FastIron(config-pim-router)#disable-pim
```

Syntax: [no] disable-pim

Use the [no] version of the command to re-enable PIM.

Configuring PIM interface parameters

After you enable IP multicast routing and PIM Sparse at the global level, you must enable it on the individual interfaces connected to the PIM Sparse network. To do so, use the following CLI method.

To enable PIM Sparse mode on an interface, enter commands such as the following.
FastIron(config)#interface ethernet 2/2
FastIron(config-if-2/2)#ip address 207.95.7.1 255.255.255.0
FastIron(config-if-2/2)#ip pim-sparse

Syntax: [no] ip pim-sparse

The commands in this example add an IP interface to port 2/2, then enable PIM Sparse on the interface.

If the interface is on the border of the PIM Sparse domain, you also must enter the following command.

FastIron(config-if-2/2)#ip pim border

Syntax: [no] ip pim border

NOTE
You cannot configure a Brocade routing interface as a PMBR interface for PIM Sparse in the current software release.

Configuring BSRs

In addition to the global and interface parameters in the sections above, you need to identify an interface on at least one Layer 3 Switch as a candidate PIM Sparse Bootstrap router (BSR) and candidate PIM Sparse Rendezvous Point (RP).

NOTE
It is possible to configure the Layer 3 Switch as only a candidate BSR or RP, but Brocade recommends that you configure the same interface on the same Layer 3 Switch as both a BSR and an RP.

This section presents how to configure BSRs. Refer to “Configuring RPs” on page 854 for instructions on how to configure RPs.

To configure the Layer 3 Switch as a candidate BSR and RP, enter commands such as the following.

FastIron(config)#router pim
FastIron(config-pim-router)#bsr-candidate ethernet 2/2 30 255
BSR address: 207.95.7.1, hash mask length: 30, priority: 255

This command configures the PIM Sparse interface on port 2/2 as a BSR candidate, with a hash mask length of 30 and a priority of 255. The information shown in italics above is displayed by the CLI after you enter the candidate BSR configuration command.

Syntax: [no] bsr-candidate ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num> <hash-mask-length> [<priority>]

The <slotnum> parameter is required on chassis devices.

The <portnum> | loopback <num> | ve <num> parameter specifies the interface. The Layer 3 Switch will advertise the specified interface IP address as a candidate BSR:

- Enter ethernet [<slotnum>/]<portnum> for a physical interface (port).
- Enter ve <num> for a virtual interface.
- Enter loopback <num> for a loopback interface.

The <hash-mask-length> parameter specifies the number of bits in a group address that are significant when calculating the group-to-RP mapping. You can specify a value from 1 – 32.
NOTE
Brocade recommends you specify 30 for IP version 4 (IPv4) networks.

The `<priority>` specifies the BSR priority. You can specify a value from 0 – 255. When the election process for BSR takes place, the candidate BSR with the highest priority becomes the BSR. The default is 0.

**Configuring RPs**

Enter a command such as the following to configure the Layer 3 Switch as a candidate RP.

```
FastIron(config-pim-router)#rp-candidate ethernet 2/2
```

**Syntax:** `[no] rp-candidate ethernet [slotnum]/portnum | loopback <num> | ve <num>

The `<slotnum>` parameter is required on chassis devices.

The `portnum` | loopback `<num>` | ve `<num>` parameter specifies the interface. The Layer 3 Switch will advertise the specified interface IP address as a candidate RP:

- Enter `ethernet [slotnum]/portnum` for a physical interface (port).
- Enter `ve <num>` for a virtual interface.
- Enter `loopback <num>` for a loopback interface.

By default, this command configures the Layer 3 Switch as a candidate RP for all group numbers beginning with 224. As a result, the Layer 3 Switch is a candidate RP for all valid PIM Sparse group numbers. You can change this by adding or deleting specific address ranges. The following example narrows the group number range for which the Layer 3 Switch is a candidate RP by explicitly adding a range.

```
FastIron(config-pim-router)#rp-candidate add 224.126.0.0 16
```

**Syntax:** `[no] rp-candidate add <group-addr> <mask-bits>

The `<group-addr>` `<mask-bits>` specifies the group address and the number of significant bits in the subnet mask. In this example, the Layer 3 Switch is a candidate RP for all groups that begin with 224.126. When you add a range, you override the default. The Layer 3 Switch then becomes a candidate RP only for the group address ranges you add.

You also can change the group numbers for which the Layer 3 Switch is a candidate RP by deleting address ranges. For example, to delete all addresses from 224.126.22.0 – 224.126.22.255, enter the following command.

```
FastIron(config-pim-router)#rp-candidate delete 224.126.22.0 24
```

**Syntax:** `rp-candidate delete <group-addr> <mask-bits>

The usage of the `<group-addr>` `<mask-bits>` parameter is the same as for the `rp-candidate add` command.

If you enter both commands shown in the example above, the net effect is that the Layer 3 Switch becomes a candidate RP for groups 224.126.0.0 – 224.126.21.255 and groups 224.126.23.0 – 224.126.255.255.

**Updating PIM-Sparse forwarding entries with new RP configuration**

If you make changes to your static RP configuration, the entries in the PIM-Sparse multicast forwarding table continue to use the old RP configuration until they are aged out.
The `clear pim rp-map` command allows you to update the entries in the static multicast forwarding table immediately after making RP configuration changes. This command is meant to be used with `rp-address` command.

To update the entries in a PIM sparse static multicast forwarding table with new RP configuration, enter the following command at the privileged EXEC level of the CLI.

```
FastIron#clear pim rp-map
```

**Syntax:** `clear pim rp-map`

**Statically specifying the RP**

Brocade recommends that you use the PIM Sparse protocol RP election process so that a backup RP can automatically take over if the active RP router becomes unavailable. However, if you do not want the RP to be selected by the RP election process but instead you want to explicitly identify the RP by its IP address, you can do using the following CLI method.

If you explicitly specify the RP, the Layer 3 Switch uses the specified RP for all group-to-RP mappings and overrides the set of candidate RPs supplied by the BSR.

**NOTE**

Specify the same IP address as the RP on all PIM Sparse routers within the PIM Sparse domain. Make sure the router is on the backbone or is otherwise well connected to the rest of the network.

To specify the IP address of the RP, enter commands such as the following.

```
FastIron(config)#router pim
FastIron(config-pim-router)#rp-address 207.95.7.1
```

**Syntax:** `[no] rp-address <ip-addr>`

The `<ip-addr>` parameter specifies the IP address of the RP.

The command in the example above identifies the router interface at IP address 207.95.7.1 as the RP for the PIM Sparse domain. The Layer 3 Switch will use the specified RP and ignore group-to-RP mappings received from the BSR.

**Changing the Shortest Path Tree (SPT) threshold**

In a typical PIM Sparse domain, there may be two or more paths from a DR (designated router) for a multicast source to a PIM group receiver:

- **Path through the RP** – This is the path the Layer 3 Switch uses the first time it receives traffic for a PIM group. However, the path through the RP may not be the shortest path from the Layer 3 Switch to the receiver.

- **Shortest Path** – Each PIM Sparse router that is a DR for a multicast source calculates a shortest path tree (SPT) to all the PIM Sparse group receivers within the domain, with the Layer 3 Switch itself as the root of the tree. The first time a Brocade Layer 3 Switch configured as a PIM router receives a packet for a PIM receiver, the Layer 3 Switch sends the packet to the RP for the group. The Layer 3 Switch also calculates the SPT from itself to the receiver. The next time the Layer 3 Switch receives a PIM Sparse packet for the receiver, the Layer 3 Switch sends the packet toward the receiver using the shortest route, which may not pass through the RP.

By default, the device switches from the RP to the SPT after receiving the first packet for a given PIM Sparse group. The Layer 3 Switch maintains a separate counter for each PIM Sparse source-group pair.
After the Layer 3 Switch receives a packet for a given source-group pair, the Layer 3 Switch starts a PIM data timer for that source-group pair. If the Layer 3 Switch does not receive another packet for the source-group pair before the timer expires, it reverts to using the RP for the next packet received for the source-group pair. In accordance with the PIM Sparse RFC recommendation, the timer is 210 seconds and is not configurable. The counter is reset to zero each time the Layer 3 Switch receives a packet for the source-group pair.

You can change the number of packets that the Layer 3 Switch sends using the RP before switching to using the SPT. To do so, use the following CLI method.

```
FastIron(config)#router pim
FastIron(config-pim-router)#spt-threshold 1000
```

**Syntax:** `[no] spt-threshold infinity | <num>

The `infinity | <num>` parameter specifies the number of packets. If you specify infinity, the Layer 3 Switch sends packets using the RP indefinitely and does not switch over to the SPT. If you enter a specific number of packets, the Layer 3 Switch does not switch over to using the SPT until it has sent the number of packets you specify using the RP.

**Changing the PIM join and prune message interval**

By default, the Layer 3 Switch sends PIM Sparse Join/Prune messages every 60 seconds. These messages inform other PIM Sparse routers about clients who want to become receivers (Join) or stop being receivers (Prune) for PIM Sparse groups.

You can change the Join/Prune message interval using the following CLI method.

```
NOTE
Use the same Join/Prune message interval on all the PIM Sparse routers in the PIM Sparse domain. If the routers do not all use the same timer interval, the performance of PIM Sparse can be adversely affected.
```

To change the Join/Prune interval, enter commands such as the following.

```
FastIron(config)#router pim
FastIron(config-pim-router)#message-interval 30
```

**Syntax:** `[no] message-interval <num>

The `<num>` parameter specifies the number of seconds and can from 1 – 65535. The default is 60.

**Dropping PIM traffic in hardware**

Unwanted PIM Dense or PIM Sparse multicast traffic can be dropped in hardware on Layer 3 Switches. This feature does not apply to DVMRP traffic. Refer to “Passive multicast route insertion” on page 895.

**Anycast RP**

**Platform Support:**

- FastIron X Series devices running software release FSX 05.1.00 and later
- TurboIron X Series devices running software release 04.2.00 and later
Anycast RP is a method of providing intra-domain redundancy and load-balancing between multiple Rendezvous Points (RP) in a Protocol Independent Multicast Sparse mode (PIM-SM) network. It is accomplished by configuring all RPs within a domain with the same anycast RP address which is typically a loopback IP address. Multicast Source Discovery Protocol (MSDP) is used between all of the RPs in a mesh configuration to keep all RPs in sync regarding the active sources.

PIM-SM routers are configured to register (statically or dynamically) with the RP using the same anycast RP address. Since multiple RPs have the same anycast address, an Interior Gateway Protocol (IGP) such as OSPF routes the PIM-SM router to the RP with the best route. If the PIM-SM routers are distributed evenly throughout the domain, the loads on RPs within the domain will be distributed. If the RP with the best route goes out of service, the PIM-SM router IGP changes the route to the closest operating RP that has the same anycast address.

This configuration works because MSDP is configured between all of the RPs in the domain. Consequently, all of the RPs share information about active sources.

**Configuring anycast RP**

To configure anycast RP, you must do the following:

- Configure a loopback interface with the anycast RP address on each of the RPs within the domain and enable PIM-SM on these interfaces.
- You must explicitly configure router-id. Refer to “RP 1 configuration” on page 858.
- Ensure that the anycast RP address is leaked into the IGP domain. This is typically done by enabling the IGP on the loopback interface (in passive mode) or redistributing the connected loopback IP address into the IGP.

**NOTE**
The anycast RP address *must* not be the IGP router-id.

- Enable PIM-SM on all interfaces on which multicast routing is desired.
- Enable an IGP on each of the loopback interfaces and physical interfaces configured for PIM-SM.
- Configure loopback interfaces with unique IP addresses on each of the RPs for MSDP peering. This loopback interface is also used as the MSDP originator-id.
- The non-RP PIM-SM routers may be configured to use the anycast RP address statically or dynamically (by the PIMv2 bootstrap mechanism).
- On TurboIron X Series devices running software release 04.2.00 and later, anycast RP is supported on a fully-meshed topology. Configure MSDP peers and configure mesh-groups that use a fully meshed peer topology. MSDP peering can be established between physical interfaces or loopback interfaces. MSDP is used between all intra-domain RPs in a full-mesh configuration to provide redundancy and backup of PIM-SM network.

**Example to configure anycast RP - two directly connected RPs**

The example shown in Figure 114 is a simple anycast-enabled network with two RPs and two PIM-SM routers. Loopback 1 in RP 1 and RP 2 have the same IP address. Loopback 2 in RP1 and Loopback 2 in RP2 have different IP addresses and are configured as MSDP peering IP addresses in a mesh configuration.
In the PIM configuration for PIM-SM routers PIMR1 and PIMR2 the RP address is configured to be the anycast RP address that was configured on the Loopback 1 interfaces on RP1 and RP2. OSPF is configured as the IGP for the network and all of the devices are in OSPF area 0.

Since PIMR1 has a lower cost path to RP1 and PIMR2 has a lower cost path to RP2 they will register with the respective RPs when both are up and running. This shares the load between the two RPs. If one of the RPs fails, the higher-cost path to the IP address of Loopback 1 on the RPs is used to route to the still-active RP.

The configuration examples demonstrate the commands required to enable this application.

**FIGURE 114** Example of an anycast RP network

**RP 1 configuration**

The following commands provide the configuration for the RP 1 router in *Figure 114*.

```
RP1(config)#router ospf
RP1(config-ospf-router)# area 0
RP1(config-ospf-router)# exit
RP1(config)# interface loopback 1
RP1(config-lbif-1)# ip ospf area 0
RP1(config-lbif-1)# ip ospf passive
RP1(config-lbif-1)# ip address 10.0.0.1/32
RP1(config-lbif-1)# ip pim-sparse
RP1(config-lbif-1)# exit
RP1(config)# interface loopback 2
RP1(config-lbif-2)# ip ospf area 0
RP1(config-lbif-2)# ip ospf passive
RP1(config-lbif-2)# ip address 10.1.1.1/32
RP1(config-lbif-2)# exit
RP1(config)# interface ethernet 5/1
RP1(config-if-e1000-5/1)# ip ospf area 0
RP1(config-if-e1000-5/1)# ip address 192.1.1.1/24
RP1(config-if-e1000-5/1)# ip pim-sparse
RP1(config)# interface ethernet 5/2
```
RP1(config-if-e1000-5/2)# ip ospf area 0
RP1(config-if-e1000-5/2)# ip ospf cost 5
RP1(config-if-e1000-5/2)# ip address 192.2.1.1/24
RP1(config-if-e1000-5/2)# ip pim-sparse
RP1(config)# interface ethernet 5/3
RP1(config-if-e1000-5/3)# ip ospf area 0
RP1(config-if-e1000-5/3)# ip ospf cost 10
RP1(config-if-e1000-5/3)# ip address 192.3.1.1/24
RP1(config-if-e1000-5/3)# ip pim-sparse
RP1(config-if-e1000-5/3)# exit
RP1(config)# router pim
RP1(config-pim-router)# rp-candidate loopback 1
RP1(config-pim-router)# exit
RP1(config)# router msdp
RP1(config-msdp-router)# msdp-peer 10.1.1.2 connect-source loopback 2
RP1(config-msdp-router)# originator-id loopback 2
RP1(config)# ip router-id 10.1.1.1

RP 2 configuration
The following commands provide the configuration for the RP 2 router in Figure 114.

RP2(config)# router ospf
RP2(config-ospf-router)# area 0
RP2(config-ospf-router)# exit
RP2(config)# interface loopback 1
RP2(config-lbif-1)# ip ospf area 0
RP2(config-lbif-1)# ip ospf passive
RP2(config-lbif-1)# ip address 10.0.0.1/32
RP2(config-lbif-1)# ip pim-sparse
RP2(config-lbif-1)# exit
RP2(config)# interface loopback 2
RP2(config-lbif-2)# ip ospf area 0
RP2(config-lbif-2)# ip ospf passive
RP2(config-lbif-2)# ip address 10.1.1.2/32
RP2(config-lbif-2)# exit
RP2(config)# interface ethernet 5/1
RP2(config-if-e1000-5/1)# ip ospf area 0
RP2(config-if-e1000-5/1)# ip address 192.1.1.2/24
RP2(config-if-e1000-5/1)# ip pim-sparse
RP2(config)# interface ethernet 5/2
RP2(config-if-e1000-5/2)# ip ospf area 0
RP2(config-if-e1000-5/2)# ip ospf cost 5
RP2(config-if-e1000-5/2)# ip address 192.5.2.1/24
RP2(config-if-e1000-5/2)# ip pim-sparse
RP2(config)# interface ethernet 5/3
RP2(config-if-e1000-5/3)# ip ospf area 0
RP2(config-if-e1000-5/3)# ip ospf cost 10
RP2(config-if-e1000-5/3)# ip address 192.6.1.2/24
RP2(config-if-e1000-5/3)# ip pim-sparse
RP2(config-if-e1000-5/3)# exit
RP2(config)# router pim
RP2(config-pim-router)# rp-candidate loopback 1
RP2(config-pim-router)# exit
RP2(config)# router msdp
RP2(config-msdp-router)# msdp-peer 10.1.1.1 connect-source loopback 2
RP2(config-msdp-router)# originator-id loopback 2
RP2(config)# ip router-id 10.1.1.2
**PIMR1 configuration**

The following commands provide the configuration for the PIMR1 router in Figure 114.

```plaintext
PIMR1(config)# router ospf
PIMR1(config-ospf-router)# area 0
PIMR1(config-ospf-router)# exit
PIMR1(config)# interface ethernet 6/2
PIMR1(config-if-e1000-6/2)# ip ospf area 0
PIMR1(config-if-e1000-6/2)# ip ospf cost 5
PIMR1(config-if-e1000-6/2)# ip address 192.2.1.2/24
PIMR1(config-if-e1000-6/2)# ip pim-sparse
PIMR1(config)# interface ethernet 6/3
PIMR1(config-if-e1000-6/3)# ip ospf area 0
PIMR1(config-if-e1000-6/3)# ip ospf cost 10
PIMR1(config-if-e1000-6/3)# ip address 192.6.1.1/24
PIMR1(config-if-e1000-6/3)# ip pim-sparse
PIMR1(config)# interface ethernet 6/3
PIMR1(config-if-e1000-6/3)# ip ospf area 0
PIMR1(config-if-e1000-6/3)# ip ospf cost 10
PIMR1(config-if-e1000-6/3)# ip address 192.6.1.1/24
PIMR1(config-if-e1000-6/3)# ip pim-sparse
PIMR1(config)# router pim
PIMR1(config-pim-router)# rp-address 10.0.0.1
PIMR1(config-pim-router)# exit
```

**PIMR2 configuration**

The following commands provide the configuration for the PIMR2 router in Figure 114.

```plaintext
PIMR2(config)# router ospf
PIMR2(config-ospf-router)# area 0
PIMR2(config-ospf-router)# exit
PIMR2(config)# interface ethernet 1/2
PIMR2(config-if-e1000-1/2)# ip ospf area 0
PIMR2(config-if-e1000-1/2)# ip ospf cost 5
PIMR2(config-if-e1000-1/2)# ip address 192.5.2.2/24
PIMR2(config-if-e1000-1/2)# ip pim-sparse
PIMR2(config)# interface ethernet 1/3
PIMR2(config-if-e1000-1/3)# ip ospf area 0
PIMR2(config-if-e1000-1/3)# ip ospf cost 10
PIMR2(config-if-e1000-1/3)# ip address 192.3.1.2/24
PIMR2(config-if-e1000-1/3)# ip pim-sparse
PIMR2(config)# interface ethernet 1/3
PIMR2(config-if-e1000-1/3)# ip ospf area 0
PIMR2(config-if-e1000-1/3)# ip ospf cost 10
PIMR2(config-if-e1000-1/3)# ip address 192.3.1.2/24
PIMR2(config-if-e1000-1/3)# ip pim-sparse
PIMR2(config)# router pim
PIMR2(config-pim-router)# rp-address 10.0.0.1
PIMR2(config-pim-router)# exit
```

**Example to configure anycast RP - triangular mesh topology**

The example shown in Figure 115 is an anycast-enabled network with three RPs connected in a triangular mesh topology. Loopback 2 in RP 1, RP 2, and RP 3 have the same IP address, which is the anycast RP address. Loopback 1 in RP1, RP2, and RP3 have different IP addresses and are configured as MSDP peering IP addresses in a triangular mesh configuration.

OSPF is configured as the IGP for the network and all of the devices are in OSPF area 0. This example demonstrates only anycast RP configurations. Assuming a PIM-SM network with three anycast RPs configured, the RP address is configured to be the anycast RP address that was configured on Loopback interface 2 of RP1, RP2, and RP3. Based on the IGP routes, all routers in the network are registered to the shortest path anycast RP. This shares the load between all the RPs, and provides hot backup.
The configuration examples demonstrate the commands required to enable this application.

**FIGURE 115**  Anycast enabled network in a triangular mesh topology

**RP 1 Configuration**

The following commands provide the configuration for the RP 1 router in Figure 115.

```
RP1(config)#router ospf
RP1(config-ospf-router)# area 0
RP1(config-ospf-router)# exit
RP1(config)# interface loopback 1
RP1(config-lbif-1)# ip ospf area 0
RP1(config-lbif-1)# ip ospf passive
RP1(config-lbif-1)# ip address 100.1.1.1/32
RP1(config-lbif-1)# exit
RP1(config)# interface loopback 2
RP1(config-lbif-2)# ip ospf area 0
RP1(config-lbif-2)# ip ospf passive
RP1(config-lbif-2)# ip pim-sparse
RP1(config-lbif-2)# ip address 100.2.1.1/32
RP1(config-lbif-2)# exit
RP1(config)# interface ethernet 1
RP1(config-if-e1000-1)# ip ospf area 0
RP1(config-if-e1000-1)# ip ospf cost 2
RP1(config-if-e1000-1)# ip address 192.1.1.1/24
RP1(config-if-e1000-1)# ip pim-sparse
RP1(config)# interface ethernet 5
RP1(config-if-e1000-5)# ip ospf area 0
RP1(config-if-e1000-5)# ip address 192.3.1.1/24
RP1(config-if-e1000-5)# ip pim-sparse
RP1(config)# router pim
RP1(config-pim-router)# rp-address 100.2.1.1
RP1(config-pim-router)# exit
RP1(config)# router msdp
RP1(config-msdp-router)# msdp-peer 10.0.1.2 connect-source loopback 1
RP1(config-msdp-router)# msdp-peer 10.0.1.3 connect-source loopback 1
RP1(config-msdp-router)# mesh-group mesh1 100.1.1.2
RP1(config-msdp-router)# mesh-group mesh1 100.1.1.3
RP1(config-msdp-router)# originator-id loopback 1
RP1(config-msdp-router)# exit
RP1(config)# ip router-id 100.1.1.1
```
RP 2 Configuration

The following commands provide the configuration for the RP 2 router in Figure 115.

```
RP2(config)#router ospf
RP2(config-ospf-router)# area 0
RP2(config-ospf-router)# exit
RP2(config)# interface loopback 1
RP2(config-lbif-1)# ip ospf area 0
RP2(config-lbif-1)# ip ospf passive
RP2(config-lbif-1)# ip address 100.1.1.2/32
RP2(config-lbif-1)# exit
RP2(config)# interface loopback 2
RP2(config-lbif-2)# ip ospf area 0
RP2(config-lbif-2)# ip ospf passive
RP2(config-lbif-2)# ip address 100.2.1.1/32
RP2(config-lbif-2)# ip pim-sparse
RP2(config-lbif-2)# exit
RP2(config)# interface ethernet 1
RP2(config-if-e1000-1)# ip ospf area 0
RP2(config-if-e1000-1)# ip ospf cost 2
RP2(config-if-e1000-1)# ip address 192.1.1.2/24
RP2(config-if-e1000-1)# ip pim-sparse
RP2(config-if-e1000-1)# exit
RP2(config)# interface ethernet 3
RP2(config-if-e1000-3)# ip ospf area 0
RP2(config-if-e1000-3)# ip ospf cost 2
RP2(config-if-e1000-3)# ip address 192.2.1.2/24
RP2(config-if-e1000-3)# ip pim-sparse
RP2(config-if-e1000-3)# exit
RP2(config)# router pim
RP2(config-pim-router)# rp-address 100.2.1.1
RP2(config-pim-router)# exit
RP2(config)# router msdp
RP2(config-msdp-router)# msdp-peer 100.1.1.1 connect-source loopback 1
RP2(config-msdp-router)# msdp-peer 100.1.1.3 connect-source loopback 1
RP2(config-msdp-router)# mesh-group mesh1 100.1.1.1
RP2(config-msdp-router)# mesh-group mesh1 100.1.1.3
RP2(config-msdp-router)# originator-id loopback 1
RP2(config-msdp-router)# exit
RP2(config)# ip router-id 100.1.1.2
```

RP 3 Configuration

The following commands provide the configuration for the RP 3 router in Figure 115.

