 500000 bits during the third and fourth one-second intervals, and consequently drops the excess traffic.

FIGURE 107  Fixed Rate Limiting

NOTE
The software counts the bytes or kilobits by polling statistics counters for the port every 100 milliseconds, which provides 10 readings each second. Due to the polling interval, the Fixed Rate Limiting policy has an accuracy of within 10% of the port's line rate. It is therefore possible for the policy to sometimes allow more traffic than the limit you specify, but the extra traffic is never more than 10% of the port's line rate.

Configuration notes

- Rate limiting is available only on inbound ports.
- Fixed rate limiting is not supported on 10 GbE ports on FastIron switches.
- Fixed rate limiting is supported on GbE and 10 GbE ports on TurboIron switches.
- Fixed rate limiting is not supported on tagged ports in the base Layer 3 and full Layer 3 images.
- The rate limit on IPv6 hardware takes several seconds to take effect at higher configured rate limit values. For example, if the configured rate limit is 750 Mbps, line-rate limiting could take up to 43 seconds to take effect.
Configuring a port-based rate limiting policy

To configure rate limiting on a FastIron port, enter commands such as the following.

```plaintext
FastIron(config)#interface ethernet 24
FastIron(config-if-e1000-24)#rate input fixed 500000
```

These commands configure a fixed rate limiting policy that allows port 24 to receive a maximum of 500000 bits per second (62500 bytes per second). If the port receives additional bytes during a given one-second interval, the port drops all inbound packets on the port until the next one-second interval starts.

To configure rate limiting on a TurboIron port, enter commands such as the following.

```plaintext
TurboIron(config)#interface ethernet 24
TurboIron(config-if-e1000-24)#rate input fixed 64
```

These commands configure a fixed rate limiting policy that allows port 24 to receive a maximum of 64 kilobits per second (65536 bytes per second). If the port receives additional bits during a given one-second interval, the port drops all inbound packets on the port until the next one-second interval starts.

**Syntax:** `[no] rate-limit input fixed <average-rate>`

For FastIron devices, the `<average-rate>` parameter specifies the maximum number of bits per second (bps) the port can receive. The minimum rate that can be configured is 64,000 bits per second.

For TurboIron devices, the `<average-rate>` parameter specifies the maximum number of kilobits per second (kbps) the port can receive. The minimum rate that can be configured is 64,000 bytes per second.

Configuring an ACL-based rate limiting policy

**Platform Support:**

- FastIron X Series devices running software release 02.3.03 and later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

IP ACL-based rate limiting of inbound traffic provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs. This feature is available in the Layer 2 and Layer 3 code.

To configure ACL-based rate limiting on a Brocade device, you create individual traffic policies, then reference the traffic policies in one or more ACL entries (also called clauses or statements). The traffic policies become effective on ports to which the ACLs are bound.

For configuration procedures for ACL-based rate limiting, refer to Chapter 25, “Configuring Traffic Policies”.

Displaying the fixed rate limiting configuration

To display the fixed rate limiting configuration on the device, enter the following command.
Rate shaping overview

Syntax: show rate-limit fixed

The command lists the ports on which fixed rate limiting is configured, and provides the information listed in Table 130 for each of the ports.

**TABLE 130 CLI display of Fixed Rate Limiting information**

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total rate-limited interface count</td>
<td>The total number of ports that are configured for Fixed Rate Limiting.</td>
</tr>
<tr>
<td>Port</td>
<td>The port number.</td>
</tr>
<tr>
<td>Configured Input Rate</td>
<td>The maximum rate requested for inbound traffic. The rate is measured in bits per second (bps) for FastIron devices, or kilobits per second (kbps) for TurboIron devices.</td>
</tr>
<tr>
<td>Actual Input Rate</td>
<td>The actual maximum rate provided by the hardware. The rate is measured in bps for FastIron devices, or kilobits per second (kbps) for TurboIron devices.</td>
</tr>
</tbody>
</table>

Rate shaping overview

Platform Support:

- FastIron X Series devices running software release 03.0.00 and later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

Outbound Rate Shaping is a port-level feature that is used to shape the rate and control the bandwidth of outbound traffic on a port. This feature smooths out excess and bursty traffic to the configured maximum limit before it is sent out on a port. Packets are stored in available buffers and then forwarded at a rate no greater than the configured limit. This process provides for better control over the inbound traffic of neighboring devices.

The device has one global rate shaper for a port and one rate shaper for each port priority queue. Rate shaping is done on a single-token basis, where each token is defined to be 1 byte.

Configuration notes

The following rules apply when configuring outbound rate shapers:
- Outbound rate shapers can be configured only on physical ports, not on virtual or loopback ports.

- For trunk ports, the rate shaper must be configured on individual ports of a trunk using the `config-trunk-ind` command (trunk configuration level); you cannot configure a rate shaper for a trunk.

- When outbound rate shaping is enabled on a port on an IPv4 device, the port QoS queuing method (qos mechanism) will be strict mode. This applies to IPv4 devices only. On IPv6 devices, the QoS mechanism is whatever method is configured on the port, even when outbound rate shaping is enabled.

- You can configure a rate shaper for a port and for the individual priority queues of that port. However, if a port rate shaper is configured, that value overrides the rate shaper value of a priority queue if the priority queue rate shaper is greater than the rate shaper for the port.

- On FastIron X Series devices, configured rate shaper values are rounded up to the nearest multiple of 651 Kbps. The maximum configurable limit is 2665845 Kbps.

- On TurboIron X Series devices, configured rate shaper values are rounded up to the nearest values programmable by the hardware.

- On FastIron CX Series devices, configured rate shaper values are rounded up to the nearest values programmable by the hardware.

### Configuring outbound rate shaping for a port

To configure the maximum rate at which outbound traffic is sent out on a port, enter commands such as the following.

```
FastIron(config)#interface e 1/2
FastIron(config-if-e1000-2)#rate-limit output shaping 1300
```

The above commands affect FastIron X Series, FastIron CX Series, and TurboIron X Series systems differently:

- On FastIron X Series devices, the configured 1300 Kbps outbound rate shaping on port 2 is rounded up to the nearest multiple of 651 Kbps, which is 1302 Kbps. This value is the actual limit on the port for outbound traffic.

- On TurboIron X Series devices, the configured 1300 Kbps outbound rate shaping on port 2 is rounded up to the nearest value programmable by the hardware, which is 1344 Kbps. This value is the actual limit on the port for outbound traffic.

- On FastIron CX Series devices, the configured outbound rate shaper of 651 Kbps on port 1/15 is rounded to 616 Kbps. The configured 1300 Kbps limit on port 15 is rounded to 1232 Kbps.

**Syntax:** `[no] rate-limit output shaping <value>`

On FastIron X Series devices, you can configure up to 2665845 Kbps for `<value>`.

On TurboIron X Series devices, you can specify a value up to the port line rate for `<value>`.

On FastIron CX Series devices, you can specify a value up to the port line rate for `<value>`.

### Configuring outbound rate shaping for a specific priority

To configure the maximum rate at which outbound traffic is sent out on a port priority queue, enter commands such as the following.
Rate shaping overview

FastIron(config)#interface e 1/2
FastIron(config-if-e1000-2)#rate-limit output shaping 500 priority 7

The above commands affect FastIron X Series, FastIron CX Series, and TurboIron X Series systems differently:

- On FastIron X Series devices, the configured 500 Kbps limit for outbound traffic on Priority queue 7 on port 2 is rounded up to the nearest multiple of 651 Kbps, which is 651 Kbps.
- On TurboIron X Series devices, the configured 500 Kbps limit for outbound traffic on Priority queue 7 on port 2 is rounded up to the nearest multiple of 504 Kbps, which is 504 Kbps.
- On FastIron CX Series devices, the configured 500 Kbps limit for outbound traffic on priority queue 7 on port 2 is rounded to a value that is programmable by the hardware, which is 440 Kbps.

Syntax: `[no] rate-limit output shaping <value> priority <priority-queue>

On FastIron X Series devices, you can configure up to 2665845 Kbps for `<value>`. On TurboIron X Series devices, you can specify a value up to the port line rate for `<value>`. On FastIron CX Series devices, you can specify a value up to the port line rate for `<value>`. Specify 0-7 for `<priority-queue>`

Configuring outbound rate shaping for a trunk port

This feature is supported on individual ports of a static trunk group. It is also supported on LACP trunk ports on FastIron X Series devices starting in release FSX 04.3.00. However, it is not supported on LACP trunk ports on TurboIron X Series devices or for FastIron CX devices.

To configure the maximum rate at which outbound traffic is sent out on a trunk port, enter the following on each trunk port where outbound traffic will be shaped.

FastIron(config)#trunk e 1/13 to 1/16
FastIron(config-trunk-13-16)#config-trunk-ind
FastIron(config-trunk-13-16)#rate-limit output shaping ethe 1/15 651
FastIron(config-trunk-13-16)#rate-limit output shaping ethe 1/14 1300

The above commands configure an outbound rate shaper on port 1/14 and port 1/15. The commands affect FastIron X Series devices, FastIron CX Series devices, and TurboIron X Series devices differently:

- On FastIron X Series devices, the configured outbound rate shaper (651 Kbps) on port 1/15 is the maximum rate of outbound traffic that is sent out on that port, since 651 Kbps is a multiple of 651 Kbps. The configured 1300 Kbps limit on port 14 is rounded up to 1302 Kbps.
- On TurboIron X Series devices, the configured outbound rate shaper of 651 Kbps on port 1/15 is rounded up to 704 Kbps. The configured outbound rate shaper of 1300 on port 1/14 is rounded up to 1344 Kpbs.
- On FastIron CX Series devices, the configured outbound rate shaper (651 Kbps) on port 1/15 is the rounded to 616 Kbps. The configured 1300 Kbps limit on port 14 is rounded to 1232 Kbps.

Syntax: `[no] rate-limit output shaping ethernet [<stack-unit>/<slotnum>/]<portnum> <value>

The `<slotnum>` parameter is required on chassis devices.
The `<stack-unit>` parameter is required on stacking devices.
On FastIron X Series devices, you can configure up to 2665845 Kbps for `<value>`.
On TurboIron X Series devices, you can specify a <value> up to the port line rate. On FastIron CX Series devices, you can specify a <value> up to the port line rate.

**Displaying rate shaping configurations**

To display the configured outbound rate shaper on a device, enter the following command.

```
FastIron#show rate-limit output-shaping
```

```
Outbound Rate Shaping Limits in Kbps:

<table>

Chapter 24

Configuring Rate Limiting on FGS, FGS-STK, FLS, FLS-STK, and FWS Devices

Overview

This chapter describes how to configure fixed rate limiting on inbound and outbound ports on FGS, FLS, FWS, FGS-STK, and FLS-STK devices using the CLI.

NOTE
This chapter applies to the FGS, FLS, FWS, FGS-STK, and FLS-STK devices. To configure rate limiting on a FastIron X Series device, refer to Chapter 23, “Configuring Rate Limiting and Rate Shaping on the FastIron X Series, FCX Series, and Turbolron Series”.

These devices support port-based fixed rate limiting on inbound ports and outbound ports.

Fixed Rate Limiting allows you to specify the maximum number of bytes a given port can send or receive. The port drops bytes that exceed the limit you specify. You can configure a Fixed Rate Limiting policy on a port inbound or outbound direction. Fixed rate limiting applies to all traffic on the rate limited port.

When you specify the maximum number of bytes, you specify it in kilobits per second (Kbps). The Fixed Rate Limiting policy applies to one-second intervals and allows the port to send or receive the number of bytes you specify in the policy, but drops additional bytes. Unused bandwidth is not carried over from one interval to the next.

NOTE
Brocade recommends that you do not use Fixed Rate Limiting on ports that send or receive route control traffic or Spanning Tree Protocol (STP) control traffic. If the port drops control packets due to the Fixed Rate Limiting policy, routing or STP can be disrupted.

Rate limiting in hardware

Each device supports line-rate rate limiting in hardware. The device creates entries in Content Addressable Memory (CAM) for the rate limiting policies. The CAM entries enable the device to perform the rate limiting in hardware instead of sending the traffic to the CPU. The device sends the first packet in a given traffic flow to the CPU, which creates a CAM entry for the traffic flow. A CAM entry consists of the source and destination addresses of the traffic. The device uses the CAM entry for rate limiting all the traffic within the same flow. A rate limiting CAM entry remains in the CAM for two minutes before aging out.

How fixed rate limiting works

Fixed Rate Limiting counts the number of bytes that a port either sends or receives, in one second intervals. The direction that the software monitors depends on the direction you specify when you configure the rate limit on the port. If the number of bytes exceeds the maximum number you specify when you configure the rate, the port drops all further packets for the rate-limited direction, for the duration of the one-second interval.
Once the one-second interval is complete, the port clears the counter and re-enables traffic.

**Figure 108** shows an example of how Fixed Rate Limiting works. In this example, a Fixed Rate Limiting policy is applied to a port to limit the inbound traffic to 500000 bits (62500 bytes) a second. During the first two one-second intervals, the port receives less than 500000 bits in each interval. However, the port receives more than 500000 bits during the third and fourth one-second intervals, and consequently drops the excess traffic.

**FIGURE 108  Fixed Rate Limiting**

![Fixed Rate Limiting Diagram](image)

**NOTE**
The software counts the bytes by polling statistics counters for the port every 100 milliseconds, which provides 10 readings each second. Due to the polling interval, the Fixed Rate Limiting policy has an accuracy of within 10% of the port's line rate. It is therefore possible for the policy to sometimes allow more traffic than the limit you specify, but the extra traffic is never more than 10% of the port's line rate.

### Configuring fixed rate limiting on inbound ports

Inbound rate limiting allows you to specify the maximum number of Kbps a given port can receive.

### Minimum and maximum rates

**Table 131** lists the minimum and maximum inbound rate limits on GbE and 10-GbE ports.

<table>
<thead>
<tr>
<th>Port type</th>
<th>Minimum rate</th>
<th>Maximum rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>GbE</td>
<td>65 Kbps</td>
<td>1000000 Kbps</td>
</tr>
<tr>
<td>10-GbE</td>
<td>65 Kbps</td>
<td>10000000 Kbps</td>
</tr>
</tbody>
</table>
Configuration notes

Inbound rate limiting is **supported** on:

- GbE ports
- 10-GbE ports
- Trunk ports

Inbound rate limiting is **not supported** on:

- Ports on which LACP is enabled
- Virtual interfaces
- Loopback interfaces

Fixed rate limiting is **supported** on:

- inbound ports only

Fixed rate limiting is **not supported** on:

- 10 Gbps Ethernet ports
- Tagged ports in the base Layer 3 and full Layer 3 images

Configuration syntax

To configure inbound rate limiting on a port, enter commands such as the following.

```bash
FastIron(config)#interface ethernet 0/2/1
FastIron(config-if-e10000-0/2/1)#rate-limit input fixed 1000000
```

Rate Limiting on Port 0/2/1 - Config: 1000000 Kbps, Actual: 1000000 Kbps

The above commands configure a fixed rate limiting policy that allows port 0/2/1, a 10-GbE port, to receive a maximum of 1000000 kilobits per second. If the port receives additional bits during a given one-second interval, the port drops all inbound packets on the port until the next one-second interval starts.

```bash
FastIron(config)#interface ethernet 0/1/10
FastIron(config-if-e1000-0/1/10)#rate-limit input fixed 1000
```

Rate Limiting on Port 0/1/10 - Config: 1000 Kbps, Actual: 1000 Kbps

The above commands configure a fixed rate limiting policy that allows port 0/1/10, a GbE port, to receive a maximum of 1000 kilobits per second. If the port receives additional bits during a given one-second interval, the port drops all inbound packets on the port until the next one-second interval starts.

Syntax: `[no] rate-limit input fixed <average-rate>`

The `<average-rate>` parameter specifies the maximum number of kilobits per second (Kbps) the port can receive. **Table 131** lists the minimum and maximum rates.

Configuring fixed rate limiting on outbound ports

Outbound rate limiting allows you to specify the maximum number of kilobits a given port can transmit.
FGS, FLS, FWS, FGS-STK, and FLS-STK devices support the following types of outbound fixed rate limiting on Gbps and 10 Gbps Ethernet ports.

- **Port-based** – Limits the rate of outbound traffic on an individual physical port or trunk port, to a specified rate. Traffic that exceeds the maximum rate is dropped. Only one port-based outbound rate limiting policy can be applied to a port.

- **Port- and priority-based** – Limits the rate on an individual 802.1p priority queue on an individual physical port or trunk port. Traffic that exceeds the rate is dropped. Only one priority-based rate limiting policy can be specified per priority queue for a port. This means that a maximum of eight port- and priority-based policies can be configured on a port.

### Minimum and maximum rates

Table 132 lists the minimum and maximum outbound rate limits on GbE and 10-GbE ports.

<table>
<thead>
<tr>
<th>Port type</th>
<th>Minimum rate</th>
<th>Maximum rate</th>
<th>Granularity</th>
</tr>
</thead>
<tbody>
<tr>
<td>GbE</td>
<td>65 Kbps</td>
<td>1000000 Kbps</td>
<td>65 Kbps</td>
</tr>
<tr>
<td>10-GbE</td>
<td>2500 Kbps</td>
<td>10000000 Kbps</td>
<td>2500 Kbps</td>
</tr>
</tbody>
</table>

### Configuration notes

- Outbound rate limiting is supported on:
  - GbE ports
  - 10-GbE ports
  - Trunk ports
- Outbound rate limiting is not supported on:
  - Ports on which LACP is enabled
  - Virtual interfaces
  - Loopback interfaces
- Because of the hardware architecture of the FastIron GS and FastIron LS, the effect of outbound rate limiting differs on GbE ports compared to 10-GbE ports. For example, applying the same rate limiting value on GbE and 10-GbE ports will produce different results.
- You can configure both outbound port-base rate limiting and outbound port- and priority-based rate limiting on a single physical port or trunk port. However, if a priority-based limit for a given port is greater than the port-based rate limit, then the port-based rate limit will override the priority-based rate limit. Similarly, if the port-based rate limit is greater than the priority-based limit, then the priority-based rate limit will override the port-based rate limit.

### Port-based rate limiting

To configure port-based fixed rate limiting on an outbound port, enter commands such as the following.

```
FastIron(config)#interface ethernet 0/1/34
FastIron(config-if-e1000-0/1/34)#rate-limit output fixed 32
```

Outbound Rate Limiting on Port 0/1/34 Config: 32 Kbps, Actual: 65 Kbps
The above commands configure a fixed rate limiting policy that allows port 0/1/34 to transmit 32 Kbps. Since port 0/1/34 is a GbE port and the minimum rate is 65 Kbps (refer to Table 132), the system will adjust the configured rate of 32 Kbps to an actual rate to 65 Kbps. If the port transmits additional bits during a given one-second interval, the port will drop all outbound packets on the port until the next one-second interval starts.

```
FastIron(config)#interface ethernet 0/2/1
FastIron(config-if-e1000-0/2/1)#rate-limit output fixed 32
```

Outbound Rate Limiting on Port 0/2/1 Config: 32 Kbps, Actual: 2500 Kbps

The above commands configure a fixed rate limiting policy that allows port 0/2/1 to transmit 32 Kbps per second. Since port 0/2/1 is a 10-GbE port and the minimum rate is 2500 Kbps (refer to Table 132), the system will adjust the configured rate of 32 Kbps to an actual rate of 2500 Kbps. If the port transmits additional bits during a given one-second interval, the port will drop all outbound packets on the port until the next one-second interval starts.

Syntax: `[no] rate-limit output fixed <average-rate>`

The `<average-rate>` parameter specifies the average number of kilobits per second (Kbps) the port can send. Table 132 lists the minimum and maximum rates for GbE and 10-GbE ports.

### Port- and priority-based rate limiting

Port- and priority-based rate limiting limits the rate on an individual 802.1p priority queue on an individual physical port or trunk port.

To configure port- and priority-based fixed rate limiting on an outbound port, enter commands such as the following.

```
FastIron(config)#interface ethernet 0/1/35
FastIron(config-if-e1000-0/1/35)#rate-limit output fixed 1000 priority 7
```

Outbound Rate Limiting on Port 0/1/35 for Priority 7
Config: 1000 Kbps, Actual: 975 Kbps

The above commands configure a fixed rate limiting policy that allows traffic with a priority of 7 on port 0/1/35 to transmit 1000 Kbps per second. The system rounds the configured rate to 975 Kbps. If the port transmits additional bits during a given one-second interval, the port will drop all outbound packets on the port until the next one-second interval starts.

### Configuring an ACL-based rate limiting policy

FGS, FLS, FWS, FGS-STK, and FLS-STK devices support IP ACL-based rate limiting of inbound traffic. ACL-based rate limiting provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs.

To configure ACL-based rate limiting, you create individual traffic policies, then reference the traffic policies in one or more ACL entries (also called clauses or statements). The traffic policies become effective on ports to which the ACLs are bound.

For configuration procedures for ACL-based rate limiting, refer to Chapter 25, “Configuring Traffic Policies”.
Displaying the fixed rate limiting configuration

You can display the fixed rate limiting configuration for inbound and outbound traffic.

Inbound ports

To display the fixed rate limiting configuration on inbound ports, enter the following command.