```
RP3(config)#router ospf
RP3(config-ospf-router)# area 0
RP3(config-ospf-router)# exit
RP3(config)# interface loopback 1
RP3(config-lbif-1)# ip ospf area 0
RP3(config-lbif-1)# ip ospf passive
RP3(config-lbif-1)# ip address 100.1.1.3/32
RP3(config-lbif-1)# exit

Sing a PIM Sparse configuration information
and statistics

You can display the following PIM Sparse information:

- Basic PIM Sparse configuration information
- Group information
- BSR information
- Candidate RP information
- RP-to-group mappings
- RP information for a PIM Sparse group
- RP set list
- PIM Neighbor information
- The PIM flow cache
- The PIM multicast cache
- PIM traffic statistics

**Displaying basic PIM Sparse configuration information**

To display basic configuration information for PIM Sparse, enter the following command at any CLI level.
FastIron# show ip pim sparse

Global PIM Sparse Mode Settings
Hello interval: 60, Neighbor timeout: 180
Bootstrap Msg interval: 130, Candidate-RP Advertisement interval: 60
Join/Prune interval: 60, SPT Threshold: 1

Interface Ethernet e3/8
TTL Threshold: 1, Enabled
Local Address: 207.95.8.1

Interface Ve 1
TTL Threshold: 1, Enabled
Local Address: 207.95.6.1

Syntax: show ip pim sparse

This example shows the PIM Sparse configuration information on PIM Sparse router A in Figure 113.

This display shows the following information.

<table>
<thead>
<tr>
<th>TABLE 141</th>
<th>Output of show ip pim sparse</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field...</strong></td>
<td><strong>Displays...</strong></td>
</tr>
<tr>
<td><strong>Global PIM Sparse mode settings</strong></td>
<td></td>
</tr>
<tr>
<td>Hello interval</td>
<td>How frequently the Layer 3 Switch sends PIM Sparse hello messages to its PIM Sparse neighbors. This field show the number of seconds between hello messages. PIM Sparse routers use hello messages to discover one another.</td>
</tr>
<tr>
<td>Neighbor timeout</td>
<td>How many seconds the Layer 3 Switch will wait for a hello message from a neighbor before determining that the neighbor is no longer present and removing cached PIM Sparse forwarding entries for the neighbor.</td>
</tr>
<tr>
<td>Bootstrap Msg interval</td>
<td>How frequently the BSR configured on the Layer 3 Switch sends the RP set to the RPs within the PIM Sparse domain. The RP set is a list of candidate RPs and their group prefixes. A candidate RP group prefix indicates the range of PIM Sparse group numbers for which it can be an RP. <strong>NOTE:</strong> This field contains a value only if an interface on the Layer 3 Switch is elected to be the BSR. Otherwise, the field is blank.</td>
</tr>
<tr>
<td>Candidate-RP Advertisement interval</td>
<td>How frequently the candidate PR configured on the Layer 3 Switch sends candidate RP advertisement messages to the BSR. <strong>NOTE:</strong> This field contains a value only if an interface on the Layer 3 Switch is configured as a candidate RP. Otherwise, the field is blank.</td>
</tr>
<tr>
<td>Join/Prune interval</td>
<td>How frequently the Layer 3 Switch sends PIM Sparse Join/Prune messages for the multicast groups it is forwarding. This field show the number of seconds between Join/Prune messages. The Layer 3 Switch sends Join/Prune messages on behalf of multicast receivers who want to join or leave a PIM Sparse group. When forwarding packets from PIM Sparse sources, the Layer 3 Switch sends the packets only on the interfaces on which it has received join requests in Join/Prune messages for the source group. You can change the Join/Prune interval if needed. Refer to “Changing the PIM join and prune message interval” on page 856.</td>
</tr>
<tr>
<td>SPT Threshold</td>
<td>The number of packets the Layer 3 Switch sends using the path through the RP before switching to using the SPT path.</td>
</tr>
</tbody>
</table>
Displaying a list of multicast groups

To display a list of the IP multicast groups the Layer 3 Switch is forwarding, enter the following command at any CLI level.

```
FastIron# show ip pim group
Total number of groups: 1
Index 1         Group 228.1.0.88
    Group member at  e2: v33 EX 0,
    Group member at  e13: v55 EX 0,
    Group member at  e1: v5 EX 0,
```

**Syntax:** `show ip pim group`

This display shows the following information.

**TABLE 142** Output of `show ip pim group`

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Total number of Groups</strong></td>
<td>Lists the total number of IP multicast groups the Layer 3 Switch is forwarding. <strong>NOTE:</strong> This list can include groups that are not PIM Sparse groups. If interfaces on the Layer 3 Switch are configured for regular PIM (dense mode) or DVMRP, these groups are listed too.</td>
</tr>
<tr>
<td><strong>Index</strong></td>
<td>The index number of the table entry in the display.</td>
</tr>
<tr>
<td><strong>Group</strong></td>
<td>The multicast group address</td>
</tr>
<tr>
<td><strong>Group member</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Ports</strong></td>
<td>The Layer 3 Switch ports connected to the receivers of the groups.</td>
</tr>
</tbody>
</table>

**Displaying BSR information**

To display BSR information, enter the following command at any CLI level.
FastIron# show ip pim bsr

PIMv2 Bootstrap information

This system is the elected Bootstrap Router (BSR)
  BSR address: 207.95.7.1
  Uptime: 00:33:52, BSR priority: 5, Hash mask length: 32
  Next bootstrap message in 00:00:20

Next Candidate-RP-advertisement in 00:00:10
  RP: 207.95.7.1
  group prefixes:
    224.0.0.0 / 4
Candidate-RP-advertisement period: 60

This example shows information displayed on a Layer 3 Switch that has been elected as the BSR.
The following example shows information displayed on a Layer 3 Switch that is not the BSR. Notice
that some fields shown in the example above do not appear in the example below.

FastIron# show ip pim bsr

PIMv2 Bootstrap information
  local BSR address = 207.95.7.1
  local BSR priority = 5

Syntax: show ip pim bsr

This display shows the following information.

<table>
<thead>
<tr>
<th>TABLE 143</th>
<th>Output of show ip pim bsr</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field...</strong></td>
<td><strong>Displays...</strong></td>
</tr>
</tbody>
</table>
| BSR address or local BSR address | The IP address of the interface configured as the PIM Sparse Bootstrap Router (BSR).
  **NOTE:** If the word “local” does not appear in the field, this Layer 3 Switch is the BSR. If the word “local” does appear, this Layer 3 Switch is not the BSR. |
| Uptime | The amount of time the BSR has been running.
  **NOTE:** This field appears only if this Layer 3 Switch is the BSR. |
| BSR priority or local BSR priority | The priority assigned to the interface for use during the BSR election process. During BSR election, the priorities of the candidate BSRs are compared and the interface with the highest BSR priority becomes the BSR.
  **NOTE:** If the word “local” does not appear in the field, this Layer 3 Switch is the BSR. If the word “local” does appear, this Layer 3 Switch is not the BSR. |
| Hash mask length | The number of significant bits in the IP multicast group comparison mask. This mask determines the IP multicast group numbers for which the Layer 3 Switch can be a BSR.
The default is 32 bits, which allows the Layer 3 Switch to be a BSR for any valid IP multicast group number.
  **NOTE:** This field appears only if this Layer 3 Switch is the BSR. |
| Next bootstrap message in | Indicates how many seconds will pass before the BSR sends its next Bootstrap message.
  **NOTE:** This field appears only if this Layer 3 Switch is the BSR. |
| Next Candidate-RP-advertisement message in | Indicates how many seconds will pass before the BSR sends its next candidate PR advertisement message.
  **NOTE:** This field appears only if this Layer 3 Switch is the BSR. |
| RP | Indicates the IP address of the Rendezvous Point (RP).
  **NOTE:** This field appears only if this Layer 3 Switch is the BSR. |
### Displaying Pim resources

To display the hardware resource information such as hardware allocation, availability, and limit for software data structure, enter the following command.

```
FastIron# show ip pim resource
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>group prefixes</td>
<td>Indicates the multicast groups for which the RP listed by the previous field is a candidate RP.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> This field appears only if this Layer 3 Switch is the BSR.</td>
</tr>
<tr>
<td>Candidate-RP-advertisement period</td>
<td>Indicates how frequently the BSR sends candidate RP advertisement messages.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> This field appears only if this Layer 3 Switch is the BSR.</td>
</tr>
</tbody>
</table>

**TABLE 143** Output of show ip pim bsr (Continued)

<table>
<thead>
<tr>
<th>Field</th>

igmp gbl sorted list 2000 0 2000 0 500000 0
```

**Syntax:** show ip pim resource

For the Turbolon devices, the number of Hardware (Hw) resources available are 2048.

For each software data structure listed in the output, the following information is shown.
To display candidate RP information, enter the following command at any CLI level.

```
FastIron# show ip pim rp-candidate
```

Next Candidate-RP-advertisement in 00:00:10
RP: 207.95.7.1
    group prefixes:
    224.0.0.0 / 4

Candidate-RP-advertisement period: 60

This example shows information displayed on a Layer 3 Switch that is a candidate RP. The following example shows the message displayed on a Layer 3 Switch that is not a candidate RP.

```
FastIron# show ip pim rp-candidate
```

This system is not a Candidate-RP.

**Syntax:** show ip pim rp-candidate

This display shows the following information.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Candidate-RP-advertisement in</td>
<td>Indicates how many seconds will pass before the BSR sends its next RP</td>
</tr>
<tr>
<td></td>
<td>message.</td>
</tr>
<tr>
<td>NOTE: This field appears only if</td>
<td>This Layer 3 Switch is a candidate RP.</td>
</tr>
<tr>
<td>the Layer 3 Switch is a candidate</td>
<td></td>
</tr>
<tr>
<td>RP</td>
<td>Indicates the IP address of the Rendezvous Point (RP).</td>
</tr>
<tr>
<td>NOTE: This field appears only if</td>
<td>This Layer 3 Switch is a candidate RP.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Displaying RP-to-group mappings

To display RP-to-group mappings, enter the following command at any CLI level.

```
FastIron# show ip pim rp-map
Number of group-to-RP mappings: 6

Group address       RP address
---------------------
1 239.255.163.1  99.99.99.5
2 239.255.163.2  99.99.99.5
3 239.255.163.3  99.99.99.5
4 239.255.162.1  43.43.43.1
5 239.255.162.2  99.99.99.5
6 239.255.162.3  99.99.99.5
```

**Syntax:** `show ip pim rp-map`

This display shows the following information.

**TABLE 145** Output of show ip pim rp-candidate (Continued)

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>group prefixes</td>
<td>Indicates the multicast groups for which the RP listed by the previous field is a candidate RP.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> This field appears only if this Layer 3 Switch is a candidate RP.</td>
</tr>
<tr>
<td>Candidate-RP-advertisement period</td>
<td>Indicates how frequently the BSR sends candidate RP advertisement messages.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> This field appears only if this Layer 3 Switch is a candidate RP.</td>
</tr>
</tbody>
</table>

**Displaying RP information for a PIM Sparse group**

To display RP information for a PIM Sparse group, enter the following command at any CLI level.

```
FastIron# show ip pim rp-hash 239.255.162.1
   RP: 207.95.7.1, v2
       Info source: 207.95.7.1, through bootstrap
```

**Syntax:** `show ip pim rp-hash <group-addr>`

The `<group-addr>` parameter is the address of a PIM Sparse IP multicast group.

This display shows the following information.
Displaying the RP set list

To display the RP set list, enter the following command at any CLI level.

Syntax: show ip pim rp-set

This display shows the following information.

<table>
<thead>
<tr>
<th>TABLE 147</th>
<th>Output of show ip pim rp-hash</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field...</strong></td>
<td><strong>Displays...</strong></td>
</tr>
<tr>
<td>RP</td>
<td>Indicates the IP address of the Rendezvous Point (RP) for the specified PIM Sparse group. Following the IP address is the port or virtual interface through which this Layer 3 Switch learned the identity of the RP.</td>
</tr>
<tr>
<td>Info source</td>
<td>Indicates the IP address on which the RP information was received. Following the IP address is the method through which this Layer 3 Switch learned the identity of the RP.</td>
</tr>
</tbody>
</table>

**TABLE 148**  
Output of show ip pim rp-set

<table>
<thead>
<tr>
<th><strong>This field...</strong></th>
<th><strong>Displays...</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of group prefixes</td>
<td>The number of PIM Sparse group prefixes for which the RP is responsible.</td>
</tr>
<tr>
<td>Group prefix</td>
<td>Indicates the multicast groups for which the RP listed by the previous field is a candidate RP.</td>
</tr>
<tr>
<td>RPs expected/received</td>
<td>Indicates how many RPs were expected and received in the latest Bootstrap message.</td>
</tr>
<tr>
<td>RP &lt;num&gt;</td>
<td>Indicates the RP number. If there are multiple RPs in the PIM Sparse domain, a line of information for each of them is listed, and they are numbered in ascending numerical order.</td>
</tr>
<tr>
<td>priority</td>
<td>The RP priority of the candidate RP. During the election process, the candidate RP with the highest priority is elected as the RP.</td>
</tr>
<tr>
<td>age</td>
<td>The age (in seconds) of this RP-set. <strong>NOTE:</strong> If this Layer 3 Switch is not a BSR, this field contains zero. Only the BSR ages the RP-set.</td>
</tr>
</tbody>
</table>

**Displaying multicast neighbor information**

To display information about the Layer 3 Switch PIM neighbors, enter the following command at any CLI level.

FastIron# show ip pim rp-set
Group address Static-RP-address Override
----------------------------------------------
Access-List 44 99.99.99.5 On
Number of group prefixes Learnt from BSR: 1
Group prefix = 239.255.162.0/24 #RPs expected: 1
#RPs received: 1
RP 1: 43.43.43.1 priority=0 age=0
This display shows the following information.

### TABLE 149  Output of show ip pim nbr

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The interface through which the Layer 3 Switch is connected to the neighbor.</td>
</tr>
<tr>
<td>Neighbor</td>
<td>The IP interface of the PIM neighbor interface.</td>
</tr>
</tbody>
</table>
| Holdtime sec  | Indicates how many seconds the neighbor wants this Layer 3 Switch to hold the entry for this neighbor in memory. The neighbor sends the Hold Time in its Hello packets:  
  • If the Layer 3 Switch receives a new Hello packet before the Hold Time received in the previous packet expires, the Layer 3 Switch updates its table entry for the neighbor.  
  • If the Layer 3 Switch does not receive a new Hello packet from the neighbor before the Hold time expires, the Layer 3 Switch assumes the neighbor is no longer available and removes the entry for the neighbor. |
| Age sec       | The number of seconds since the Layer 3 Switch received the last hello message from the neighbor. |
| UpTime sec    | The number of seconds the PIM neighbor has been up. This timer starts when the Layer 3 Switch receives the first Hello messages from the neighbor. |

### Displaying information about an upstream neighbor device

You can view information about the upstream neighbor device for a given source IP address for IP Protocol Independent Multicast (PIM) and Distance Vector Multicast Routing Protocol (DVMRP) packets. For PIM, the software uses the IP route table or multicast route table to lookup the upstream neighbor device. For DVMRP, the software uses the DVMRP route table to locate the upstream neighbor device.

Enter the following command at the Privileged EXEC level of the CLI.

```
FastIron# show ip pim rpf 1.1.20.2
directly connected or through an L2 neighbor
```

**Syntax:** `show ip pim | dvmrp rpf <IP address>`

where `<IP address>` is a valid source IP address

**NOTE**

If there are multiple equal cost paths to the source, the `show ip pim rpf` command output may not be accurate. If your system has multiple equal cost paths, use the command `show ip pim mcachewto view information about the upstream neighbor.`
Displaying the PIM flow cache

To display the PIM flow cache for FastIron devices, enter the following command at any CLI level.

FastIron# show ip pim flowcache 238.0.0.1

Multicast flow (24.1.1.100 238.0.0.1):
VIdx for source vlan forwarding: 2080
[mcastPrintMll]: vrId 0, ipGrp 238.0.0.1, grpPrefix 32, ipSrc 24.1.1.100, srcPre 32, nextHopIdx 0

1 flow printed

Syntax: show ip pim flowcache

This display shows the following information.

TABLE 150 Output of show ip pim flowcache

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Indicates the source of the PIM Sparse group.</td>
</tr>
<tr>
<td>Group</td>
<td>Indicates the PIM Sparse group.</td>
</tr>
<tr>
<td>Parent</td>
<td>Indicates the port or virtual interface from which the Layer 3 Switch receives packets from the group source.</td>
</tr>
<tr>
<td>CamFlags</td>
<td>This field is used by Brocade technical support for troubleshooting.</td>
</tr>
<tr>
<td>CamIndex</td>
<td>This field is used by Brocade technical support for troubleshooting.</td>
</tr>
<tr>
<td>Fid</td>
<td>This field is used by Brocade technical support for troubleshooting.</td>
</tr>
<tr>
<td>Flags</td>
<td>This field is used by Brocade technical support for troubleshooting.</td>
</tr>
</tbody>
</table>

Displaying the PIM multicast cache

To display the PIM multicast cache, enter the following command at any CLI level.

FastIron# show ip pim mcache

(* 228.1.0.88) RP 1.1.1.1, in e21 (e21), cnt=0
Source is directly connected
Sparse Mode, RPT=1 SPT=0 REG=0 MSDP Adv=0 MSDP Create=0
L3 (SW) 3: e2(VL33), e1(VL5), TR(e13,e14)(VL55)
fast=1 slow=0 pru=1 graft
age=0s up-time=4123m HW=0

Syntax: show ip pim mcache

This display shows the following information.
### TABLE 151 Output of show ip pim mcache

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>(&lt;source&gt;, &lt;group&gt;)</td>
<td>The comma-separated values in parentheses is a source-group pair. The &lt;source&gt; is the PIM source for the multicast &lt;group&gt;. For example, the following entry means source 209.157.24.162 for group 239.255.162.1: (209.157.24.162,239.255.162.1) If the &lt;source&gt; value is * (asterisk), this cache entry uses the RP path. The * value means “all sources”. If the &lt;source&gt; is a specific source address, this cache entry uses the SPT path.</td>
</tr>
<tr>
<td>RP&lt;ip-addr&gt;</td>
<td>Indicates the RP for the group for this cache entry. <strong>NOTE:</strong> The RP address appears only if the RPT flag is set to 1 and the SPT flag is set to 0 (see below).</td>
</tr>
<tr>
<td>forward port</td>
<td>The port through which the Layer 3 Switch reaches the source.</td>
</tr>
<tr>
<td>Count</td>
<td>The number of packets forwarded using this cache entry.</td>
</tr>
<tr>
<td>Sparse Mode</td>
<td>Indicates whether the cache entry is for regular PIM (dense mode) or PIM Sparse. This flag can have one of the following values: • 0 – The entry is not for PIM Sparse (and is therefore for the dense mode of PIM). • 1 – The entry is for PIM Sparse.</td>
</tr>
<tr>
<td>RPT</td>
<td>Indicates whether the cache entry uses the RP path or the SPT path. The RPT flag can have one of the following values: • 0 – The SPT path is used instead of the RP path. • 1 – The RP path is used instead of the SPT path. <strong>NOTE:</strong> The values of the RP and SPT flags are always opposite (one is set to 0 and the other is set to 1).</td>
</tr>
<tr>
<td>SPT</td>
<td>Indicates whether the cache entry uses the RP path or the SPT path. The SP flag can have one of the following values: • 0 – The RP path is used instead of the SPT path. • 1 – The SPT path is used instead of the RP path. <strong>NOTE:</strong> The values of the RP and SPT flags are always opposite (one is set to 0 and the other is set to 1).</td>
</tr>
<tr>
<td>Register Suppress</td>
<td>Indicates whether the Register Suppress timer is running. This field can have one of the following values: • 0 – The timer is not running. • 1 – The timer is running.</td>
</tr>
<tr>
<td>member ports</td>
<td>Indicates the Layer 3 Switch physical ports to which the receivers for the source and group are attached. The receivers can be directly attached or indirectly attached through other PIM Sparse routers.</td>
</tr>
<tr>
<td>virtual ports</td>
<td>Indicates the virtual interfaces to which the receivers for the source and group are attached. The receivers can be directly attached or indirectly attached through other PIM Sparse routers.</td>
</tr>
<tr>
<td>prune ports</td>
<td>Indicates the physical ports on which the Layer 3 Switch has received a prune notification (in a Join/Prune message) to remove the receiver from the list of recipients for the group.</td>
</tr>
<tr>
<td>virtual prune ports</td>
<td>Indicates the virtual interfaces ports on which the Layer 3 Switch has received a prune notification (in a Join/Prune message) to remove the receiver from the list of recipients for the group.</td>
</tr>
</tbody>
</table>
Displaying PIM traffic statistics

To display PIM traffic statistics, use the following CLI method.

FastIron# show ip pim traffic

<table>
<thead>
<tr>
<th>Port</th>
<th>Hello</th>
<th>J/P</th>
<th>Register</th>
<th>RegStop</th>
<th>Assert</th>
</tr>
</thead>
<tbody>
<tr>
<td>e3/8</td>
<td>19 Rx</td>
<td>32</td>
<td>0</td>
<td>37 Tx</td>
<td>0</td>
</tr>
<tr>
<td>v1</td>
<td>18 Rx</td>
<td>20</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>v2</td>
<td>0</td>
<td>0</td>
<td>16</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Total 37 Rx 57 Tx 32 Rx 0 Tx 0 Rx 0 Tx 0 Rx 0 Tx 0 Rx 0 Tx

IGMP Statistics:
Total Recv/Xmit 85/110
Total Discard/chksum 0/0

Syntax: show ip pim traffic

NOTE
If you have configured interfaces for standard PIM (dense mode) on the Layer 3 Switch, statistics for these interfaces are listed first by the display.

This display shows the following information.

| TABLE 152  | Output of show ip pim traffic

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The port or virtual interface on which the PIM interface is configured.</td>
</tr>
<tr>
<td>Hello</td>
<td>The number of PIM Hello messages sent or received on the interface.</td>
</tr>
<tr>
<td>J/P</td>
<td>The number of Join/Prune messages sent or received on the interface.</td>
</tr>
<tr>
<td>Register</td>
<td>The number of Register messages sent or received on the interface.</td>
</tr>
<tr>
<td>RegStop</td>
<td>The number of Register Stop messages sent or received on the interface.</td>
</tr>
<tr>
<td>Assert</td>
<td>The number of Assert messages sent or received on the interface.</td>
</tr>
<tr>
<td>Total Recv/Xmit</td>
<td>The total number of IGMP messages sent and received by the Layer 3 Switch.</td>
</tr>
<tr>
<td>Total Discard/chksum</td>
<td>The total number of IGMP messages discarded, including a separate counter for those that failed the checksum comparison.</td>
</tr>
</tbody>
</table>

Displaying and clearing PIM errors

If you want to determine how many PIM errors there are on the device, enter the following command.

FastIron# show ip pim error
**** Warning counter pim route change = 1
HW tagged replication enabled, SW processed pkts 0
Syntax: show ip pim error

This command displays the number of warnings and non-zero PIM errors on the device. This count can increase during transition periods such as reboots and topology changes; however, if the device is stable, the number of errors should not increase. If warnings keep increasing in a stable topology, then there may be a configuration error or problems on the device.

To clear the counter for PIM errors, enter the following command.

FastIron# clear pim counters

Syntax: clear pim counters

PIM Passive

Platform Support:

- FastIron X Series devices running software release FSX 05.1.00 and later

PIM Passive is used to reduce and minimize unnecessary PIM Hello and other PIM control messages.

PIM Passive allows you to specify that the interface is “passive” in regards to PIM. No PIM control packets are sent or processed (if received), but hosts can still send and receive multicast traffic and IGMP control traffic on that interface. Also, PIM Passive prevents any malicious router from taking over as the designated router (DR), which can prevent all hosts on the LAN from joining multicast traffic outside the LAN.