```
FastIron#show rate-limit fixed input
Total rate-limited interface count: 11.
Port    Configured Input Rate        Actual Input Rate
1          1000000                 1000000
3          10000000                10005000
7          10000000                10000000
9           7500000                7502000
11          8000000                 7999000
12          8000000                 7999000
13          8000000                 7999000
14          8000000                 7999000
15          8000000                 7999000
21          8000000                 8000000
25           7500000                7502000
```

Syntax:  show rate-limit fixed input

The command lists the ports on which fixed rate limiting is configured, and provides the information listed in Table 133 for each of the ports.

**TABLE 133**  CLI display of Fixed Rate Limiting information on inbound ports

<table>
<thead>
<tr>

Chapter 25

Configuring Traffic Policies

About traffic policies

This chapter describes how traffic policies are implemented and configured in the FastIron and TurboIron X Series devices.

Brocade devices use traffic policies for the following:

- to rate limit inbound traffic
- to count the packets and bytes per packet to which ACL permit or deny clauses are applied

Traffic policies consist of policy names and policy definitions:

- **Traffic policy name** – This is a string of up to 8 alphanumeric characters that identifies individual traffic policy definitions.
- **Traffic policy definition (TPD)** – This is the command filter associated with a traffic policy name. A TPD can define any one of the following:
  - Rate limiting policy
  - ACL counting policy
  - Combined rate limiting and ACL counting policy

The maximum number of supported active TPDs is a system-wide parameter and depends on the device you are configuring. The total number of active TPDs cannot exceed the system maximum. Refer to “Maximum number of traffic policies supported on a device” on page 772.

When you apply a traffic policy to an interface, you do so by adding a reference to the traffic policy in an ACL entry, instead of applying the individual traffic policy to the interface. The traffic policy becomes an active traffic policy or active TPD when you bind its associated ACL to an interface.

To configure traffic policies for ACL-based rate limiting, refer to “Configuring ACL-based fixed rate limiting” on page 774 and “Configuring ACL-based adaptive rate limiting” on page 775.

To configure traffic policies for ACL counting, refer to “Enabling ACL statistics” on page 778.

Configuration notes and feature limitations

Note the following when configuring traffic policies:

- Traffic policies are supported on all TurboIron X Series, FastIron GS and FastIron LS devices, and on FastIron X Series devices running software release 02.3.03 or later.
- This feature is supported in the Layer 2 and Layer 3 code.
- This feature applies to IP ACLs only.
- Traffic policies are not supported on 10 Gbps Ethernet interfaces.
- The maximum number of supported active TPDs is a system-wide parameter and depends on the device you are configuring. The total number of active TPDs cannot exceed the system maximum. Refer to “Maximum number of traffic policies supported on a device” on page 772.
• The FastIron GS and FastIron LS devices do not support the use of traffic policies for ACL counting only.

• You can reference the same traffic policy in more than one ACL entry within an access list. For example, two or more ACL statements in ACL 101 can reference a TPD named TPD1.

• You can reference the same traffic policy in more than one access list. For example, ACLs 101 and 102 could both reference a TPD named TPD1.

• To modify or delete an active traffic policy, you must first unbind the ACL that references the traffic policy.

• When you define a TPD (when you enter the CLI command `traffic-policy`), explicit marking of CoS parameters, such as traffic class and 802.1p priority, are not available on the device. In the case of a TPD defining rate limiting, the device re-marks CoS parameters based on the DSCP value in the packet header and the determined conformance level of the rate limited traffic, as shown in Table 135.

**Table 135** CoS parameters for packets that use rate limiting traffic policies

<table>
<thead>
<tr>
<th>If the packet conformance level is...</th>
<th>and the packet DSCP value is...</th>
<th>the device sets the traffic class and 802.1p priority to...</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td>56 – 63</td>
<td>7 (highest priority queue)</td>
</tr>
<tr>
<td></td>
<td>N/A</td>
<td>0 (lowest priority queue)</td>
</tr>
</tbody>
</table>

• When you define a TPD, reference the TPD in an ACL entry, then apply the ACL to a VE in the Layer 3 router code, the rate limit policy is accumulative for all of the ports in the port region. If the VE/VLAN contains ports that are in different port regions, the rate limit policy is applied per port region.

For example, TPD1 has a rate limit policy of 600M and is referenced in ACL 101. ACL 101 is applied to VE 1, which contains ports e 1/11 to e 1/14. Because ports e 1/11 and 1/12 are in a different port region than e 1/13 and 1/14, the rate limit policy will be 600M for ports e 1/11 and 1/12, and 600M for ports e 1/13 and 1/14.

**Maximum number of traffic policies supported on a device**

The maximum number of supported active traffic policies is a system-wide parameter and depends on the device you are configuring, as follows:

• By default, up to 1024 active traffic policies are supported on Layer 2 and on Layer 3 switches. This value is fixed on Layer 2 switches and cannot be modified.

• The number of active traffic policies supported on Layer 3 switches varies depending on the configuration and the available system memory. The default value and also the maximum number of traffic policies supported on Layer 3 switches is 1024.
Setting the maximum number of traffic policies supported on a Layer 3 device

If desired you can adjust the maximum number of active traffic policies that a Layer 3 device will support. To do so, enter commands such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)# system-max hw-traffic-conditioner 25
FastIron(config)# write memory
FastIron(config)# reload
```

**NOTE**
You must save the configuration and reload the software to place the change into effect.

**Syntax:** `[no] system-max hw-traffic-conditioner <num>`

`<num>` is a value from 0 to `n`, where 0 disables hardware resources for traffic policies, and `n` is a number up to 1024. The maximum number you can configure depends on the configuration and available memory on your device. If the configuration you enter causes the device to exceed the available memory, the device will reject the configuration and display a warning message on the console.

**NOTE**
Brocade does not recommend setting the system-max for traffic policies to 0 (zero), since this renders traffic policies ineffective.

### ACL-based rate limiting using traffic policies

ACL-based rate limiting provides the facility to limit the rate for IP traffic that matches the permit conditions in extended IP ACLs. This feature is available in the Layer 2 and Layer 3 code.

To configure ACL-based rate limiting, you create individual traffic policies, then reference the traffic policies in one or more ACL entries (also called clauses or statements). The traffic policies become effective on ports to which the ACLs are bound. Refer to “About traffic policies” on page 771.

When you configure a traffic policy for rate limiting, the device automatically enables rate limit counting, similar to the two-rate three-color marker (trTCM) mechanism described in RFC 2698 for adaptive rate limiting, and the single-rate three-color marker (srTCM) mechanism described in RFC 2697 for fixed rate limiting. This feature counts the number of bytes and trTCM or srTCM conformance level per packet to which rate limiting traffic policies are applied. Refer to “ACL and rate limit counting” on page 778.

You can configure ACL-based rate limiting on the following interface types:

- physical Ethernet interfaces
- virtual interfaces
- trunk ports
- specific VLAN members on a port (New in 02.3.03 – refer to “Applying an IPv4 ACL to specific VLAN members on a port (Layer 2 devices only)” on page 657)
- a subset of ports on a virtual interface (New in 02.3.03 – refer to “Applying an IPv4 ACL to a subset of ports on a virtual interface (Layer 3 devices only)” on page 658.)
Support for fixed rate limiting and adaptive rate limiting

FastIron X Series and TurboIron X Series devices support the following types of ACL-based rate limiting:

- **Fixed rate limiting** – Enforces a strict bandwidth limit. The device forwards traffic that is within the limit but either drops all traffic that exceeds the limit, or forwards all traffic that exceeds the limit at the lowest priority level, according to the action specified in the traffic policy.

- **Adaptive rate limiting** – Enforces a flexible bandwidth limit that allows for bursts above the limit. You can configure Adaptive Rate Limiting to forward, modify the IP precedence of and forward, or drop traffic based on whether the traffic is within the limit or exceeds the limit.

**NOTE**
FCX devices do not support adaptive rate limiting.

Configuring ACL-based fixed rate limiting

Use the procedures in this section to configure ACL-based fixed rate limiting. Before configuring this feature, see what to consider in “Configuration notes and feature limitations” on page 771.

Fixed rate limiting enforces a strict bandwidth limit. The port forwards traffic that is within the limit. If the port receives more than the specified number of fragments in a one-second interval, the device either drops or forwards subsequent fragments in hardware, depending on the action you specify.

To implement the ACL-based fixed rate limiting feature, first create a traffic policy, then reference the policy in an extended ACL statement. Lastly, bind the ACL to an interface. Follow the steps below.

1. Create a traffic policy. Enter a command such as the following.
   
   ```
   FastIron(config)# traffic-policy TPD1 rate-limit fixed 100 exceed-action drop
   ```

2. Create an extended ACL entry or modify an existing extended ACL entry that references the traffic policy.

   **Example**
   
   ```
   FastIron(config)# access-list 101 permit ip host 210.10.12.2 any traffic-policy TPD1
   ```

3. Bind the ACL to an interface.

   ```
   FastIron(config)# int e 5
   FastIron(config-if-e5)# ip access-group 101 in
   FastIron(config-if-e5)# exit
   ```

The above commands configure a fixed rate limiting policy that allows port e5 to receive a maximum traffic rate of 100 kbps. If the port receives additional bits during a given one-second interval, the port drops the additional inbound packets that are received within that one-second interval.

**Syntax:**

- [no] traffic-policy `<TPD name>` rate-limit fixed `<cir value>` exceed-action `<action>` [count]
- access-list `<num>` permit | deny... traffic policy `<TPD name>`
- [no] ip access-group `<num>` in
NOTE
For brevity, some parameters were omitted from the above access-list syntax.

The software allows you to add a reference to a non-existent TPD in an ACL statement and to bind that ACL to an interface. The software does not issue a warning or error message for non-existent TPDs.

Use the no form of the command to delete a traffic policy definition. Note that you cannot delete a traffic policy definition if it is currently in use on a port. To delete a traffic policy, first unbind the associated ACL.

<TPD name> is the name of the traffic policy definition. This value can be 8 or fewer alphanumeric characters.

rate-limit fixed specifies that the traffic policy will enforce a strict bandwidth.

<cir value> is the committed information rate in kbps. This value can be from 64 – 1000000 Kbps.

exceed-action <action> specifies the action to be taken when packets exceed the configured cir value. Refer to “Specifying the action to be taken for packets that are over the limit” on page 777.

The count parameter is optional and enables ACL counting. Refer to “ACL and rate limit counting” on page 778.

Configuring ACL-based adaptive rate limiting

Use the procedures in this section to configure ACL-based adaptive rate limiting. Before configuring this feature, see what to consider in “Configuration notes and feature limitations” on page 771.

Table 136 lists the configurable parameters for ACL-based adaptive rate limiting.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Committed Information Rate (CIR)</td>
<td>The guaranteed kilobit rate of inbound traffic that is allowed on a port.</td>
</tr>
<tr>
<td>Committed Burst Size (CBS)</td>
<td>The number of bytes per second allowed in a burst before some packets will exceed the committed information rate. Larger bursts are more likely to exceed the rate limit. The CBS must be a value greater than zero (0). Brocade recommends that this value be equal to or greater than the size of the largest possible IP packet in a stream. For TurboIron X Series devices, the CBS value is specified in kilobits.</td>
</tr>
<tr>
<td>Peak Information Rate (PIR)</td>
<td>The peak maximum kilobit rate for inbound traffic on a port. The PIR must be equal to or greater than the CIR.</td>
</tr>
<tr>
<td>Peak Burst Size (PBS)</td>
<td>The number of bytes per second allowed in a burst before all packets will exceed the peak information rate. The PBS must be a value greater than zero (0). Brocade recommends that this value be equal to or greater than the size of the largest possible IP packet in the stream. For TurboIron X Series devices, the PBS value is specified in kilobits.</td>
</tr>
</tbody>
</table>

If a port receives more than the configured bit or byte rate in a one-second interval, the port will either drop or forward subsequent data in hardware, depending on the action you specify.

To implement the ACL-based adaptive rate limiting feature, first create a traffic policy then reference the policy in an extended ACL statement. Lastly, bind the ACL to an interface. Follow the steps below.
1. Create a traffic policy. Enter a command such as the following.

```
FastIron(config)# traffic-policy TPDAfour rate-limit adaptive cir 10000 cbs 1600 pir 20000 pbs 4000 exceed-action drop
```

2. Create a new extended ACL entry or modify an existing extended ACL entry that references the traffic policy.

   **Example**

```
FastIron(config)# access-list 104 permit ip host 210.10.12.2 any traffic-policy TPDAfour
```

3. Bind the ACL to an interface.

```
FastIron(config)# int e7
FastIron(config-if-e7)# ip access-group 104 in
FastIron(config-if-e7)# exit
```

The above commands configure an adaptive rate limiting policy that enforces a guaranteed committed rate of 10000 kbps on port e7 and allows bursts of up to 1600 bytes. It also enforces a peak rate of 20000 kbps and allows bursts of 4000 bytes above the PIR limit. If the port receives additional bits during a given one-second interval, the port drops all packets on the port until the next one-second interval starts.

**Syntax:** 

```
[no] traffic-policy <TPD name> rate-limit adaptive cir <cir value> cbs <cbs value> pir <pir value> pbs <pbs value> exceed-action <action> [count]
```

**Syntax:** 

```
access-list <num> permit | deny.... traffic policy <TPD name>
```

**Syntax:** 

```
[no] ip access-group <num> in
```

---

**NOTE**

For brevity, some parameters were omitted from the above access-list syntax.

The software allows you to add a reference to a non-existent TPD in an ACL statement and to bind that ACL to an interface. The software does not issue a warning or error message for non-existent TPDs.

Use the `no` form of the command to delete a traffic policy definition. Note that you cannot delete a traffic policy definition if it is currently in use on a port. To delete a traffic policy, first unbind the associated ACL.

<TPD name> is the name of the traffic policy definition. This value can be 8 or fewer alphanumeric characters.

rate-limit adaptive specifies that the policy will enforce a flexible bandwidth limit that allows for bursts above the limit.

<cir value> is the committed information rate in kbps. Refer to Table 136.

<cbs value> is the committed burst size in bytes. Refer to Table 136.

<pir value> is the peak information rate in kbps. Refer to Table 136.

<pbs value> is the peak burst size in bytes. Refer to Table 136.

exceed-action <action> specifies the action to be taken when packets exceed the configured values. Refer to “Specifying the action to be taken for packets that are over the limit” on page 777.

The count parameter is optional and enables ACL counting. Refer to “ACL and rate limit counting” on page 778.
Specifying the action to be taken for packets that are over the limit

You can specify the action to be taken when packets exceed the configured cir value for fixed rate limiting, or the cir, cbs, pir, and pbs values for adaptive rate limiting. You can specify one of the following actions:

- Drop packets that exceed the limit
- Permit packets that exceed the limit and forward them at the lowest priority level

Dropping packets that exceed the limit

This section shows some example configurations and provides the CLI syntax for configuring a port to drop packets that exceed the configured limits for rate limiting.

**Example**
The following shows an example fixed rate limiting configuration.

```
FastIron(config)# traffic-policy TPD1 rate-limit fixed 10000 exceed-action drop
```

The above command sets the fragment threshold at 10,000 per second. If the port receives more than 10,000 packet fragments in a one-second interval, the device drops the excess fragments.

**Syntax:** `traffic-policy <TPD name> rate-limit fixed <cir value> exceed-action drop`

**Example**
The following shows an example adaptive rate limiting configuration.

```
FastIron(config)# traffic-policy TPDAfour rate-limit adaptive cir 10000 cbs 1600
pir 20000 pbs 4000 exceed-action drop
```

The above commands configure an adaptive rate limiting policy that enforces a guaranteed committed rate of 10000 kbps on port e7 and allows bursts of up to 1600 bytes. It also enforces a peak rate of 20000 kbps and allows bursts of 4000 bytes above the PIR limit. If the port receives additional bits during a given one-second interval, the port drops all packets on the port until the next one-second interval starts.

**Syntax:** `traffic-policy rate-limit adaptive cir <cir value> cbs <cbs value> pir <pir value> pbs <pbs value> exceed-action drop`

Permitting packets that exceed the limit

This section shows some example configurations and provides the CLI syntax for configuring a port to permit packets that exceed the configured limit for rate limiting.

**Example**
The following shows an example fixed rate limiting configuration.

```
FastIron(config)# traffic-policy TPD1 rate-limit fixed 10000 exceed-action permit-at-low-pri
```

The above command sets the fragment threshold at 10,000 per second. If the port receives more than 10,000 packet fragments in a one-second interval, the device takes the specified action. The action specified with this command is to permit excess fragments and forward them at the lowest priority level.

**Syntax:** `[no] traffic-policy <TPD name> rate-limit fixed <cir value> exceed-action permit-at-low-pri`
**Example**

The following shows an example adaptive rate limiting configuration.

```
FastIron(config)# traffic-policy TPDAfour rate-limit adaptive cir 10000 cbs 1600
pir 20000 pbs 4000 exceed-action permit-at-low-pri
```

The above commands configure an adaptive rate limiting policy that enforces a guaranteed committed rate of 10000 kbps on port e7 and allows bursts of up to 1600 bytes. It also enforces a peak rate of 20000 kbps and allows bursts of 4000 bytes above the PIR limit. If the port receives additional bits during a given one-second interval, the port permits all packets on the port and forwards the packets at the lowest priority level.

**Syntax:** `traffic-policy rate-limit adaptive cir <cir value> cbs <cbs value> pir <pir value> pbs <pbs value> exceed-action permit-at-low-pri`

---

**ACL and rate limit counting**

**Platform Support:**
- FastIron X Series devices running software release 02.3.03 and later
- TurboIron X Series devices running software release 04.1.00 and later

**ACL counting**, also called **ACL statistics**, enables the Brocade device to count the number of packets and the number of bytes per packet to which ACL filters are applied.

**Rate limit counting** counts the number of bytes and conformance level per packet to which rate limiting traffic policies are applied. The device uses the counting method similar to the two-rate three-color marker (trTCM) mechanism described in RFC 2698 for adaptive rate limiting, and the single-rate three-color marker (srTCM) mechanism described in RFC 2697 for fixed rate limiting. Rate limit counting is automatically enabled when a traffic policy is enforced (active). You can view these counters using the show commands listed in “Viewing traffic policies” on page 781.

For more information about traffic policies, refer to “About traffic policies” on page 771.

---

**Enabling ACL statistics**

**NOTE**

**ACL statistics** and **ACL counting** are used interchangeably throughout this chapter and mean the same thing.

**NOTE**

The FastIron GS and FastIron LS do not support the use of traffic policies for ACL statistics only. However, these models do support the use of traffic policies for ACL statistics together with rate limiting traffic policies. Refer to “Enabling ACL statistics with rate limiting traffic policies” on page 779.

Use the procedures in this section to configure ACL statistics. Before configuring this feature, see what to consider in “Configuration notes and feature limitations” on page 771.

To enable ACL statistics on a FastIron X Series device, first create a traffic policy, then reference the traffic policy in an extended ACL entry. Lastly, bind the ACL to an interface. The ACL counting policy becomes effective on ports to which the ACLs are bound.
You also can enable ACL statistics when you create a traffic policy for rate limiting. Refer to “Enabling ACL statistics with rate limiting traffic policies” on page 779.

Follow the steps given below to implement the ACL counting feature.

1. Create a traffic policy. Enter a command such as the following
   
   ```
   FastIron(config)# traffic-policy TPD5 count
   ```

2. Create an extended ACL entry or modify an existing extended ACL entry that references the traffic policy definition.
   
   **Example**
   
   ```
   FastIron(config)# access-list 101 permit ip host 210.10.12.2 any traffic-policy TPD5
   ```

3. Bind the ACL to an interface.
   
   ```
   FastIron(config)# int e 4
   FastIron(config-if-e4)# ip access-group 101 in
   FastIron(config-if-e4)# exit
   ```

The above commands configure an ACL counting policy and apply it to port e4. Port e4 counts the number of packets and the number of bytes on the port that were permitted or denied by ACL filters.

**Syntax:** `[no] traffic-policy <TPD name> count

**Syntax:** `access-list <num> permit | deny.... traffic policy <TPD name>

**Syntax:** `[no] ip access-group <num> in

**NOTE**

For brevity, some parameters were omitted from the above access-list syntax.

The software allows you to add a reference to a non-existent TPD in an ACL statement and to bind that ACL to an interface. The software does not issue a warning or error message for non-existent TPDs.

Use the **no** form of the command to delete a traffic policy definition. Note that you cannot delete a traffic policy definition if it is currently in use on a port. To delete a traffic policy, first unbind the associated ACL.

`<TPD name>` is the name of the traffic policy definition. This value can be 8 alphanumeric characters or less.

**Enabling ACL statistics with rate limiting traffic policies**

**NOTE**

FCX devices do not support ACL statistics in software release 06.0.00.

The configuration example in the section “Enabling ACL statistics” on page 778 shows how to enable ACL counting without having to configure parameters for rate limiting. You also can enable ACL counting while defining a rate limiting traffic policy, as illustrated in the following configuration examples.

**Example**

To enable ACL counting while defining traffic policies for fixed rate limiting, enter commands such as the following at the Global CONFIG Level of the CLI.

ACL and rate limit counting

Syntax: [no] traffic-policy <TPD name> rate-limit fixed <cir value> exceed-action <action> count

Example

To enable ACL counting while defining traffic policies for adaptive rate limiting, enter commands such as the following at the Global CONFIG Level of the CLI.

```
traffic-policy TPDA4 rate-limit adaptive cir 10000 cbs 1600 pir 20000 pbs 4000
count exceed-action drop
traffic-policy TPDA5 rate-limit adaptive cir 10000 cbs 1600 pir 20000 pbs 4000
exceed-action permit-at-low-pri count
```

Syntax: traffic-policy rate-limit adaptive cir <cir value> cbs <cbs value> pir <pir value> pbs <pbs value> exceed-action <action> count

Viewing ACL and rate limit counters

When ACL counting is enabled on the Brocade device, you can use show commands to display the total packet count and byte count of the traffic filtered by ACL statements. The output of the show commands also display the rate limiting traffic counters, which are automatically enabled for active rate limiting traffic policies.

Use either the show access-list accounting command or the show statistics traffic-policy command to display ACL and traffic policy counters. The output of these commands are identical. The following shows an example output.

```
FastIron# show access-list accounting traffic-policy g_voip
Traffic Policy - g_voip:
General Counters:
Port Region#                  Byte Count             Packet Count
------------------   --------------------   ----------------------
7 (4/1 - 4/12)                   85367040                   776064
All port regions               84367040                   776064
Rate Limiting Counters:
Port Region#        Green Conformance  Yellow Conformance     Red Conformance
------------------  ------------------  ------------------  ------------------
7 (4/1 - 4/12)      329114195612139520   37533986897781760                   0
All port regions    329114195612139520   37533986897781760                   0
```

Syntax: show access-list accounting traffic-policy [<TPD name>]

or

Syntax: show statistics traffic-policy [<TPD name>]

Table 137 explains the output of the show access-list accounting and show statistics traffic-policy commands.

<table>
<thead>
<tr>
<th>TABLE 137</th>
<th>ACL and rate limit counting statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This line...</strong></td>
<td><strong>Displays...</strong></td>
</tr>
<tr>
<td>Traffic Policy</td>
<td>The name of the traffic policy.</td>
</tr>
<tr>
<td>General Counters</td>
<td></td>
</tr>
</tbody>
</table>
Clearing ACL and rate limit counters

The Brocade device keeps a running tally of the number of packets and the number of bytes per packet that are filtered by ACL statements and rate limiting traffic policies. You can clear these accumulated counters, essentially resetting them to zero. To do so, use either the `clear access-list account traffic-policy` or the `clear statistics traffic-policy` command.

To clear the counters for ACL counting and rate limit counting, enter commands such as the following.

```
FastIron(config)# clear access-list accounting traffic-policy CountOne
FastIron(config)# clear statistics traffic-policy CountTwo
```

**Syntax:**
- `clear access-list accounting traffic-policy <TPD name>`
- `clear statistics traffic-policy <TPD name>`

where `<TPD name>` is the name of the traffic policy definition for which you want to clear traffic policy counters.

### VIEWING TRAFFIC POLICIES

To view traffic policies that are currently defined on the Brocade device, enter the `show traffic-policy` command. An example display output is shown below. **Table 138** defines the output.

```
FastIron# show traffic-policy t_voip
Traffic Policy - t_voip:
Metering Enabled, Parameters:
    Mode: Adaptive Rate-Limiting
cir: 100 kbps,  cbs: 2000 bytes,  pir: 200 kbps,  pbs: 4000 bytes
Counting Not Enabled
Number of References/Bindings:1
```

**Syntax:** `show traffic-policy [<TPD name>]`

To display all traffic policies, enter the `show traffic-policy` command without entering a TPD name.
### View Traffic Policies

<table>
<thead>
<tr>
<th>This line...</th>
<th>Displays...</th>

Configuring IP Multicast Traffic Reduction for FastIron Devices

Chapter 26

IGMP snooping for FGS and FGS-STK, FLS and FLS-STK, FWS, and FCX devices

NOTE

- FGS and FLS devices running software release 03.0.00 and later
- FWS devices running software release 04.3.00 or later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FCX-S devices running software release 06.0.00 and later

NOTE
FastIron CX devices also support IGMP Proxy. For more information see “IGMP Proxy” on page 921.

IGMP snooping overview

When a device processes a multicast packet, by default, the device broadcasts the packets to all ports except the incoming port of a VLAN. Packets are flooded by hardware without going to the CPU. This behavior causes some clients to receive unwanted traffic.

IGMP snooping provides multicast containment by forwarding traffic to only the ports that have IGMP receivers for a specific multicast group (destination address). A device maintains the IGMP group membership information by processing the IGMP reports and leave messages, so traffic can be forwarded to ports receiving IGMP reports.

An IPv4 multicast address is a destination address in the range of 224.0.0.0 to 239.255.255.255. Addresses of 224.0.0.X are reserved. Because packets destined for these addresses may require VLAN flooding, devices do not do snooping in the reserved range. Data packets destined to addresses in reserved range are flooded to the entire VLAN by hardware, and mirrored to the CPU. Multicast data packets destined for the non-reserved range of addresses are snooped. A client must send IGMP reports in order to receive traffic. If an application outside the reserved range requires VLAN flooding, the user must configure a static group that applies to the entire VLAN. In addition, a static group with the drop option can discard multicast data packets to a specified group in hardware, including addresses in the reserved range.
An IGMP device is responsible for broadcasting general queries periodically, and sending group queries when it receives a leave message, to confirm that none of the clients on the port still want specific traffic before removing the traffic from the port. IGMPv2 lets clients specify what group (destination address) will receive the traffic but not to specify the source of the traffic. IGMPv3 is for source-specific multicast traffic, adding the capability for clients to INCLUDE or EXCLUDE specific traffic sources. An IGMPv3 device port state could be INCLUDE or EXCLUDE, and there are different types of group records for client reports.

The interfaces respond to general or group queries by sending a membership report that contains one or more of the following records associated with a specific group:

- Current-state record that indicates from which sources the interface wants to receive and not receive traffic. This record contains the source address of interfaces and whether or not traffic will be included (IS_IN) or not excluded (IS_EX) from this source.
- Filter-mode-change record. If the interface state changes from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if the interface state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.
- An IGMPv2 leave report is equivalent to a TO_IN (empty) record in IGMPv3. This record means that no traffic from this group will be received regardless of the source.
- An IGMPv2 group report is equivalent to an IS_EX (empty) record in IGMPv3. This record means that all traffic from this group will be received regardless of source.
- Source-list-change record. If the interface wants to add or remove traffic sources from its membership report, the report can contain an ALLOW record, which includes a list of new sources from which the interface wishes to receive traffic. It can also contain a BLOCK record, which lists the current traffic sources from which the interface wants to stop receiving traffic.

IGMP protocols provide a method for clients and a device to exchange messages, and let the device build a database indicating which port wants what traffic. The protocols do not specify forwarding methods. They require IGMP snooping or multicast protocols such as PIM or DVMRP to handle packet forwarding. PIM and DVMRP can route multicast packets within and outside a VLAN, while IGMP snooping can switch packets only within a VLAN. Currently, FGS, FLS, FGS-STK, FLS-STK, FWS, and FCX devices do not support multicast routing.

If a VLAN is not IGMP snooping-enabled, it floods multicast data and control packets to the entire VLAN in hardware. When snooping is enabled, IGMP packets are trapped to the CPU. Data packets are mirrored to the CPU in addition to being VLAN flooded. The CPU then installs hardware resources, so that subsequent data packets can be switched to desired ports in hardware without going to the CPU. If there is no client report or port to queriers for a data stream, the hardware resource drops it. The hardware can either match the group address only (* G), or both the source and group (S G) of the data stream. If any IGMPv3 is configured in any port of a VLAN, this VLAN uses (S G) match; otherwise, it uses (* G). This is 32-bit IP address matching, not 23-bit multicast MAC address 01-00-5e-xx-xx-xx matching.

FGS, FLS, FGS-STK, FLS-STK, FWS, and FCX devices have 16K of hardware resources allocated to MAC learning, IGMP, and MLD snooping. If a data packet does not match any of these resources, it might be sent to the CPU, which increases the CPU burden. This can happen if the device runs out of hardware resource, or is unable to install resources for a specific matching address due to hashing collision. The hardware hashes addresses into 16K entries, with some addresses hashed into the same entry. If the collision number in an entry is more than the hardware chain length, the resource cannot be installed. The chain length can be configured using the hash-chain-length command.

```
FastIron(config)# hash-chain-length 8
```

Syntax: [no] hash-chain-length <num>
The `<num>` parameter range is 4 to 32, in multiples of 4. If the input value is not a multiple of 4, then it will be changed to the multiple of 4 lower than then the input value (e.g. 11 will be changed to 8). The default hash chain length is 4. A chain length of more than 4 may affect line rate switching.

**NOTE**
For this command to take effect, you must save the configuration and reload the switch.

The hardware resource limit applies only to the VLANs where IGMP snooping is enabled. Multicast streams are switched in hardware without using any pre-installed resources in a VLAN where snooping is not enabled.

FGS, FLS, FGS-STK, FLS-STK, FWS, and FCX devices support up to 32K of IGMP groups, which are produced by client membership reports.

**Configuration notes**

- Servers (traffic sources) are not required to send IGMP memberships.
- The default IGMP version is V2.
- Hardware resource is installed only when there is data traffic. If a VLAN is configured for IGMPv3, the hardware matches (S G), otherwise it matches (* G).
- A user can configure the maximum numbers of groups and hardware switched data streams.
- The device supports static groups that apply to the entire VLAN, or to just a few ports. The device acts as a proxy to send IGMP reports for the static groups when receiving queries. The static group has a drop option to discard multicast data packets in hardware.
- A user can configure static router ports to force all multicast traffic to these specific ports.
- The devices support fast leave for IGMPv2. Fast leave stops traffic immediately when the port receives a leave message.
- The devices support tracking and fast leave for IGMPv3, tracking all IGMPv3 clients. If the only client on a port leaves, traffic is stopped immediately.
- An IGMP device can be configured as a querier (active) or non-querier (passive). Queriers send queries. Non-queriers listen for queries and forward them to the entire VLAN.
- Every VLAN can be independently configured to be a querier or a non-querier.
- If a VLAN has a connection to a PIM/DVMRP-enabled port on another router, this VLAN should be configured as a non-querier (passive). When multiple snooping devices connect together and there is no connection to PIM/DVMRP ports, one device should be configured as a querier (active). If multiple devices are configured as active (queriers), only one will keep sending queries after exchanging queries.
- An IGMP device can be configured to rate-limit the forwarding IGMPv2 membership reports to queriers.
- The querier must configure an IP address to send out queries.

The implementation allows snooping on some VLANs or all VLANs. Each VLAN can independently enable or disable IGMP, or configure V2 or V3. In general, global configuration commands `ip multicast` apply to every VLAN except those that have local `multicast` configurations (which supersede the global configuration). IGMP also allows independent configuration of individual ports in a VLAN for either IGMPv2 or IGMPv3. Configuring a specific version on a port or a VLAN only applies to the device’s sent queries. The device always processes client reports of any version regardless of the configured version.
IGMP snooping requires hardware resources. If resources are inadequate, the data stream without a resource is mirrored to CPU in addition to being VLAN flooded, which can cause high CPU usage. Brocade recommends that you avoid global enabling of snooping unless necessary.

When any port in a VLAN is configured for IGMPv3, the VLAN matches both source and group (S G) in hardware switching. If no ports are configured for IGMPv3, the VLAN matches group only (* G). Matching (S G) requires more hardware resources than matching (* G) when there are multiple servers sharing the same group. For example, two data streams from different sources to the same group require two (S G) entries in IGMPv3, but only one (* G) in IGMPv2. To conserve resources, IGMPv3 should be used only in source-specific applications. When VLANs are be independently configured for versions, some VLANs can match (* G) while others match (S G).

IGMP snooping requires clients to send membership reports in order to receive data traffic. If a client application does not send reports, you must configure static groups to force traffic to client ports. A static group can apply to only some ports or to the entire VLAN.

### Configuring queriers and non-queriers

An IGMP snooping-enabled device can be configured as a querier (active) or non-querier (passive). An IGMP querier sends queries; a non-querier listens for IGMP queries and forwards them to the entire VLAN. Starting in FGS software release 03.0.00, VLANs can be independently configured to be queriers or non-queriers. If a VLAN has a connection to a PIM/DVMRP-enabled port on another router, the VLAN should be configured as a non-querier. When multiple IGMP snooping devices are connected together, and there is no connection to a PIM/DVMRP-enabled port, one of the devices should be configured as a querier. If multiple devices are configured as queriers, after these devices exchange queries, then all except the winner stop sending queries. The device with the lowest address becomes the querier. Although the system will work when multiple devices are configured as queriers, Brocade recommends that only one device (preferably the one with the traffic source) is configured as a querier.

The non-queriers always forward multicast data traffic and IGMP messages to router ports which receive IGMP queries or PIM/DVMRP hellos. Brocade recommends that you configure the device with the data traffic source (server) as a querier. If a server is attached to a non-querier, the non-querier always forwards traffic to the querier regardless of whether there are any clients on the querier.

---

**NOTE**

In a topology of one or more connecting devices, at least one device must be running PIM/DVMRP, or configured as active. Otherwise, none of the devices can send out queries, and traffic cannot be forwarded to clients.

### VLAN specific configuration

You can configure IGMP snooping on some VLANs or on all VLANs. Each VLAN can be independently enabled or disabled for IGMP snooping, and can be configured for IGMPv2 or IGMPv3. In general, the `ip multicast` commands apply globally to all VLANs except those configured with VLAN-specific `multicast` commands. The VLAN-specific multicast commands supersede the global `ip multicast` commands.
Using IGMPv2 with IGMPv3

IGMP snooping can be configured for IGMPv2 or IGMPv3 on individual ports on a VLAN. An interface or router sends the queries and reports that include its IGMP version specified on it. The version configuration only applies to sending queries. The snooping device recognizes and processes IGMPv2 and IGMPv3 packets regardless of the version configuration.

To avoid version deadlock, an interface retains its version configuration even when it receives a report with a lower version.

PIM SM traffic snooping overview

Platform Support:
- FGS and FLS devices running software release 02.6.00 and later
- FWS devices running software release 04.3.00 or later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FCX-S devices running software release 06.0.00 and later

When multiple PIM sparse routers connect through a snooping-enabled device, the device always forwards multicast traffic to these routers. For example, PIM sparse routers R1, R2 and R3 connect through a device. Assume R2 needs traffic, and R1 sends it to the device, which forwards it to both R2 and R3, even though R3 does not need it. A PIM snooping-enabled device listens to join and prune messages exchanged by PIM sparse routers, and stops traffic to the router that sends prune messages. This allows the device to forward the data stream to R2 only.

PIM SM traffic snooping requires IP multicast traffic reduction to be enabled on the device. IP multicast traffic reduction configures the device to listen for IGMP messages. PIM SM traffic snooping provides a finer level of multicast traffic control by configuring the device to listen specifically for PIM SM join and prune messages sent from one PIM SM router to another through the device.

Configuration notes

This feature applies only to PIM SM version 2 (PIM V2).

Application example

Figure 109 shows an example application of the PIM SM traffic snooping feature. In this example, a device is connected through an IP router to a PIM SM group source that is sending traffic for two PIM SM groups. The device also is connected to a receiver for each of the groups.
When PIM SM traffic snooping is enabled, the device starts listening for PIM SM join and prune messages and IGMP group membership reports. Until the device receives a PIM SM join message or an IGMP group membership report, the device forwards IP multicast traffic out all ports. Once the device receives a join message or group membership report for a group, the device forwards subsequent traffic for that group only on the ports from which the join messages or IGMP reports were received.

In this example, the router connected to the receiver for group 239.255.162.1 sends a join message toward the group source. Since PIM SM traffic snooping is enabled on the device, the device examines the join message to learn the group ID, then makes a forwarding entry for the group ID and the port connected to the receiver router. The next time the device receives traffic for 239.255.162.1 from the group source, the device forwards the traffic only on port 5/1, since that is the only port connected to a receiver for the group.

Notice that the receiver for group 239.255.162.69 is directly connected to the device. As result, the device does not see a join message on behalf of the client. However, since IP multicast traffic reduction also is enabled, the device uses the IGMP group membership report from the client to select the port for forwarding traffic to group 239.255.162.69 receivers.

The IP multicast traffic reduction feature and the PIM SM traffic snooping feature together build a list of groups and forwarding ports for the VLAN. The list includes PIM SM groups learned through join messages as well as MAC addresses learned through IGMP group membership reports. In this case, even though the device never sees a join message for the receiver for group 239.255.162.69, the device nonetheless learns about the receiver and forwards group traffic to the receiver.

The device stops forwarding IP multicast traffic on a port for a group if the port receives a prune message for the group.

Notice that the ports connected to the source and the receivers are all in the same port-based VLAN on the device. This is required for the PIM SM snooping feature. The devices on the edge of the Global Ethernet cloud are configured for IP multicast traffic reduction and PIM SM traffic snooping. Although this application uses multiple devices, the feature has the same requirements and works the same way as it does on a single device.
Configuring IGMP snooping

To configure IGMP snooping on an FGS, FLS, FGS-STK, FLS-STK, FWS, and FCX devices, you need to perform the following global and VLAN-specific tasks.

**Global tasks**

Perform the following global tasks:

- “Configuring the hardware and software resource limits” on page 789
- “Enabling or disabling transmission and receipt of IGMP packets on a port” on page 790
- “Configuring the global IGMP mode” on page 790 (Must be enabled for IGMP snooping)
- “Modifying the age interval” on page 790
- “Modifying the query interval (Active IGMP snooping mode only)” on page 791
- “Configuring the global IGMP version” on page 791
- “Configuring report control” on page 791 (rate limiting)
- “Modifying the wait time before stopping traffic when receiving a leave message” on page 792
- “Modifying the multicast cache age time” on page 792
- “Enabling or disabling error and warning messages” on page 792
- “Enabling or disabling PIM sparse snooping” on page 792

**VLAN-specific tasks**

Perform the following VLAN-specific tasks:

- “Configuring the IGMP mode for a VLAN” on page 793 (active or passive)
- “Disabling IGMP snooping for the VLAN” on page 793
- “Disabling PIM sparse mode snooping for the VLAN” on page 793
- “Configuring the IGMP version for the VLAN” on page 793
- “Configuring the IGMP version for individual ports” on page 794
- “Configuring static groups to the entire VLAN or to specific ports” on page 794
- “Configuring static router ports” on page 794
- “Turning off static group proxy” on page 795
- “Enabling IGMPv3 membership tracking and fast leave for the VLAN” on page 795
- “Configuring fast leave for IGMPv2” on page 796
- “Enabling fast convergence” on page 796

**Configuring the hardware and software resource limits**

The system supports up to 8K of hardware-switched multicast streams. The configurable range is from 256 to 8192 with a default of 4096. Enter a command such as the following to define the maximum number of IGMP snooping cache entries.

```
FastIron(config)# system-max igmp-snoop-mcache 8000
```

**Syntax:** `[no] system-max igmp-snoop-mcache <num>`
The system supports up to 32K of groups. The configurable range is 256 to 32768 and the default is 8192. The configured number is the upper limit of an expandable database. Client memberships exceeding the group limits are not processed. Enter a command such as the following to define the maximum number of IGMP group addresses.

```
FastIron(config)# system-max igmp-max-group-addr 1600
```

**Syntax:** `[no] system-max igmp-max-group-addr <num>`

### Enabling or disabling transmission and receipt of IGMP packets on a port

When a VLAN is snooping-enabled, all IGMP packets are trapped to CPU without hardware VLAN flooding. The CPU can block IGMP packets to and from a multicast-disabled port, and does not add it to the output interfaces of hardware resources. This prevents the disabled port from receiving multicast traffic. However, if static groups to the entire VLAN are defined, the traffic from these groups is VLAN flooded, including to disabled ports. Traffic from disabled ports cannot be blocked in hardware, and is switched in the same way as traffic from enabled ports.

This command has no effect on a VLAN that is not snooping-enabled because all multicast traffic is VLAN flooded.

```
FastIron(config)# interface ethernet 0/1/3
FastIron(config-if-e1000-0/1/3)# ip-multicast-disable
```

**Syntax:** `[no] ip-multicast-disable`

### Configuring the global IGMP mode

You can configure active or passive IGMP modes on an FGS, FWS, FLS, or FCX device. The default mode is passive. If you specify an IGMP mode for a VLAN, it overrides the global setting.

- **Active** - When active IGMP mode is enabled, an FGS, FWS, FLS, or FCX device actively sends out IGMP queries to identify multicast groups on the network, and makes entries in the IGMP table based on the group membership reports it receives.
- **Passive** - When passive IGMP mode is enabled, it forwards reports to the router ports which receive queries. IGMP snooping in the passive mode does not send queries. However, it forwards queries to the entire VLAN.

To globally set the IGMP mode to active, enter the following command.

```
FastIron(config)# ip multicast active
```

**Syntax:** `[no] ip multicast [active | passive]`

If you do not enter either `active` or `passive`, the passive mode is assumed.