The following guidelines apply to PIM Passive on FESX/SX devices:

1. This is a Layer 3 interface [Ethernet/Ve] level feature.
2. Since the loopback interfaces are never used to form PIM neighbors, this feature is not supported on loopback interface.
3. Both PIM SM and PIM DM modes support this feature.
4. Applying the PIM Passive on an interface requires PIM to be enabled on that interface.
5. The sent and received statistics of a PIM Hello message are not changed for an interface, while it is configured as PIM passive.

To enable PIM Passive on an interface, enter the following command:

FastIron# config term
FastIron(config)# router pim
FastIron(config-pim-router)# exit
FastIron(config)# interface ethernet 2
FastIron(config-if-e1000-2)# ip pim
FastIron(config-if-e1000-2)# ip pim passive
FastIron(config-if-e1000-2)# exit
FastIron(config)# interface ve 2
FastIron(config-vif-2)# ip pim-sparse
FastIron(config-vif-2)# ip pim passive
FastIron(config-vif-2)# exit

Syntax: [no] ip pim passive

Use the show ip pim interface command to display multicast boundary information related to PIM passive. For example outputs, see “Displaying multicast boundaries” on page 839.
Multicast Source Discovery Protocol (MSDP)

**Platform Support:**
- FastIron X Series devices running software release FSX 05.1.00 and later
- TurboIron X Series devices running software release 04.2.00 and later

The Multicast Source Discovery Protocol (MSDP) is used by Protocol Independent Multicast (PIM) Sparse routers to exchange routing information for PIM Sparse multicast groups across PIM Sparse domains. Routers running MSDP can discover PIM Sparse sources that are in other PIM Sparse domains.

For TurboIron X Series devices running software release 04.2.00 and later, you must configure a fully meshed topology between MSDP peers. This is mandated for this release because of lack of any EGP that provides a peer RPF check for SA messages that are forwarded between MSDP peers.

PIM Sparse routers use MSDP to register PIM Sparse multicast sources in a domain with the Rendezvous Point (RP) for that domain.

*Figure 116* shows an example of some PIM Sparse domains. For simplicity, this example shows only one Designated Router (DR), one group source, and one receiver for the group. Only one PIM Sparse router within each domain needs to run MSDP.

*FIGURE 116* PIM Sparse domains joined by MSDP routers
In this example, the source for PIM Sparse multicast group 232.0.1.95 is in PIM Sparse domain 1. The source sends a packet for the group to its directly attached DR. The DR sends a Group Advertisement message for the group to the domain RP. The RP is configured for MSDP, which enables the RP to exchange source information with other PIM Sparse domains by communicating with RPs in other domains that are running MSDP.

The RP sends the source information to each of its peers by sending a Source Active message. The message contains the IP address of the source, the group address to which the source is sending, and the IP address of the RP interface with its peer. By default, the IP address included in the RP address field of the SA message is the IP address of the originating RP. However, if MSDP is instructed to use a specific address as the IP address of the RP in a Source Address message (CLI command `originator-id <type> <number>`), the Source Active message can be the IP address of any interface on the originating RP. The interface is usually a loopback interface.

In this example, the Source Active message contains the following information:

- Source address: 206.251.14.22
- Group address: 232.1.0.95
- RP address: 206.251.17.41
Figure 116 shows only one peer for the MSDP router (which is also the RP here) in domain 1, so the Source Active message goes to only that peer. When an MSDP router has multiple peers, it sends a Source Active message to each of those peers. Each peer sends the Source Advertisement to its other MSDP peers. The RP that receives the Source Active message also sends a Join message for the group if the RP that received the message has receivers for the group.

**Peer Reverse Path Forwarding (RPF) flooding**

When the MSDP router (also the RP) in domain 2 receives the Source Active message from its peer in domain 1, the MSDP router in domain 2 forwards the message to all its other peers. The propagation process is sometimes called “peer Reverse Path Forwarding (RPF) flooding”. This term refers to the fact that the MSDP router uses its PIM Sparse RPF tree to send the message to its peers within the tree. In Figure 116, the MSDP router floods the Source Active message it receives from its peer in domain 1 to its other peers, in domains 3 and 4.

Note that the MSDP router in domain 2 does not forward the Source Active back to its peer in domain 1, because that is the peer from which the router received the message. An MSDP router never sends a Source Active message back to the peer that sent it. The peer that sent the message is sometimes called the “RPF peer”. The MSDP router uses the unicast routing table for its Exterior Gateway Protocol (EGP) to identify the RPF peer by looking for the route entry that is the next hop toward the source. Often, the EGP protocol is Border Gateway Protocol (BGP) version 4.

**NOTE**

On FastIron devices, MSDP depends on BGP for interdomain operations.

The MSDP routers in domains 3 and 4 also forward the Source Active message to all their peers except the ones that sent them the message. Figure 116 does not show additional peers.

**Source active caching**

When an MSDP router that is also an RP receives a Source Active message, the RP checks its PIM Sparse multicast group table for receivers for the group. If the DR has a receiver for the group being advertised in the Source Active message, the DR sends a Join message for that receiver back to the DR in the domain from which the Source Active message came. Usually, the DR is also the MSDP router that sent the Source Active message.

In Figure 116, if the MSDP router and RP in domain 4 has a table entry for the receiver, the RP sends a Join message on behalf of the receiver back through the RPF tree to the RP for the source, in this case the RP in domain 1.

Some MSDP routers that are also RPs can cache Source Active messages. If the RP is not caching Source Active messages, the RP does not send a Join message unless it already has a receiver that wants to join the group. Otherwise, the RP does not send a Join message and does not remember the information in the Source Active message after forwarding it. If the RP receives a request from a receiver for the group, the RP and receiver must wait for the next Source Active message for that group before the RP can send a Join message for the receiver.

However, if Source Active caching is enabled on the MSDP and RP router, the RP caches the Source Active messages it receives. In this case, even if the RP does not have a receiver for a group when the RP receives the Source Active message for the group, the RP can immediately send a Join for a new receiver that wants to join the group, without waiting for the next Source Active message from the RP in the source domain.
The maximum size of the cache used to store MSDP Source Active messages is 8K and the default size is 4K.

**Configuring MSDP**

To configure MSDP on a Layer 3 Switch, perform the following tasks:

- Enable MSDP
- Configure the MSDP peers

**NOTE**
The PIM Sparse Rendezvous Point (RP) is also an MSDP peer.

**NOTE**
Routers that run MSDP must also run BGP. Also, the source address used by the MSDP router must be the same source address used by BGP. This limitation is not applicable to TurboIron device because BGP is not supported on the device.

**Enabling MSDP**

To enable MSDP, enter the following command.

```
FastIron(config)# router msdp
```

**NOTE**
When enabling and disabling MSDP, you do not need to save the configuration and reload the software. The configuration change takes effect immediately, as soon as you enter the CLI command.

**Syntax:** [no] router msdp

**Configuring MSDP peers**

On a Brocade device, you can configure a maximum of 15 MSDP peers. To configure an MSDP peer, enter a command such as the following at the MSDP configuration level.

```
FastIron(config-msdp-router)# msdp-peer 205.216.162.1
```

**Syntax:** [no] msdp-peer <ip-addr> [connect-source loopback <num>]

The `<ip-addr>` parameter specifies the IP address of the neighbor.

The `connect-source loopback <num>` parameter specifies the loopback interface you want to use as the source for sessions with the neighbor.

**NOTE**
It is strongly recommended that you use the `connect-source loopback <num>` parameter when issuing the `msdp-peer` command. If you do not use this parameter, the Layer 3 Switch uses the subnet interface configured on the port.

Also, make sure the IP address of the connect-source loopback is the same as the source IP address used by the MSDP router, the PIM-RP, and the BGP router. This limitation is not applicable to TurboIron device because BGP is not supported on the device.
The commands in the following example add an MSDP neighbor and specify a loopback interface as the source interface for sessions with the neighbor. By default, the Layer 3 Switch uses the subnet address configured on the physical interface where you configure the neighbor as the source address for sessions with the neighbor.

```
FastIron(config)# interface loopback 1
FastIron(config-lbif-1)# ip address 9.9.9.9/32
FastIron(config-lbif-1)# exit
FastIron(config)# router msdp
FastIron(config-msdp-router)# msdp-peer 2.2.2.99 connect-source loopback 1
```

### Designating an interface IP address as the RP IP address

When an RP receives a Source Active message, it checks its PIM Sparse multicast group table for receivers for the group. If it finds a receiver, the RP sends a Join message for that receiver back to the RP that originated the Source Active message. The originator RP is identified by its RP address.

By default, the IP address included in the RP address field of the SA message is the IP address of the originating RP. Beginning with this release, an SA message can use the IP address of any interface on the originating RP. (The interface is usually a loopback interface.)

To designate an interface IP address to be the IP address of the RP, enter commands such as the following:

```
FastIron(config)# interface loopback 2
FastIron(config-lbif-2)# ip address 2.2.2.99/32
FastIron(config)# router msdp
FastIron(config-msdp-router)# originator-id loopback 2
FastIron(config-msdp-router)# exit
```

**Syntax:**

```
[no] originator-id <type> <number>
```

The `originator-id` parameter instructs MSDP to use the specified address as the IP address of the RP in an SA message. This address must be the address of the interface used to connect the RP to the source. There are no default originator-ids.

The `<type>` parameter indicates the type of interface used by the RP. Ethernet, loopback and virtual routing interfaces (ve) can be used.

The `<number>` parameter specifies the interface number (for example: loopback number, port number or virtual routing interface number.)

### Filtering MSDP source-group pairs

The following commands allow you to filter individual source-group pairs in MSDP Source-Active messages:

- **`sa-filter in`** – Filters source-group pairs received in Source-Active messages from an MSDP neighbor
- **`sa-filter originate`** – Filters source-group pairs in Source-Active messages in advertisements to an MSDP neighbor
Filtering incoming source-active messages

The following example configures filters for incoming Source-Active messages from three MSDP neighbors:

- For peer 2.2.2.99, all source-group pairs in Source-Active messages from the neighbor are filtered out (dropped).
- For peer 2.2.2.97, all source-group pairs except those with 10.x.x.x as the source are permitted.
- For peer 2.2.2.96, all source-group pairs except those associated with RP 2.2.42.3 are permitted.

Example

The following commands configure an IP address on port 3/1. This is the port on which the MSDP neighbors will be configured.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-3/1)# ip address 2.2.2.98/24
FastIron(config-if-3/1)# exit
```

The following commands configure a loopback interface. The Layer 3 Switch will use this interface as the source address for communicating with the MSDP neighbors.

```
FastIron(config)# interface loopback 1
FastIron(config-lbif-1)# ip address 9.9.9.8/32
FastIron(config-lbif-1)# exit
```

The following commands configure extended ACLs. The ACLs will be used in route maps, which will be used by the Source-Active filters.

```
FastIron(config)# access-list 123 permit 10.0.0.0 0.255.255.255 any
FastIron(config)# access-list 124 permit 2.2.42.3 0.0.0.0 any
FastIron(config)# access-list 125 permit any any
```

The following commands configure the route maps.

```
FastIron(config)# route-map msdp_map deny 1
FastIron(config-route-map msdp_map)# match ip address 123
FastIron(config-route-map msdp_map)# exit
FastIron(config)# route-map msdp2_map permit 1
FastIron(config-route-map msdp2_map)# match ip address 125
FastIron(config-route-map msdp2_map)# exit
FastIron(config)# route-map msdp2_rp_map deny 1
FastIron(config-route-map msdp2_rp_map)# match ip route-source 124
FastIron(config-route-map msdp2_rp_map)# exit
```

The following commands enable MSDP and configure the MSDP neighbors on port 3/1.

```
FastIron(config)# router msdp
FastIron(config-msdp-router)# msdp-peer 2.2.2.99 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 2.2.2.97 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 2.2.2.96 connect-source loopback 1
FastIron(config-msdp-router)# exit
```
The following commands configure the Source-Active filters.

FastIron(config)# router msdp
FastIron(config-msdp-router)# sa-filter in 2.2.2.99
FastIron(config-msdp-router)# sa-filter in 2.2.2.97 route-map msdp_map
FastIron(config-msdp-router)# sa-filter in 2.2.2.96 route-map msdp2_map
rp-route-map msdp2_rp_map

The **sa-filter** commands configure the following filters:

- **sa-filter in 2.2.2.99** – This command drops all source-group pairs received from neighbor 2.2.2.99.

  **NOTE**
  The default action is to deny all source-group pairs from the specified neighbor. If you want to permit some pairs, use route maps.

- **sa-filter in 2.2.2.97 route-map msdp_map** – This command drops source-group pairs received from neighbor 2.2.2.97 if the pairs have source address 10.x.x.x and any group address.

- **sa-filter in 2.2.2.96 route-map msdp2_map rp-route-map msdp2_rp_map** – This command accepts all source-group pairs except those associated with RP 2.2.42.3.

**CLI syntax**

**Syntax:** `[no] sa-filter in <ip-addr> [route-map <map-tag>] [rp-route-map <rp-map-tag>]`

The `<ip-addr>` parameter specifies the IP address of the MSDP neighbor. The filter applies to Active-Source messages received from this neighbor.

The **route-map** `<map-tag>` parameter specifies a route map. The Layer 3 Switch applies the filter to source-group pairs that match the route map. Use the **match ip address** `<acl-id>` command in the route map to specify an extended ACL that contains the source and group addresses.

The **rp-route-map** `<rp-map-tag>` parameter specifies a route map to use for filtering based on Rendezvous Point (RP) address. Use this parameter if you want to filter Source-Active messages based on their origin. If you use the **route-map** parameter instead, messages are filtered based on source-group pairs but not based on origin. Use the **match ip route-source** `<acl-id>` command in the route map to specify the RP address.

**NOTE**
The default filter action is deny. If you want to permit some source-group pairs, use a route map. A permit action in the route map allows the Layer 3 Switch to receive the matching source-group pairs. A deny action in the route map drops the matching source-group pairs.

**Filtering advertised source-active messages**

The following example configures the Layer 3 Switch to advertise all source-group pairs except the ones that have source address 10.x.x.x.

**Example**

The following commands configure an IP address on port 3/1. This is the port on which the MSDP neighbors will be configured.

FastIron(config)# interface ethernet 3/1
FastIron(config-if-3/1)# ip address 2.2.2.98/24
FastIron(config-if-3/1)# exit
The following commands configure a loopback interface. The Layer 3 Switch will use this interface as the source address for communicating with the MSDP neighbors.

```
FastIron(config)# interface loopback 1
FastIron(config-lbif-1)# ip address 9.9.9.8/32
FastIron(config-lbif-1)# exit
```

The following command configures an extended ACL to specify the source and group addresses you want to filter.

```
FastIron(config)# access-list 123 permit 10.0.0.0 0.255.255.255 any
```

The following commands configure a route map. The map matches on source address 10.x.x.x and any group address. Since the action is deny, the Source-Active filter that uses this route map will remove the source-group pairs that match this route map from the Source-Active messages to the neighbor.

```
FastIron(config)# route-map msdp_map deny 1
FastIron(config-route-map msdp_map)# match ip address 123
FastIron(config-route-map msdp_map)# exit
```

The following commands enable MSDP and configure MSDP neighbors.

```
FastIron(config)# router msdp
FastIron(config-msdp-router)# msdp-peer 2.2.2.99 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 2.2.2.97 connect-source loopback 1
FastIron(config-msdp-router)# exit
```

The following commands configure the Source-Active filter.

```
FastIron(config)# router msdp
FastIron(config-msdp-router)# sa-filter originate route-map msdp_map
```

This filter removes source-group pairs that match route map msdp_map from Source-Active messages before sending them to MSDP neighbors.

**CLI syntax**

Syntax: `[no] sa-filter originate [route-map <map-tag>]`

The `route-map <map-tag>` parameter specifies a route map. The Layer 3 Switch applies the filter to source-group pairs that match the route map. Use the `match ip address <acl-id>` command in the route map to specify an extended ACL that contains the source and group addresses.

**NOTE**

The default filter action is deny. If you want to permit some source-group pairs, use a route map. A permit action in the route map allows the Layer 3 Switch to receive the matching source-group pairs. A deny action in the route map drops the matching source-group pairs.

**MSDP mesh groups**

A PIM Sparse domain can have several RPs that are connected to each other to form an MSDP mesh group. To qualify as a mesh group, the RPs have to be fully meshed; that is, each RP must be connected to all peer RPs in a domain. (See Figure 117.)
A mesh group reduces the forwarding of SA messages within a domain. Instead of having every RP in a domain forward SA messages to all the RPs within that domain, only one RP forwards the SA message. Since an MSDP mesh group is fully meshed, peers do not forward SA messages received in a domain from one member to every member of the group. The RP that originated the SA or the first RP in a domain that receives the SA message is the only one that can forward the message to the members of a mesh group. An RP can forward an SA message to any MSRP router as long as that peer is farther away from the originating RP than the current MSRP router.

Figure 117 shows an example of an MSDP mesh group. In a PIM-SM mesh group the RPs are configured to be peers of each other. They can also be peers of RPs in other domains.

**Configuring an MSDP mesh group**

To configure an MSDP mesh group, enter commands such as the following on each device that will be included in the mesh group:

```plaintext
FESX Router(config)# router msdp
FESX Router(config-msdp-router)# msdp-peer 1.1.3.1 connect-source loopback 1
FESX Router(config-msdp-router)# msdp-peer 1.1.4.1 connect-source loopback 1
FESX Router(config-msdp-router)# msdp-peer 1.1.2.1 connect-source loopback 1
FESX Router(config-msdp-router)# msdp-peer 17.17.17.7
FESX Router(config-msdp-router)# mesh-group 1234 1.1.4.1
FESX Router(config-msdp-router)# mesh-group 1234 1.1.3.1
FESX Router(config-msdp-router)# mesh-group 1234 1.1.2.1
FESX Router(config-msdp-router)# exit
```

**Syntax:**

```
[no] mesh-group <group-name> <peer-address>
```

The example configuration above reflects the configuration in Figure 117. On RP 1.1.1.1, you specify its peers within the same domain (1.1.3.1, 1.1.4.1, and 1.1.2.1).

You first configure the MSDP peers using the `msdp-peer` command to assign their IP addresses and the loopback interfaces. This information will be used as the source for sessions with the neighbor.

Next, place the MSDP peers within a domain into a mesh group. Use the `mesh-group` command. There are no default mesh groups.

The `group-name` parameter identifies the group. Enter up to 31 characters for group-name. You can have up to 4 mesh groups within a multicast network. Each mesh group can include up to 32 peers.

The `peer-address` parameter specifies the IP address of the MSDP peer that is being placed in the group.

**NOTE**

On each of the device that will be part of the mesh-group, there must be a mesh-group definition for all the peers in the mesh-group.

Up to 32 MSDP peers can be configured per mesh group.

**Example configuration**

In Figure 117, devices A, B, C, and D are in Mesh Group 1234. The example configuration following the figure shows how the devices are configured to be part of the MSDP mesh group. The example also shows the features that need to be enabled for the MSDP mesh group to work.

**FIGURE 117  MSDP mesh group 1234**
### Configuration for Device A

The following set of commands configure the MSDP peers of Device A (1.1.1.1) that are inside and outside MSDP mesh group 1234. Device A peers inside the mesh group 1234 are 1.1.2.1, 1.1.3.1, and 1.1.4.1. Device 17.17.17.7 is a peer of Device A, but is outside mesh group 1234. Multicast is enabled on Device A interfaces. PIM and BGP are also enabled.

```
FastIron(config)# router pim
FastIron(config)# router msdp
FastIron(config-msdp-router)# msdp-peer 1.1.3.1 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 1.1.4.1 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 1.1.2.1 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 17.17.17.7
FastIron(config-msdp-router)# mesh-group 1234 1.1.4.1
FastIron(config-msdp-router)# mesh-group 1234 1.1.3.1
FastIron(config-msdp-router)# mesh-group 1234 1.1.2.1
FastIron(config-msdp-router)# exit

FastIron(config)# interface loopback 1
FastIron(config-lbif-1)# ip address 1.1.1.1 255.255.255.0
FastIron(config-lbif-1)# ip pim-sparse
FastIron(config-lbif-1)# exit

FastIron(config)# interface ethernet 1/1
FastIron(config-if-1/1)# ip address 14.14.14.1 255.255.255.0
FastIron(config-if-1/1)# ip pim-sparse
FastIron(config-if-1/1)# exit
```
FastIron(config)# interface ethernet 2/1
FastIron(config-if-2/1)# ip address 12.12.12.1 255.255.255.0
FastIron(config-if-2/1)# ip pim-sparse
FastIron(config-if-2/1)# exit

FastIron(config)# interface ethernet 2/20
FastIron(config-if-2/20)# ip address 159.159.159.1 255.255.255.0
FastIron(config-if-2/20)# ip pim-sparse
FastIron(config-if-2/20)# exit

FastIron(config)# interface ethernet 4/1
FastIron(config-if-4/1)# ip address 31.31.31.1 255.255.255.0
FastIron(config-if-4/1)# ip pim-sparse
FastIron(config-if-4/1)# exit

FastIron(config)# interface ethernet 4/8
FastIron(config-if-4/8)# ip address 17.17.17.1 255.255.255.0
FastIron(config-if-4/8)# ip pim-sparse
FastIron(config-if-4/8)# ip pim border
FastIron(config-if-4/8)# exit

FastIron(config)# router pim
FastIron(config-router-pim)# bsr-candidate loopback 1 1 31
FastIron(config-router-pim)# rp-candidate loopback 1
FastIron(config-router-pim)# exit

FastIron(config)# router bgp
FastIron(config-bgp-router)# local-as 111
FastIron(config-bgp-router)# neighbor 31.31.31.3 remote-as 333
FastIron(config-bgp-router)# neighbor 31.31.31.3 next-hop-self
FastIron(config-bgp-router)# neighbor 12.12.12.2 remote-as 222
FastIron(config-bgp-router)# neighbor 12.12.12.2 next-hop-self
FastIron(config-bgp-router)# neighbor 17.17.17.7 remote-as 777
FastIron(config-bgp-router)# neighbor 17.17.17.7 next-hop-self
FastIron(config-bgp-router)# redistribute connected
FastIron(config-bgp-router)# write memory

Configuration for Device B

The following set of commands configure the MSDP peers of Device B. All Device B peers (1.1.1.1, 1.1.3.1, and 1.1.4.1) are in the MSDP mesh group 1234. Multicast is enabled on Device B interfaces. PIM and BGP are also enabled.

FastIron(config)# router pim

FastIron(config)# router msdp
FastIron(config-msdp-router)# msdp-peer 1.1.3.1 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 1.1.1.1 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 1.1.4.1 connect-source loopback 1
FastIron(config-msdp-router)# mesh-group 1234 1.1.1.1
FastIron(config-msdp-router)# mesh-group 1234 1.1.3.1
FastIron(config-msdp-router)# mesh-group 1234 1.1.4.1
FastIron(config-msdp-router)# exit
FastIron(config)# interface loopback 1
FastIron(config-lbif-1)# ip address 1.1.2.1 255.255.255.0
FastIron(config-lbif-1)# ip pim-sparse
FastIron(config-lbif-1)# exit

FastIron(config)# interface ethernet 1/1
FastIron(config-if-1/1)# ip address 12.12.12.2 255.255.255.0
FastIron(config-if-1/1)# ip pim-sparse
FastIron(config-if-1/1)# exit

FastIron(config)# interface ethernet 1/12
FastIron(config-if-1/12)# ip address 165.165.165.1 255.255.255.0
FastIron(config-if-1/12)# ip pim-sparse
FastIron(config-if-1/12)# exit

FastIron(config)# interface ethernet 1/24
FastIron(config-if-1/24)# ip address 168.72.2.2 255.255.255.0

Configuration for Device C

The following set of commands configure the MSDP peers of Device C (1.1.3.1) that are inside and outside MSDP mesh group 1234. Device C peers inside the mesh group 1234 are 1.1.1.1, 1.1.2.1, and 1.1.4.1. Device 35.35.35.5 is a peer of Device C, but is outside mesh group 1234. Multicast is enabled on Device C interfaces. PIM and BGP are also enabled. This configuration is not applicable to TurboIron device because BGP is not supported on the device.

FastIron(config)# router pim

FastIron(config)# router msdp
FastIron(config-msdp-router)# msdp-peer 35.35.35.5
FastIron(config-msdp-router)# msdp-peer 1.1.2.1 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 1.1.4.1 connect-source loopback 1
FastIron(config-msdp-router)# msdp-peer 1.1.1.1 connect-source loopback 1
FastIron(config-msdp-router)# mesh-group 1234 1.1.2.1
FastIron(config-msdp-router)# mesh-group 1234 1.1.1.1

Displaying MSDP information

You can display the following MSDP information:

- Summary information – the IP addresses of the peers, the state of the Layer 3 Switch MSDP session with each peer, and statistics for Keepalive, Source Active, and Notification messages sent to and received from each of the peers.
- Peer information – the IP address of the peer, along with detailed MSDP and TCP statistics.
- Source Active cache entries – the Source Active messages cached by the Layer 3 Switch.

Displaying summary information

To display summary MSDP information, enter the following command at any level of the CLI:

```shell
FastIron(config-msdp-router)# show ip msdp summary
```

**Syntax:** show ip msdp summary

**MSDP Peer Status Summary**

<table>
<thead>
<tr>
<th>Peer Address</th>
<th>State</th>
<th>KA In</th>
<th>KA Out</th>
<th>SA In</th>
<th>SA Out</th>
</tr>

## TCP Statistics

TABLE 154  MSDP peer information  (Continued)
TCP connection state: The state of the connection with the neighbor. The connection can have one of the following states:
- **LISTEN** – Waiting for a connection request.
- **SYN-SENT** – Waiting for a matching connection request after having sent a connection request.
- **SYN-RECEIVED** – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request.
- **ESTABLISHED** – Data can be sent and received over the connection. This is the normal operational state of the connection.
- **FIN-WAIT-1** – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent.
- **FIN-WAIT-2** – Waiting for a connection termination request from the remote TCP.
- **CLOSE-WAIT** – Waiting for a connection termination request from the local user.
- **CLOSING** – Waiting for a connection termination request acknowledgment from the remote TCP.
- **LAST-ACK** – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request).
- **TIME-WAIT** – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request.
- **CLOSED** – There is no connection state.

| **Local host** | The IP address of the MSDP router interface with the peer. |
| **Local port** | The TCP port the MSDP router is using for the BGP4 TCP session with the neighbor. |
| **Remote host** | The IP address of the neighbor. |
| **Remote port** | The TCP port number of the peer end of the connection. |
| **ISentSeq** | The initial send sequence number for the session. |
| **SendNext** | The next sequence number to be sent. |
| **TotUnAck** | The number of sequence numbers sent by the MSDP router that have not been acknowledged by the neighbor. |
| **SendWnd** | The size of the send window. |
| **TotSent** | The number of sequence numbers sent to the neighbor. |
| **ReTrans** | The number of sequence numbers that the MSDP router retransmitted because they were not acknowledged. |
| **IRcvSeq** | The initial receive sequence number for the session. |
| **RcvNext** | The next sequence number expected from the neighbor. |
| **RcvWnd** | The size of the receive window. |
| **TotalRcv** | The number of sequence numbers received from the neighbor. |
| **RcvQue** | The number of sequence numbers in the receive queue. |
| **SendQue** | The number of sequence numbers in the send queue. |
**Displaying source active cache information**

To display the Source Actives in the MSDP cache, use the following CLI method.

FastIron(config-msdp-router)# show ip msdp sa-cache

<table>
<thead>
<tr>
<th>Index</th>
<th>SourceAddr</th>
<th>GroupAddr</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

**Clearing MSDP information**

You can clear the following MSDP information:

- Peer information
- Source Active cache
- MSDP statistics

**Clearing peer information**

To clear MSDP peer information, enter the following command at the Privileged EXEC level of the CLI:

FastIron# clear ip msdp peer 205.216.162.1

Remote connection closed

**Syntax:**  clear ip msdp peer <ip-addr>
The command in this example clears the MSDP peer connection with MSDP router 205.216.162.1. The CLI displays a message to indicate when the connection has been successfully closed.

**Clearing the source active cache**

To clear the entries from the Source Active cache, enter the following command at the Privileged EXEC level of the CLI:

```
FastIron# clear ip msdp sa-cache
```

**Syntax:** `clear ip msdp sa-cache [source-addr | group-addr]`

The command in this example clears all the cache entries. Use the `<source-addr>` parameter to clear only the entries for a specified course. Use the `<group-addr>` parameter to clear only the entries for a specific group.

**Clearing MSDP statistics**

To clear MSDP statistics, enter the following command at the Privileged EXEC level of the CLI:

```
FastIron# clear ip msdp statistics
```

**Syntax:** `clear ip msdp statistics [ip-addr]`

The command in this example clears statistics for all the peers. To clear statistics for a specific peer, enter the peer IP address.

### Passive multicast route insertion

**Platform Support:**
- FastIron X Series devices running software release 02.4.00 and later
- FCX-S devices running software release 06.0.00 and later
- TurboIron X Series devices running software release 04.2.00 and later

Passive Multicast Route Insertion (PMRI) enables a Layer 3 switch running PIM Sparse to create an entry for a multicast route (e.g., (S,G)), with no directly attached clients or when connected to another PIM router (transit network).

PMRI is critical for Service Providers wanting to deliver IP-TV services or multicast-based video services. Service Providers, who have transit networks, distribute multicast-based video services to other Service Providers, regardless of whether a client subscribes to a video service.

To configure PMRI, enter the following command at the `router pim` level of the CLI.

```
FastIron(config)# router pim
FastIron# (config-pim-router)# hardware-drop
```

**NOTE**

On FCX devices, hardware-drop is enabled by default.

**Syntax:** `[no] hardware-drop`
DVMRP overview

Brocade routers provide multicast routing with the Distance Vector Multicast Routing Protocol (DVMRP) routing protocol. DVMRP uses Internet Group Membership Protocol (IGMP) to manage the IP multicast groups.

DVMRP is a broadcast and pruning multicast protocol that delivers IP multicast datagrams to its intended receivers. The receiver registers the interested groups using IGMP. DVMRP builds a multicast delivery tree with the sender forming the root. Initially, multicast datagrams are delivered to all nodes on the tree. Those leaves that do not have any group members send prune messages to the upstream router, noting the absence of a group. The upstream router maintains a prune state for this group for the given sender. A prune state is aged out after a given configurable interval, allowing multicasts to resume.

DVMRP employs reverse path forwarding and pruning to keep source specific multicast delivery trees with the minimum number of branches required to reach all group members. DVMRP builds a multicast tree for each source and destination host group.

NOTE
FastIron CX devices do not support DVMRP.

Initiating DVMRP multicasts on a network

Once DVMRP is enabled on each router, a network user can begin a video conference multicast from the server on R1. Multicast Delivery Trees are initially formed by source-originated multicast packets that are propagated to downstream interfaces as seen in Figure 118. When a multicast packet is received on a DVMRP-capable router interface, the interface checks its DVMRP routing table to determine whether the interface that received the message provides the shortest path back to the source. If the interface does provide the shortest path, the interface forwards the multicast packet to adjacent peer DVMRP routers, except for the router interface that originated the packet. Otherwise, the interface discards the multicast packet and sends a prune message back upstream. This process is known as reverse path forwarding.

In Figure 118, the root node (R1) is forwarding multicast packets for group 229.225.0.2 that it receives from the server to its downstream nodes, R2, R3, and R4. Router R4 is an intermediate router with R5 and R6 as its downstream routers. Because R5 and R6 have no downstream interfaces, they are leaf nodes.

When you enable PMRI, the show ip pim mcache command output displays the multicast cache entry along with a drop flag, indicating that the device is dropping packets in hardware. If the HW flag is set to 1 (HW=1), it implies that the packets are being dropped in hardware. If the HW flag is set to 0, (HW=0), it indicates that the packets are being processed in software. The following shows an example display output.

FastIron# show ip pim mcache
1 (10.10.10.18 226.0.1.56) in v10 {e1}, cnt=2
Source is directly connected
Sparse Mode, RPT=0 SPT=1 REG=1 MSDP Adv=0 MSDP Create=0
fast=0 slow=0 pru=1 graft age drop
age=0s up-time=2m HW=1 L2-vidx=8191
The receivers in this example are those workstations that are resident on routers R2, R3, and R6.

**Pruning a multicast tree**

After the multicast tree is constructed, *pruning* of the tree will occur after IP multicast packets begin to traverse the tree.

As multicast packets reach leaf networks (subnets with no downstream interfaces), the local IGMP database checks for the recently arrived IP multicast packet address. If the local database does not contain the address (the address has not been learned), the router prunes (removes) the address from the multicast tree and no longer receives multicasts until the prune age expires.

In Figure 119, Router 5 is a leaf node with no group members in its local database. Consequently, Router 5 sends a prune message to its upstream router. This router will not receive any further multicast traffic until the prune age interval expires.

**FIGURE 118**  Downstream broadcast of IP multicast packets from source host

**FIGURE 119**  Pruning leaf nodes from a multicast tree
Grafts to a multicast tree

A DVMRP router restores pruned branches to a multicast tree by sending graft messages towards the upstream switch. Graft messages start at the leaf node and travel up the tree, first sending the message to its neighbor upstream switch.

In the example above, if a new 229.255.0.1 group member joins on switch S6, which had been pruned previously, a graft will be sent upstream to S4. Since the forwarding state for this entry is in a prune state, S4 sends a graft to S1. Once S4 has joined the tree, it and S6 will once again receive multicast packets.

You do not need to perform any configuration to maintain the multicast delivery tree. The prune and graft messages automatically maintain the tree.

Configuring DVMRP

Enabling DVMRP on the Layer 3 Switch and interface

Suppose you want to initiate the use of desktop video for fellow users on a sprawling campus network. All destination workstations have the appropriate hardware and software but the Layer 3 Switches that connect the various buildings need to be configured to support DVMRP multicasts from the designated video conference server as seen in Figure 118.
Configuring DVMRP

DVMRP is enabled on each of the Brocade Layer 3 Switches shown in Figure 118, on which multicasts are expected. You can enable DVMRP on each Layer 3 Switch independently or remotely from one Layer 3 Switch by a Telnet connection. Follow the same steps for each Layer 3 Switch.

**Globally enabling and disabling DVMRP**

To globally enable DVMRP, enter the following command.

Router1(config)#router dvmrp

Syntax: [no] router dvmrp

The behavior of the [no] router dvmrp command is as follows:

- Entering a router dvmrp command to enable DVMRP does not require a software reload.
- Entering a no router dvmrp command removes all configuration for PIM multicast on a Layer 3 Switch (router pim level) only.

**Globally enabling or disabling DVMRP without deleting multicast configuration**

As stated above enter no router dvmrp removed PIM configuration. If you want to disable or enable DVMRP without removing PIM configuration, enter the following command.

FastIron(config)#router dvmrp
FastIron(config-pim-router)#disable-dvmrp

Syntax: [no] disable-dvmrp

Use the [no] version of the command to re-enable DVMRP.

**Enabling DVMRP on an interface**

After globally enabling DVMRP on a Layer 3 Switch, enable it on each interface that will support the protocol.

To enable DVMRP on S1 and interface 3, enter the following.

Router1(config)#router dvmrp
Router1(config-dvmrp-router)#int e 3
Router1(config-if-3)#ip dvmrp

**Modifying DVMRP global parameters**

DVMRP global parameters come with preset values. The defaults work well in most networks, but you can modify the following global parameters if you need to:

- Neighbor timeout
- Route expire time
- Route discard time
- Prune age
- Graft retransmit time
- Probe interval
- Report interval
- Trigger interval
• Default route

**Modifying neighbor timeout**

The neighbor timeout specifies the period of time that a router will wait before it defines an attached DVMRP neighbor router as down. Possible values are 40 – 8000 seconds. The default value is 180 seconds.

To modify the neighbor timeout value to 100, enter the following.

```
FastIron(config-dvmrp-router)#nbr 100
```

**Syntax:** nbr-timeout <40-8000>

The default is 180 seconds.

**Modifying Route Expires Time**

The Route Expire Time defines how long a route is considered valid in the absence of the next route update. Possible values are from 20 – 4000 seconds. The default value is 200 seconds.

To modify the route expire setting to 50, enter the following.

```
FastIron(config-dvmrp-router)#route-expire-timeout 50
```

**Syntax:** route-expire-timeout <20-4000>

**Modifying Route Discard Time**

The Route Discard Time defines the period of time before a route is deleted. Possible values are from 40 – 8000 seconds. The default value is 340 seconds.

To modify the route discard setting to 150, enter the following.

```
FastIron(config-dvmrp-router)#route-discard-timeout 150
```

**Syntax:** route-discard-timeout <40-8000>

**Modifying Prune Age**

The Prune Age defines how long a prune state will remain in effect for a source-routed multicast tree. After the prune age period expires, flooding will resume. Possible values are from 20 – 3600 seconds. The default value is 180 seconds.

To modify the prune age setting to 150, enter the following.

```
FastIron(config-dvmrp-router)#prune 25
```

**Syntax:** prune-age <20-3600>

**Modifying Graft Retransmit Time**

The Graft Retransmit Time defines the initial period of time that a router sending a graft message will wait for a graft acknowledgement from an upstream router before re-transmitting that message.

Subsequent retransmissions are sent at an interval twice that of the preceding interval. Possible values are from 5 – 3600 seconds. The default value is 10 seconds.
To modify the setting for graft retransmit time to 120, enter the following.

```
FastIron(config-dvmrp-router)#graft 120
```

**Syntax:** `graft-retransmit-time <5-3600>`

### Modifying Probe Interval

The Probe Interval defines how often neighbor probe messages are sent to the ALL-DVMRP-ROUTERS IP multicast group address. A router probe message lists those neighbor DVMRP routers from which it has received probes. Possible values are from 5 – 30 seconds. The default value is 10 seconds.

To modify the probe interval setting to 10, enter the following.

```
FastIron(config-dvmrp-router)#probe 10
```

**Syntax:** `probe-interval <5-30>`

### Modifying Report Interval

The Report Interval defines how often routers propagate their complete routing tables to other neighbor DVMRP routers. Possible values are from 10 – 2000 seconds. The default value is 60 seconds.

To support propagation of DVMRP routing information to the network every 90 seconds, enter the following.

```
FastIron(config-dvmrp-router)#report 90
```

**Syntax:** `report-interval <10-2000>`

### Modifying Trigger Interval

The Trigger Interval defines how often trigger updates, which reflect changes in the network topology, are sent. Example changes in a network topology include router up or down or changes in the metric. Possible values are from 5 – 30 seconds. The default value is 5 seconds.

To support the sending of trigger updates every 20 seconds, enter the following.

```
FastIron(config-dvmrp-router)#trigger-interval 20
```

**Syntax:** `trigger-interval <5-30>`

### Modifying default route

To define the default gateway for DVMRP, enter the following.

```
FastIron(config-dvmrp-router)#default-gateway 192.35.4.1
```

**Syntax:** `default-gateway <ip-addr>`

### Modifying DVMRP interface parameters

DVMRP global parameters come with preset values. The defaults work well in most networks, but you can modify the following interface parameters if you need to:

- **TTL**
• Metric
• Advertising

**Modifying the TTL**

The TTL defines the minimum value required in a packet in order for the packet to be forwarded out the interface. For example, if the TTL for an interface is set at 10 it means that only those packets with a TTL value of 10 or more are forwarded. Likewise, if an interface is configured with a TTL Threshold value of 1, all packets received on that interface are forwarded. Possible values are from 1 – 64. The default value is 1.

To set a TTL of 64, enter the following.

```
FastIron(config)#int e 1/4
FastIron(config-if-1/4)#ip dvmrp ttl 60
```

Syntax: `ttl-threshold <1-64>`

**Modifying the metric**

The router uses the metric when establishing reverse paths to some networks on directly attached interfaces. Possible values are from 1 – 31 hops. The default is 1.

**NOTE**

This command is not supported on Brocade Layer 2 Switches.

To set a metric of 15 for a DVMRP interface, enter the following.

```
FastIron(config)#interface 3/5
FastIron(config-if-3/5)#ip dvmrp metric 15
```

Syntax: `ip dvmrp metric <1-31>`

**Enabling advertising**

You can turn the advertisement of a local route on (enable) or off (disable) on the interface. By default, advertising is enabled.

To enable advertising on an interface, enter the following.

```
FastIron(config-if-1/4)#ip dvmrp advertise-local on
```

Syntax: `advertise-local on | off`

**Displaying information about an upstream neighbor device**

You can view information about the upstream neighbor device for a given source IP address for IP PIM packets. The software uses the IP route table or multicast route table to lookup the upstream neighbor device.

The following shows example messages that the Brocade device can display with this command.
Syntax: show ip dvmrp rpf <IP address>
where <IP address> is a valid source IP address

NOTE
If there are multiple equal cost paths to the source, the show ip dvmrp rpf command output may not be accurate. If your system has multiple equal cost paths, use the command show ip dvmrp mcache to view information about the upstream neighbor.

Configuring an IP tunnel

IP tunnels are used to send traffic through routers that do not support IP multicasting. IP Multicast datagrams are encapsulated within an IP packet and then sent to the remote address. Routers that are not configured for IP Multicast route the packet as a normal IP packet. When the IP Multicast router at the remote end of the tunnel receives the packet, the router strips off the IP encapsulation and forwards the packet as an IP Multicast packet.

NOTE
An IP tunnel must have a remote IP interface at each end. Also, for IP tunneling to work, the remote routers must be reachable by an IP routing protocol.

NOTE
Multiple tunnels configured on a router cannot share the same remote address.

Example
To configure an IP tunnel as seen in Figure 120, enter the IP tunnel destination address on an interface of the router.

To configure an IP address on Router A, enter the following.

FastIron(config)#int e1
FastIron(config-if-1)#ip tunnel 192.3.45.6

NOTE
The IP tunnel address represents the configured IP tunnel address of the destination router. In the case of Router A, its destination router is Router B. Router A is the destination router of Router B.

For router B, enter the following.

FastIron(config-if-1)#ip tunnel 192.58.4.1

FIGURE 120  IP in IP tunneling on multicast packets in a unicast network
Using ACLs to control multicast features

You can use ACLs to control the following multicast features:

- Limit the number of multicast groups that are covered by a static rendezvous point (RP)
- Control which multicast groups for which candidate RPs sends advertisement messages to bootstrap routers
- Identify which multicast group packets will be forwarded or blocked on an interface

Using ACLs to limit static RP groups

You can limit the number of multicast groups covered by a static RP using standard ACLs. In the ACL, you specify the group to which the RP address applies. The following examples set the RP address to be applied to multicast groups with some minor variations.

To configure an RP that covers multicast groups in 239.255.162.x, enter commands such as the following.

```
FastIron(config)#access-list 2 permit 239.255.162.0 0.0.0.255
FastIron(config)#router pim
FastIron(config-pim-router)#rp-address 43.43.43.1 2
```

To configure an RP that covers multicast groups in the 239.255.162.x range, except the 239.255.162.2 group, enter commands such as the following.

```
FastIron(config)#access-list 5 deny host 239.255.162.2
FastIron(config)#access-list 5 permit 239.255.0.0 0.0.255.255
FastIron(config)#router pim
FastIron(config-pim-router)#bsr-candidate ve 43 32 100
FastIron(config-pim-router)#rp-candidate ve 43
FastIron(config-pim-router)#rp-address 99.99.99.5 5
```

To configure an RP for multicast groups using the override switch, enter commands such as the following.

```
FastIron(config)#access-list 44 permit 239.255.162.0 0.0.0.255
FastIron(config)#router pim
FastIron(config-pim-router)#rp-address 43.43.43.1
FastIron(config-pim-router)#rp-address 99.99.99.5 44 override
```

Syntax: `[no] rp-address <ip-address> [access-list-num] [override]`
The access-list-num parameter is the number of the standard ACL that will filter the multicast group.

**NOTE**

Extended ACLs cannot be used to limit static RP groups.

The override parameter directs the Layer 3 Switch to ignore the information learned by a BSR if there is a conflict between the RP configured in this command and the information that is learned by the BSR. In previous releases, static RP configuration precedes the RP address learned from the PIM Bootstrap protocol. With this enhancement, an RP address learned dynamically from PIM Bootstrap protocol takes precedence over static RP configuration unless the override parameter is used.

You can use the `show ip pim rp-set` command to display the ACLs used to filter the static RP groups.

**Example**

```
FastIron#show ip pim rp-set
Group address Static-RP-address Override
---------------------------------------------------
Access-List 44 99.99.99.5 On
Number of group prefixes Learnt from BSR: 1
Group prefix = 224.0.0.0/4 #RPs: 1
  RP 1: 43.43.43.1 priority=0 age=0
```

In the example above, the display shows the following information:

- The Group Address table shows the static RP address that is covered by the access list, and whether or not the override parameter has been enabled.
- The Group prefix line shows the multicast group prefix for the static RP.
- The RP #line shows the configured IP address of the RP candidate.

The `show ip pim rp-map` command to show the group-to-RP mapping.

```
FastIron#show ip pim rp-map
Number of group-to-RP mappings: 6
  Group address  RP address
  ---------------------------
  1 239.255.163.1  43.43.43.1
  2 239.255.163.2  43.43.43.1
  3 239.255.163.3  43.43.43.1
  4 239.255.162.1  99.99.99.5
  5 239.255.162.2  99.99.99.5
  6 239.255.162.3  99.99.99.5
```

The display shows the multicast group addresses covered by the RP candidate and the IP address of the RP for the listed multicast group. In the example above, you see the following:

- The first three lines show the multicast group addresses that are covered by the RP candidate.
- The last three lines show the multicast group addresses covered by the static RP.
Using ACLs to limit PIM RP candidate advertisement

You can use standard ACLs to control the groups for which the candidate RP will send advertisement messages to the bootstrap router. For example, ACL 5 can be configured to be applied to the multicast groups within the IP address 239.x.x.x range. You can configure the Layer 3 Switch to advertise itself as a candidate RP to the bootstrap router only for groups in the range of 239.x.x.x. Enter commands such as the following.

```
FastIron(config)#interface ethernet 1/1
FastIron(config-if-1/1)#ip address 99.99.99.5 255.255.255.0
FastIron(config-if-1/1)#ip pim-sparse
FastIron(config-if-1/1)#exit
FastIron(config)#access-list 5 deny host 239.255.162.2
FastIron(config)#access-list 5 permit 239.0.0.0 0.0.255.255
FastIron(config)#router pim
FastIron(config-pim-router)#bsr-candidate ethernet 1/1 32 100
FastIron(config-pim-router)#rp-candidate ethernet 1/1 group-list 5
```

The example above shows a configuration for an Ethernet interface. To configure ACLs that are applied to a virtual routing interface, enter commands such as the following.

```
FastIron(config)#interface ve 16
FastIron(config-vif-16)#ip address 16.16.16.1 255.255.255.0
FastIron(config-vif-16)#ip pim-sparse
FastIron(config-vif-16)#exit
FastIron(config)#access-list 5 deny host 239.255.162.2
FastIron(config)#access-list 5 permit 239.255.0.0 0.0.255.255
FastIron(config)#router pim
FastIron(config-pim-router)#bsr-candidate ve 16 32 100
FastIron(config-pim-router)#rp-candidate ve 16 group-list 5
```

To configure ACLs that are applied to a loopback interface, enter commands such as the following.