### Modifying the age interval

When the device receives a group membership report, it makes an entry for that group in the IGMP group table. The age interval specifies how long the entry can remain in the table before the device receives another group membership report. When multiple devices connect together, all devices should be configured for the same age interval, which should be at least twice the length of the query interval, so that missing one report won't stop traffic. Non-querier age intervals should be the same as the age interval of the querier.

To modify the age interval, enter a command such as the following.

```
FastIron(config)# ip multicast age-interval 280
```
Syntax: [no] ip multicast age-interval <interval>

The <interval> parameter specifies the aging time. You can specify a value from 20 - 7200 seconds. The default is 140 seconds.

*Modifying the query interval (Active IGMP snooping mode only)*

For a device with an active IGMP mode, you can modify the query interval to specify how often the device sends group membership queries. When multiple queriers connect together, they should all be configured with the same query interval.

To modify the query interval, enter a command such as the following.

FastIron(config)# ip multicast query-interval 120

Syntax: [no] ip multicast query-interval <interval>

The <interval> parameter specifies the time between queries. You can specify a value from 10 - 3600 seconds. The default is 60 seconds.

*Configuring the global IGMP version*

You can globally specify IGMPv2 or IGMPv3 for the device. The default is IGMPv2. For example, the following command causes the device to use IGMPv3.

FastIron(config)# ip multicast version 3

Syntax: [no] ip multicast version 2|3

You can also optionally specify the IGMP version for individual VLANs, or individual ports within VLANs. When no IGMP version is specified for a VLAN, the global IGMP version is used. When an IGMP version is specified for individual ports within a VLAN, the ports use that version, instead of the VLAN version or the global version. The default is IGMPv2.

*Configuring report control*

A device in passive mode forwards reports and leave messages from clients to the upstream router ports that are receiving queries.

You can configure report control to rate-limit report forwarding within the same group to no more than once every 10 seconds. This rate-limiting does not apply to the first report answering a group-specific query.

**NOTE**

This feature applies to IGMPv2 only. The leave messages are not rate limited.

IGMPv2 membership reports of the same group from different clients are considered to be the same and are rate-limited.

Use the following command to alleviate report storms from many clients answering the upstream router query.

FastIron(config)# ip multicast report-control

Syntax: [no] ip multicast report-control
The original command, `ip igmp-report-control`, has been renamed to `ip multicast report-control`. The original command is still accepted; however, it is renamed when you issue a `show configuration` command.

**Modifying the wait time before stopping traffic when receiving a leave message**

You can define the wait time before stopping traffic to a port when a leave message is received. The device sends group-specific queries once per second to ask if any client in the same port still needs this group. The value range is from 1 to 5, and the default is 2. Due to internal timer granularity, the actual wait time is between n and (n+1) seconds (n is the configured value).

```
FastIron(config)# ip multicast leave-wait-time 1
```

**Syntax**: `[no] ip multicast leave-wait-time <num>`

**Modifying the multicast cache age time**

You can set the time for an mcache to age out when it does not receive traffic. The traffic is hardware switched. One minute before aging out an mcache, the device mirrors a packet of this mcache to CPU to reset the age. If no data traffic arrives within one minute, this mcache is deleted.

A lower value quickly removes resources consumed by idle streams, but it mirrors packets to CPU often. A higher value is recommended only data streams are continually arriving. The range is 60 to 3600 seconds, and the default is 60 seconds.

```
FastIron(config)# ip multicast mcache-age 180
```

**Syntax**: `[no] ip multicast mcache-age <num>`

**Enabling or disabling error and warning messages**

The device prints error or warning messages when it runs out of software resources or when it receives packets with the wrong checksum or groups. These messages are rate-limited. You can turn off these messages by entering a command such as the following.

```
FastIron(config)# ip multicast verbose-off
```

**Syntax**: `[no] ip multicast verbose-off`

**Enabling or disabling PIM sparse snooping**

PIM snooping should be used only in topologies where multiple PIM sparse routers connect through a device. PIM snooping does not work on a PIM dense mode router which does not send join messages, and traffic to PIM dense ports is stopped. A PIM snooping-enabled device displays a warning if it receives PIM dense join/prune messages. Configure PIM sparse snooping by entering a command such as the following.

```
FastIron(config)# ip pimsm-snooping
```

**Syntax**: `[no] ip pimsm-snooping`

**NOTE**

The device must be in passive mode before it can be configured for PIM snooping.
Configuring the IGMP mode for a VLAN

You can configure a VLAN to use the active or passive IGMP mode. The default mode is passive. The setting specified for the VLAN overrides the global setting:

- **Active** - An active IGMP mode device actively sends out IGMP queries to identify multicast groups on the network, and makes entries in the IGMP table based on the group membership reports received.
- **Passive** - A passive IGMP mode device forwards reports to the router ports which receive queries. IGMP snooping in the passive mode forwards queries to the entire VLAN, but it does not send queries.

To set the IGMP mode for VLAN 20 to active, enter the following commands.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast active
```

Syntax: `[no] multicast active | passive`

Disabling IGMP snooping for the VLAN

When IGMP snooping is enabled globally, you can still disable it for a specific VLAN. For example, the following commands cause IGMP snooping to be disabled for VLAN 20. This setting overrides the global setting.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast disable-multicast-snoop
```

Syntax: `[no] multicast disable-multicast-snoop`

Enabling PIM sparse mode snooping for the VLAN

You can enable PIM snooping for a specific VLAN. For example, the following commands enable PIM snooping on VLAN 20.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast pimsm-snooping
```

Syntax: `[no] multicast pimsm-snooping`

Disabling PIM sparse mode snooping for the VLAN

When PIM snooping is enabled globally, you can still disable it for a specific VLAN. For example, the following commands disable PIM snooping for VLAN 20. This setting overrides the global setting.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast disable-pimsm-snoop
```

Syntax: `[no] multicast disable-pimsm-snoop`

Configuring the IGMP version for the VLAN

You can specify the IGMP version for a VLAN. For example, the following commands configure VLAN 20 to use IGMPv3.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast version 3
```
IGMP snooping for FGS and FGS-STK, FLS and FLS-STK, FWS, and FCX devices

Syntax: [no] multicast version 2 | 3

If no IGMP version is specified, then the globally-configured IGMP version is used. If an IGMP version is specified for individual ports, those ports use that version, instead of the VLAN version.

Configuring the IGMP version for individual ports

You can specify the IGMP version for individual ports in a VLAN. For example, the following commands configure ports 0/1/4, 0/1/5, 0/1/6 and 0/2/1 to use IGMPv3. The other ports either use the IGMP version specified with the multicast version command, or the globally-configured IGMP version.

FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast port-version 3 ethe 0/2/1 ethe 0/1/4 to 0/1/6

Syntax: [no] multicast port-version 2 | 3 <port-numbers>

Configuring static groups to the entire VLAN or to specific ports

A snooping-enabled VLAN cannot forward multicast traffic to ports that do not receive IGMP membership reports. If clients cannot send reports, you can configure a static group which applies to the entire VLAN or only to specific ports. The static group allows packets to be forwarded to the static group ports even though they have no client membership reports. The static group to the entire VLAN is used in VLAN flooding, which consumes less hardware resource than the static group to ports.

The static group drop option discards data traffic to a group in hardware. The group can be any multicast group including groups in the reserved range of 224.0.0.X. The drop option does not apply to IGMP packets, which are always trapped to CPU when snooping is enabled. The drop option applies to the entire VLAN, and cannot be configured for a port list. When the drop option is not specified, the group must exist outside the reserved range.

FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast static-group 224.1.1.1 count 2 ethe 0/1/3 ethe 0/1/5 to 0/1/7
FastIron(config-vlan-20)# multicast static-group 239.1.1.1 count 3 drop
FastIron(config-vlan-20)# multicast static-group 239.1.1.1

Syntax: [no] multicast static-group <ipv4-address> [count <num>] [<port-numbers> | drop]

The ipv4-address parameter is the address of the multicast group.

The count is optional, which allows a contiguous range of groups. Omitting the count <num> is equivalent to the count being 1.

If no <port-numbers> are entered, the static groups apply to the entire VLAN.

Configuring static router ports

FGS, FLS, FGS-STK, FLS-STK, FWS, and FCX devices forward all multicast control and data packets to router ports which receive queries. Although router ports are learned, you can force multicast traffic to specified ports even though these ports never receive queries. To configure static router ports, enter commands such as the following.

FastIron(config)# vlan 70
FastIron(config-vlan-70)# multicast router-port e 0/1/4 to 0/1/5 e 0/1/8

Syntax: [no] multicast router-port <port-numbers>
Turning off static group proxy

If a device has been configured for static groups, it acts as a proxy and sends membership reports for the static groups when it receives general or group-specific queries. When a static group configuration is removed, it is deleted from active group table immediately. However, leave messages are not sent to the querier, and the querier should age the group out. Proxy activity can be turned off. The default is on. To turn proxy activity off for VLAN 20, enter commands similar to the following.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast proxy-off
```

Syntax: \[no\] multicast proxy-off

Enabling IGMPv3 membership tracking and fast leave for the VLAN

Platform Support:
- FGS and FLS devices running software release 04.2.00 and later
- FWS devices running software release 04.3.00 or later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FCX-S devices running software release 06.0.00 and later

IGMPv3 gives clients membership tracking and fast leave capability. In IGMPv2, only one client on an interface needs to respond to a router's queries. This can leave some clients invisible to the router, making it impossible to track the membership of all clients in a group. When a client leaves the group, the device sends group-specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the device waits a few seconds before it stops the traffic. You can configure the wait time using the `ip multicast leave-wait-time` command.

IGMPv3 requires every client to respond to queries, allowing the device to track all clients. When tracking is enabled, and an IGMPv3 client sends a leave message and there is no other client, the device immediately stops forwarding traffic to the interface. This feature requires the entire VLAN be configured for IGMPv3 with no IGMPv2 clients. If a client does not send a report during the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.

Every group on a physical port keeps its own tracking record. However, it can only track group membership; it cannot track by (source, group). For example, Client A and Client B belong to group1 but each receives traffic streams from different sources. Client A receives a stream from (source_1, group1) and Client B receives a stream from (source_2, group1). The device still waits for the configured leave-wait-time before it stops the traffic because these two clients are in the same group. If the clients are in different groups, then the waiting period is not applied and traffic is stopped immediately.

To enable the tracking and fast leave feature for VLAN 20, enter the following commands.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast tracking
```

Syntax: \[no\] multicast tracking

The membership tracking and fast leave features are supported for IGMPv3 only. If any port or any client is not configured for IGMPv3, then the multicast tracking command is ignored.
Configuring fast leave for IGMPv2

When a device receives an IGMPv2 leave message, it sends out multiple group-specific queries. If no other client replies within the waiting period, the device stops forwarding traffic. When fast-leave-v2 is configured, when the device receives a leave message, it immediately stops forwarding to that port. The device does not send group specific-queries. You must ensure that no snooping-enabled ports have multiple clients. When two devices connect together, the querier should not be configured for fast-leave-v2, since the port might have multiple clients through the non-querier. The number of queries, and the waiting period (in seconds) can be configured using the `ip multicast leave-wait-time` command. The default is 2 seconds. To configure fast leave for IGMPv2, enter the following commands.

```plaintext
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast fast-leave-v2
```

Syntax: `[no] multicast fast-leave-v2`

Enabling fast convergence

In addition to sending periodic general queries, an active device sends general queries when it detects a new port. However, because the device does not recognize the other device's port up event, multicast traffic might still require up to the query-interval time to resume after a topology change. Fast convergence allows the device to listen to topology change events in L2 protocols such as spanning tree, and then send general queries to shorten the convergence time.

If the L2 protocol cannot detect a topology change, fast convergence may not work in some cases. For example, if the direct connection between two devices switches from one interface to another, the rapid spanning tree protocol (802.1w) considers this optimization, rather than a topology change. In this example, other devices will not receive topology change notifications, and will be unable to send queries to speed up the convergence. Fast convergence works well with the regular spanning tree protocol in this case.

To enable fast-convergence, enter the following commands.

```plaintext
FastIron(config)# vlan 70
FastIron(config-vlan-70)# multicast fast-convergence
```

Syntax: `multicast fast-convergence`

Displaying IGMP snooping information

You can display the following IGMP snooping information:

- IGMP information
- Information about VLANs
- Group and forwarding information for VLANs
- PIM sparse snooping information
- IGMP memory pool usage
- Status of IGMP traffic
- IGMP information by VLAN
**Displaying IGMP information**

To display information about possible IGMP errors, enter the following command.

```
FastIron# show ip multicast error
snoop SW processed pkt: 173, up-time 160 sec
```

**Syntax: show ip multicast error**

The following table describes the output from the `show ip multicast error` command.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW processed pkt</td>
<td>The number of multicast packets processed by IGMP snooping.</td>
</tr>
<tr>
<td>up-time</td>
<td>The time since the IGMP snooping is enabled.</td>
</tr>
</tbody>
</table>

**Displaying IGMP group information**

To display information about IGMP groups, enter the following command.

```
FastIron# show ip multicast group
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL70 : 3 groups, 4 group-port, tracking_enabled

<table>
<thead>
<tr>
<th>group</th>
<th>p-port</th>
<th>ST</th>
<th>QR</th>
<th>life</th>
<th>mode</th>
<th>source</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>224.1.1.2</td>
<td>0/1/33</td>
<td>no</td>
<td>yes</td>
<td>120</td>
<td>EX</td>
</tr>
<tr>
<td>2</td>
<td>224.1.1.1</td>

</tbody>
</table>
```

In this example, an IGMPv2 group is in EXCLUDE mode with a source of 0. The group only excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

To display detailed IGMP group information, enter the following command.

```
FastIron# show ip multicast group 226.1.1.1 detail
Display group 226.1.1.1 in all interfaces in details.

<table>
<thead>
<tr>
<th>group</th>
<th>p-port</th>
<th>ST</th>
<th>QR</th>
<th>life</th>
<th>mode</th>
<th>source</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>226.1.1.1</td>
<td>0/1/35</td>
<td>yes</td>
<td>yes</td>
<td>120</td>
<td>EX</td>
</tr>
</tbody>
</table>
| group: 226.1.1.1, EX, permit 0 (source, life):
  life=120, deny 0: |
| 2     | 226.1.1.1 | 0/1/33 | yes  | yes  | 120  | EX     |
| group: 226.1.1.1, EX, permit 0 (source, life):
  life=120, deny 0: |
```

If the tracking and fast leave features are enabled, you can display the list of clients that belong to a particular group by entering the following command.
Syntax:  show ip multicast group <group-address> [detail] [tracking]

If you want a report for a specific multicast group, enter that group's address for <group-address>.

Enter detail to display the source list of a specific VLAN.

Enter tracking for information on interfaces that have tracking enabled.

The following table describes the information displayed by the show ip multicast group command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>The address of the group (destination address in this case, 224.1.1.1)</td>
</tr>
<tr>
<td>p-port</td>
<td>The physical port on which the group membership was received.</td>
</tr>
<tr>
<td>ST</td>
<td>Yes indicates that the IGMP group was configured as a static group; No means the address was learned from reports.</td>
</tr>
<tr>
<td>QR</td>
<td>Yes means the port is a querier port; No means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the device.</td>
</tr>
<tr>
<td>life</td>
<td>The number of seconds the group can remain in EXCLUDE mode. An EXCLUDE mode changes to INCLUDE mode if it does not receive an &quot;IS_EX&quot; or &quot;TO_EX&quot; message during a certain period of time. The default is 140 seconds. There is no life displayed in INCLUDE mode.</td>
</tr>
<tr>
<td>mode</td>
<td>Indicates current mode of the interface: INCLUDE or EXCLUDE. If the interface is in INCLUDE mode, it admits traffic only from the source list. If an interface is in EXCLUDE mode, it denies traffic from the source list and accepts the rest.</td>
</tr>
<tr>
<td>source</td>
<td>Identifies the source list that will be included or excluded on the interface. For example, if an IGMPv2 group is in EXCLUDE mode with a source of 0, the group excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.</td>
</tr>
</tbody>
</table>

Displaying IGMP snooping Mcache information

The IGMP snooping mcache contains multicast forwarding information for VLANs. To display information in the multicast forwarding mcache, enter the following command.

FastIron# show ip multicast mcache
Example:  (S G) cnt=: cnt: SW proc. count
         OIF: 0/1/22 TR(0/1/32,0/1/33), TR is trunk, 0/1/32 primary, 0/1/33 output
         vlan 1, 1 caches. use 1 VIDX
         l  (1.2.10.102 225.1.1.1) cnt=46
         OIF: 0/1/4
         age=0m up-time=45m vidx=4130 (ref-cnt=1)
         vlan 70, 1 caches. use 1 VIDX
         l  (* 226.1.2.3) cnt=69
         OIF: 0/1/14
         age=0m up-time=59m vidx=4129 (ref-cnt=1)
Syntax: show ip multicast mcache

The following table describes the output of the `show ip multicast mcache` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>(source group)</td>
<td>Source and group addresses of this data stream. (* group) means match group only; (source group) means match both.</td>
</tr>
<tr>
<td>cnt</td>
<td>The number of packets processed in software. Packets are switched in hardware in FGS software release 03.0.00, which increases this number slowly.</td>
</tr>
<tr>
<td>OIF</td>
<td>The output interfaces. If <code>entire vlan</code> is displayed, this indicates that static groups apply to the entire VLAN.</td>
</tr>
<tr>
<td>age</td>
<td>The mcache age. The mcache will be reset to 0 if traffic continues to arrive, otherwise the mcache will be aged out when it reaches the time defined by the <code>ip multicast mcache-age</code> command.</td>
</tr>
<tr>
<td>uptime</td>
<td>The up time of this mcache in minutes.</td>
</tr>
<tr>
<td>vidx</td>
<td>Vidx specifies output port list index. Range is from 4096 to 8191.</td>
</tr>
<tr>
<td>ref-cnt</td>
<td>The vidx is shared among mcaches having the same output interfaces. Ref-cnt indicates the number of mcaches using this vidx.</td>
</tr>
</tbody>
</table>

**Displaying PIM sparse snooping information**

PIM sparse mode snooping allows a device to listen for join/prune messages exchanged between PIM routers, which helps reduce unwanted traffic. To display PIM snooping information, enter the following command.

```
FastIron# show ip multicast pimsm-snooping
vlan 1, has 1 caches.
  1  (1.2.10.102 225.1.1.1) has 0 pim join ports out of 1 OIF
vlan 70, has 1 caches.
  1  (* 226.1.2.3) has 2 pim join ports out of 2 OIF
    0/1/14 (age=60), 0/1/13 (age=60),
    0/1/14 has 1 src: 1.1.30.99(60)
    0/1/13 has 1 src: 1.1.30.99(60)
```

This output shows the number of OIF due to PIM out of the total OIF. The join/prune messages are source-specific. In this case, if the mcache is in (* G), the display function will also print the traffic source information.

**Displaying software resource usage for VLANs**

To display information about the software resources used, enter the following command.

```
FastIron# show ip multicast resource
+-------------+----------+----------+--------+----------+----------+----------+----------+
|              | alloc    | in-use   | avail   | get-fail| limit    | get-mem  | size     |

</table>
Displaying IGMP snooping information by VLAN

You can display IGMP snooping information for all VLANs or for a specific VLAN. For example, to display IGMP snooping information for VLAN 70, enter the following command.

```
FastIron# show ip multicast vlan 70
version=2, query-t=30, group-aging-t=140, max-resp-t=3, other-qr-present-t=63
VL70: dft V2, vlan cfg passive, , pimsm (vlan cfg), track, 0 grp, 1 (*G) cache,
rtr ports,
    router ports: 0/1/13(140) 1.1.70.3, 0/1/20(180) 1.1.70.2, 0/1/14(180)
0/1/13 has 0 groups, non-QR (passive), default V2
0/1/14 has 0 groups, non-QR (passive), default V2
0/1/20 has 0 groups, non-QR (passive), default V2
```

**Syntax:** `show ip multicast vlan [<vlan-id>]`

If you do not specify a `<vlan-id>`, information for all VLANs is displayed.

The following table describes the information displayed by the `show ip multicast vlan` command.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>version</strong></td>
<td>The IGMP version number</td>
</tr>
<tr>
<td><strong>query-t</strong></td>
<td>How often a querier sends a general query on the interface.</td>
</tr>
<tr>
<td><strong>group-aging-t</strong></td>
<td>The number of seconds membership groups can be members of this group before aging out.</td>
</tr>
<tr>
<td><strong>rtr-port</strong></td>
<td>The router ports which are the ports receiving queries. The display <strong>router ports:</strong> 0/1/13(140) 1.1.70.3 means port 0/1/13 has a querier with 1.1.70.3 address, and a remaining life of 140 seconds.</td>
</tr>
<tr>
<td><strong>max-resp-t</strong></td>
<td>The maximum number of seconds a client waits before it replies to the query.</td>
</tr>
<tr>
<td><strong>non-QR</strong></td>
<td>Indicates that the port is a non-querier.</td>
</tr>
<tr>
<td><strong>QR</strong></td>
<td>Indicates that the port is a querier.</td>
</tr>
</tbody>
</table>
Clear IGMP snooping commands

The clear IGMP snooping commands should be used only in troubleshooting conditions, or to recover from errors.

Clear IGMP counters on VLANs

To clear IGMP snooping on error and traffic counters for all VLANs, enter the following command.

```
FastIron# clear ip multicast counters
Syntax: clear ip multicast counters
```

Clear IGMP mcache

To clear the mcache on all VLANs, enter the following command.

```
FastIron# clear ip multicast mcache
Syntax: clear ip multicast mcache
```

Clear mcache on a specific VLAN

To clear the mcache on a specific VLAN, enter the following command.

```
FastIron# clear ip multicast vlan <vlan-id> mcache
Syntax: clear ip multicast vlan <vlan-id> mcache
```

The `<vlan-id>` parameter specifies the specific VLAN to clear the cache.

Clear traffic on a specific VLAN

To clear the traffic counters on a specific VLAN, enter the following command.

```
FastIron# clear ip multicast vlan <vlan-id> traffic
Syntax: clear ip multicast vlan <vlan-id> traffic
```

The `<vlan-id>` parameter specifies the specific VLAN on which to clear the traffic counters.
Chapter 27

IGMP snooping overview

**NOTE**

When a device processes a multicast packet, by default, it broadcasts the packets to all ports except the incoming port of a VLAN. Packets are flooded by hardware without going to the CPU. This behavior causes some clients to receive unwanted traffic.

IGMP snooping provides multicast containment by forwarding traffic to only the ports that have IGMP receivers for a specific multicast group (destination address). A device maintains the IGMP group membership information by processing the IGMP reports and leave messages, so traffic can be forwarded to ports receiving IGMP reports.

An IPv4 multicast address is a destination address in the range of 224.0.0.0 to 239.255.255.255. Addresses of 224.0.0.X are reserved. Because packets destined for these addresses may require VLAN flooding, devices do not snoop in the reserved range. Data packets destined to addresses in the reserved range are flooded to the entire VLAN by hardware, and mirrored to the CPU. Multicast data packets destined for the non-reserved range of addresses are snooped. A client must send IGMP reports in order to receive traffic. If an application outside the reserved range requires VLAN flooding, the user must configure a static group that applies to the entire VLAN.

An IGMP device's responsibility is to broadcast general queries periodically, and to send group queries when receiving a leave message, to confirm that none of the clients on the port still want specific traffic before removing the traffic from the port. IGMP V2 lets clients specify what group (destination address) will receive the traffic but not to specify the source of the traffic. IGMP V3 is for source-specific multicast traffic, adding the capability for clients to INCLUDE or EXCLUDE specific traffic sources. An IGMP V3 device port state could be INCLUDE or EXCLUDE, and there are different types of group records for client reports.

The interfaces respond to general or group queries by sending a membership report that contains one or more of the following records associated with a specific group:

- **Current-state record** that indicates from which sources the interface wants to receive and not receive traffic. This record contains the source address of interfaces and whether or not traffic will be included (IS_IN) or not excluded (IS_EX) from this source.
- **Filter-mode-change record**. If the interface state changes from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if the interface state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.
- An IGMP V2 leave report is equivalent to a TO_IN (empty) record in IGMP V3. This record means that no traffic from this group will be received regardless of the source.
- An IGMP V2 group report is equivalent to an IS_EX (empty) record in IGMP V3. This record means that all traffic from this group will be received regardless of source.
- Source-list-change record. If the interface wants to add or remove traffic sources from its membership report, the report can contain an ALLOW record, which includes a list of new sources from which the interface wishes to receive traffic. It can also contain a BLOCK record, which lists the current traffic sources from which the interface wants to stop receiving traffic.

IGMP protocols provide a method for clients and a device to exchange messages, and let the device build a database indicating which port wants what traffic. The protocols do not specify forwarding methods. They require IGMP snooping or multicast protocols such as PIM or DVMRP to handle packet forwarding. PIM and DVMRP can route multicast packets within and outside a VLAN, while IGMP snooping can switch packets only within a VLAN.

If a VLAN is not IGMP snooping-enabled, it floods multicast data and control packets to the entire VLAN in hardware. When snooping is enabled, IGMP packets are trapped to the CPU. Data packets are mirrored to the CPU in addition to being VLAN flooded. The CPU then installs hardware resources, so that subsequent data packets can be switched to desired ports in hardware without going to the CPU. If there is no client report or port to queriers for a data stream, the hardware resource drops it.

On TurboIron X Series devices, the hardware can either match the group address only (* G), or both the source and group (S G) of the data stream. If any IGMPv3 is configured in any port of a VLAN, this VLAN uses (S G) match; otherwise, it uses (* G). This is 32-bit IP address matching, not 23-bit multicast MAC address 01-00-5e-xx-xx-xx matching.

TurboIron X Series devices support up to 2K of IGMP groups, which are produced by client membership reports.

**MAC-based implementation on FastIron X Series devices**

**NOTE**
The MAC-based implementation applies to FastIron X Series devices only. This feature is not supported on TurboIron X Series devices.

On both switch and router software images, IGMP snooping is MAC-based. This differs from IGMP snooping on the BigIron router images, which match on both IP source and group (S,G) entries programmed in the Layer 4 CAM. In contrast, the FastIron X Series images match on Layer 2 destination MAC address entries (*,G).

When Layer 2 CAM is used, traffic is switched solely based on the destination MAC address. Consequently, traffic of the same group coming to the same port, regardless of its source, is switched in the same way. In addition, the lowest 23 bits of the group address are mapped to a MAC address. In this way, multiple groups (for example, 224.1.1.1 and 225.1.1.1) have the same MAC address. Groups having the same MAC address are switched to the same destination ports, which are the superset of individual group output ports. Thus, the use of Layer 2 CAM might cause unwanted packets to be sent to some ports. However, the switch generally needs far less Layer 2 CAM than it does Layer 4 CAM, which is required for each stream with a different source and group.

**IGMP V1, V2, and V3 snooping support**

Table 139 shows IGMP snooping version support by software release on FastIron X Series and TurboIron X Series devices.
Queriers and non-queriers

An IGMP snooping-enabled Brocade device can be configured as a querier (active) or non-querier (passive). An IGMP querier sends queries; a non-querier listens for IGMP queries and forwards them to the entire VLAN. VLANs can be independently configured to be queriers or non-queriers. If a VLAN has a connection to a PIM/DVMRP-enabled port on another router, the VLAN should be configured as a non-querier. When multiple IGMP snooping devices are connected together, and there is no connection to a PIM/DVMRP-enabled port, one of the devices should be configured as a querier. If multiple devices are configured as queriers, after these devices exchange queries, then all except the winner stop sending queries. The device with the lowest address becomes the querier. Although the system will work when multiple devices are configured as queriers, Brocade recommends that only one device (preferably the one with the traffic source) is configured as a querier.

The non-queriers always forward multicast data traffic and IGMP messages to router ports which receive IGMP queries or PIM/DVMRP hellos. Brocade recommends that you configure the device with the data traffic source (server) as a querier. If a server is attached to a non-querier, the non-querier always forwards traffic to the querier regardless of whether there are any clients on the querier.

NOTE
In a topology of one or more connecting devices, at least one device must be running PIM/DVMRP, or configured as active. Otherwise, none of the devices can send out queries, and traffic cannot be forwarded to clients.

IGMP snooping enhancements in software release 04.1.00

This section describes the enhancements to IGMP snooping in software release 04.1.00. These features are also supported on TurboIron X Series devices, except where noted.
Support for IGMP V3 snooping

Refer to “IGMP snooping overview” on page 803.

VLAN-specific configuration

IGMP snooping can be enabled on some VLANs or on all VLANs. Each VLAN can be independently configured to be a querier or non-querier and can be configured for IGMP V2 or IGMP V3. In general, the `ip multicast` commands apply globally to all VLANs except those configured with VLAN-specific `multicast` commands. The VLAN-specific multicast commands supersede the global `ip multicast` commands.

IGMP snooping can be configured for IGMP V2 or IGMP V3 on individual ports of a VLAN. An interface or router sends the queries and reports that include its IGMP version specified on it. The version configuration only applies to sending queries. The snooping device recognizes and processes IGMP V2 and IGMP V3 packets regardless of the version configuration.

To avoid version deadlock, an interface retains its version configuration even when it receives a report with a lower version.

Tracking and fast leave

Brocade devices support fast leave for IGMP V2, and tracking and fast leave for IGMP V3. Fast leave stops the traffic immediately when the port receives a leave message. Tracking traces all IGMP V3 clients. Refer to “IGMP V3 membership tracking and fast leave” on page 818 and “Fast leave for IGMP V2” on page 819.

IGMP snooping and layer 3 multicast routing together on the same device

NOTE
This feature is not supported on TurboIron X Series devices.

Software release FSX 04.1.00 adds support for global Layer 2 IP multicast traffic reduction (IGMP snooping) and Layer 3 multicast routing (DVMRP/PIM-Sparse/PIM-Dense) together on the same device in the full Layer 3 software image, as long as the Layer 2 feature configuration is at the VLAN level. Releases prior to FSX 04.1.00 support global Layer 2 IP multicast traffic reduction and Layer 3 multicast routing. However, they were mutually exclusive and configuring IGMP snooping on a VLAN together with DVMRP/PIM-Sparse/PIM-Dense was not allowed. Refer to “IP multicast protocols and IGMP snooping on the same device” on page 922.

Configuration notes and feature limitations for FastIron X Series devices

The following details apply to FastIron X Series devices:

- Layer 2 IGMP snooping is automatically enabled with Layer 3 multicast routing. If Layer 3 multicast routing is enabled on your system, do not attempt to enable Layer 2 IGMP snooping.
- The default IGMP version is V2.
- A user can configure the maximum numbers of group address entries.
• An IGMP device can be configured to rate-limit the forwarding IGMP V2 membership reports to queriers.
• The device supports static groups. The device acts as a proxy to send IGMP reports for the static groups when receiving queries.
• A user can configure static router ports to force all multicast traffic to these specific ports.
• If a VLAN has a connection to a PIM/DVMRP-enabled port on another router, the VLAN should be configured as a non-querier (passive). When multiple snooping devices connect together and there is no connection to PIM/DVMRP ports, one device should be configured as a querier (active). If multiple devices are configured as active (queriers), only one will keep sending queries after exchanging queries.
• The querier must configure an IP address to send out queries.
• IGMP snooping requires hardware resource. Hardware resource is installed only when there is data traffic. If resource is inadequate, the data stream without a resource is mirrored to the CPU in addition to being VLAN flooded, which can cause high CPU usage. Brocade recommends that you avoid global enabling of snooping unless necessary.
• IGMP snooping requires clients to send membership reports in order to receive data traffic. If a client application does not send reports, you must configure static groups on the snooping VLAN to force traffic to client ports. Note that servers (traffic sources) are not required to send IGMP memberships.

Configuration notes and feature limitations for TurboIron X Series devices

The following details apply to TurboIron X Series devices:
• Servers (traffic sources) are not required to send IGMP memberships.
• The default IGMP version is V2.
• Hardware resource is installed only when there is data traffic. If a VLAN is configured for IGMPv3, the hardware matches (S G), otherwise it matches (* G).
• A user can configure the maximum numbers of groups and hardware switched data streams.
• The device supports static groups that apply to the entire VLAN, or to just a few ports. The device acts as a proxy to send IGMP reports for the static groups when receiving queries.
• A user can configure static router ports to force all multicast traffic to these specific ports.
• Fast leave for IGMPv2 is supported. Fast leave stops traffic immediately when the port receives a leave message.
• Tracking and fast leave for IGMPv3 is supported. If the only client on a port leaves, traffic is stopped immediately.
• An IGMP device can be configured as a querier (active) or non-querier (passive). Queriers send queries. Non-queriers listen for queries and forward them to the entire VLAN.
• Every VLAN can be independently configured to be a querier or a non-querier.
• If a VLAN has a connection to a PIM/DVMRP-enabled port on another router, this VLAN should be configured as a non-querier (passive). When multiple snooping devices connect together and there is no connection to PIM/DVMRP ports, one device should be configured as a querier (active). If multiple devices are configured as active (queriers), only one will keep sending queries after exchanging queries.
PIM SM traffic snooping overview

When multiple PIM sparse routers connect through a snooping-enabled device, the Brocade device always forwards multicast traffic to these routers. For example, PIM sparse routers R1, R2 and R3 connect through a device. Assume R2 needs traffic, and R1 sends it to the device, which forwards it to both R2 and R3, even though R3 does not need it. A PIM SM snooping-enabled device listens to join and prune messages exchanged by PIM sparse routers, and stops traffic to the router that sends prune messages. This allows the device to forward the data stream to R2 only.

PIM SM traffic snooping requires IGMP snooping to be enabled on the device. IGMP snooping configures the device to listen for IGMP messages. PIM SM traffic snooping provides a finer level of multicast traffic control by configuring the device to listen specifically for PIM SM join and prune messages sent from one PIM SM router to another through the device.

PIM SM snooping support

Table 140 shows PIM SM snooping version support by software release on FastIron X Series and TurboIron X Series devices.

Application examples

Figure 110 shows an example application of the PIM SM traffic snooping feature. In this example, a device is connected through an IP router to a PIM SM group source that is sending traffic for two PIM SM groups. The device also is connected to a receiver for each of the groups.

When PIM SM traffic snooping is enabled, the device starts listening for PIM SM join and prune messages and IGMP group membership reports. Until the device receives a PIM SM join message or an IGMP group membership report, the device forwards IP multicast traffic out all ports. Once the device receives a join message or group membership report for a group, the device forwards subsequent traffic for that group only on the ports from which the join messages or IGMP reports were received.

In this example, the router connected to the receiver for group 239.255.162.1 sends a join message toward the group source. Since PIM SM traffic snooping is enabled on the device, the device examines the join message to learn the group ID, then makes a forwarding entry for the group ID and the port connected to the receiver router. The next time the device receives traffic for 239.255.162.1 from the group source, the device forwards the traffic only on port 5/1, since that is the only port connected to a receiver for the group.

Notice that the receiver for group 239.255.162.69 is directly connected to the device. As result, the device does not see a join message on behalf of the client. However, since IGMP snooping also is enabled, the device uses the IGMP group membership report from the client to select the port for forwarding traffic to group 239.255.162.69 receivers.

The IGMP snooping feature and the PIM SM traffic snooping feature together build a list of groups and forwarding ports for the VLAN. The list includes PIM SM groups learned through join messages as well as MAC addresses learned through IGMP group membership reports. In this case, even though the device never sees a join message for the receiver for group 239.255.162.69, the device nonetheless learns about the receiver and forwards group traffic to the receiver.

The device stops forwarding IP multicast traffic on a port for a group if the port receives a prune message for the group.

Notice that the ports connected to the source and the receivers are all in the same port-based VLAN on the device. This is required for the PIM SM snooping feature. The devices on the edge of the Global Ethernet cloud are configured for IGMP snooping and PIM SM traffic snooping. Although this application uses multiple devices, the feature has the same requirements and works the same way as it does on a single device.

The following figure shows another example application for PIM SM traffic snooping. This example shows devices on the edge of a Global Ethernet cloud (a Layer 2 Packet over SONET cloud). Assume that each device is attached to numerous other devices such as other Layer 2 Switches and Layer 3 Switches (routers).

NOTE
This example assumes that the devices are actually Brocade devices running Layer 2 Switch software.
The devices on the edge of the Global Ethernet cloud are configured for IGMP snooping and PIM SM traffic snooping. Although this application uses multiple devices, the feature has the same requirements and works the same way as it does on a single device.

**Configuration notes and limitations**

- PIM SM snooping applies only to PIM SM version 2 (PIM SM V2).
- Starting with software release FSX 04.1.00, PIM SM traffic snooping is supported in the Layer 2, base Layer 3, and full Layer 3 code. Releases prior to FSX 04.1.00 support PIM SM traffic snooping in the Layer 2 code only.
- Turbolron X Series devices running software release TIX 04.1.00 support PIM SM traffic snooping in the Layer 2 code.
- IGMP snooping must be enabled on the device that will be running PIM SM snooping. The PIM SM traffic snooping feature requires IGMP snooping.

**NOTE**
Use the passive mode of IGMP snooping instead of the active mode. The passive mode assumes that a router is sending group membership queries as well as join and prune messages on behalf of receivers. The active mode configures the device to send group membership queries.
• All the device ports connected to the source and receivers or routers must be in the same port-based VLAN.

• The PIM SM snooping feature assumes that the group source and the device are in different subnets and communicate through a router. The source must be in a different IP subnet than the receivers. A PIM SM router sends PIM join and prune messages on behalf of a multicast group receiver only when the router and the source are in different subnet. When the receiver and source are in the same subnet, they do not need the router in order to find one another. They find one another directly within the subnet.

The device forwards all IP multicast traffic by default. Once you enable IGMP snooping and PIM SM traffic snooping, the device initially blocks all PIM SM traffic instead of forwarding it. The device forwards PIM SM traffic to a receiver only when the device receives a join message from the receiver. Consequently, if the source and the downstream router are in the same subnet, and PIM SM traffic snooping is enabled, the device blocks the PIM SM traffic and never starts forwarding the traffic. This is because the device never receives a join message from the downstream router for the group. The downstream router and group find each other without a join message because they are in the same subnet.

**NOTE**
If the “route-only” feature is enabled on a Layer 3 Switch, PIM SM traffic snooping will not be supported.

## Configuring IGMP snooping

Configuring IGMP snooping on a Brocade device consists of the following global, VLAN-specific, and port-specific tasks:

### Global tasks

Perform the following global tasks:

- “Configuring the IGMP V3 snooping software resource limits”
- “Enabling IGMP snooping globally on the device”
- “Configuring the global IGMP mode”
- “Configuring the global IGMP version”
- “Modifying the age interval for group membership entries”
- “Modifying the query interval (active IGMP snooping mode only)”
- “Modifying the maximum response time”
- “Configuring report control” (rate limiting)
- “Modifying the wait time before stopping traffic when receiving a leave message”
- “Modifying the multicast cache age time”
- “Enabling or disabling error and warning messages”

### VLAN-specific tasks

Perform the following VLAN-specific tasks:

- “Configuring the IGMP mode for a VLAN” (active or passive)
- “Disabling IGMP snooping on a VLAN”
Configuring IGMP snooping

- “Configuring the IGMP version for a VLAN”
- “Configuring static router ports.”
- “Turning off static group proxy”
- “IGMP V3 membership tracking and fast leave”
- “Fast leave for IGMP V2”
- “Fast convergence”

Port-specific tasks
Perform the following port-specific tasks:
- “Disabling transmission and receipt of IGMP packets on a port”
- “Configuring the IGMP version for individual ports in a VLAN”

Configuring the IGMP V3 snooping software resource limits
By default, FastIron X Series devices support up to 512 IGMP snooping multicast cache (mcache) entries and a maximum of 8K IGMP group addresses. TurboIron X Series devices by default support up to 512 IGMP snooping multicast cache (mcache) entries and a maximum of 1K IGMP group addresses. If necessary, you can change the default values using the procedures in this section.

About IGMP snooping mcache entries and group addresses
An IGMP snooping group address entry is created when an IGMP join message is received for a group. An IGMP snooping mcache entry is created when data traffic is received for that group. Each mcache entry represents one data stream. The egress port list for the mcache entry is obtained from the IGMP group address entry. If there is no existing IGMP group address entry when an mcache entry is created, data traffic for that multicast group is dropped in hardware. If there is an existing IGMP group address entry when an mcache is created, data traffic for that multicast group is switched in hardware.

Changing the maximum number of supported IGMP snooping mcache entries
Platform Support:
- FastIron X Series devices running software release 04.1.00 or later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

When IGMP snooping is enabled, by default, the system supports up to 512 IGMP snooping mcache entries. If necessary, you can change the maximum number of IGMP snooping cache entries supported on the device. To do so, enter a command such as the following.

```
FastIron(config)# system-max igmp-snoop-mcache 2000
```

Syntax: `[no] system-max igmp-snoop-mcache <num>`
where `<num>` is a value between 256 and 8192 on FastIron X Series devices, or a value between 512 and 2048 on TurboIron X Series devices. The default for both device types is 512.

Setting the maximum number of IGMP group addresses
- FastIron X Series devices running software release 04.1.00 or later – L2, BL3, L3
• TurboIron X Series devices running software release 04.1.00 and later

When IGMP snooping is enabled, by default, FastIron X Series devices support up to 8K of IGMP group addresses, and the configurable range is from 256 to 32768. TurboIron X Series devices support up to 4K of IGMP group addresses by default, and the configurable range is from 4096 to 8192. The configured number is the upper limit of an expandable database. Client memberships exceeding the group limit are not processed. Enter a command such as the following to define the maximum number of IGMP group addresses.

```
FastIron(config)# system-max igmp-max-group-addr 1600
```

**Syntax:** `[no] system-max igmp-max-group-addr <num>`

where `<num>` is a value between 256 and 32768 on FastIron X Series devices, and the default is 8192. On TurboIron X Series devices, `<num>` is a value between 4096 and 8192 and the default is 4096.

### Enabling IGMP snooping globally on the device

Use the procedures in this section to enable IGMP snooping on a global basis.