```
FastIron(config)#interface loopback 1
FastIron(config-lbif-1)#ip address 88.88.88.8 255.255.255.0
FastIron(config-lbif-1)#ip pim-sparse
FastIron(config-lbif-1)#exit
FastIron(config)#access-list 5 deny host 239.255.162.2
FastIron(config)#access-list 5 permit 239.255.0.0 0.0.255.255
FastIron(config)#router pim
FastIron(config-pim-router)#bsr-candidate loopback 1 32 100
FastIron(config-pim-router)#rp-candidate loopback 1 group-list 5
```

Syntax: `[no] rp-candidate ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num> [group-list <access-list-num>]`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` | `loopback <num>` | `ve <num>` parameter specifies the interface. The Layer 3 Switch will advertise the specified interface IP address as a candidate RP:

- Enter `ethernet [<slotnum>/]<portnum>` for a physical interface (port).
- Enter `ve <num>` for a virtual interface.
- Enter `loopback <num>` for a loopback interface.

The `group-list <access-list-num>` indicates that a standard ACL is used to filter for which multicast group the advertisement will be made.
Disabling CPU processing for select multicast groups

Platform Support:

- FESX and FSX devices running software release 04.1.00 and later – L2, BL3, L3

In IPv4 multicast, Brocade Layer 3 switches do not forward multicast packets with destination addresses in the range between 224.0.0.0 and 224.0.0.255. These group addresses are reserved for various routing protocols. By default, packets destined to these groups are processed by the CPU. However, when a large number of packets for these groups are received by the Brocade device all at once, CPU resources may be overloaded. To alleviate the load on the CPU, you could disable CPU processing of packets for these groups. When applied, this feature protects the CPU from traffic sent to IPv4 multicast addresses in the range 224.0.0.1 - 224.0.0.254, and instead floods these packets in hardware within the incoming VLAN.

This feature can be applied on a VLAN or a VLAN-group. If applied on a VLAN, traffic received on a port of the VLAN will be flooded to all other ports of the VLAN. If applied on a VLAN-group, traffic will be flooded only at the individual VLAN level. Once this feature is applied on a VLAN or VLAN-group, ports that are statically or dynamically added to the VLAN or VLAN-group will inherit the configuration. Likewise, ports that are statically or dynamically removed from the VLAN or VLAN-group will drop the configuration.

This feature can be enabled for packets destined to a multicast group or set of groups in the range 224.0.0.1 – 224.0.0.254, except for the reserved multicast addresses listed in the following table.

### TABLE 156 Reserved multicast addresses

<table>
<thead>
<tr>
<th>Multicast address</th>
<th>Reserved for...</th>
</tr>
</thead>
<tbody>
<tr>
<td>224.0.0.1</td>
<td>all nodes</td>
</tr>
<tr>
<td>224.0.0.2</td>
<td>PIM</td>
</tr>
<tr>
<td>224.0.0.3</td>
<td>DVMRP</td>
</tr>
<tr>
<td>224.0.0.4</td>
<td>DVMRP</td>
</tr>
<tr>
<td>224.0.0.5</td>
<td>OSPF</td>
</tr>
<tr>
<td>224.0.0.6</td>
<td>OSPF</td>
</tr>
<tr>
<td>224.0.0.9</td>
<td>RIP V2</td>
</tr>
<tr>
<td>224.0.0.13</td>
<td>PIM V2</td>
</tr>
<tr>
<td>224.0.0.18</td>
<td>VRRP</td>
</tr>
<tr>
<td>224.0.0.22</td>
<td>IGMP V3 reports</td>
</tr>
</tbody>
</table>

### CLI command syntax

To disable CPU processing for selective multicast groups, enter commands such as the following.

```
FastIron# config t
FastIron(config)# vlan 5
FastIron(config-vlan-5)# disable multicast-to-cpu 224.0.0.5
FastIron(config-vlan-5)# disable multicast-to-cpu 224.0.0.14 224.0.0.230
```
Configuring a static multicast route

Static multicast routes allow you to control the network path used by multicast traffic. Static multicast routes are especially useful when the unicast and multicast topologies of a network are different. You can avoid the need to make the topologies similar by instead configuring static multicast routes.

**NOTE**
This feature is not supported for DVMRP.

You can configure more than one static multicast route. The Layer 3 Switch always uses the most specific route that matches a multicast source address. Thus, if you want to configure a multicast static route for a specific multicast source and also configure another multicast static route for all other sources, you can configure two static routes as shown in the examples below.
To add static routes to multicast router A (refer to Figure 121), enter commands such as the following.

PIMRouterA(config)#ip mroute 1 207.95.10.0 255.255.255.0 interface ethernet 1/2 distance 1
PIMRouterA(config)#ip mroute 2 0.0.0.0 0.0.0.0 interface ethernet 2/3 distance 1
PIMRouterA(config)#write memory

Syntax: mroute <route-num> <ip-addr> interface ethernet [slotnum]/<portnum> | ve <num> [distance <num>]

or

Syntax: mroute <route-num> <ip-addr> rpf_address <rpf-num>

The <route-num> parameter specifies the route number.
The <ip-addr> command specifies the PIM source for the route.

NOTE
In IP multicasting, a route is handled in terms of its source, rather than its destination.

You can use the ethernet [slotnum]/<portnum> parameter to specify a physical port or the ve <num> parameter to specify a virtual interface.

NOTE
The ethernet [slotnum]/<portnum> parameter does not apply to PIM SM.

The distance <num> parameter sets the administrative distance for the route. When comparing multiple paths for a route, the Layer 3 Switch prefers the path with the lower administrative distance.

NOTE
Regardless of the administrative distances, the Layer 3 Switch always prefers directly connected routes over other routes.

The rpf_address <rpf-num> parameter specifies an RPF number.

The example above configures two static multicast routes. The first route is for a specific source network, 207.95.10.0/24. If the Layer 3 Switch receives multicast traffic for network 207.95.10.0/24, the traffic must arrive on port 1/2. The second route is for all other multicast traffic. Traffic from multicast sources other than 207.95.10.0/24 must arrive on port 2/3.

Figure 121 shows an example of an IP Multicast network. The two static routes configured in the example above apply to this network. The commands in the example above configure PIM router A to accept PIM packets from 207.95.10.0/24 when they use the path that arrives at port 1/2, and accept all other PIM packets only when they use the path that arrives at port 2/3.

The distance parameter sets the administrative distance. This parameter is used by the software to determine the best path for the route. Thus, to ensure that the Layer 3 Switch uses the default static route, assign a low administrative distance value. When comparing multiple paths for a route, the Layer 3 Switch prefers the path with the lower administrative distance.

FIGURE 121  Example of multicast static routes
To add a static route to a virtual interface, enter commands such as the following.

```
FastIron(config)#mroute 3 0.0.0.0 0.0.0.0 int ve 1 distance 1
FastIron(config)#write memory
```

### Tracing a multicast route

The Brocade implementation of Mtrace is based on “A ‘traceroute’ facility for IP Multicast”, an Internet draft by S. Casner and B. Fenner. To trace a PIM route, use the following CLI method.

**NOTE**

This feature is not supported for DVMRP.

To trace a PIM route to PIM source 209.157.24.62 in group 239.255.162.1, enter a command such as the following.

```
FastIron#mtrace source 209.157.24.62 group 239.255.162.1
```

Type `Control-c` to abort

Tracing the route for tree 209.157.23.188

```
0 207.95.7.2
0 207.95.7.2 Thresh 0
1 207.95.7.1 Thresh 0
2 207.95.8.1 Thresh 0
3 207.157.24.62
```

**Syntax:**  
`mtrace source <ip-addr> group <multicast-group>`

The `source <ip-addr>` parameter specifies the address of the route source.

**NOTE**

In IP multicasting, a route is handled in terms of its source, rather than its destination. When you trace an IP route, you specify its destination, but when you trace a PIM route, you specify its source.

The `group <multicast-group>` parameter specifies the PIM group the source IP address is in.
Figure 122 shows an example of an IP multicast group. The command example shown above is entered on PIM router A.

**FIGURE 122  Example of a PIM group**

The command example above indicates that the source address 209.157.24.62 is three hops (three PIM switches) away from PIM Switch A. In PIM terms, each of the three switches has a forwarding state for the specified source address and multicast group. The value following “Thresh” in some of the lines indicates the TTL threshold. The threshold 0 means that all multicast packets are forwarded on the interface. If an administrator has set the TTL threshold to a higher value, only packets whose TTL is higher than the threshold are forwarded on the interface. The threshold is listed only for the PIM switch hops between the source and destination.

**Displaying the multicast configuration for another multicast router**

The Brocade implementation of Mrinfo is based on the DVMRP Internet draft by T. Pusateri, but applies to PIM and not to DVMRP. To display the PIM configuration of another PIM router, use the following CLI method.

**NOTE**
This feature is not supported for DVMRP.

To display another PIM router PIM configuration, enter a command such as the following.

```
FastIron#mrinfo 207.95.8.1
207.95.8.1 -> 207.95.8.10 [PIM/0 /1]
207.95.10.2 -> 0.0.0.0 [PIM/0 /1 /leaf]
209.157.25.1 -> 0.0.0.0 [PIM/0 /1 /leaf]
209.157.24.1 -> 0.0.0.0 [PIM/0 /1 /leaf]
207.95.6.1 -> 0.0.0.0 [PIM/0 /1 /leaf]
128.2.0.1 -> 0.0.0.0 [PIM/0 /1 /leaf]
```

**Syntax:** `mrinfo <ip-addr>`

The `<ip-addr>` parameter specifies the IP address of the PIM router.
The output in this example is based on the PIM group shown in Figure 122 on page 911. The output shows the PIM interfaces configured on PIM router C (207.95.8.1). In this example, the PIM router has six PIM interfaces. One of the interfaces goes to PIM router B. The other interfaces go to leaf nodes, which are multicast end nodes attached to the router PIM interfaces. (For simplicity, the figure shows only one leaf node.)

When the arrow following an interface in the display points to a router address, this is the address of the next hop PIM router on that interface. In this example, PIM interface 207.95.8.1 on PIM router 207.95.8.1 is connected to PIM router 207.95.8.10. The connection can be a direct one or can take place through non-PIM routers. In this example, the PIM routers are directly connected.

When the arrow following an interface address points to zeros (0.0.0.0), the interface is not connected to a PIM router. The interface is instead connected to a leaf node.

**NOTE**
This display shows the PIM interface configuration information, but does not show the link states for the interfaces.

The information in brackets indicates the following:

- The multicast interface type (always PIM; this display is not supported for DVMRP)
- The Time-to-Live (TTL) for the interface.
- The metric for the interface
- Whether the interface is connected to a leaf node (“leaf” indicates a leaf node and blank indicates another PIM router)

For example, the information for the first interface listed in the display is “PIM/0/1”. This information indicates that the interface is a PIM interface, has a TTL of 0, and a metric of 1. The interface is not a leaf node interface and thus is an interface to another PIM router.

The information for the second interface in the display is “PIM/0/1/leaf”. This information indicates that the interface is a PIM interface, has a TTL of 0 and a metric of 1, and is connected to a leaf node.

### IGMP V3

**Platform Support:**

- FastIron X Series devices running software release 02.4.00 and later
- TurboIron X Series devices running software release 04.2.00 and later

The Internet Group Management Protocol (IGMP) allows an IPV4 interface to communicate IP Multicast group membership information to its neighboring routers. The routers in turn limit the multicast of IP packets with multicast destination addresses to only those interfaces on the router that are identified as IP Multicast group members. This release introduces the support of IGMP version 3 (IGMP V3) on Layer 3 Switches.

In IGMP V2, when a router sent a query to the interfaces, the clients on the interfaces respond with a membership report of multicast groups to the router. The router can then send traffic to these groups, regardless of the traffic source. When an interface no longer needs to receive traffic from a group, it sends a leave message to the router which in turn sends a group-specific query to that interface to see if any other clients on the same interface is still active.
In contrast, IGMP V3 provides selective filtering of traffic based on traffic source. A router running IGMP V3 sends queries to every multicast enabled interface at the specified interval. These queries determine if any interface wants to receive traffic from the router. The queries include the IP address of the traffic source (S) or the ID of the multicast group (G, or both).

The interfaces respond to these queries by sending a membership report that contains one or more of the following records that are associated with a specific group:

- Current-State Record that indicates from which sources the interface wants to receive and not receive traffic. The record contains source address of interfaces and whether or not traffic will be received or included (IS_IN) or not received or excluded (IS_EX) from that source.

- Filter-mode-change record. If the interface changes its current state from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if an interface current state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.

IGMP V2 Leave report is equivalent to a TO_IN(empty) record in IGMP V3. This record means that no traffic from this group will be received regardless of the source.

An IGMP V2 group report is equivalent to an IS_EX(empty) record in IGMP V3. This record means that all traffic from this group will be received regardless of source.

- Source-List-Change Record. If the interface wants to add or remove traffic sources from its membership report, the membership report can have an ALLOW record, which contains a list of new sources from which the interface wishes to receive traffic. It can also contains a BLOCK record, which lists current traffic sources from which the interfaces wants to stop receiving traffic.

In response to membership reports from the interfaces, the router sends a Group-Specific or a Group-and-Source Specific query to the multicast interfaces. Each query is sent three times with a one-second interval in between each transmission to ensure the interfaces receive the query. For example, a router receives a membership report with a Source-List-Change record to block old sources from an interface. The router sends Group-and-Source Specific Queries to the source and group (S,G) identified in the record. If none of the interfaces is interested in the (S,G), it is removed from (S,G) list for that interface on the router.

Each IGMP V3-enabled router maintains a record of the state of each group and each physical port within a virtual routing interface. This record contains the group, group-timer, filter mode, and source records information for the group or interface. Source records contain information on the source address of the packet and source timer. If the source timer expires when the state of the group or interface is in Include mode, the record is removed.

**Default IGMP version**

IGMP V3 is available on devices running software release 02.4.00 and later; however, Brocade devices are shipped with IGMP V2 enabled. You must enable IGMP V3 globally or per interface.

Also, you must specify what version of IGMP you want to run on a device globally, on each interface (physical port or virtual routing interface), and on each physical port within a virtual routing interface. If you do not specify an IGMP version, IGMP V2 will be used.

**Compatibility with IGMP V1 and V2**

Different multicast groups, interfaces, and routers can run their own version of IGMP. Their version of IGMP is reflected in the membership reports that the interfaces send to the router. Routers and interfaces must be configured to recognized the version of IGMP you want them to process.
An interface or router sends the queries and reports that include its IGMP version specified on it. It may recognize a query or report that has a different version, but it may not process them. For example, an interface running IGMP V2 can recognize IGMP V3 packets, but cannot process them. Also, a router running IGMP V3 can recognize and process IGMP V2 packet, but when that router sends queries to an IGMP V2 interface, the host on that interface may not recognize the IGMP V3 queries. The interface or router does not automatically downgrade the IGMP version running on them to avoid version deadlock.

If an interface continuously receives queries from routers that are running versions of IGMP that are different from what is on the interface, the interface logs warning messages in the syslog every five minutes. Reports sent by interfaces to routers that contain different versions of IGMP do not trigger warning messages; however, you can see the versions of the packets using the `show ip igmp traffic` command.

The version of IGMP can be specified globally, per interface (physical port or virtual routing interface), and per physical port within a virtual routing interface. The IGMP version set on a physical port within a virtual routing interface supersedes the version set on a physical or virtual routing interface. Likewise, the version on a physical or virtual routing interface supersedes the version set globally on the device. The sections below present how to set the version of IGMP.

### Globally enabling the IGMP version

**Using the CLI**

To globally identify the IGMP version on a Brocade device, enter the following command.

```
FastIron(config)# ip igmp version 3
```

**Syntax:** `ip igmp version <version-number>`

Enter 1, 2, or 3 for `<version-number>`. Version 2 is the default version.

### Enabling the IGMP version per interface setting

To specify the IGMP version for a physical port, enter a command such as the following.

```
FastIron(config)# interface eth 1/5
FastIron(config-if-1/5)# ip igmp version 3
```

To specify the IGMP version for a virtual routing interface on a physical port, enter a command such as the following.

```
FastIron(config)# interface ve 3
FastIron(config-vif-1)# ip igmp version 3
```

**Syntax:** `[no] ip igmp version <version-number>`

Enter 1, 2, or 3 for `<version-number>`. Version 2 is the default version.

### Enabling the IGMP version on a physical port within a virtual routing interface

To specify the IGMP version recognized by a physical port that is a member of a virtual routing interface, enter a command such as the following.
FastIron(config)# interface ve 3
FastIron(config-vif-3)# ip igmp version 2
FastIron(config-vif-3)# ip igmp port-version 3 e1/3-e1/7 e2/9

In this example, the second line sets IGMP V2 on virtual routing interface 3. However, the third line set IGMP V3 on ports 1/3 through 1/7 and port e2/9. All other ports in this virtual routing interface are configured with IGMP V2.

**Syntax:** ip igmp port-version <version-number> ethernet [<slotnum>/]<port-number>

Enter 1, 2, or 3 for <version-number>. IGMP V2 is the default version.

The ethernet <port-number> parameter specifies which physical port within a virtual routing interface is being configured. If you are entering this command on a chassis device, specify the slot number as well as the port number.

### Enabling membership tracking and fast leave

IGMP V3 provides membership tracking and fast leave to clients. In IGMP V2, only one client on an interface needs to respond to a router queries; therefore, some of the clients may be invisible to the router, making it impossible for the router to track the membership of all clients in a group. Also, when a client leaves the group, the router sends group specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the router waits three seconds before it stops the traffic.

IGMP V3 contains the tracking and fast leave feature that you enable on virtual routing interfaces. Once enabled, all physical ports on that virtual routing interface will have the feature enabled. IGMP V3 requires all clients to respond to general and group specific queries so that all clients on an interface can be tracked. Fast leave allows clients to leave the group without the three second waiting period, if the following conditions are met:

- If the interface, to which the client belongs, has IGMP V3 clients only. Therefore, all physical ports on a virtual routing interface must have IGMP V3 enabled and no IGMP V1 or V2 clients can be on the interface. (Although IGMP V3 can handle V1 and V2 clients, these two clients cannot be on the interface in order for fast leave to take effect.)
- No other client on the interface is receiving traffic from the group to which the client belongs.

Every group on the physical interface of a virtual routing interface keeps its own tracking record. However, it can track group membership only; it cannot track by (source, group).

For example, two clients (Client A and Client B) belong to group1 but each is receiving traffic streams from different sources. Client A receives a stream from (source_1, group1) and Client B receives it from (source_2, group1). The router still waits for three seconds before it stops the traffic because the two clients are in the same group. If the clients are in different groups, then the three second waiting period is not applied and traffic is stopped immediately. The `show ip igmp group tracking` command displays that clients in a group that are being tracked.

If a client sends a leave message, the client is immediately removed from the group. If a client does not send a report during the the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.

### Using the CLI

To enable the tracking and fast leave feature, enter commands such as the following.

```
FastIron(config)# interface ve 13
FastIron(config-vif-13)# ip igmp tracking
```
Syntax: ip igmp tracking

Setting the query interval

The IGMP query interval period defines how often a router will query an interface for group membership. Possible values are 10 – 3,600 seconds and the default value is 60 seconds, but the value you enter must be a little more than twice the group membership time.

To modify the default value for the IGMP query interval, enter the following.

FastIron(config)# ip igmp query-interval 120

Syntax: ip igmp query-interval <10-3600>

The interval must be a little more than two times the group membership time.

Setting the group membership time

Group membership time defines how long a group will remain active on an interface in the absence of a group report. Possible values are from 20 – 7200 seconds and the default value is 140 seconds.

To define an IGMP membership time of 240 seconds, enter the following.

FastIron(config)# ip igmp group-membership-time 240

Syntax: ip igmp group-membership-time <20-7200>

Setting the maximum response time

The maximum response time defines the maximum number of seconds that a client can wait before it replies to the query sent by the router. Possible values are 1 – 10. The default is 10.

To change the IGMP maximum response time, enter a command such as the following at the global CONFIG level of the CLI.

FastIron(config)# ip igmp max-response-time 8

Syntax: [no] ip igmp max-response-time <num>

The <num> parameter specifies the maximum number of seconds for the response time. Enter a value from 1 – 10. The default is 10.

IGMP V3 and source specific multicast protocols

Enabling IGMP V3 enables source specific multicast (SSM) filtering for DVMRP and PIM Dense (PIM-DM) for multicast group addresses in the 224.0.1.0 through 239.255.255.255 address range. However, if PIM Sparse is used as the multicast protocol, the SSM protocol should be enabled if you want to filter unwanted traffic before the Shortest Path Tree protocol switchover occurs for groups in the 232/8 range. Not configuring the SSM protocol in PIM Sparse may cause the switch or router to leak unwanted packets with the same group, but containing undesired sources, to clients. After SPT switch over, the leak stops and source specific multicast works correctly even without configuring the SSM protocol.
If the SSM protocol is not enabled and before the SPT switchover, the multicast router creates one (*, G) entry for the entire multicast group, which can have many sources. If the SSM protocol is enabled, one (S,G) entry is created for every member of the multicast group, even for members with non-existent traffic. For example, if there are 1,000 members in the group, 1,000 (S,G) entries will be created. Therefore, enabling the SSM protocol for PIM-SM requires more resources than leaving the protocol disabled.

**Enabling SSM**

**NOTE**

On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

To enable the SSM protocol on a Brocade device running PIM-SM, enter a command such as the following.

```
FastIron(config)# router pim
FastIron(config-pim-router)# ssm-enable
```

**Syntax:** `[no] ssm-enable`

Enter the `ssm-enable` command under the `router pim` level to globally enable the SSM protocol on a Layer 3 Switch.

**Displaying IGMP V3 information on Layer 3 Switches**

The sections below present the `show` commands available for IGMP V3 on Layer 3 Switches. For show commands on Layer 2 Switches, use the `show ip multicast` commands which are discussed in the section “IGMP snooping show commands” on page 821.

**Displaying IGMP group status**

**NOTE**

This report is available on Layer 3 Switches.

To display the status of all IGMP multicast groups on a device, enter the following command.

```
FastIron# show ip igmp group
```

```
Interface v18 : 1 groups
  group        phy-port static querier life mode    #_src
  1     239.0.0.1        e4/20    no     yes          include 19
Interface v110 : 3 groups
  group        phy-port static querier life mode    #_src
  2     239.0.0.1        e4/5     no     yes          include 10
  3     239.0.0.1        e4/6     no     yes     100  exclude 13
  4     224.1.10.1       e4/5     no     yes          include 1
```

To display the status of one IGMP multicast group, enter a command such as the following.

```
FastIron# show ip igmp group 239.0.0.1
```

```
Interface v110 : 1 groups
  group        phy-port static querier life mode    #_src
  1     239.0.0.1        e4/5     no     yes          include 10
```

To display the status of one IGMP multicast group, enter a command such as the following.
If the tracking and fast leave feature is enabled, you can display the list of clients that belong to a particular group by entering commands such as the following.

FastIron#show ip igmp group 239.0.0.1 detail
Display group 239.0.0.1 in all interfaces.
Interface v18 : 1 groups
  group                      phy-port  static   querier life mode    #_src
1  239.0.0.1    e4/20  no   yes       include 19
   group: 239.0.0.1, include, permit 19 (source, life):
      (3.3.3.1 40) (3.3.3.2 40) (3.3.3.3 40) (3.3.3.4 40) (3.3.3.5 40)
      (3.3.3.6 40) (3.3.3.7 40) (3.3.3.8 40) (3.3.3.9 40) (3.3.3.10 40)
      (3.3.3.11 40) (3.3.3.12 40) (3.3.3.13 40) (3.3.3.14 40) (3.3.3.15 40)
      (3.3.3.16 40) (3.3.3.17 40) (3.3.3.18 40) (3.3.3.19 40)
Interface v110 : 1 groups
  group                     phy-port  static   querier life mode    #_src
2  239.0.0.1    e4/5    no   yes       include 10
   group: 239.0.0.1, include, permit 10 (source, life):
      (2.2.3.0 80) (2.2.3.1 80) (2.2.3.2 80) (2.2.3.3 80) (2.2.3.4 80)
      (2.2.3.5 80) (2.2.3.6 80) (2.2.3.7 80) (2.2.3.8 80) (2.2.3.9 80)

FastIron#show ip igmp group 224.1.10.1 tracking
Display group 224.1.10.1 in all interfaces with tracking enabled.
Interface v13 : 1 groups, tracking_enabled
  group                    phy-port  static   querier life mode    #_src
1  224.1.10.1    e4/15  no   yes       include 3
   receive reports from 3 clients:
      110.110.110.7 110.110.110.8 110.110.110.9

Syntax: show ip igmp group [ <group-address> [detail] [tracking] ]

If you want a report for a specific multicast group, enter that group address for <group-address>. Omit the <group-address> if you want a report for all multicast groups.

Enter detail if you want to display the source list of the multicast group.

Enter tracking if you want information on interfaces that have tracking enabled.

The following table defines the statistics for the show ip igmp group command output.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group</td>
<td>The address of the multicast group</td>
</tr>
<tr>
<td>Phy-port</td>
<td>The physical port on which the multicast group was received.</td>
</tr>
<tr>
<td>Static</td>
<td>A &quot;yes&quot; entry in this column indicates that the multicast group was configured as a static group; &quot;No&quot; means it was not. Static multicast groups can be configured in IGMP V2 using the ip igmp static command. In IGMP V3, static sources cannot be configured in static groups.</td>
</tr>
<tr>
<td>Querier</td>
<td>&quot;Yes&quot; means that the port is a querier port; &quot;No&quot; means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the port.</td>
</tr>
<tr>
<td>Life</td>
<td>Shows the number of seconds the interface can remain in exclude mode. An exclude mode changes to include mode if it does not receive an &quot;IS_EX&quot; or &quot;TO_EX&quot; message during a certain period of time. The default is 140 seconds. There is no &quot;life&quot; displayed in include mode.</td>
</tr>
</tbody>
</table>
Displaying the IGMP status of an interface

You can display the status of a multicast enabled port by entering a command such as the following.

**NOTE**

This report is available on Layer 3 Switches.

FastIron#show ip igmp interface
query interval = 60, max response time= 3, group membership time=140
v5: default V2,         PIM dense, addr=1.1.1.2
   e4/12   has    0 groups, non-Querier (age=40), default V2
v18: default V2,         DVMRP, addr=2.2.2.1
   e4/20   has    0 groups, Querier, default V2
v20: configured V3,     PIM dense (port down), addr=1.1.20.1
v110: configured V3,    PIM dense, addr=110.110.110.1
   e4/6   has    2 groups, Querier, default V3
       group: 239.0.0.1, exclude, life=100, deny 13
       group: 224.1.10.1, include, permit 2
   e4/5   has    3 groups, Querier, default V3
       group: 224.2.2.2, include, permit 100
       group: 239.0.0.1, include, permit 10
       group: 224.1.10.1, include, permit 1

Syntax: show ip igmp interface [ ve | ethernet <number> <group-address>]

Enter ve and its <number> or ethernet and its <number> to display information for a specific virtual routing interface or ethernet interface.

Entering an address for <group-address> displays information for a specified group on the specified interface.

The report shows the following information.
Displaying IGMP traffic status

To display the traffic status on each virtual routing interface, enter the following command.

**NOTE**
This report is available on Layer 3 Switches.

```plaintext
FastIron#show ip igmp traffic
Recv QryV2 QryV3 G-Qry GSQry MbrV2 MbrV3 Leave IsIN IsEX ToIN ToEX ALLOW BLK
v5  29   0   0   0   0   0   0   0   0   0   0   0   0
v18  15   0   0   0   30   0   0   0   0   0   0   0   0
v110  0   0   0   0   97   0   142   37   2   2   3   2

<tr>
<td>IsEX</td>
<td>Number of source addresses that were excluded in the traffic.</td>
</tr>
</tbody>
</table>
Clearing IGMP statistics

To clear statistics for IGMP traffic, enter the following command.

```
FastIron# clear igmp traffic
```

**Syntax:**  `clear igmp traffic`

This command clears all the multicast traffic information on all interfaces on the device.

IGMP Proxy

**Platform Support:**

- FastIron X Series devices running software release 03.2.00 or later
- FCX-S devices running software release 06.0.00 and later

IGMP Proxy provides a means for the FastIron X Series routers to receive any or all multicast traffic from an upstream device if the router is not able to run PIM.

IGMP Proxy enables the router to issue IGMP host messages on behalf of hosts that the router discovered through standard PIM interfaces. The router acts as a proxy for its hosts and performs the host portion of the IGMP task on the upstream interface as follows:

- When queried, the router sends group membership reports for the groups learned
- When one of its hosts joins a multicast address group to which none of its other hosts belong, the router sends unsolicited membership reports to that group.
- When the last of its hosts in a particular multicast group leaves the group, the FastIron X Series router sends an unsolicited leave group membership report to group for all routers (multicast IP address 244.0.0.2)

**Configuration notes**

When using IGMP Proxy, you must do the following.

1. Configure PIM on all multicast client ports to build the group membership table. The group membership table will be reported by the proxy interface. Refer to “Globally enabling and disabling PIM” on page 844.
2. Enable IP multicast on an interface to an upstream FastIron X Series router that will be the IGMP proxy interface and configure IGMP Proxy on that interface

Also note the following limitations:

- IGMP Proxy is available in full-Layer 3 images, starting with FSX software release 03.2.00.
IGMP Proxy cannot be enabled on the same interface on which PIM SM, PIM DM, or DVMRP is enabled.

IGMP Proxy is only supported in a PIM Dense environment where there are IGMP clients connected to the Brocade device. The Brocade device will not send IGMP reports on an IGMP proxy interface for remote clients connected to a PIM neighbor, as it will not be aware of groups that the remote clients are interested in.

### Configuring IGMP Proxy

Follow the steps given below to configure IGMP Proxy.

1. Configure router PIM globally.
   
   FastIron(config)# router pim

2. Configure an IP address on the interface (physical or virtual routing interface) that will serve as the IGMP proxy for an upstream device by entering commands such as the following.
   
   FastIron(config)# int e 1/3
   FastIron(config-if-e1000-1/3)# ip address 207.95.5.1/24

3. Enable IGMP Proxy on the interface.
   
   FastIron(config-if-e1000-1/3)# ip igmp proxy

_Syntex:_ `[no] ip igmp proxy`

Once IGMP Proxy is configured and the FastIron X Series router receives a query on an IGMP Proxy interface, the router sends a report in response to the query before the IGMP maximum response time expires.

### Displaying IGMP Proxy traffic

Use the `show ip igmp traffic` command to see traffic for IGMP Proxy.

FastIron#show ip igmp traffic

<table>
<thead>

_Syntex:_ `show ip igmp traffic`

Refer to “Displaying IGMP traffic status” on page 920 to interpret the information in the output. The fields in bold show information for IGMP Proxy.

---

**IP multicast protocols and IGMP snooping on the same device**

**Platform Support:** FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
Software release FSX 04.1.00 adds support for global Layer 2 IP multicast traffic reduction (IGMP snooping) and Layer 3 multicast routing (DVMRP/PIM-Sparse/PIM-Dense) together on the same device in the full Layer 3 software image, as long as the Layer 2 feature configuration is at the VLAN level. Releases prior to FSX 04.1.00 support global Layer 2 IP multicast traffic reduction and Layer 3 multicast routing. However, they were mutually exclusive and configuring IGMP snooping on a VLAN together with DVMRP/PIM-Sparse/PIM-Dense was not allowed. For Layer 2 multicast traffic reduction, IGMP snooping is performed independently within all VLANs that have the feature configured. Layer 3 multicast routing is performed between the IP interfaces that are configured for DVMRP/PIM-Sparse/PIM-Dense. A Layer 3 interface could be a physical, loopback, or VE port configured with an IP address.

If there are two sources for a single group, where one source sends traffic into a VLAN with IGMP snooping enabled, while the other source sends traffic to a PIM enabled Layer 3 interface, a client for the group in the same VLAN as the first source will only receive traffic from that source. It will not receive traffic from the second source connected to the Layer 3 interface. Similarly, if there is another IP interface with a Layer 3 client or PIM/DVMRP neighbor that requests traffic for the same group, it will only receive traffic from the second source and not the first.

**Configuration example**

Figure 123 and Figure 124 show an example IGMP snooping and PIM forwarding configuration.

**FIGURE 123** Example 1: IGMP Snooping and PIM forwarding

**FIGURE 124** Example 2: IGMP Snooping and PIM Forwarding
CLI commands

The following are the CLI commands for the configuration example shown in Figure 123 and Figure 124.

1. On the FESXv4 device, configure IGMP Snooping on VLAN 10.

   FastIron(config)# vlan 10 by port
   FastIron(config-vlan-10)# untagged e 1 to 4
   Added untagged port(s) ethe 1 to 4 to port-vlan 10.
   FastIron(config-vlan-10)# router-interface ve 10
   FastIron(config-vlan-10)# ip multicast active
   FastIron(config-vlan-10)# interface ve 10
   FastIron(config-vif-10)# ip address 10.10.10.10/24

2. On the FESXv4 device, enable PIM routing between VLAN/VE 20 and Interface e 13.

   FastIron(config)# vlan 20 by port
   FastIron(config-vlan-20)# untagged e 21 to 24
   Added untagged port(s) ethe 21 to 24 to port-vlan 20.
   FastIron(config-vlan-20)# router-interface ve 20
   FastIron(config-vlan-20)# exit
   FastIron(config)# router pim
   FastIron(config-pim-router)# exit
   FastIron(config)# interface ve 20
   FastIron(config-vif-20)# ip address 20.20.20.10/24
   FastIron(config-vif-20)# ip pim
3. Configure the FES/FESX neighboring device.

   FastIron(config)# ip route 20.20.20.0 255.255.255.0 30.30.30.10
   FastIron(config)# router pim
   FastIron(config-pim-router)# exit
   FastIron(config)# interface ethernet 3
   FastIron(config-if-e1000-3)# ip address 30.30.30.20/24
   FastIron(config-if-e1000-3)# ip pim
   FastIron(config-if-e1000-3)# interface ethernet 4
   FastIron(config-if-e1000-4)# ip address 40.40.40.20/24
   FastIron(config-if-e1000-4)# ip pim
IP multicast protocols and IGMP snooping on the same device
Configuring LLDP and LLDP-MED

LLDP and LLDP-MED are supported in the following releases:

- FastIron X Series devices running software release 04.0.00 or later – L2, BL3, L3
- FGS and FLS devices running software release 04.0.00 or later – L2, BL3
- FWS devices running software release 04.3.00 or later
- Turbolron X Series devices running software release 04.1.00 or later
- FCX-S devices running software release 06.0.00 and later

**NOTE**
Turbolron X Series devices support LLDP only. LLDP-MED is not supported on these devices.

This chapter describes how to configure the following protocols:

**Link layer discovery protocol (LLDP)** – The Layer 2 network discovery protocol described in the IEEE 802.1AB standard, Station and Media Access Control Connectivity Discovery. This protocol enables a station to advertise its capabilities to, and to discover, other LLDP-enabled stations in the same 802 LAN segments.

**LLDP media endpoint devices (LLDP-MED)** – The Layer 2 network discovery protocol extension described in the ANSI/TIA-1057 standard, LLDP for Media Endpoint Devices. This protocol enables a switch to configure and manage connected Media Endpoint devices that need to send media streams across the network (e.g., IP telephones and security cameras).

LLDP enables network discovery between Network Connectivity devices (such as switches), whereas LLDP-MED enables network discovery at the edge of the network, between Network Connectivity devices and media Endpoint devices (such as IP phones).

The information generated by LLDP and LLDP-MED can be used to diagnose and troubleshoot misconfigurations on both sides of a link. For example, the information generated can be used to discover devices with misconfigured or unreachable IP addresses, and to detect port speed and duplex mismatches.

LLDP and LLDP-MED facilitate interoperability across multiple vendor devices. Brocade devices running LLDP can interoperate with third-party devices running LLDP.

The Brocade LLDP and LLDP-MED implementation adheres to the IEEE 802.1AB and TIA-1057 standards.

**Terms used in this chapter**

**Endpoint device** – An LLDP-MED device located at the network edge, that provides some aspect of IP communications service based on IEEE 802 LAN technology. An Endpoint device is classified in one of three class types (I, II, or III) and can be an IP telephone, softphone, VoIP gateway, or conference bridge, among others.
**LLDP overview**

LLDP enables a station attached to an IEEE 802 LAN/MAN to advertise its capabilities to, and to discover, other stations in the same 802 LAN segments.

The information distributed by LLDP (the advertisement) is stored by the receiving device in a standard Management Information Base (MIB), accessible by a Network Management System (NMS) using a management protocol such as the Simple Network Management Protocol (SNMP). The information also can be viewed from the CLI, using `show LLDP` commands.

*Figure 125* illustrates LLDP connectivity.

---

**LLDP agent** – The protocol entity that implements LLDP for a particular IEEE 802 device. Depending on the configured LLDP operating mode, an LLDP agent can send and receive LLDP advertisements (frames), or send LLDP advertisements only, or receive LLDP advertisements only.

**LLDPDU** (LLDP Data Unit) – A unit of information in an LLDP packet that consists of a sequence of short variable length information elements, known as **TLVs**. LLDP pass-through is not supported in conformance to IEEE standard.

**MIB** (Management Information Base) – A virtual database that identifies each manageable object by its name, syntax, accessibility, and status, along with a text description and unique object identifier (OID). The database is accessible by a Network Management Station (NMS) using a management protocol such as the Simple Network Management Protocol (SNMP).

**Network connectivity device** – A forwarding 802 LAN device, such as a router, switch, or wireless access point.

**Station** – A node in a network.

**TLV** (Type-Length-Value) – An information element in an LLDPDU that describes the type of information being sent, the length of the information string, and the value (actual information) that will be transmitted.

**TTL** (Time-to-Live) – Specifies the length of time that the receiving device should maintain the information acquired through LLDP in its MIB.
**Benefits of LLDP**

LLDP provides the following benefits:

- **Network Management:**
  - Simplifies the use of and enhances the ability of network management tools in multi-vendor environments
  - Enables discovery of accurate physical network topologies such as which devices are neighbors and through which ports they connect
  - Enables discovery of stations in multi-vendor environments

- **Network Inventory Data:**
  - Supports optional system name, system description, system capabilities and management address
  - System description can contain the device product name or model number, version of hardware type, and operating system
  - Provides device capability, such as switch, router, or WLAN access port

- **Network troubleshooting:**
  - Information generated by LLDP can be used to detect speed and duplex mismatches
  - Accurate topologies simplify troubleshooting within enterprise networks
LLDP-MED overview

LLDP-MED is an extension to LLDP. This protocol enables advanced LLDP features in a Voice over IP (VoIP) network. Whereas LLDP enables network discovery between Network Connectivity devices, LLDP-MED enables network discovery between Network Connectivity devices and media Endpoints such as, IP telephones, softphones, VoIP gateways and conference bridges.

Figure 126 demonstrates LLDP-MED connectivity.

Benefits of LLDP-MED

LLDP-MED provides the following benefits:

- Vendor-independent management capabilities, enabling different IP telephony systems to interoperate in one network.
- Automatically deploys network policies, such as Layer 2 and Layer 3 QoS policies and Voice VLANs.
- Supports E-911 Emergency Call Services (ECS) for IP telephony
- Collects Endpoint inventory information
- Network troubleshooting
  - Helps to detect improper network policy configuration

### LLDP-MED class

An LLDP-MED class specifies an Endpoint type and its capabilities. An Endpoint can belong to one of three LLDP-MED class types:

- **Class 1 (Generic endpoint)** – A Class 1 Endpoint requires basic LLDP discovery services, but does not support IP media nor does it act as an end-user communication appliance. A Class 1 Endpoint can be an IP communications controller, other communication-related server, or other device requiring basic LLDP discovery services.

- **Class 2 (Media endpoint)** – A Class 2 Endpoint supports media streams and may or may not be associated with a particular end user. Device capabilities include media streaming, as well as all of the capabilities defined for Class 1 Endpoints. A Class 2 Endpoint can be a voice/media gateway, conference, bridge, media server, etc..

- **Class 3 (Communication endpoint)** – A Class 3 Endpoint supports end user IP communication. Capabilities include aspects related to end user devices, as well as all of the capabilities defined for Class 1 and Class 2 Endpoints. A Class 3 Endpoint can be an IP telephone, softphone (PC-based phone), or other communication device that directly supports the end user.

  Discovery services defined in Class 3 include location identifier (ECS/E911) information and inventory management.

The LLDP-MED device class is advertised when LLDP-MED is enabled on a port. Figure 126 illustrates LLDP-MED connectivity and supported LLDP-MED classes.

### General operating principles

LLDP and LLDP-MED use the services of the Data Link sublayers, Logical Link Control and Media Access Control, to transmit and receive information to and from other **LLDP Agents** (protocol entities that implement LLDP).

LLDP is a one-way protocol. An LLDP agent can transmit and receive information to and from another LLDP agent located on an adjacent device, but it cannot solicit information from another LLDP agent, nor can it acknowledge information received from another LLDP agent.

### Operating modes

When LLDP is enabled on a global basis, by default, each port on the Brocade device will be capable of transmitting and receiving LLDP packets. You can disable a port’s ability to transmit and receive LLDP packets, or change the operating mode to one of the following:

- Transmit LLDP information only
- Receive LLDP information only
**General operating principles**

**Transmit mode**

An LLDP agent sends LLDP packets to adjacent LLDP-enabled devices. The LLDP packets contain information about the transmitting device and port.

An LLDP agent initiates the transmission of LLDP packets whenever the transmit countdown timing counter expires, or whenever LLDP information has changed. When a transmit cycle is initiated, the LLDP manager extracts the MIB objects and formats this information into TLVs. The TLVs are inserted into an LLDPDU, addressing parameters are prepended to the LLDPDU, and the information is sent out LLDP-enabled ports to adjacent LLDP-enabled devices.

**Receive mode**

An LLDP agent receives LLDP packets from adjacent LLDP-enabled devices. The LLDP packets contain information about the transmitting device and port.

When an LLDP agent receives LLDP packets, it checks to ensure that the LLDPDUs contain the correct sequence of mandatory TLVs, then validates optional TLVs. If the LLDP agent detects any errors in the LLDPDUs and TLVs, it drops them in software. TLVs that are not recognized but do not contain basic formatting errors, are assumed to be valid and are assigned a temporary identification index and stored for future possible after retrieval by network management. All validated TLVs are stored in the neighbor database.

**LLDP packets**

LLDP agents transmit information about a sending device/port in packets called LLDP Data Units (LLDPDUs). All the LLDP information to be communicated by a device is contained within a single 1500 byte packet. A device receiving LLDP packets is not permitted to combine information from multiple packets.

As shown in Figure 127, each LLDPDU has three mandatory TLVs, an End of LLDPDU TLV, plus optional TLVs as selected by network management.

**FIGURE 127  LLDPDU packet format**

<table>
<thead>

<th>Optional TLV</th>
<th>End of LLDPDU TLV</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>M</td>
<td>M</td>
<td>M</td>
<td></td>
<td>M</td>
<td>M</td>
</tr>
</tbody>
</table>

M = mandatory TLV (required for all LLDPDUs)

Each LLDPDU consists of an untagged Ethernet header and a sequence of short, variable length information elements known as TLVs.

TLVs have Type, Length, and Value fields, where:

- **Type** identifies the kind of information being sent
- **Length** indicates the length (in octets) of the information string
- **Value** is the actual information being sent (for example, a binary bit map or an alpha-numeric string containing one or more fields).
TLV support

This section lists the LLDP and LLDP-MED TLV support.

**LLDP TLVs**

There are two types of LLDP TLVs, as specified in the IEEE 802.3AB standard:

- **Basic management TLVs** consist of both optional general system information TLVs as well as mandatory TLVs.
  
  Mandatory TLVs cannot be manually configured. They are always the first three TLVs in the LLDPDU, and are part of the packet header.
  
  General system information TLVs are optional in LLDP implementations and are defined by the Network Administrator.

Brocade devices support the following Basic Management TLVs:

- Chassis ID (mandatory)
- Port ID (mandatory)
- Time to Live (mandatory)
- Port description
- System name
- System description
- System capabilities
- Management address
- End of LLDPDU

- **Organizationally-specific TLVs** are optional in LLDP implementations and are defined and encoded by individual organizations or vendors. These TLVs include support for, but are not limited to, the IEEE 802.1 and 802.3 standards and the TIA-1057 standard.

Brocade devices support the following Organizationally-specific TLVs:

- **802.1 organizationally-specific TLVs**
  
  Port VLAN ID
  
  VLAN name TLV

- **802.3 organizationally-specific TLVs**
  
  MAC/PHY configuration/status
  
  Power through MDI
  
  Link aggregation
  
  Maximum frame size

**LLDP-MED TLVs**

Brocade devices honor and send the following LLDP-MED TLVs, as defined in the TIA-1057 standard:

- LLDP-MED capabilities
- Network policy
• Location identification
• Extended power-via-MDI

**Mandatory TLVs**

When an LLDP agent transmits LLDP packets to other agents in the same 802 LAN segments, the following mandatory TLVs are always included:

• Chassis ID
• Port ID
• Time to Live (TTL)

This section describes the above TLVs in detail.

**Chassis ID**

The Chassis ID identifies the device that sent the LLDP packets.

There are several ways in which a device may be identified. A chassis ID subtype, included in the TLV and shown in Table 160, indicates how the device is being referenced in the Chassis ID field.

<table>
<thead>
<tr>
<th>ID subtype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reserved</td>
</tr>
<tr>
<td>1</td>
<td>Chassis component</td>
</tr>
<tr>
<td>2</td>
<td>Interface alias</td>
</tr>
<tr>
<td>3</td>
<td>Port component</td>
</tr>
<tr>
<td>4</td>
<td>MAC address</td>
</tr>
<tr>
<td>5</td>
<td>Network address</td>
</tr>
<tr>
<td>6</td>
<td>Interface name</td>
</tr>
<tr>
<td>7</td>
<td>Locally assigned</td>
</tr>
<tr>
<td>8 – 255</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Brocade devices use chassis ID subtype 4, the base MAC address of the device. Other third party devices may use a chassis ID subtype other than 4. The chassis ID will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (`show lldp local-info`).

Chassis ID (MAC address): 0012.f233.e2c0

The chassis ID TLV is always the first TLV in the LLDPDU.

**Port ID**

The Port ID identifies the port from which LLDP packets were sent.

There are several ways in which a port may be identified, as shown in Figure 161. A port ID subtype, included in the TLV, indicates how the port is being referenced in the Port ID field.
Brocade devices use port ID subtype 3, the permanent MAC address associated with the port. Other third party devices may use a port ID subtype other than 3. The port ID appears similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info).

Port ID (MAC address): 0012.f233.e2d3

The LLDPDU format is shown in “LLDPDU packet format” on page 932.

The Port ID TLV format is shown below.

**FIGURE 128  Port ID TLV packet format**

<table>
<thead>
<tr>
<th>TLV Type = 3</th>
<th>TLV Information String Length = 2</th>
<th>Time to Live (TTL)</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 bits</td>
<td>9 bits</td>
<td>2 octets</td>
</tr>
</tbody>
</table>

**TTL value**

The Time to Live (TTL) Value is the length of time the receiving device should maintain the information acquired by LLDP in its MIB.

The TTL value is automatically computed based on the LLDP configuration settings. The TTL value will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info).

Time to live: 40 seconds

If the TTL field has a value other than zero, the receiving LLDP agent is notified to completely replace all information associated with the LLDP agent/port with the information in the received LLDPDU.

If the TTL field value is zero, the receiving LLDP agent is notified that all system information associated with the LLDP agent/port is to be deleted. This TLV may be used, for example, to signal that the sending port has initiated a port shutdown procedure.

The LLDPDU format is shown in “LLDPDU packet format” on page 932.

The TTL TLV format is shown below.

**TABLE 161  Port ID subtypes**

<table>
<thead>
<tr>
<th>ID subtype</th>

</tr>
</tbody>
</table>
**MIB support**

Brocade devices support the following standard MIB modules:

- LLDP-MIB
- LLDP-EXT-DOT1-MIB
- LLDP-EXT-DOT3-MIB
- LLDP-EXT-MED-MIB

**Syslog messages**

Syslog messages for LLDP provide management applications with information related to MIB data consistency and general status. These Syslog messages correspond to the lldpRemTableTablesChange SNMP notifications. Refer to “Enabling LLDP SNMP notifications and syslog messages” on page 941.

Syslog messages for LLDP-MED provide management applications with information related to topology changes. These Syslog messages correspond to the lldpXMedTopologyChangeDetected SNMP notifications. Refer to “Enabling SNMP notifications and syslog messages for LLDP-MED topology changes” on page 954.

**Configuring LLDP**

This section describes how to enable and configure LLDP.

Table 162 lists the LLDP global-level tasks and the default behavior/value for each task.

<table>
<thead>
<tr>

</tbody>
</table>

**Configuration notes and considerations**

- LLDP is supported on Ethernet interfaces only.
- If a port is 802.1X-enabled, the transmission and reception of LLDP packets will only take place while the port is authorized.
- Cisco Discovery Protocol (CDP) and Brocade Discovery Protocol (FDP) run independently of LLDP. Therefore, these discovery protocols can run simultaneously on the same device.
- By default, the Brocade device limits the number of neighbors per port to four, and staggers the transmission of LLDP packets on different ports, in order to minimize any high-usage spikes to the CPU.
- By default, the Brocade device forwards
- Ports that are in blocking mode (spanning tree) can still receive LLDP packets from a forwarding port.
- Auto-negotiation status indicates what is being advertised by the port for 802.3 auto-negotiation.

**Enabling and disabling LLDP**

LLDP is enabled by default on individual ports. However, to run LLDP, you must first enable it on a global basis (on the entire device).