**Configuration notes for layer devices**

- If Layer 3 multicast routing is enabled on your system, do not attempt to enable Layer 2 IGMP snooping. Layer 2 IGMP snooping is automatically enabled with Layer 3 multicast routing.
- If the "route-only" feature is enabled on the Layer 3 Switch, then IP multicast traffic reduction will not be supported.
- IGMP snooping is not supported on the default VLAN of Layer 3 Switches.

**Releases prior to FSX 04.1.00**

Use the following command to globally enable IGMP snooping in releases prior to FSX 04.1.00.

```
FastIron(config)# ip multicast
```

The above command enables IGMP V2. Starting with software release 04.1.00, IGMP V3 is also supported. Refer to “Releases FSX and TIX 04.1.00 and later” on page 813.

**Syntax:** `[no] ip multicast`

**Releases FSX and TIX 04.1.00 and later**

In releases 04.1.00 and later, when you globally enable IGMP snooping, you can specify IGMP V2 or IGMP V3 for the device. The following command enables IGMP V3.

```
FastIron(config)# ip multicast version 3
```

**Syntax:** `[no] ip multicast version 2|3`

If you do not specify a version number, IGMP V2 is assumed.

### Configuring the IGMP mode

You can configure active or passive IGMP modes on the Brocade device. The default mode is passive. If you specify an IGMP mode for a VLAN, it overrides the global setting.
• **Active** - When active IGMP mode is enabled, a Brocade device actively sends out IGMP queries to identify multicast groups on the network, and makes entries in the IGMP table based on the group membership reports it receives.

**NOTE**
Routers in the network generally handle this operation. Use the active IGMP mode only when the device is in a stand-alone Layer 2 Switched network with no external IP multicast router attachments. In this case, enable the active IGMP mode on only one of the devices and leave the other devices configured for passive IGMP mode.

• **Passive** - When passive IGMP mode is enabled, it forwards reports to the router ports which receive queries. IGMP snooping in the passive mode does not send queries. However, it forwards queries to the entire VLAN.

**Configuring the global IGMP mode**
To globally set the IGMP mode to active, enter the following command.

```
FastIron(config)# ip multicast active
```

**Syntax:** `[no] ip multicast [active | passive]`
If you do not enter either `active` or `passive`, the passive mode is assumed.

**Configuring the IGMP mode for a VLAN**

**Platform Support:**
• FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
• TurboIron X Series devices running software release 04.1.00 and later
If you specify an IGMP mode for a VLAN, it overrides the global setting.
To set the IGMP mode for VLAN 20 to active, enter the following commands.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast active
```

**Syntax:** `[no] multicast active | passive`

**Configuring the IGMP version**

**Platform Support:**
• FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
• TurboIron X Series devices running software release 04.1.00 and later

**Configuring the global IGMP version**
To globally specify IGMP V2 or IGMP V3, refer to “Releases FSX and TIX 04.1.00 and later” on page 813.
**Configuring the IGMP version for a VLAN**

You can specify the IGMP version for a VLAN. For example, the following commands configure VLAN 20 to use IGMP V3.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast version 3
```

Syntax: `[no] multicast version 2 | 3`

If no IGMP version is specified, then the globally-configured IGMP version is used. If an IGMP version is specified for individual ports, those ports use that version, instead of the VLAN version.

**Configuring the IGMP version for individual ports in a VLAN**

You can specify the IGMP version for individual ports in a VLAN. For example, the following commands configure ports 4, 5, and 6 to use IGMP V3. The other ports either use the IGMP version specified with the multicast version command, or the globally-configured IGMP version.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast port-version 3 ethe 2/4 to 2/6
```

Syntax: `[no] multicast port-version 2 | 3 <port-numbers>`

**Disabling IGMP snooping on a VLAN**

Platform Support:

- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

When IGMP snooping is enabled globally, you can still disable it for a specific VLAN. For example, the following commands cause IGMP snooping to be disabled for VLAN 20. This setting overrides the global setting.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast disable-multicast-snoop
```

Syntax: `[no] multicast disable-multicast-snoop`

**Disabling transmission and receipt of IGMP packets on a port**

When a VLAN is snooping-enabled, all IGMP packets are trapped to the CPU without hardware VLAN flooding. The CPU can block IGMP packets to and from a multicast-disabled port, and does not add it to the output interfaces of hardware resources. This prevents the disabled port from receiving multicast traffic. However, if static groups to the entire VLAN are defined, the traffic from these groups is VLAN flooded, including to disabled ports. Traffic from disabled ports cannot be blocked in hardware, and is switched in the same way as traffic from enabled ports.

This command has no effect on a VLAN that is not snooping-enabled because all multicast traffic is VLAN flooded.

To disable transmission and receipt of IGMP packets on a port, enter commands such as the following.
Configuring IGMP snooping

- FastIron(config)# interface ethernet 3
- FastIron(config-if-e1000-3)# ip-multicast-disable

The above commands disable IGMP snooping on port 1/5 but does not affect the state of IGMP on other ports.

Syntax: [no] ip-multicast-disable

Modifying the age interval for group membership entries

When the device receives a group membership report, it makes an entry for that group in the IGMP group table. The age interval specifies how long the entry can remain in the table before the device receives another group membership report. When multiple devices connect together, all devices should be configured for the same age interval, which should be at least twice the length of the query interval, so that missing one report won't stop traffic. Non-querier age intervals should be the same as the age interval of the querier.

To modify the age interval, enter a command such as the following.

- FastIron(config)# ip multicast age-interval 280

Syntax: [no] ip multicast age-interval <interval>

The <interval> parameter specifies the aging time. You can specify a value from 20 - 7200 seconds. The default is 260 seconds.

Modifying the query interval (active IGMP snooping mode only)

If IP multicast traffic reduction is set to active mode, you can modify the query interval to specify how often the device sends group membership queries. When multiple queriers connect together, they should all be configured with the same query interval.

To modify the query interval, enter a command such as the following.

- FastIron(config)# ip multicast query-interval 120

Syntax: [no] ip multicast query-interval <interval>

The <interval> parameter specifies the time between queries. You can specify a value from 10 - 3600 seconds. The default is 125 seconds.

Modifying the maximum response time

The maximum response time is the number of seconds that a client can wait before responding to a query sent by the switch. The default response time is 10 seconds maximum.

To change the maximum response time, enter a command such as the following.

- FastIron(config)# ip multicast max-response-time 5

Syntax: [no] ip multicast max-response-time <interval>

For <interval>, enter a value from 1 – 10 seconds. The default is 10 seconds.
Configuring report control

A device in passive mode forwards reports and leave messages from clients to the upstream router ports that are receiving queries.

You can configure report control to rate-limit report forwarding within the same group to no more than once every 10 seconds. This rate-limiting does not apply to the first report answering a group-specific query.

**NOTE**
This feature applies to IGMP V2 only. The leave messages are not rate limited.

IGMP V2 membership reports of the same group from different clients are considered to be the same and are rate-limited.

Use the following command to alleviate report storms from many clients answering the upstream router query.

FastIron(config)# ip multicast report-control

**Syntax:** `[no] ip multicast report-control`

The original command, `ip igmp-report-control`, has been renamed to `ip multicast report-control`. The original command is still accepted; however, it is renamed when you issue a `show configuration` command.

Modifying the wait time before stopping traffic when receiving a leave message

You can define the wait time before stopping traffic to a port when a leave message is received. The device sends group-specific queries once per second to ask if any client in the same port still needs this group. The value range is from 1 to 5, and the default is 2. Due to internal timer granularity, the actual wait time is between \( n \) and \((n+1)\) seconds (\(n\) is the configured value).

FastIron(config)# ip multicast leave-wait-time 1

**Syntax:** `[no] ip multicast leave-wait-time <num>`

\(<num>\) is the number of seconds from 1 to 5. The default is 2 seconds.

Modifying the multicast cache age time

You can set the time for an mcache to age out when it does not receive traffic. The traffic is hardware switched. One minute before aging out an mcache, the device mirrors a packet of this mcache to CPU to reset the age. If no data traffic arrives within one minute, this mcache is deleted. A lower value quickly removes resources consumed by idle streams, but it mirrors packets to CPU often. A higher value is recommended only data streams are continually arriving.

FastIron(config)# ip multicast mcache-age 180

**Syntax:** `[no] ip multicast mcache-age <num>`

\(<num>\) is the number of seconds from 60 to 3600. The default is 120 seconds.
Enabling or disabling error and warning messages

The device prints error or warning messages when it runs out of software resources or when it receives packets with the wrong checksum or groups. These messages are rate-limited. You can turn off these messages by entering a command such as the following.

```
FastIron(config)# ip multicast verbose-off
```

Syntax: `[no] ip multicast verbose-off`

Configuring static router ports

The Brocade device forwards all multicast control and data packets to router ports which receive queries. Although router ports are learned, you can force multicast traffic to specified ports even though these ports never receive queries. To configure static router ports, enter commands such as the following.

```
FastIron(config)# vlan 70
FastIron(config-vlan-70)# multicast router-port e 4 to 5 e 8
```

Syntax: `[no] multicast router-port <port-numbers>`

Turning off static group proxy

If a device has been configured for static groups, it acts as a proxy and sends membership reports for the static groups when it receives general or group-specific queries. When a static group configuration is removed, it is deleted from the active group table immediately. However, leave messages are not sent to the querier, and the querier should age out the group. Proxy activity can be turned off. The default is on. To turn proxy activity off for VLAN 20, enter commands similar to the following.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast proxy-off
```

Syntax: `[no] multicast proxy-off`

IGMP V3 membership tracking and fast leave

Platform Support:
- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

IGMP V3 gives clients membership tracking and fast leave capability. In IGMP V2, only one client on an interface needs to respond to a router’s queries. This can leave some clients invisible to the router, making it impossible to track the membership of all clients in a group. When a client leaves the group, the device sends group-specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the device waits a few seconds before it stops the traffic. You can configure the wait time using the `ip multicast leave-wait-time` command.
IGMP V3 requires every client to respond to queries, allowing the device to track all clients. When tracking is enabled, and an IGMP V3 client sends a leave message and there is no other client, the device immediately stops forwarding traffic to the interface. This feature requires the entire VLAN be configured for IGMP V3 with no IGMP V2 clients. If a client does not send a report during the specified group membership time (the default is 260 seconds), that client is removed from the tracking list.

Every group on a physical port keeps its own tracking record. However, it can only track group membership; it cannot track by (source, group). For example, Client A and Client B belong to group1 but each receives traffic streams from different sources. Client A receives a stream from (source_1, group1) and Client B receives a stream from (source_2, group1). The device still waits for the configured leave-wait-time before it stops the traffic because these two clients are in the same group. If the clients are in different groups, then the waiting period is not applied and traffic is stopped immediately.

**Enabling IGMP V3 membership tracking and fast leave for the VLAN**

To enable the tracking and fast leave feature for VLAN 20, enter the following commands.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast tracking
```

**Syntax:** `[no] multicast tracking`

The membership tracking and fast leave features are supported for IGMP V3 only. If any port or any client is not configured for IGMP V3, then the multicast tracking command is ignored.

**Fast leave for IGMP V2**

**Platform Support:**

- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

When a device receives an IGMP V2 leave message, it sends out multiple group-specific queries. If no other client replies within the waiting period, the device stops forwarding traffic. When fast-leave-v2 is configured, when the device receives a leave message, it immediately stops forwarding to that port. The device does not send group specific-queries. You must ensure that no snooping-enabled ports have multiple clients. When two devices connect together, the querier should not be configured for fast-leave-v2, since the port might have multiple clients through the non-querier. The number of queries, and the waiting period (in seconds) can be configured using the `ip multicast leave-wait-time` command. The default is 2 seconds.

**Enabling fast leave for IGMP V2**

To configure fast leave for IGMP V2, enter the following commands.

```
FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast fast-leave-v2
```

**Syntax:** `[no] multicast fast-leave-v2`

**Fast convergence**

**Platform Support:**
Configuring PIM SM snooping

Configuring PIM SM snooping on a Brocade device consists of the following global and VLAN-specific tasks.

Global task
Perform the following global tasks:
- “Enabling or disabling PIM SM snooping”

VLAN-specific tasks
Perform the following VLAN-specific tasks:
- “Enabling PIM SM snooping on a VLAN”
- “Disabling PIM SM snooping on a VLAN”

Enabling or disabling PIM SM snooping

PIM SM snooping should be used only in topologies where multiple PIM sparse routers connect through a device. PIM SM snooping does not work on a PIM dense mode router which does not send join messages, and traffic to PIM dense ports is stopped. A PIM SM snooping-enabled device displays a warning if it receives PIM dense join/prune messages.

To enable PIM sparse snooping globally, enter a command such as the following.

```
FastIron(config)# ip pimsm-snooping
```

This command enables PIM SM traffic snooping. The PIM SM traffic snooping feature assumes that the network has routers that are running PIM SM.
NOTE
The device must be in passive mode before it can be configured for PIM SM snooping.

To disable the feature, enter the following command.

FastIron(config)# no ip pimsm-snooping

If you also want to disable IP multicast traffic reduction, enter the following command.

FastIron(config)# no ip multicast

Syntax: [no] ip pimsm-snooping

Enabling PIM SM snooping on a VLAN

You can enable PIM SM snooping for a specific VLAN. For example, the following commands enable PIM SM snooping on VLAN 20.

FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast pimsm-snooping

Syntax: [no] multicast pimsm-snooping

Disabling PIM SM snooping on a VLAN

When PIM SM snooping is enabled globally, you can still disable it for a specific VLAN. For example, the following commands disable PIM SM snooping for VLAN 20. This setting overrides the global setting.

FastIron(config)# vlan 20
FastIron(config-vlan-20)# multicast disable-pimsm-snoop

Syntax: [no] multicast disable-pimsm-snoop

IGMP snooping show commands

This section shows how to display information about IGMP snooping, including:

- "Displaying the IGMP snooping configuration"
- "Displaying IGMP snooping errors"
- "Displaying IGMP group information"
- "Displaying IGMP snooping mcache information"
- "Displaying usage of hardware resource by multicast groups"
- "Displaying software resource usage for VLANs"
- "Displaying the status of IGMP snooping traffic"

Displaying the IGMP snooping configuration

To display the global IGMP snooping configuration, enter the following command at any level of the CLI.
IGMP snooping show commands

To display the IGMP snooping information for a specific VLAN (release 04.1.00 or later), enter a command such as the following.

```
FastIron# show ip multicast vlan 10
Version=3, Intervals: Query=10, Group Age=260, Max Resp=10, Other Qr=30
VL10: cfg V3, vlan cfg passive, , pimsm (vlan cfg), 3 grp, 1 (SG) cache, no rtr
port,
  e2 has 3 groups, non-QR (passive), default V3
  **** Warning! has V2 client (life=240),
    group: 239.0.0.3, life = 240
    group: 224.1.1.2, life = 240
    group: 224.1.1.1, life = 240
  e4 has 0 groups, non-QR (passive), default V3
```

Syntax: `show ip multicast vlan [<vlan-id>]`

If you do not specify a `<vlan-id>`, information for all VLANs is displayed.

This display shows the following information.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>The global IGMP version. In this example, the device is configured for IGMP version 2.</td>
</tr>
<tr>
<td>Query</td>
<td>How often a querier sends a general query on the interface. In this example, the general queries are sent every 125 seconds.</td>
</tr>
<tr>
<td>Group Age</td>
<td>The number of seconds membership groups can be members of this group before aging out.</td>
</tr>
<tr>
<td>Max Resp</td>
<td>The maximum number of seconds a client waits before replying to a query.</td>
</tr>
<tr>
<td>Other Qr</td>
<td>How long it took a switch with a lower IP address to become a new querier. This value is 2 x Query + Max Resp.</td>
</tr>
<tr>
<td>cfg</td>
<td>The IGMP version for the specified VLAN. In this example, VL10: cfg V3 indicates that VLAN 10 is configured for IGMP V3.</td>
</tr>
<tr>
<td>vlan cfg</td>
<td>The IGMP configuration mode, which is either passive or active.</td>
</tr>
<tr>
<td>pimsm</td>
<td>Indicates that PIM SM is enabled on the VLAN.</td>
</tr>
<tr>
<td>rtr port</td>
<td>The router ports, which are the ports receiving queries.</td>
</tr>
</tbody>
</table>

**Displaying IGMP snooping errors**

To display information about possible IGMP errors, enter the following command.

```
FastIron# show ip multicast error
snoop SW processed pkt: 173, up-time 160 sec
```

Syntax: `show ip multicast error`

The following table describes the output from the `show ip multicast error` command.
IGMP snooping show commands

Displaying IGMP group information

Platform Support:

- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

To display information about IGMP groups, enter the following command.

```
FastIron# show ip multicast group
```

### Syntax: `show ip multicast group` [ `<group-address>` ] [ `detail` ] [ `tracking` ]

**This field Displays**

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW processed pkt</td>
<td>The number of multicast packets processed by IGMP snooping.</td>
</tr>
<tr>
<td>up-time</td>
<td>The time since the IGMP snooping is enabled.</td>
</tr>
</tbody>
</table>

In this example, an IGMP V2 group is in EXCLUDE mode with a source of 0. The group only excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

To display detailed IGMP group information for a specific group, enter the following command.

```
FastIron# show ip multicast group 226.1.1.1 detail
```

**If the tracking and fast leave features are enabled, you can display the list of clients that belong to a particular group by entering the following command.**

```
FastIron# show ip multicast group 224.1.1.1 tracking
```

### Syntax: `show ip multicast group [ `<group-address>` ] [ `detail` ] [ `tracking` ]`
If you want a report for a specific multicast group, enter that group’s address for `<group-address>`. Enter detail to display the source list of a specific VLAN. Enter tracking for information on interfaces that have tracking enabled.

The following table describes the information displayed by the `show ip multicast group` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>The address of the group (destination address in this case, 224.1.1.1)</td>
</tr>
<tr>
<td>p-port</td>
<td>The physical port on which the group membership was received.</td>
</tr>
<tr>
<td>ST</td>
<td><em>Yes</em> indicates that the IGMP group was configured as a static group; <em>No</em> means the address was learned from reports.</td>
</tr>
<tr>
<td>QR</td>
<td><em>Yes</em> means the port is a querier port; <em>No</em> means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the device.</td>
</tr>
<tr>
<td>life</td>
<td>The number of seconds the group can remain in EXCLUDE mode. An EXCLUDE mode changes to INCLUDE mode if it does not receive an &quot;IS_EX&quot; or &quot;TO_EX&quot; message during a certain period of time. The default is 260 seconds. There is no life displayed in INCLUDE mode.</td>
</tr>
<tr>
<td>mode</td>
<td>Indicates current mode of the interface: INCLUDE or EXCLUDE. If the interface is in INCLUDE mode, it admits traffic only from the source list. If an interface is in EXCLUDE mode, it denies traffic from the source list and accepts the rest.</td>
</tr>
<tr>
<td>source</td>
<td>Identifies the source list that will be included or excluded on the interface. For example, if an IGMP V2 group is in EXCLUDE mode with a source of 0, the group excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.</td>
</tr>
</tbody>
</table>

**Displaying IGMP snooping mcache information**

**Platform Support:**
- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

The IGMP snooping mcache contains multicast forwarding information for VLANs. To display information in the multicast forwarding mcache, enter the following command.

```
FastIron# show ip multicast mcache
```

Example: (S G) cnt=0: cnt is number of SW processed packets
- OIF: el/22 TR(1/32,1/33), TR is trunk, el/32 primary, el/33 output
- vlan 10, 1 caches. use 1 VIDX
  - 1 (10.10.10.2 239.0.0.3) cnt=0
    - OIF: tag e2
      - age=2s up-time=2s change=2s vidx=8191 (ref-cnt=1)

**Syntax: show ip multicast mcache**

The following table describes the output of the `show ip multicast mcache` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>(source group)</td>
<td>Source and group addresses of this data stream. (+ group) means match group only; (source group) means match both.</td>
</tr>
<tr>
<td>cnt</td>
<td>The number of packets processed in software. Packets are switched in hardware, which increases this number slowly.</td>
</tr>
</tbody>
</table>
You can display how much hardware resource (CAM and FID) is currently being used by multicast groups by entering a command such as the following at any level of the CLI.

```
FastIron# show ip multicast hardware
Hw resource is shared by groups with the same lower 23 bits
VLAN ID 2
Total number of HW resource in vlan: 1
  Group: 0.1.1.1, HW-ref-cnt=1, vidx 8191
    Forwarding Port: 2
VLAN ID 1
Total number of HW resource in vlan: 0
```

If you want to display the amount of hardware resource that is currently being used by a specific group, enter a command such as the following at any level of the CLI.

```
FastIron# show ip multicast hardware 239.255.163.2
VLAN ID 100
  Group: 239.255.163.2, HW-ref-cnt=1, fid 08a9, cam 10, dma=8,
    Forwarding Port: 1 2
group 239.255.163.2 in 1 vlans
```

Syntax: `show ip multicast hardware [ <group-address> | vlan <vlan-id> ]`

Enter the address of a group for `<group-address>` if you want to display the hardware resource usage of a particular group.

Likewise, enter the ID of a VLAN for `<vlan-id>` if you want display the hardware resource usage of groups in a VLAN.