To enable LLDP globally, enter the following command at the global CONFIG level of the CLI.

```plaintext
FastIron(config)#lldp run
```

**Syntax:** `[no] lldp run

**Enabling support for tagged LLDP packets**

**Platform Support:**

- FastIron X Series devices running software release 04.2.00 or later
By default, Brocade devices do not accept tagged LLDP packets from other vendors’ devices. To enable support, apply the command `lldp tagged-packets process` at the Global CONFIG level of the CLI. When enabled, the device will accept incoming LLDP tagged packets if the VLAN tag matches any of the following:

- a configured VLAN on the port
- the default VLAN for a tagged port
- the configured untagged VLAN for a dual-mode port

To enable support for tagged LLDP packets, enter the following command.

```
FastIron(config)#lldp tagged-packets process
```

**Syntax:** `[no] lldp tagged-packets process`

### Changing a port LLDP operating mode

LLDP packets are not exchanged until LLDP is enabled on a global basis. When LLDP is enabled on a global basis, by default, each port on the Brocade device will be capable of transmitting and receiving LLDP packets. You can disable a port’s ability to transmit and receive LLDP packets, or change the operating mode to one of the following:

- Transmit LLDP information only
- Receive LLDP information only

You can configure a different operating mode for each port on the Brocade device. For example, you could disable the receipt and transmission of LLDP packets on port e 2/1, configure port e 2/3 to only receive LLDP packets, and configure port e 2/5 to only transmit LLDP packets.

The following sections show how to change the operating mode.

**Enabling and disabling receive and transmit mode**

To disable the receipt and transmission of LLDP packets on individual ports, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#no lldp enable ports e 2/4 e 2/5
```

The above command disables LLDP on ports 2/4 and 2/5. These ports will not transmit nor receive LLDP packets.

To enable LLDP on a port after it has been disabled, enter the following command.

```
FastIron(config)#lldp enable ports e 2/4
```

**Syntax:** `[no] lldp enable ports ethernet <port-list> | all`

Use the `[no]` form of the command to disable the receipt and transmission of LLDP packets on a port.

For `port-list`, specify the ports in one of the following formats:

- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`
You can list all of the ports individually, use the keyword to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword all instead of listing the ports individually.

**NOTE**
When a port is configured to both receive and transmit LLDP packets and the MED capabilities TLV is enabled, LLDP-MED is enabled as well. LLDP-MED is not enabled if the operating mode is set to receive only or transmit only.

---

**Enabling and disabling receive only mode**

When LLDP is enabled on a global basis, by default, each port on the Brocade device will be capable of transmitting and receiving LLDP packets. To change the LLDP operating mode from receive and transmit mode to receive only mode, simply disable the transmit mode. Enter a command such as the following at the Global CONFIG level of the CLI.

```bash
FastIron(config)#no lldp enable transmit ports e 2/4 e 2/5 e 2/6
```

The above command changes the LLDP operating mode on ports 2/4, 2/5, and 2/6 from transmit and receive mode to receive only mode.

To change a port LLDP operating mode from transmit only to receive only, first disable the transmit only mode, then enable the receive only mode. Enter commands such as the following.

```bash
FastIron(config)#no lldp enable transmit ports e 2/7 e 2/8 e 2/9
FastIron(config)#lldp enable receive ports e 2/7 e 2/8 e 2/9
```

The above commands change the LLDP operating mode on ports 2/7, 2/8, and 2/9, from transmit only to receive only. Note that if you do not disable the transmit only mode, you will configure the port to both transmit and receive LLDP packets.

**NOTE**
LLDP-MED is not enabled when you enable the receive only operating mode. To enable LLDP-MED, you must configure the port to both receive and transmit LLDP packets. Refer to “Enabling and disabling receive and transmit mode” on page 938.

**Syntax:** `[no] lldp enable receive ports ethernet <port-list> | all`

Use the [no] form of the command to disable the receive only mode.

For `port-list`, specify the ports in one of the following formats:

- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`

You can list all of the ports individually, use the keyword to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword all instead of listing the ports individually.

**Enabling and Disabling Transmit Only Mode**

When LLDP is enabled on a global basis, by default, each port on the Brocade device will be capable of transmitting and receiving LLDP packets. To change the LLDP operating mode to transmit only mode, simply disable the receive mode. Enter a command such as the following at the Global CONFIG level of the CLI.

```bash
FastIron(config)#no lldp enable receive ports e 2/4 e 2/5 e 2/6
```
The above command changes the LLDP operating mode on ports 2/4, 2/5, and 2/6 from transmit and receive mode to transmit only mode. Any incoming LLDP packets will be dropped in software.

To change a port LLDP operating mode from receive only to transmit only, first disable the receive only mode, then enable the transmit only mode. For example, enter commands such as the following at the Global CONFIG level of the CLI.

FastIron(config)#no lldp enable receive ports e 2/7 e 2/8
FastIron(config)#lldp enable transmit ports e 2/7 e 2/8

The above commands change the LLDP operating mode on ports 2/7 and 2/8 from receive only mode to transmit only mode. Any incoming LLDP packets will be dropped in software. Note that if you do not disable receive only mode, you will configure the port to both receive and transmit LLDP packets.

**NOTE**
LLDP-MED is not enabled when you enable the transmit only operating mode. To enable LLDP-MED, you must configure the port to both receive and transmit LLDP packets. Refer to “Enabling and disabling receive and transmit mode” on page 938.

**Syntax:** 
[no] lldp enable transmit ports ethernet <port-list> | all

Use the [no] form of the command to disable the transmit only mode.

For *port-list*, specify the ports in one of the following formats:

- FastIron chassis devices – *slotnum/portnum*
- FESX, and FWSX compact switches – *portnum*

You can list all of the ports individually, use the keyword **to** to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword **all** instead of listing the ports individually.

**Specifying the maximum number of LLDP neighbors**

You can change the limit of the number of LLDP neighbors for which LLDP data will be retained, per device as well as per port.

**Per device**

You can change the maximum number of neighbors for which LLDP data will be retained for the entire system.

For example, to change the maximum number of LLDP neighbors for the entire device to 26, enter the following command.

FastIron(config)#lldp max-total-neighbors 26

**Syntax:** 
[no] lldp max-total-neighbors <value>

Use the [no] form of the command to remove the static configuration and revert to the default value of 392.

where `<value>` is a number between 16 and 65536. The default number of LLDP neighbors per device is 392.
Use the `show lldp` command to view the configuration.

**Per port**

You can change the maximum number of LLDP neighbors for which LLDP data will be retained for each port. By default, the maximum number is four and you can change this to a value between one and 64.

For example, to change the maximum number of LLDP neighbors to six, enter the following command.

```
FastIron(config)#lldp max-neighbors-per-port 6
```

**Syntax:** `[no] lldp max-neighbors-per-port <value>`

Use the `[no]` form of the command to remove the static configuration and revert to the default value of four.

where `<value>` is a number from 1 to 64. The default is number of LLDP neighbors per port is four.

Use the `show lldp` command to view the configuration.

**Enabling LLDP SNMP notifications and syslog messages**

SNMP notifications and Syslog messages for LLDP provide management applications with information related to MIB data updates and general status.

When you enable LLDP SNMP notifications, corresponding Syslog messages are enabled as well. When you enable LLDP SNMP notifications, the device will send traps and corresponding Syslog messages whenever there are changes to the LLDP data received from neighboring devices.

LLDP SNMP notifications and corresponding Syslog messages are disabled by default. To enable them, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#lldp enable snmp notifications ports e 4/2 to 4/6
```

The above command enables SNMP notifications and corresponding Syslog messages on ports 4/2 and 4/6. By default, the device will send no more than one SNMP notification and Syslog message within a five second period. If desired, you can change this interval. Refer to “Specifying the minimum time between SNMP traps and syslog messages” on page 942.

**Syntax:** `[no] lldp enable snmp notifications ports ethernet <port-list> | all`

For `port-list`, specify the ports in one of the following formats:

- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually.
Configuring LLDP

Specifying the minimum time between SNMP traps and syslog messages

When SNMP notifications and Syslog messages for LLDP are enabled, the device will send no more than one SNMP notification and corresponding Syslog message within a five second period. If desired, you can throttle the amount of time between transmission of SNMP traps (lldpRemTablesChange) and Syslog messages from five seconds up to a value equal to one hour (3600 seconds).

NOTE
Because LLDP Syslog messages are rate limited, some LLDP information given by the system will not match the current LLDP statistics (as shown in the show lldp statistics command output).

To change the minimum time interval between traps and Syslog messages, enter a command such as the following.

FastIron(config)#lldp snmp-notification-interval 60

When the above command is applied, the LLDP agent will send no more than one SNMP notification and Syslog message every 60 seconds.

Syntax: [no] lldp snmp-notification-interval <seconds>

where <seconds> is a value between 5 and 3600. The default is 5 seconds.

Changing the minimum time between LLDP transmissions

The LLDP transmit delay timer limits the number of LLDP frames an LLDP agent can send within a specified time frame. When you enable LLDP, the system automatically sets the LLDP transmit delay timer to two seconds. If desired, you can change the default behavior from two seconds to a value between 1 and 8192 seconds.

NOTE
The LLDP transmit delay timer must not be greater than one quarter of the LLDP transmission interval (CLI command lldp transmit-interval).

The LLDP transmit delay timer prevents an LLDP agent from transmitting a series of successive LLDP frames during a short time period, when rapid changes occur in LLDP. It also increases the probability that multiple changes, rather than single changes, will be reported in each LLDP frame.

To change the LLDP transmit delay timer, enter a command such as the following at the Global CONFIG level of the CLI.

FastIron(config)#lldp transmit-delay 7

The above command causes the LLDP agent to wait a minimum of seven seconds after transmitting an LLDP frame and before sending another LLDP frame.

Syntax: [no] lldp transmit-delay <seconds>

where <seconds> is a value between 1 and 8192. The default is two seconds. Note that this value must not be greater than one quarter of the LLDP transmission interval (CLI command lldp transmit-interval).
Changing the interval between regular LLDP transmissions

The LLDP transmit interval specifies the number of seconds between regular LLDP packet transmissions. When you enable LLDP, by default, the device will wait 30 seconds between regular LLDP packet transmissions. If desired, you can change the default behavior from 30 seconds to a value between 5 and 32768 seconds.

To change the LLDP transmission interval, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#lldp transmit-interval 40
```

The above command causes the LLDP agent to transmit LLDP frames every 40 seconds.

Syntax: `[no] lldp transmit-interval <seconds>`
where `<seconds>` is a value from 5 to 32768. The default is 30 seconds.

**NOTE**
Setting the transmit interval or transmit holdtime multiplier, or both, to inappropriate values can cause the LLDP agent to transmit LLDPDUs with TTL values that are excessively high. This in turn can affect how long a receiving device will retain the information if it is not refreshed.

Changing the holdtime multiplier for transmit TTL

The holdtime multiplier for transmit TTL is used to compute the actual time-to-live (TTL) value used in an LLDP frame. The TTL value is the length of time the receiving device should maintain the information in its MIB. When you enable LLDP, the device automatically sets the holdtime multiplier for TTL to four. If desired, you can change the default behavior from four to a value between two and ten.

To compute the TTL value, the system multiplies the LLDP transmit interval by the holdtime multiplier. For example, if the LLDP transmit interval is 30 and the holdtime multiplier for TTL is 4, then the value 120 is encoded in the TTL field in the LLDP header.

To change the holdtime multiplier, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#lldp transmit-hold 6
```

Syntax: `[no] lldp transmit-hold <value>`
where `<value>` is a number from 2 to 10. The default value is 4.

**NOTE**
Setting the transmit interval or transmit holdtime multiplier, or both, to inappropriate values can cause the LLDP agent to transmit LLDPDUs with TTL values that are excessively high. This in turn can affect how long a receiving device will retain the information if it is not refreshed.

Changing the minimum time between port reinitializations

The LLDP re-initialization delay timer specifies the minimum number of seconds the device will wait from when LLDP is disabled on a port, until it will honor a request to re-enable LLDP on that port. When you enable LLDP, the system sets the re-initialization delay timer to two seconds. If desired, you can change the default behavior from two seconds to a value between one and ten seconds.
To set the re-initialization delay timer, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#lldp reinit-delay 5
```

The above command causes the device to wait five seconds after LLDP is disabled, before attempting to honor a request to re-enable it.

**Syntax:** `[no] lldp reinit-delay <seconds>`

where `<seconds>` is a value from 1 – 10. The default is two seconds.

## LLDP TLVs advertised by the Brocade device

When LLDP is enabled on a global basis, the Brocade device will automatically advertise the following information, except for the features noted:

**General system information:**
- Management address
- Port description
- System capabilities
- System description (not automatically advertised)
- System name

**802.1 capabilities:**
- VLAN name (not automatically advertised)
- Untagged VLAN ID

**802.3 capabilities:**
- Link aggregation information
- MAC/PHY configuration and status
- Maximum frame size
- Power-via-MDI information (not automatically advertised)

The above TLVs are described in detail in the following sections.

**NOTE**
The system description, VLAN name, and power-via-MDI information TLVs are not automatically enabled. The following sections show how to enable these advertisements.

### General system information

Except for the system description, the Brocade device will advertise the following system information when LLDP is enabled on a global basis:

- Management address
- Port description
- System capabilities
- System description (not automatically advertised)
- System name
Management Address
A management address is normally an IPv4 or IPv6 address that can be used to manage the device. Management address advertising has two modes: default, or explicitly configured. The default mode is used when no addresses are configured to be advertised for a given port. If any addresses are configured to be advertised for a given port, then only those addresses are advertised. This applies across address types, so for example, if just one IPv4 address is explicitly configured to be advertised for a port, then no IPv6 addresses will be advertised for that port (since none were configured to be advertised), even if IPv6 addresses are configured within the system.

NOTE
IPv6 management addresses are supported starting in release FSX 05.1.00.

If no management address is explicitly configured to be advertised, the Brocade device will use the first available IPv4 address and the first available IPv6 address (so it may advertise IPv4, IPv6 or both). A Layer 3 switch will select the first available address of each type from those configured on the following types of interfaces, in the following order of preference:

- Physical port on which LLDP will be transmitting the packet
- Virtual router interface (VE) on a VLAN that the port is a member of
- Dedicated management port
- Loopback interface
- Virtual router interface (VE) on any other VLAN
- Other physical port
- Other interface

For IPv6 addresses, link-local and anycast addresses will be excluded from these searches.

If no IP address is configured on any of the above, the port’s current MAC address will be advertised.

To advertise a IPv4 management address, enter a command such as the following:

```
FastIron(config)#lldp advertise management-address ipv4 209.157.2.1 ports e 1/4
```

The management address will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info):

```
Management address (IPv4): 209.157.2.1
```

**Syntax:**

```
[no] lldp advertise management-address ipv4 <ipv4 address> ports ethernet <port list> | all
```

To support an IPv6 management address, there is a similar command that has equivalent behavior as the IPv4 command.

To advertise an IPv6 management address, enter a command such as the following:

```
FastIron(config)#lldp advertise management-address ipv6 1234:5678::90 ports e 2/7
```

**Syntax:**

```
[no] lldp advertise management-address ipv6 <ipv6 address> ports ethernet <port list> | all
```

<ipv4 address> or <ipv6 address> or both are the addresses that may be used to reach higher layer entities to assist discovery by network management. In addition to management addresses, the advertisement will include the system interface number associated with the management address.
For `<port list>`, specify the port(s) in the format `<slotnum>/portnum>`, where `<slotnum>` is required on chassis devices only. You can list all of the ports individually; use the keyword to specify a range of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually.

**Port description**
The port description TLV identifies the port from which the LLDP agent transmitted the advertisement. The port description is taken from the ifDescr MIB object from MIB-II.

By default, the port description is automatically advertised when LLDP is enabled on a global basis. To disable advertisement of the port description, enter a command such as the following.

```
FastIron(config)#no lldp advertise port-description ports e 2/4 to 2/12
```

The port description will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (`show lldp local-info`).

```
Port description: “GigabitEthernet20”
```

**Syntax:** `[no] lldp advertise port-description ports ethernet `<port-list>` | all`

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

**System capabilities**
The system capabilities TLV identifies the primary functions of the device and indicates whether these primary functions are enabled. The primary functions can be one or more of the following (more than one for example, if the device is both a bridge and a router):

- Repeater
- Bridge
- WLAN access point
- Router
- Telephone
- DOCSIS cable device
- Station only (devices that implement end station capability)
- Other

System capabilities for Brocade devices are based on the type of software image in use (e.g., Layer 2 switch or Layer 3 router). The enabled capabilities will be the same as the available capabilities, except that when using a router image (base or full Layer 3), if the global route-only feature is turned on, the bridge capability will not be included, since no bridging takes place.
By default, the system capabilities are automatically advertised when LLDP is enabled on a global basis. To disable this advertisement, enter a command such as the following.

```
FastIron(config)#no lldp advertise system-capabilities ports e 2/4 to 2/12
```

The system capabilities will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (``show lldp local-info``).

```
System capabilities :   bridge
Enabled capabilities:   bridge
```

Syntax:  `[no] lldp advertise system-capabilities ports ethernet <port-list> | all`

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword *to* to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword *all* instead of listing the ports individually. Note that using the keyword *all* may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

**System description**

The system description is the network entity, which can include information such as the product name or model number, the version of the system hardware type, the software operating system level, and the networking software version. The information corresponds to the sysDescr MIB object in MIB-II.

To advertise the system description, enter a command such as the following.

```
FastIron(config)#lldp advertise system-description ports e 2/4 to 2/12
```

The system description will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (``show lldp local-info``).

```
+ System description  : "Brocade Communications, Inc.,FESX424-PREM-PoE, IronWare Version 04.0.00b256T3e1 Compiled on Sep 04 2007 at 0\3:54:29 labeled as SXS04000b256"
```

**NOTE**

The contents of the show command output will vary depending on which TLVs are configured to be advertised.

Syntax:  `[no] lldp advertise system-description ports ethernet <port-list> | all`

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`
You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

**System name**

The system name is the system administratively assigned name, taken from the `sysName` MIB object in MIB-II. The `sysName` MIB object corresponds to the name defined with the CLI command `hostname`. By default, the system name is automatically advertised when LLDP is enabled on a global basis. To disable this advertisement, enter a command such as the following.

```
FastIron(config)#no lldp advertise system-name ports e 2/4 to 2/12
```

The system name will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (`show lldp local-info`).

```
System name:  “FESX424_POE”
```

**Syntax:** `[no] lldp advertise system-name ports ethernet <port-list> [ all ]

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FEX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

**802.1 capabilities**

Except for the VLAN name, the Brocade device will advertise the following 802.1 attributes when LLDP is enabled on a global basis:

- VLAN name (not automatically advertised)
- Untagged VLAN ID

**VLAN name**

The VLAN name TLV contains the name and VLAN ID of a VLAN configured on a port. An LLDPDU may include multiple instances of this TLV, each for a different VLAN.

To advertise the VLAN name, enter a command such as the following.

```
FastIron(config)#lldp advertise vlan-name vlan 99 ports e 2/4 to 2/12
```
Configuring LLDP

The VLAN name will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info).

```
VLAN name (VLAN 99): “Voice-VLAN-99”
```

Syntax: `[no] lldp advertise vlan-name vlan <vlan ID> ports ethernet <port-list> | all

For `<vlan ID>`, enter the VLAN ID to advertise.

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

Untagged VLAN id

The port VLAN ID TLV advertises the Port VLAN Identifier (PVID) that will be associated with untagged or priority-tagged frames. If the port is not an untagged member of any VLAN (i.e., the port is strictly a tagged port), the value zero will indicate that.

By default, the port VLAN ID is automatically advertised when LLDP is enabled on a global basis. To disable this advertisement, enter a command such as the following.

```
FastIron(config)#no lldp advertise port-vlan-id ports e 2/4 to 2/12
```

The untagged VLAN ID will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info).

```
Port VLAN ID: 99
```

Syntax: `[no] lldp advertise port-vlan-id ports ethernet <port-list> | all

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.
802.3 capabilities

Except for Power-via-MDI information, the Brocade device will advertise the following 802.3 attributes when LLDP is enabled on a global basis:

- Link aggregation information
- MAC/PHY configuration and status
- Maximum frame size
- Power-via-MDI information (not automatically advertised)

Link aggregation

The link-aggregation TLV indicates the following:

- Whether the link is capable of being aggregated
- Whether the link is currently aggregated
- The primary trunk port

Brocade devices advertise link aggregation information about standard link aggregation (LACP) as well as static trunk configuration.

By default, link-aggregation information is automatically advertised when LLDP is enabled on a global basis. To disable this advertisement, enter a command such as the following.

```
FastIron(config)#no lldp advertise link-aggregation ports e 2/12
```

Syntax: `[no] lldp advertise link-aggregation ports ethernet <port-list> | all`

The link aggregation advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (`show lldp local-info`).

```
Link aggregation: not capable
```

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

MAC/PHY configuration status

The MAC/PHY configuration and status TLV includes the following information:

- Auto-negotiation capability and status
- Speed and duplex mode
- Flow control capabilities for auto-negotiation
- Port speed down-shift and maximum port speed advertisement
• If applicable, indicates if the above settings are the result of auto-negotiation during link initiation or of a manual set override action

The advertisement reflects the effects of the following CLI commands:

• speed-duplex
• flow-control
• gig-default
• link-config

By default, the MAC/PHY configuration and status information are automatically advertised when LLDP is enabled on a global basis. To disable this advertisement, enter a command such as the following.

```
FastIron(config)#no lldp advertise mac-phy-config-status ports e 2/4 to 2/12
```

The MAC/PHY configuration advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info).

```
+ 802.3 MACPHY : auto-negotiation enabled
  Advertised capabilities: 10baseT-HD, 10baseT-FD, 100baseTX-HD, 100baseTX-FD,
  fdxSPause, fdxBPause, 1000baseT-HD, 1000baseT-FD
  Operational MAU type: 100BaseTX-FD

Syntax: [no] lldp advertise mac-phy-config-status ports ethernet <port-list> | all
```

For `<port-list>`, specify the ports in one of the following formats:

• FastIron chassis devices – `<slotnum/portnum>`
• FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

**Maximum frame size**

The maximum frame size TLV provides the maximum 802.3 frame size capability of the port. This value is expressed in octets and includes the four-octet Frame Check Sequence (FCS). The default maximum frame size is 1522. The advertised value may change depending on whether the `aggregated-vlan` or `jumbo` CLI commands are in effect.

By default, the maximum frame size is automatically advertised when LLDP is enabled on a global basis. To disable this advertisement, enter a command such as the following.

```
FastIron(config)#no lldp advertise max-frame-size ports e 2/4 to 2/12
```

The maximum frame size advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info).

```
Maximum frame size: 1522 octets
```
Configuring LLDP

Syntax: [no] lldp advertise max-frame-size ports ethernet <port-list> | all

For <port-list>, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword `all` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

**Power-via-MDI**

The power-via-MDI TLV provides general information about Power over Ethernet (POE) capabilities and status of the port. It indicates the following:

- POE capability (supported or not supported)
- POE status (enabled or disabled)
- Power Sourcing Equipment (PSE) power pair – indicates which pair of wires is in use and whether the pair selection can be controlled. The Brocade implementation always uses pair A, and cannot be controlled.
- Power class – Indicates the range of power that the connected powered device has negotiated or requested.

**NOTE**

The power-via-MDI TLV described in this section applies to LLDP. There is also a power-via-MDI TLV for LLDP-MED devices, which provides extensive POE information. Refer to “Extended power-via-MDI information” on page 964.

To advertise the power-via-MDI information, enter a command such as the following.

```
FastIron(config)#lldp advertise power-via-mdi ports e 2/4 to 2/12
```

The power-via-MDI advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (`show lldp local-info`).