The display shows the following information.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN ID</td>
<td>The port-based VLAN to which the information listed below applies.</td>
</tr>
<tr>
<td>Total number of HW resource in VLAN</td>
<td>The number of resources in the VLAN.</td>
</tr>
</tbody>
</table>
IGMP snooping show commands

Displaying software resource usage for VLANs

Platform Support:
- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

To display information about the software resources used, enter the following command:

```
FastIron# show ip multicast resource
```

This field... Displays...
--- | --------------------------------------------------
Group | Address of the IP multicast group that is using the entry. In the display above, group “0.1.1.1” is using this entry. The field HW-ref-cnt shows the number of groups that are sharing this entry. Multiple groups could share one entry because only low 23 bits are significant.
NOTE: The vidx, fid, cam, and dma values are used by Brocade Technical Support for troubleshooting.

Forwarding Port | The forwarding ports for the IP multicast group.

This field... Displays...
--- | --------------------------------------------------
Group | Address of the IP multicast group that is using the entry. In the display above, group “0.1.1.1” is using this entry. The field HW-ref-cnt shows the number of groups that are sharing this entry. Multiple groups could share one entry because only low 23 bits are significant.
NOTE: The vidx, fid, cam, and dma values are used by Brocade Technical Support for troubleshooting.

Platform Support:
- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

To display information about the software resources used, enter the following command.

```
FastIron# show ip multicast resource
```

This field... Displays...
--- | --------------------------------------------------
alloc in-use | The allocated number of units.
in-use | The number of units which are currently being used.
avail | The number of available units.
get-fail | This displays the number of resource failures.
NOTE: It is important to pay attention to this field.
limit | The upper limit of this expandable field. The limit of multicast group is configured by the system-max igmp-max-group-addr command. The limit of snoop mcache entry is configured by the system-max multicast-snoop-mcache command.
get-mem | The number of memory allocation. This number should continue to increase.
size | The size of a unit (in bytes).
init | The initial allocated amount of memory. More memory may be allocated if resources run out.
Available vidx | The output interface (OIF) port mask used by mcache. The entire device has a maximum of 4096 vidx. Different mcaches with the same OIF share the same vidx. If vidx is not available, the stream cannot be hardware-switched.

deleted ... | ... entries deleted ...
snoop mcache entry | 128 2 126 0 8192 3 56 128
total pool memory 109056 bytes

PIM SM snooping show commands

This section shows how to display information about PIM SM snooping, including:

- “Displaying PIM SM snooping information”
- “Displaying PIM SM snooping information on a Layer 2 switch”
- “Displaying PIM SM snooping information for a specific group or source group pair”

Displaying PIM SM snooping information

To display PIM SM snooping information, enter the following command.

```
FastIron# show ip multicast pimsm-snooping
vlan 1, has 2 caches.
1  (* 230.1.1.1) has 1 pim join ports out of 1 OIF
   1 (age=60)
   1 has 1 src: 20.20.20.66(60)
2  (* 230.2.2.2) has 1 pim join ports out of 1 OIF
   1 (age=60)
   1 has 1 src: 20.20.20.66(60)
```

This output shows the number of PIM join outgoing interfaces (OIF) out of the total OIF. The join/prune messages are source-specific. In this case, if the mcache is in (* G), the display function will also print the traffic source information.

**Syntax:** show ip multicast pimsm-snooping [vlan-id]

Use the <vlan-id> parameter to display PIM SM snooping information for a specific VLAN.

Displaying PIM SM snooping information on a Layer 2 switch

You can display PIM SM snooping information for all groups by entering the following command at any level of the CLI on a Layer 2 Switch.
Syntax: show ip pimsm-snooping vlan <vlan-id>

Enter the ID of the VLAN for the vlan <vlan-id> parameter.

If you want to display PIM SM snooping information for one source or one group, enter a command as in the following example. The command also displays the (source, port) list of the group.

FastIron# show ip multicast pimsm-snooping vlan 100
VLAN ID 100, total 3 entries
PIMSM Neighbor list:
  1.100.100.12 : 3/3 expire 120 s
  1.100.100.10 : 3/2 expire 170 s
  1.100.100.7 : 3/1 expire 160 s
1 Group: 224.0.1.22, fid 08ac, NO cam
   Forwarding Port: 3/3
   PIMv2 Group Port: 3/3
   (Source, Port) list: 1 entries
2 Group: 239.255.162.2, fid 08aa, cam 8
   Forwarding Port: 3/1 3/2
   PIMv2 Group Port: 3/1 3/2
   (Source, Port) list: 3 entries
3 Group: 239.255.163.2, fid 08a9, cam 10
   Forwarding Port: 3/1 3/2
   PIMv2 Group Port: 3/1 3/2
   (Source, Port) list: 3 entries
VLAN ID 4008, total 0 entries
PIMSM Neighbor list:

Syntax: show ip pimsm-snooping <group-address> | <source-address>

If the address you entered is within the range of source addresses, then the router treats it as the source address. Likewise, if the address falls in the range of group addresses, then the router assumes that you are requesting a report for that group.

This display shows the following information.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN ID</td>
<td>The port-based VLAN to which the information listed below apply and the number of members in the VLAN.</td>
</tr>
<tr>
<td>PIM SM Neighbor list</td>
<td>The PIM SM routers that are attached to the Layer 2 Switch ports. The value following “expires” indicates how many seconds the Layer 2 Switch will wait for a hello message from the neighbor before determining that the neighbor is no longer present and removing the neighbor from the list.</td>
</tr>
<tr>
<td>Multicast Group</td>
<td>The IP address of the multicast group.</td>
</tr>
</tbody>
</table>

NOTE: The fid and camindex values are used by Brocade Technical Support for troubleshooting.
Clear commands for IGMP snooping

Platform Support:

- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
• TurboIron X Series devices running software release 04.1.00 and later

The clear IGMP snooping commands should be used only in troubleshooting conditions, or to recover from errors.

Clearing the IGMP mcache

To clear the mcache on all VLANs, enter the following command.

FastIron# clear ip multicast mcache

Syntax: clear ip multicast mcache

Clearing the mcache on a specific VLAN

To clear the mcache on a specific VLAN, enter the following command.

FastIron# clear ip multicast vlan 10 mcache

Syntax: clear ip multicast vlan <vlan-id> mcache

The <vlan-id> parameter specifies the specific VLAN to clear the cache.

Clearing traffic on a specific VLAN

To clear the traffic counters on a specific VLAN, enter the following command.

FastIron# clear ip multicast vlan 10 traffic

Syntax: clear ip multicast vlan <vlan-id> traffic

The <vlan-id> parameter specifies the specific VLAN on which to clear the traffic counters.

Clearing IGMP counters on VLANs

To clear IGMP snooping on error and traffic counters for all VLANs, enter the following command.

FastIron# clear ip multicast counters

Syntax: clear ip multicast counters
Clear commands for IGMP snooping
Chapter 28

Configuring IP Multicast Protocols

This chapter describes how to configure Brocade Layer 3 Switches for Protocol Independent Multicast (PIM) and Distance Vector Multicast Routing Protocol (DVMRP). Brocade Layer 3 Switches support the following IP multicast versions:

- Internet Group Management Protocol (IGMP) V1 and V2
- Internet Group Management Protocol (IGMP) V3
- PIM Dense mode (PIM DM) V1 (draft-ietf-pim-dm-05) and V2 (draft-ietf-pim-v2-dm-03)
- PIM Sparse mode (PIM SM) V2 (RFC 2362)
- PIM Passive mode (multicast stub routing)
- DVMRP V2 (RFC 1075)
- Multiprotocol Source Discovery Protocol (MSDP)

**NOTE**
Each multicast protocol uses IGMP. IGMP is automatically enabled on an interface when you configure PIM or DVMRP and is disabled on the interface if you disable PIM or DVMRP.

**NOTE**
This chapter applies only to IP multicast routing. To configure Layer 2 multicast features, refer to Chapter 27, “Configuring IP Multicast Traffic Reduction for FastIron X Series and TurboIron Series Switches”.

Overview of IP multicasting

Multicast protocols allow a group or channel to be accessed over different networks by multiple stations (clients) for the receipt and transmit of multicast data.

Distribution of stock quotes, video transmissions such as news services and remote classrooms, and video conferencing are all examples of applications that use multicast routing.

IPv4 multicast group addresses

In IPv4 Multicast, host groups are identified by Class D addresses, i.e., those with “1110” as their higher-order four bits. In Internet standard “dotted decimal” notation, these group addresses range from 224.0.0.0 to 239.255.255.255. However, the IANA IPv4 Multicast Address Registry (referencing RFC 3171) stipulates that the range 224.0.0.0 through 224.0.0.255 should not be used for regular multicasting applications.

“The range of addresses between 224.0.0.0 and 224.0.0.255, inclusive, is reserved for the use of routing protocols and other low-level topology discovery or maintenance protocols, such as gateway discovery and group membership reporting. Multicast routers should not forward any multicast datagram with destination addresses in this range, regardless of its TTL.”
Mapping of IPv4 Multicast group addresses to Ethernet MAC addresses

The IANA owns a block of Ethernet MAC addresses for Multicast usage that are in the range 0100.5e00.0000 through 0100.5e7F.FFFF. For a given IPv4 Multicast group, there is a simple way of obtaining the appropriate Ethernet Destination MAC address that must be used in Layer 2 encapsulation. This is defined in RFC 1112, as follows:

“An IP host group address is mapped to an Ethernet multicast address by placing the low-order 23-bits of the IP address into the low-order 23 bits of the Ethernet multicast address 01-00-5E-00-00-00 (hex). Because there are 28 significant bits in an IP host group address, more than one host group address may map to the same Ethernet multicast address.”

**NOTE**

Since there are 5 bits in the IPv4 Group address that are not used in the mapping, there is a possibility for up to 32 IPv4 Multicast Groups to use the same Ethernet Destination MAC address. Taking this into account along with the reserved IPv4 Group address range, it is discouraged for applications to use IPv4 Multicast Group Addresses that may conflict with the reserved addresses at the Layer 2 level. This is because some devices may use just the Ethernet Destination MAC address to take actions on the packet.

Supported Layer 3 multicast routing protocols

Brocade Layer 3 Switches support two different multicast routing protocols—Distance Vector Multicast Routing Protocol (DVMRP) and Protocol-Independent Multicast (PIM) protocol along with the Internet Group Membership Protocol (IGMP).

PIM and DVMRP are broadcast and pruning multicast protocols that deliver IP multicast datagrams. The protocols employ reverse path lookup check and pruning to allow source-specific multicast delivery trees to reach all group members. DVMRP and PIM build a different multicast tree for each source and destination host group.

**NOTE**

Both DVMRP and PIM can concurrently operate on different ports of a Brocade Layer 3 Switch.

Multicast terms

The following are commonly used terms in discussing multicast-capable routers. These terms are used throughout this chapter:

- **Node**: Refers to a router or Layer 3 Switch.
- **Root Node**: The node that initiates the tree building process. It is also the router that sends the multicast packets down the multicast delivery tree.
- **Upstream**: Represents the direction from which a router receives multicast data packets. An upstream router is a node that sends multicast packets.
- **Downstream**: Represents the direction to which a router forwards multicast data packets. A downstream router is a node that receives multicast packets from upstream transmissions.
- **Group Presence**: Means that a multicast group has been learned from one of the directly connected interfaces. Members of the multicast group are present on the router.
- **Intermediate nodes**: Routers that are in the path between source routers and leaf routers.
• **Leaf nodes**: Routers that do not have any downstream routers.

• **Multicast Tree**: A unique tree is built for each source group (S,G) pair. A multicast tree is comprised of a root node and one or more nodes that are leaf or intermediate nodes.

### Changing global IP multicast parameters

The following configurable parameters apply to PIM-DM, PIM-SM, and DVMRP:

- Maximum number of PIM or DVMRP groups – You can change the maximum number of groups of each type for which the software will allocate memory. By default, Layer 3 Switches support up to 1024 PIM groups and 1024 DVMRP groups.
- Internet Group Membership Protocol (IGMP) V1 and V2 parameters – You can change the query interval, group membership time, and maximum response time.
- Hardware forwarding of fragmented IP multicast packets – You can enable the Layer 3 Switch to forward all fragments of fragmented IP multicast packets in hardware.

### Changing dynamic memory allocation for IP multicast groups

Layer 3 Switches support up to 1024 PIM groups and 1024 DVMRP groups by default. Memory for the groups is allocated dynamically as needed. For each protocol, previous releases support a maximum of 255 groups and 255 IGMP memberships.

**NOTE**
The number of interface groups you can configure for DVMRP and PIM is unlimited; therefore, the `system-max dvmrp-max-int-group` and the `system-max pim-max-int-group` commands that define their maximum table sizes have been removed.

The software allocates memory globally for each group, and also allocates memory separately for each interface IGMP membership in a multicast group. An interface becomes a member of a multicast group when the interface receives an IGMP group membership report. For example, if the Layer 3 Switch learns about one multicast group, global memory for one group is used. In addition, if three interfaces on the device receive IGMP group membership reports for the group, interface memory for three IGMP memberships also is used.

Since the same group can use multiple allocations of memory (one for the group itself and one for each interface membership in the group), you can increase the maximum number of IGMP memberships, up to 8192.

**NOTE**
The total for IGMP memberships applies to the device, not to individual interfaces. You can have up to 8192 IGMP memberships on all the individual interfaces, not up to 8192 IGMP memberships on each interface.

### Increasing the number of IGMP memberships

To increase the number of IGMP membership interfaces for PIM, enter commands such as the following.
Changing global IP multicast parameters

FastIron(config)#system-max pim-max-int-group 4000
FastIron(config)#write memory

This command enables the device to have up to 4000 IGMP memberships for PIM.

**NOTE**
The **system-max pim-max-int-group** command is no longer available since you can configure an unlimited number of PIM interface groups for DVMRP.

**Syntax:** `[no] system-max pim-max-int-group <num>`

The `<num>` parameter specifies the maximum number of IGMP memberships for PIM, and can be from 256 – 8192.

To increase the number of IGMP memberships interfaces you can have for DVMRP, enter commands such as the following.

FastIron(config)#system-max dvmrp-max-int-group 3000
FastIron(config)#write memory

**NOTE**
The **system-max dvmrp-max-int-group** command is no longer available since you can configure an unlimited number of DVMRP interface groups.

**Syntax:** `[no] system-max dvmrp-max-int-group <num>`

The `<num>` parameter specifies the maximum number of IGMP memberships for DVMRP, and can be from 256 – 8192.

**NOTE**
You do not need to reload the software for these changes to take effect.

**Defining the maximum number of DVMRP cache entries**

The DVMRP cache system parameter defines the maximum number of repeated DVMRP traffic being sent from the same source address and being received by the same destination address. To define this maximum, enter a command such as the following.

FastIron(config)#system-max dvmrp-mcache 500

**Syntax:** `system-max dvmrp-mcache <num>`

The `<num>` parameter specifies the maximum number of multicast cache entries for DVMRP. Enter a number from 128 – 2048. The default is 512.

**Defining the maximum number of PIM cache entries**

The PIM cache system parameter defines the maximum number of repeated PIM traffic being sent from the same source address and being received by the same destination address. To define this maximum, enter a command such as the following.

FastIron(config)#system-max pim-mcache 999

**Syntax:** `system-max pim-mcache <num>`

The `<num>` parameter specifies the maximum number of multicast cache entries for PIM. Enter a number from 256 – 4096. The default is 1024.
Changing IGMP V1 and V2 parameters

IGMP allows Brocade routers to limit the multicast of IGMP packets to only those ports on the router that are identified as IP Multicast members. This section applies to Brocade devices that support IGMP versions 1 and 2.

The router actively sends out host queries to identify IP Multicast groups on the network, inserts the group information in an IGMP packet, and forwards the packet to IP Multicast neighbors.

The following IGMP V1 and V2 parameters apply to PIM and DVMRP:

- IGMP query interval – Specifies how often the Layer 3 Switch queries an interface for group membership. Possible values are 1 – 3600. The default is 60.
- IGMP group membership time – Specifies how many seconds an IP Multicast group can remain on a Layer 3 Switch interface in the absence of a group report. Possible values are 1 – 7200. The default is 60.
- IGMP maximum response time – Specifies how many seconds the Layer 3 Switch will wait for an IGMP response from an interface before concluding that the group member on that interface is down and removing the interface from the group. Possible values are 1 – 10. The default is 5.

To change these parameters, you must first enable IP multicast routing by entering the following CLI command at the global CLI level.

FastIron(config)#ip multicast-routing

Syntax: [no] ip multicast-routing

**NOTE**
You must enter the `ip multicast-routing` command before changing the global IP Multicast parameters. Otherwise, the changes do not take effect and the software uses the default values.

**Modifying IGMP (V1 and V2) query interval period**

The IGMP query interval period defines how often a router will query an interface for group membership. Possible values are 1-3, 600 seconds and the default value is 60 seconds.

To modify the default value for the IGMP (V1 and V2) query interval, enter the following.

FastIron(config)#ip igmp query 120

Syntax: `ip igmp query-interval <1-3600>`

**Modifying IGMP (V1 and V2) membership time**

Group membership time defines how long a group will remain active on an interface in the absence of a group report. Possible values are from 1 – 7200 seconds and the default value is 140 seconds.

To define an IGMP (V1 and V2) membership time of 240 seconds, enter the following.

FastIron(config)#ip igmp group-membership-time 240

Syntax: `ip igmp group-membership-time <1-7200>`
Modifying IGMP (V1 and V2) maximum response time

Maximum response time defines how long the Layer 3 Switch will wait for an IGMP (V1 and V2) response from an interface before concluding that the group member on that interface is down and removing the interface from the group. Possible values are 1 – 10. The default is 10.

To change the IGMP (V1 and V2) maximum response time, enter a command such as the following at the global CONFIG level of the CLI.

```plaintext
FastIron(config)#ip igmp max-response-time 8
```

Syntax: [no] ip igmp max-response-time <num>

The `<num>` parameter specifies the number of seconds and can be a value from 1 – 10. The default is 10.

Adding an interface to a multicast group

You can manually add an interface to a multicast group. This is useful in the following cases:

- Hosts attached to the interface are unable to add themselves as members of the group using IGMP.
- There are no members for the group attached to the interface.

When you manually add an interface to a multicast group, the Brocade device forwards multicast packets for the group but does not itself accept packets for the group.

You can manually add a multicast group to individual ports only. If the port is a member of a virtual routing interface, you must add the ports to the group individually.

To manually add a port to a multicast group, enter a command such as the following at the configuration level for the port.

```plaintext
FastIron(config-if-1/1)#ip igmp static-group 224.2.2.2
```

This command adds port 1/1 to multicast group 224.2.2.2.

To add a port that is a member of a virtual routing interface to a multicast group, enter a command such as the following at the configuration level for the virtual routing interface.

```plaintext
FastIron(config-vif-1)#ip igmp static-group 224.2.2.2 ethernet 5/2
```

This command adds port 5/2 in virtual routing interface 1 to multicast group 224.2.2.2.

Syntax: [no] ip igmp static-group <ip-addr> [ethernet <portnum>]

The `<ip-addr>` parameter specifies the group number.

The `ethernet <portnum>` parameter specifies the port number. Use this parameter if the port is a member of a virtual routing interface, and you are entering this command at the configuration level for the virtual routing interface.

Manually added groups are included in the group information displayed by the following commands:

- show ip igmp group
- show ip pim group
IP multicast boundaries

The multicast boundary feature is designed to selectively allow or disallow multicast flows to configured interfaces.

The **ip multicast-boundary** command allows you to configure a boundary on PIM enabled interface by defining which multicast groups may not forward packets over a specified interface. This includes incoming and outgoing packets. By default, all interfaces that are enabled for multicast are eligible to participate in a multicast flow provided they meet the multicast routing protocol criteria for participating in a flow.

**Configuration considerations**

- Only one ACL can be bound to any interface.
- Normal ACL restrictions apply as to how many software ACLs can be created, but there are no hardware restrictions on ACLs with this feature.
- Creation of a static IGMP client is allowed for a group on a port that may be prevented from participation in the group on account of an ACL bound to the port interface. In such a situation, the ACL would prevail and the port will not be added to the relevant entries.
- Only standard ACLs can be used with the multicast boundary feature. When a standard ACL is used, the address specified is treated as a group address and NOT a source address.
- When a boundary is applied to an ingress interface, all packets destined to a multicast group that is filtered out will be dropped by software. Currently, there is no support to drop such packets in hardware.

**Configuring multicast boundaries**

To define boundaries for PIM enabled interfaces, enter a commands such as the following.

```
FastIron(config)#interface ve 40
FastIron(config-vif-40)#ip multicast-boundary MyBrocadeAccessList
```

**Syntax:** `[no] ip multicast-boundary `<ACL-spec>`

Use the **ACL-spec** parameter to define the number or name identifying an access list that controls the range of group addresses affected by the boundary.

Use the **no ip multicast boundary** command to remove the boundary on a PIM enabled interface.

**NOTE**
The ACL, **MyBrocadeAccessList**, can be configured using standard ACL syntax which can be found in the ACL section.

**Displaying multicast boundaries**

To display multicast boundary information, use the **show ip pim interface** command.
NOTE
The above command displays a specified PIM enabled interface. The keyword **passive** specifies if the interface is Passive.

If no interface is specified, the `show ip pim interface` command displays information about all the PIM-enabled interfaces.

```
FastIron (config)# show ip pim interface ethernet 2
Interface e2
PIM Dense: V2[passive]
TTL Threshold: 1, Disabled, DR: itself
Local Address: 23.23.23.23

Interface e3
PIM Dense: V2
TTL Threshold: 1, Disabled, DR: itself
Local Address: 41.41.41.41

Interface v2
PIM Sparse[passive]
TTL Threshold: 1, Disabled, DR: itself
Local Address: 32.32.32.32
```

Syntax: `show ip pim interface [ethernet <slot>/<portnum> | ve <num>]`

### PIM Dense

**NOTE**
This section describes the “dense” mode of PIM, described in RFC 1075. Refer to “PIM Sparse” on page 849 for information about PIM Sparse.

**NOTE**
On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

PIM was introduced to simplify some of the complexity of the routing protocol at the cost of additional overhead tied with a greater replication of forwarded multicast packets. PIM is similar to DVMRP in that PIM builds source-routed multicast delivery trees and employs reverse path check when forwarding multicast packets.

There are two modes in which PIM operates: Dense and Sparse. The Dense Mode is suitable for densely populated multicast groups, primarily in the LAN environment. The Sparse Mode is suitable for sparsely populated multicast groups with the focus on WAN.

PIM primarily differs from DVMRP by using the IP routing table instead of maintaining its own, thereby being routing protocol independent.
Initiating PIM multicasts on a network

Once PIM is enabled on each router, a network user can begin a video conference multicast from the server on R1 as shown in Figure 111. When a multicast packet is received on a PIM-capable router interface, the interface checks its IP routing table to determine whether the interface that received the message provides the shortest path back to the source. If the interface does provide the shortest path back to the source, the multicast packet is then forwarded to all neighboring PIM routers. Otherwise, the multicast packet is discarded and a prune message is sent back upstream.

In Figure 111, the root node (R1) is forwarding multicast packets for group 229.225.0.1, which it receives from the server, to its downstream nodes, R2, R3, and R4. Router R4 is an intermediate router with R5 and R6 as its downstream routers. Because R5 and R6 have no downstream interfaces, they are leaf nodes. The receivers in this example are those workstations that are resident on routers R2, R3, and R6.

Pruning a multicast tree

As multicast packets reach these leaf routers, the routers check their IGMP databases for the group. If the group is not in a router IGMP database, the router discards the packet and sends a prune message to the upstream router. The router that discarded the packet also maintains the prune state for the source, group (S,G) pair. The branch is then pruned (removed) from the multicast tree. No further multicast packets for that specific (S,G) pair will be received from that upstream router until the prune state expires. You can configure the PIM Prune Timer (the length of time that a prune state is considered valid).

For example, in Figure 111 the sender with address 207.95.5.1 is sending multicast packets to the group 229.225.0.1. If a PIM switch receives any groups other than that group, the switch discards the group and sends a prune message to the upstream PIM switch.

In Figure 112, switch S5 is a leaf node with no group members in its IGMP database. Therefore, the switch must be pruned from the multicast tree. S5 sends a prune message upstream to its neighbor switch S4 to remove itself from the multicast delivery tree and install a prune state, as seen in Figure 112. Switch S5 will not receive any further multicast traffic until the prune age interval expires.

When a node on the multicast delivery tree has all of its downstream branches (downstream interfaces) in the prune state, a prune message is sent upstream. In the case of S4, if both S5 and S6 are in a prune state at the same time, S4 becomes a leaf node with no downstream interfaces and sends a prune message to S1. With S4 in a prune state, the resulting multicast delivery tree would consist only of leaf nodes S2 and S3.

**FIGURE 111** Transmission of multicast packets from the source to host group members
FIGURE 112  Pruning leaf nodes from a multicast tree
Grafts to a multicast Tree

A PIM switch restores pruned branches to a multicast tree by sending graft messages towards the upstream switch. Graft messages start at the leaf node and travel up the tree, first sending the message to its neighbor upstream switch.

In the example above, if a new 229.225.0.1 group member joins on switch S6, which was previously pruned, a graft is sent upstream to S4. Since the forwarding state for this entry is in a prune state, S4 sends a graft to S1. Once S4 has joined the tree, S4 and S6 once again receive multicast packets.

Prune and graft messages are continuously used to maintain the multicast delivery tree. No configuration is required on your part.

PIM DM versions

Brocade devices support PIM DM V1 and V2. The default is V2. You can specify the version on an individual interface basis.

The primary difference between PIM DM V1 and V2 is the methods the protocols use for messaging:

- PIM DM V1 – uses the Internet Group Management Protocol (IGMP) to send messages
- PIM DM V2 – sends messages to the multicast address 224.0.0.13 (ALL-PIM-ROUTERS) with protocol number 103
The CLI commands for configuring and managing PIM DM are the same for V1 and V2. The only difference is the command you use to enable the protocol on an interface.

NOTE
Version 2 is the default PIM DM version. The only difference between version 1 and version 2 is the way the protocol sends messages. The change is not apparent in most configurations. You can use version 2 instead of version 1 with no impact to your network. However, if you want to continue to use PIM DM V1 on an interface, you must change the version, then save the configuration.

NOTE
The note above does not mean you can run different PIM versions on devices that are connected to each other. The devices must run the same version of PIM. If you want to connect a Layer 3 Switch running PIM to a device that is running PIM V1, you must change the version on the Layer 3 Switch to V1 (or change the version on the device to V2, if supported).

Configuring PIM DM

NOTE
This section describes how to configure the “dense” mode of PIM, described in RFC 1075. Refer to “Configuring PIM Sparse” on page 851 for information about configuring PIM Sparse.

Enabling PIM on the router and an interface
By default, PIM is disabled. To enable PIM, perform the following:

• Enable the feature globally.
• Configure the IP interfaces that will use PIM.
• Enable PIM locally on the ports that have the IP interfaces you configured for PIM.

Suppose you want to initiate the use of desktop video for fellow users on a sprawling campus network. All destination workstations have the appropriate hardware and software but the Brocade routers that connect the various buildings need to be configured to support PIM multicasts from the designated video conference server as shown in Figure 111 on page 841.

PIM is enabled on each of the Brocade routers shown in Figure 111, on which multicasts are expected. You can enable PIM on each router independently or remotely from one of the routers with a Telnet connection. Follow the same steps for each router. A reset of the router is required when PIM is first enabled. Thereafter, all changes are dynamic.

Globally enabling and disabling PIM
To globally enable PIM, enter the following command.

FastIron(config)#router pim

Syntax: [no] router pim

The behavior of the [no] router pim command is as follows:

• Entering router pim command to enable PIM does not require a software reload.
• Entering a no router pim command removes all configuration for PIM multicast on a Layer 3 Switch (router pim level) only.
Globally Enabling and Disabling PIM without Deleting Multicast Configuration

As stated above entering a `no router pim` command deletes the PIM configuration. If you want to disable PIM without deleting any PIM configuration, enter the following command.

```
FastIron(config)#router pim
FastIron(config-pim-router)#disable-pim
```

**Syntax:** `[no] disable-pim`

Use the `[no]` version of the command to re-enable PIM.

Enabling a PIM version

**Using the CLI**

To enable PIM on an interface, globally enable PIM, then enable PIM on interface 3, enter the following commands.

```
FastIron(config)#router pim
FastIron(config)#int e 3
FastIron(config-if-e1000-3)#ip address 207.95.5.1/24
FastIron(config-if-e1000-3)#ip pim
```

**Syntax:** `[no] ip pim [version 1 | 2]`

The `version 1 | 2` parameter specifies the PIM DM version. The default version is 2.

If you have enabled PIM version 1 but need to enable version 2 instead, enter either of the following commands at the configuration level for the interface.

```
FastIron(config-if-1/1)#ip pim version 2
FastIron(config-if-1/1)#no ip pim version 1
```

To disable PIM DM on the interface, enter the following command.

```
FastIron(config-if-1/1)#no ip pim
```

**Modifying PIM global parameters**

PIM global parameters come with preset values. The defaults work well in most networks, but you can modify the following parameters if you need to:

- Neighbor timeout
- Hello timer
- Prune timer
- Prune wait timer
- Graft retransmit timer
- Inactivity timer

**Modifying neighbor timeout**

Neighbor timeout is the interval after which a PIM router will consider a neighbor to be absent. Absence of PIM hello messages from a neighboring router indicates that a neighbor is not present.

The default value is 180 seconds.

To apply a PIM neighbor timeout value of 360 seconds to all ports on the router operating with PIM, enter the following.
FastIron(config)#router pim
FastIron(config-pim-router)#nbr-timeout 360

Syntax: nbr-timeout <60-8000>
The default is 180 seconds.

Modifying hello timer
This parameter defines the interval at which periodic hellos are sent out PIM interfaces. Routers use hello messages to inform neighboring routers of their presence. The default rate is 60 seconds.

To apply a PIM hello timer of 120 seconds to all ports on the router operating with PIM, enter the following.

FastIron(config)#router pim
FastIron(config-pim-router)#hello-timer 120

Syntax: hello-timer <10-3600>
The default is 60 seconds.

Modifying prune timer
This parameter defines how long a Brocade PIM router will maintain a prune state for a forwarding entry.

The first received multicast interface is forwarded to all other PIM interfaces on the router. If there is no presence of groups on that interface, the leaf node sends a prune message upstream and stores a prune state. This prune state travels up the tree and installs a prune state.

A prune state is maintained until the prune timer expires or a graft message is received for the forwarding entry. The default value is 180 seconds.

To set the PIM prune timer to 90, enter the following.

FastIron(config)#router pim
FastIron(config-pim-router)#prune-timer 90

Syntax: prune-timer <10-3600>
The default is 180 seconds.

Modifying the prune wait timer
The CLI command prune-wait allows you to configure the amount of time a PIM router will wait before stopping traffic to neighbor routers that do not want the traffic. The value can be from zero to three seconds. The default is three seconds. A smaller prune wait value reduces flooding of unwanted traffic.

A prune wait value of zero causes the PIM router to stop traffic immediately upon receiving a prune message. If there are two or more neighbors on the physical port, then the prune-wait command should not be used because one neighbor may send a prune message while the other sends a join message at the during time or in less than three seconds.

To set the prune wait time to zero, enter the following commands.

FastIron(config)#router pim
FastIron(config-pim-router)#prune-wait 0

Syntax: prune-wait <time>
where <time> can be 0 - 3 seconds. A value of 0 causes the PIM router to stop traffic immediately upon receiving a prune message. The default is 3 seconds.

**Viewing the prune wait time**
To view the prune wait time, enter the `show ip pim dense` command at any level of the CLI.

```plaintext
FastIron# show ip pim dense
Global PIM Dense Mode Settings
Hello interval: 60, Neighbor timeout: 180
Graft Retransmit interval: 10, Inactivity interval: 180
Route Expire interval: 200, Route Discard interval: 340
Prune age: 180, Prune wait: 3
```

**Modifying graft retransmit timer**
The Graft Retransmit Timer defines the interval between the transmission of graft messages.

A graft message is sent by a router to cancel a prune state. When a router receives a graft message, the router responds with a Graft Ack (acknowledge) message. If this Graft Ack message is lost, the router that sent the graft message will resend it.

To change the graft retransmit timer from the default of 180 to 90 seconds, enter the following.

```plaintext
FastIron(config)#router pim
FastIron(config-pim-router)#graft-retransmit-timer 10
```

**Syntax:** `graft-retransmit-timer <2 -10>`
The default is 3 seconds.

**Modifying inactivity timer**
The router deletes a forwarding entry if the entry is not used to send multicast packets. The PIM inactivity timer defines how long a forwarding entry can remain unused before the router deletes it.

To apply a PIM inactivity timer of 90 seconds to all PIM interfaces, enter the following.

```plaintext
FastIron(config)#router pim
FastIron(config-pim-router)#inactivity-timer 90
```

**Syntax:** `inactivity-timer <10-3600>`
The default is 180 seconds.

**Selection of shortest path back to source**
By default, when a multicast packet is received on a PIM-capable router interface in a multi-path topology, the interface checks its IP routing table to determine the shortest path back to the source. If the alternate paths have the same cost, the first alternate path in the table is picked as the path back to the source. For example, in the table below, the first four routes have the same cost back to the source. However, 137.80.127.3 will be chosen as the path to the source since it is the first one on the list. The router rejects traffic from any port other than Port V11 on which 137.80.127.3 resides.
When the Highest IP RPF feature is enabled, the selection of the shortest path back to the source is based on which Reverse Path Forwarding (RPF) neighbor in the IP routing table has the highest IP address, if the cost of the routes are the same. For example, in the table above, Gateway 137.80.129.1 will be chosen as the shortest path to the source because it is the RPF neighbor with the highest IP address.

When choosing the RPF, the router first checks the Multicast Routing Table. If the table is not available, it chooses an RPF from the IP Routing Table. Multicast route is configured using the `ip mroute` command.

To enable the Highest IP RPF feature, enter commands such as the following.

```
FastIron(config)#router pim
FastIron(config-pim-router)#highest-ip-rpf
```

The command immediately enables the Highest IP RPF feature; there is no need to reboot the device.

**Syntax: [no] highest-ip-rpf**

Entering the `no` version of the command disables the feature; the shortest path back to the source will be based on the first entry in the IP routing table. If some PIM traffic paths were selected based on the highest IP RPF, these paths are changed immediately to use the first RPF in the routing table.

**Failover time in a multi-path topology**

When a port in a multi-path topology fails, and the failed port is the input port of the downstream router, a new path is re-established within a few seconds, depending on the routing protocol being used.

No configuration is required for this feature.

**Modifying the TTL**

The TTL defines the minimum value required in a packet for it to be forwarded out of the interface. For example, if the TTL for an interface is set at 10, it means that only those packets with a TTL value of 10 or more will be forwarded. Likewise, if an interface is configured with a TTL Threshold value of 1, all packets received on that interface will be forwarded. Possible TTL values are 1 to 31. The default TTL value is 1.
**Configuration notes**

- If the TTL for an interface is greater than 1, PIM packets received on the interface are always forwarded in software because each packet TTL must be examined. Therefore, Brocade does not recommend modifying the TTL under normal operating conditions.
- Multicast packets with a TTL value of 1 are switched within the same VLAN. These packets cannot be routed between different VLANs.

**Configuration syntax**

To configure a TTL of 24, enter the following.

```
FastIron(config-if-3/24)#ip pim ttl 24
```

Syntax: `ip pim ttl <1-31>`

**Dropping PIM traffic in hardware**

Unwanted PIM Dense or PIM Sparse multicast traffic can be dropped in hardware on Layer 3 Switches. This feature does not apply to DVMRP traffic. Refer to “Passive multicast route insertion” on page 895.

**PIM Sparse**

Brocade devices support Protocol Independent Multicast (PIM) Sparse version 2. PIM Sparse provides multicasting that is especially suitable for widely distributed multicast environments. The Brocade implementation is based on RFC 2362.

**NOTE**

On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

In a PIM Sparse network, a PIM Sparse router that is connected to a host that wants to receive information for a multicast group must explicitly send a join request on behalf of the receiver (host).

PIM Sparse routers are organized into domains. A PIM Sparse domain is a contiguous set of routers that all implement PIM and are configured to operate within a common boundary. Figure 113 shows a simple example of a PIM Sparse domain. This example shows three Layer 3 Switches configured as PIM Sparse routers. The configuration is described in detail following the figure.

**FIGURE 113** Example of a PIM Sparse domain
PIM Sparse switch types

Switches that are configured with PIM Sparse interfaces also can be configured to fill one or more of the following roles:

- **PMBR** – A PIM switch that has some interfaces within the PIM domain and other interfaces outside the PIM domain. PBMRs connect the PIM domain to the Internet.

  **NOTE**

  You cannot configure a Brocade routing interface as a PMBR interface for PIM Sparse in the current software release.

- **BSR** – The Bootstrap Router (BSR) distributes RP information to the other PIM Sparse switches within the domain. Each PIM Sparse domain has one active BSR. For redundancy, you can configure ports on multiple switches as candidate BSRs. The PIM Sparse protocol uses an election process to select one of the candidate BSRs as the BSR for the domain. The BSR with the highest BSR priority (a user-configurable parameter) is elected. If the priorities result in a tie, then the candidate BSR interface with the highest IP address is elected. In the example in Figure 113, PIM Sparse switch B is the BSR. Port 2/2 is configured as a candidate BSR.

- **RP** – The RP is the meeting point for PIM Sparse sources and receivers. A PIM Sparse domain can have multiple RPs, but each PIM Sparse multicast group address can have only one active RP. PIM Sparse switches learn the addresses of RPs and the groups for which they are responsible from messages that the BSR sends to each of the PIM Sparse switches. In the example in Figure 113, PIM Sparse Switch B is the RP. Port 2/2 is configured as a candidate Rendezvous Point (RP).

To enhance overall network performance, Brocade Layer 3 Switches use the RP to forward only the first packet from a group source to the group receivers. After the first packet, the Layer 3 Switch calculates the shortest path between the receiver and source (the Shortest Path Tree, or SPT) and uses the SPT for subsequent packets from the source to the receiver. The Layer 3 Switch calculates a separate SPT for each source-receiver pair.
NOTE
Brocade recommends that you configure the same ports as candidate BSRs and RPs.

RP paths and SPT paths

Figure 113 shows two paths for packets from the source for group 239.255.162.1 and a receiver for the group. The source is attached to PIM Sparse Switch A and the recipient is attached to PIM Sparse Switch C. PIM Sparse Switch B in is the RP for this multicast group. As a result, the default path for packets from the source to the receiver is through the RP. However, the path through the RP sometimes is not the shortest path. In this case, the shortest path between the source and the receiver is over the direct link between Switch A and Switch C, which bypasses the RP (Switch B).

To optimize PIM traffic, the protocol contains a mechanism for calculating the Shortest Path Tree (SPT) between a given source and receiver. PIM Sparse switches can use the SPT as an alternative to using the RP for forwarding traffic from a source to a receiver. By default, Brocade Layer 3 Switches forward the first packet they receive from a given source to a given receiver using the RP path, but forward subsequent packets from that source to that receiver through the SPT. In Figure 113, Switch A forwards the first packet from group 239.255.162.1 source to the destination by sending the packet to Switch B, which is the RP. Switch B then sends the packet to Switch C. For the second and all future packets that Switch A receives from the source for the receiver, Switch A forwards them directly to Switch C using the SPT path.

Configuring PIM Sparse

To configure a Brocade Layer 3 Switch for PIM Sparse, perform the following tasks:

- Configure the following global parameter:
  - Enable the PIM Sparse mode of multicast routing.

- Configure the following interface parameters:
  - Configure an IP address on the interface
  - Enable PIM Sparse.
  - Identify the interface as a PIM Sparse border, if applicable.

NOTE
You cannot configure a Brocade routing interface as a PMBR interface for PIM Sparse in the current software release.

- Configure the following PIM Sparse global parameters:
  - Identify the Layer 3 Switch as a candidate PIM Sparse Bootstrap Router (BSR), if applicable.
  - Identify the Layer 3 Switch as a candidate PIM Sparse Rendezvous Point (RP), if applicable.
  - Specify the IP address of the RP (if you want to statically select the RP).

NOTE
Brocade recommends that you configure the same Layer 3 Switch as both the BSR and the RP.
Limitations in this release

The implementation of PIM Sparse in the current software release has the following limitations:

- PIM Border Routers (PMBRs) are not supported. Thus, you cannot configure a Brocade routing interface as a PMBR interface for PIM Sparse.
- PIM Sparse and regular PIM (dense mode) cannot be used on the same interface.
- You cannot configure or display PIM Sparse information using the Web Management Interface. (You can display some general PIM information, but not specific PIM Sparse information.)

Configuring Global PIM Sparse parameters

To configure the PIM Sparse global parameters, use either of the following methods.

To configure basic global PIM Sparse parameters, enter commands such as the following on each Layer 3 Switch within the PIM Sparse domain.

```
FastIron(config)#router pim
```

Syntax: [no] router pim

NOTE
You do not need to globally enable IP multicast routing when configuring PIM Sparse.

The command in this example enables IP multicast routing, and enables the PIM Sparse mode of IP multicast routing. The command does not configure the Layer 3 Switch as a candidate PIM Sparse Bootstrap Router (BSR) and candidate Rendezvous Point (RP). You can configure a Brocade Layer 3 Switch as a PIM Sparse switch without configuring the it as a candidate BSR and RP. However, if you do configure the Layer 3 Switch as one of these, Brocade recommends that you configure it as both. Refer to “Configuring BSRs” on page 853.

The behavior of the [no] router pim command is as follows:

- Entering no router pim command to disable PIM or DVMRP does not require a software reload.
- Entering a no router pim command removes all configuration for PIM multicast on a Layer 3 Switch (router pim level) only.

Globally enabling and disabling PIM without deleting the multicast configuration

As stated above entering a no router pim command deletes the PIM configuration. If you want to disable PIM without deleting any PIM configuration, enter the following command.

```
FastIron(config)#router pim