```
+ 802.3 Power via MDI: PSE port, power enabled, class 0
  Power Pair : A (not controllable)
```

Syntax: [no] lldp advertise power-via-mdi ports ethernet <port-list> | all

For <port-list>, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`
You can list all of the ports individually, use the keyword `all` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

## Configuring LLDP-MED

This section provides the details for configuring LLDP-MED.

**NOTE**
LLDP-MED is not supported on TurboIron X Series devices.

<table>

## Enabling LLDP-MED

When LLDP is enabled globally, LLDP-MED is enabled if the LLDP-MED capabilities TLV is also enabled. By default, the LLDP-MED capabilities TLV is automatically enabled. To enable LLDP, refer to “Enabling and disabling LLDP” on page 937.

**NOTE**
LLDP-MED is not enabled on ports where the LLDP operating mode is receive only or transmit only. LLDP-MED is enabled on ports that are configured to both receive and transmit LLDP packets and have the LLDP-MED capabilities TLV enabled.
Enabling SNMP notifications and syslog messages for LLDP-MED topology changes

SNMP notifications and Syslog messages for LLDP-MED provide management applications with information related to topology changes. For example, SNMP notifications can alert the system whenever a remote Endpoint device is connected to or removed from a local port. SNMP notifications identify the local port where the topology change occurred, as well as the device capability of the remote Endpoint device that was connected to or removed from the port.

When you enable LLDP-MED SNMP notifications, corresponding Syslog messages are enabled as well. When you enable LLDP-MED SNMP notifications, the device will send traps and Syslog messages when an LLDP-MED Endpoint neighbor entry is added or removed.

SNMP notifications and corresponding Syslog messages are disabled by default. To enable them, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#lldp enable snmp med-topo-change-notifications ports e 4/4 to 4/6
```

**Syntax:** `[no] lldp enable snmp med-topo-change-notifications ports ethernet <port-list> | all`

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

Changing the fast start repeat count

The fast start feature enables a Network Connectivity Device to initially advertise itself at a faster rate for a limited time when an LLDP-MED Endpoint has been newly detected or connected to the network. This feature is important within a VoIP network, for example, where rapid availability is crucial for applications such as emergency call service location (E911).

The fast start timer starts when a Network Connectivity Device receives the first LLDP frame from a newly detected Endpoint.

The **LLDP-MED fast start repeat count** specifies the number of LLDP packets that will be sent during the LLDP-MED fast start period. By default, the device will send three packets at one-second intervals. If desired, you can change the number of packets the device will send per second, up to a maximum of 10.

**NOTE**

The LLDP-MED fast start mechanism is only intended to run on links between Network Connectivity devices and Endpoint devices. It does not apply to links between LAN infrastructure elements, including between Network Connectivity devices, or to other types of links.
To change the LLDP-MED fast start repeat count, enter commands such as the following.

```
FastIron(config)#lldp med fast-start-repeat-count 5
```

The above command causes the device to send five LLDP packets during the LLDP-MED fast start period.

**Syntax:** `[no] lldp med fast-start-repeat-count <value>

where value is a number from 1 to 10, which specifies the number of packets that will be sent during the LLDP-MED fast start period. The default is 3.

### Defining a location id

The LLDP-MED Location Identification extension enables the Brocade device to set the physical location that an attached Class III Endpoint will use for location-based applications. This feature is important for applications such as IP telephony, for example, where emergency responders need to quickly determine the physical location of a user in North America that has just dialed 911.

For each port, you can define one or more of the following location ID formats:

- Geographic location (coordinate-based)
- Civic address
- Emergency Call Services (ECS) Emergency Location Identification Number (ELIN)

The above location ID formats are defined in the following sections.

#### Coordinate-based location

Coordinate-based location is based on the IETF RFC 3825 [6] standard, which specifies a Dynamic Host Configuration Protocol (DHCP) option for the coordinate-based geographic location of a client.

When you configure an Endpoint location information using the coordinate-based location, you specify the latitude, longitude, and altitude, along with **resolution indicators** (a measure of the accuracy of the coordinates), and the reference **datum** (the map used for the given coordinates).

To configure a coordinate-based location for an Endpoint device, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#lldp med location-id coordinate-based latitude -78.303 resolution 20 longitude 34.27 resolution 18 altitude meters 50 resolution 16 wgs84
```

**Syntax:** `[no] lldp med location-id coordinate-based

- latitude <degrees> resolution <bits>
- longitude <degrees> resolution <bits>
- altitude floors <number> resolution <bits> | meters <number> resolution <bits> <datum>

latitude <degrees> is the angular distance north or south from the earth equator measured through 90 degrees. Positive numbers indicate a location north of the equator and negative numbers indicate a location south of the equator.

resolution <bits> specifies the precision of the value given for latitude. A smaller value increases the area within which the device is located. For latitude, enter a number between 1 and 34.
longitude \(<\text{degrees}>\) is the angular distance from the intersection of the zero meridian. Positive values indicate a location east of the prime meridian and negative numbers indicate a location west of the prime meridian.

resolution \(<\text{bits}>\) specifies the precision of the value given for longitude. A smaller value increases the area within which the device is located. For longitude resolution, enter a number between 1 and 34.

altitude floors \(<\text{number}>\) is the vertical elevation of a building above the ground, where 0 represents the floor level associated with the ground level at the main entrance and larger values represent floors that are above (higher in altitude) floors with lower values. For example, 2 for the 2nd floor. Sub-floors can be represented by non-integer values. For example, a mezzanine between floor 1 and floor 2 could be represented as 1.1. Similarly, the mezzanines between floor 4 and floor 5 could be represented as 4.1 and 4.2 respectively. Floors located below ground level could be represented by negative values.

resolution \(<\text{bits}>\) specifies the precision of the value given for altitude. A smaller value increases the area within which the device is located. For floors resolution, enter the value 0 if the floor is unknown, or 30 if a valid floor is being specified.

altitude meters \(<\text{number}>\) is the vertical elevation in number of meters, as opposed to floors.

resolution \(<\text{bits}>\) specifies the precision of the value given for altitude. A smaller value increases the area within which the device is located. For meters resolution, enter a value from 0 to 30.

\(<\text{Datum}>\) is the map used as the basis for calculating the location. Specify one of the following:

- \text{wgs84} – (geographical 3D) – World Geodesic System 1984, CRS Code 4327, Prime Meridian Name: Greenwich
- \text{nad83-navd88} – North American Datum 1983, CRS Code 4269, Prime Meridian Name: Greenwich; The associated vertical datum is the North American Vertical Datum of 1988 (NAVD88). Use this datum when referencing locations on land. If land is near tidal water, use \text{nad83-mllw} (below).
- \text{nad83-mllw} – North American Datum 1983, CRS Code 4269, Prime Meridian Name: Greenwich; The associated vertical datum is mean lower low water (MLLW). Use this datum when referencing locations on water, sea, or ocean.

Example coordinate-based location configuration
The following shows an example coordinate-based location configuration for the Sears Tower, at the following location.

103rd Floor
233 South Wacker Drive
Chicago, IL 60606

FastIron(config)#lldp med location-id coordinate-based latitude 41.87884
resolution 18 longitude 87.63602 resolution 18 altitude floors 103 resolution 30
wgs84

The above configuration shows the following:

- Latitude is 41.87884 degrees north (or 41.87884 degrees).
- Longitude is 87.63602 degrees west (or 87.63602 degrees).
- The latitude and longitude resolution of 18 describes a geo-location area that is latitude 41.8769531 to latitude 41.8789062 and extends from -87.6367188 to -87.6347657 degrees longitude. This is an area of approximately 373412 square feet (713.3 ft. x 523.5 ft.).
• The location is inside a structure, on the 103rd floor.
• The WGS 84 map was used as the basis for calculating the location.

**Example coordinate-based location advertisement**

The coordinate-based location advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (**show lldp local-info**).

```
+ MED Location ID
 Data Format: Coordinate-based
 Latitude Resolution : 20 bits
 Latitude Value      : -78.303 degrees
 Longitude Resolution: 18 bits
 Longitude Value     : 34.27 degrees
 Altitude Resolution : 16 bits
 Altitude Value      : 50. meters
 Datum               : WGS 84
```

**Civic address location**

When you configure a media Endpoint location using the address-based location, you specify the location the entry refers to, the country code, and the elements that describe the civic or postal address.

To configure a civic address-based location for LLDP-MED, enter commands such as the following at the Global CONFIG level of the CLI.

FastIron(config)#lldp med location-id civic-address refers-to client country US
elem 1 CA elem 3 “Santa Clara” elem 6 “4980 Great America Pkwy” elem 24 95054 elem
27 5 elem 28 551 elem 29 office elem 23 “John Doe”

**Syntax:**  [no] lldp med location-id civic-address refers-to <elem> country <country code> elem <CA type> <value> [elem <CA type> <value>] [elem <CA type> <value>]....

referred-to <elem> describes the location that the entry refers to. Specify one of the following:

• client
• dhcp-server
• network-element

where **dhcp-server** or **network-element** should only be used if it is known that the Endpoint is in close physical proximity to the DHCP server or network element.

<country code> is the two-letter ISO 3166 country code in capital ASCII letters.

**Example**

• CA – Canada
• DE – Germany
• JP – Japan
• KR – Korea
• US – United States

<CA type> is a value from 0 – 255, that describes the civic address element. For example, a CA type of 24 specifies a postal or zip code. Valid elements and their types are listed in **Table 164**.
<value> is the actual value of the elem <CA type>, above. For example, 95123 for the postal or zip code. Acceptable values are listed in Table 164, below.

**NOTE**
If the value of an element contains one or more spaces, use double quotation marks (") at the beginning and end of the string. For example, `elem 3 "Santa Clara"`.

### Table 164 Elements used with civic address

<table>
<thead>
<tr>
<th>Civic Address (CA) type</th>
<th>Description</th>
<th>Acceptable values / examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Language</td>
<td>The ISO 639 language code used for presenting the address information.</td>
</tr>

<td>Civic Address (CA) type</td>
<td>Description</td>
<td>Acceptable values / examples</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>18</td>
<td>Street suffix</td>
<td>Acceptable values for the United States are listed in the United States Postal Service Publication 28 [18], Appendix C. Example: Ave, Place</td>
</tr>
<tr>
<td>19</td>
<td>House number</td>
<td>The house number (street address) Example: 1234</td>
</tr>
<tr>
<td>20</td>
<td>House number suffix</td>
<td>A modifier to the house number. It does not include parts of the house number. Example: A, 1/2</td>
</tr>
<tr>
<td>21</td>
<td>Landmark or vanity address</td>
<td>A string name for a location. It conveys a common local designation of a structure, a group of buildings, or a place that helps to locate the place. Example: UC Berkeley</td>
</tr>
<tr>
<td>22</td>
<td>Additional location information</td>
<td>An unstructured string name that conveys additional information about the location. Example: west wing</td>
</tr>
<tr>
<td>23</td>
<td>Name (residence and office occupant)</td>
<td>Identifies the person or organization associated with the address. Example: Textures Beauty Salon</td>
</tr>
<tr>
<td>24</td>
<td>Postal / zip code</td>
<td>The valid postal / zip code for the address. Example: 95054-1234</td>
</tr>
<tr>
<td>25</td>
<td>Building (structure)</td>
<td>The name of a single building if the street address includes more than one building or if the building name is helpful in identifying the location. Example: Law Library</td>
</tr>
<tr>
<td>26</td>
<td>Unit (apartment, suite)</td>
<td>The name or number of a part of a structure where there are separate administrative units, owners, or tenants, such as separate companies or families who occupy that structure. Common examples include suite or apartment designations. Example: Apt 27</td>
</tr>
<tr>
<td>27</td>
<td>Floor</td>
<td>Example: 4</td>
</tr>
<tr>
<td>28</td>
<td>Room number</td>
<td>The smallest identifiable subdivision of a structure. Example: 7A</td>
</tr>
<tr>
<td>29</td>
<td>Placetype</td>
<td>The type of place described by the civic coordinates. For example, a home, office, street, or other public space. Example: Office</td>
</tr>
<tr>
<td>30</td>
<td>Postal community name</td>
<td>When the postal community name is defined, the civic community name (typically CA type 3) is replaced by this value. Example: Alviso</td>
</tr>
<tr>
<td>31</td>
<td>Post office box (P.O. box)</td>
<td>When a P.O. box is defined, the street address components (CA types 6, 16, 17, 18, 19, and 20) are replaced with this value. Example: P.O. Box 1234</td>
</tr>
<tr>
<td>32</td>
<td>Additional code</td>
<td>An additional country-specific code that identifies the location. For example, for Japan, this is the Japan Industry Standard (JIS) address code. The JIS address code provides a unique address inside of Japan, down to the level of indicating the floor of the building.</td>
</tr>
</tbody>
</table>
Example civic address location advertisement
The Civic address location advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info).

Example:
```
+ MED Location ID
  Data Format: Civic Address
  Location of: Client
  Country    : "US"
  CA Type    : 1
  CA Value   : "CA"
  CA Type    : 3
  CA Value   : "Santa Clara"
  CA Type    : 6
  CA Value   : "4980 Great America Pkwy."
  CA Type    : 24
  CA Value   : "95054"
  CA Type    : 27
  CA Value   : "5"
  CA Type    : 28
  CA Value   : "551"
  CA Type    : 29
  CA Value   : "office"
  CA Type    : 23
  CA Value   : "John Doe"
```

Emergency call services
The Emergency Call Service (ECS) location is used specifically for Emergency Call Services applications.

When you configure a media Endpoint location using the emergency call services location, you specify the Emergency Location Identification Number (ELIN) from the North America Numbering Plan format, supplied to the Public Safety Answering Point (PSAP) for ECS purposes.

To configure an ECS-based location for LLDP-MED, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)#lldp med location-id ecs-elin 4082071700
```

Syntax: `[no] lldp med location-id ecs-elin <number> ports ethernet <port-list> | all

<number> is a number from 10 to 25 digits in length.

For `port-list`, specify the ports in one of the following formats:
Configuring LLDP-MED

- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually.

**Example ECS ELIN location advertisements**
The ECS ELIN location advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (`show lldp local-info`).

```
+ MED Location ID
  Data Format: ECS ELIN
  Value : 4082071700
```

**Defining an LLDP-MED network policy**
An LLDP-MED network policy defines an Endpoint VLAN configuration (VLAN type and VLAN ID) and associated Layer 2 and Layer 3 priorities that apply to a specific set of applications on a port.

**NOTE**
This feature applies to applications that have specific real-time network policy requirements, such as interactive voice or video services. It is not intended to run on links other than between Network Connectivity devices and Endpoints, and therefore does not advertise the multitude of network policies that frequently run on an aggregated link.

To define an LLDP-MED network policy for an Endpoint, enter a command such as the following.

```
FastIron(config)#lldp med network-policy application voice tagged vlan 99
  priority 3 dscp 22 port e 2/6
```

The network policy advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (`show lldp local-info`).

```
+ MED Network Policy
  Application Type : Voice
  Policy Flags     : Known Policy, Tagged
  VLAN ID          : 99
  L2 Priority      : 3
  DSCP Value       : 22
```

**NOTE**
Endpoints will advertise a policy as “unknown” in the `show lldp neighbor detail` command output, if it is a policy that is required by the Endpoint and the Endpoint has not yet received it.

**Configuration syntax**
The CLI syntax for defining an LLDP-MED network policy differs for tagged, untagged, and priority tagged traffic. Refer to the appropriate syntax, below.
For tagged traffic
Syntax: [no] lldp med network-policy application <application type> tagged vlan <vlan ID> priority <0 – 7> dscp <0 – 63> ports ethernet <port-list> | all

For untagged traffic
Syntax: [no] lldp med network-policy application <application type> untagged dscp <0 – 63> ports ethernet <port-list> | all

For priority-tagged traffic
Syntax: [no] lldp med network-policy application <application type> priority-tagged priority <0 – 7> dscp <0 – 63> ports ethernet <port-list> | all

For port-list, specify the ports in one of the following formats:

- FastIron chassis devices – slotnum/portnum
- FESX, and FWSX compact switches – portnum

You can list all of the ports individually, use the keyword to to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword all instead of listing the ports individually.

<application type> indicates the primary function of the applications defined by this network policy. Application type can be one of the following:

- guest-voice – Limited voice service for guest users and visitors with their own IP telephony handsets or similar devices that support interactive voice services.
- guest-voice-signaling – Limited voice service for use in network topologies that require a different policy for guest voice signaling than for guest voice media.
- softphone-voice – Softphone voice service for use with multi-media applications that work in association with VoIP technology, enabling phone calls direct from a PC or laptop. Softphones do not usually support multiple VLANs, and are typically configured to use an untagged VLAN or a single tagged data-specific VLAN. Note that when a network policy is defined for use with an untagged VLAN, the Layer 2 priority field is ignored and only the DSCP value is relevant.
- streaming-video – Applies to broadcast- or multicast-based video content distribution and similar applications that support streaming video services requiring specific network policy treatment. Video applications that rely on TCP without buffering would not be an intended use of this application type.
- video-conferencing – Applies to dedicated video conferencing equipment and similar devices that support real-time interactive video/audio services.
- video-signaling – For use in network topologies that require a separate policy for video signaling than for video media. Note that this application type should not be advertised if all the same network policies apply as those advertised in the video conferencing policy TLV.
- voice – For use by dedicated IP telephony handsets and similar devices that support interactive voice services.
- voice-signaling – For use in network topologies that require a different policy for voice signaling than for voice media. Note that this application type should not be advertised if all the same network policies apply as those advertised in the voice policy TLV.
- tagged vlan <vlan id> specifies the tagged VLAN that the specified application type will use.
- untagged indicates that the device is using an untagged frame format.
• **priority-tagged** indicates that the device uses priority-tagged frames. In this case, the device uses the default VLAN (PVID) of the ingress port.

• **priority** \(<0 – 7>\) indicates the Layer 2 priority value to be used for the specified application type. Enter 0 to use the default priority.

• **dscp** \(<0 – 63>\) specifies the Layer 3 Differentiated Service codepoint priority value to be used for the specified application type. Enter 0 to use the default priority.

For \(<\text{port-list}>\), specify the ports in one of the following formats:

• FastIron GS and GmS-STK, FastIron LS and LS-STK and FastIron WS compact switches – \(<\text{stack-unit/slotnum/portnum}>\)

• FastIron chassis devices – \(<\text{slotnum/portnum}>\)

• FESX, and FWSX compact switches – \(<\text{portnum}>\)

You can list all of the ports individually, use the keyword to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword \textit{all} instead of listing the ports individually. Note that using the keyword \textit{all} may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

**LLDP-MED attributes advertised by the Brocade device**

LLDP-MED attributes are only advertised on a port if LLDP-MED is enabled (which is done by enabling the LLDP-MED capabilities TLV), the port operating mode is receive and transmit (the default), and the port has received an LLDP-MED advertisement from an Endpoint. By default, the Brocade device will automatically advertise the following LLDP-MED attributes when the above criteria are met:

• LLDP-MED capabilities

• Location ID

• Network policy

• Power-via-MDI information

**NOTE**

Although the Location ID and Network policy attributes are automatically advertised, they will have no effect until they are actually defined.

**LLDP-MED capabilities**

When enabled, LLDP-MED is enabled, and the LLDP-MED capabilities TLV is sent whenever any other LLDP-MED TLV is sent. When disabled, LLDP-MED is disabled and no LLDP-MED TLVs are sent.

The LLDP-MED capabilities advertisement includes the following information:

• The supported LLDP-MED TLVs

• The device type (Network Connectivity device or Endpoint (Class 1, 2, or 3))

By default, LLDP-MED information is automatically advertised when LLDP-MED is enabled. To disable this advertisement, enter a command such as the following.
LLDP-MED attributes advertised by the Brocade device

```
FastIron(config)#no lldp advertise med-capabilities ports e 2/4 to 2/12
```

**NOTE**
Disabling the LLDP-MED capabilities TLV disables LLDP-MED.

To re-enable the LLDP-MED Capabilities TLV (and LLDP-MED) after it has been disabled, enter a command such as the following.

```
FastIron(config)#lldp advertise med-capabilities ports e 2/4 to 2/12
```

The LLDP-MED capabilities advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (show lldp local-info).

```
+ MED capabilities: capabilities, networkPolicy, location, extendedPSE
MED device type : Network Connectivity
```

Syntax: `[no] lldp advertise med-capabilities ports ethernet `<port-list>` `| all`

For `<port-list>`, specify the ports in one of the following formats:

- **FastIron chassis devices** – `<slotnum/portnum>`
- **FESX, and FWSX compact switches** – `<portnum>`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

### Extended power-via-MDI information

The extended Power-via-MDI TLV enables advanced power management between LLDP-MED Endpoints and Network Connectivity Devices. This TLV provides significantly more information than the 802.1AB Power-via-MDI TLV referenced in “Power-via-MDI” on page 952. For example, this TLV enables an Endpoint to communicate a more precise required power level, thereby enabling the device to allocate less power to the Endpoint, while making more power available to other ports.

The LLDP-MED Power-via-MDI TLV advertises an Endpoint IEEE 802.3af power-related information, including the following:

- **Power type** – indicates whether the LLDP-MED device transmitting the LLPDU is a power sourcing device or a powered device:
  - **Power sourcing device/equipment (PSE)** – This is the source of the power, or the device that integrates the power onto the network. Power sourcing devices/equipment have embedded POE technology. In this case, the power sourcing device is the Brocade POE device.
  - **Powered device (PD)** – This is the Ethernet device that requires power and is situated on the other end of the cable opposite the power sourcing device.
- **Power source** – The power source being utilized by a PSE or PD, for example, primary power source, backup power source, or unknown.
For Endpoint devices, the power source information indicates the power capability of the Network Connectivity Device it is attached to. When the Network Connectivity device advertises that it is using its primary power source, the Endpoint should expect to have uninterrupted access to its available power. Likewise, if the Network Connectivity device advertises that it is using backup power, the Endpoint should not expect continuous power. The Endpoint may additionally choose to power down non-essential subsystems or to conserve power as long as the PSE is advertising that it is operating on backup power.

**NOTE**
Brocade devices always advertise the power source as “unknown”.

- **Power priority** – The in-line power priority level for the PSE or PD:
  - 3 – low
  - 2 – high
  - 1 – critical
  - unknown

- **Power level** – The total power, in tenths of watts, required by a PD from a PSE, or the total power a PSE is capable of sourcing over a maximum length cable based on its current configuration.

  If the exact power is not known for a PSE or PD, it will advertise the power level associated with its 802.3af power class (listed in Table 165).

**TABLE 165**  802.3af power classes

<table>
<thead>
<tr>
<th>Power class</th>
<th>Minimum power level output at the PSE</th>
<th>Maximum power levels at the PD</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>15.4 watts</td>
<td>0.44 – 12.95 watts</td>
</tr>
<tr>
<td>1</td>
<td>4.0 watts</td>
<td>0.44 – 3.84 watts</td>
</tr>
<tr>
<td>2</td>
<td>7.0 watts</td>
<td>3.84 – 6.49 watts</td>
</tr>
<tr>
<td>3</td>
<td>15.4 watts</td>
<td>6.49 – 12.95 watts</td>
</tr>
</tbody>
</table>

For a PD (Endpoint device), the power level represents the maximum power it can consume during normal operations in its current configuration, even if its actual power draw at that instance is less than the advertised power draw.

For a PSE (Network Connectivity device), the power level represents the amount of power that is available on the port at the time. If the PSE is operating in reduced power (i.e., it is using backup power), the reduced power capacity is advertised as long as the condition persists.

By default, LLDP-MED power-via-MDI information is automatically advertised when LLDP-MED is enabled, the port is a POE port, and POE is enabled on the port. To disable this advertisement, enter a command such as the following.

```
FastIron(config)#no lldp advertise med-power-via-mdi ports e 2/4 to 2/12
```

The LLDP-MED power-via-MDI advertisement will appear similar to the following on the remote device, and in the CLI display output on the Brocade device (`show lldp local-info`).
Syntax: `[no] lldp advertise med-power-via-mdi ports ethernet <port-list> | all`

For `<port-list>`, specify the ports in one of the following formats:

- FastIron chassis devices – `<slotnum/portnum>`
- FESX, and FWSX compact switches – `<portnum>`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually. Note that using the keyword `all` may cause undesirable effects on some ports. For example, if you configure all ports to advertise their VLAN name, and the configuration includes ports that are not members of any VLAN, the system will warn of the misconfigurations on non-member VLAN ports. The configuration will be applied to all ports, however, the ports that are not members of any VLAN will not send VLAN name advertisements.

Displaying LLDP statistics and configuration settings

You can use the following CLI `show` commands to display information about LLDP settings and statistics:

- `show lldp` – Displays a summary of the LLDP configuration settings.
- `show lldp statistics` – Displays LLDP global and per-port statistics.
- `show lldp neighbors` – Displays a list of the current LLDP neighbors.
- `show lldp neighbors detail` – Displays the details of the latest advertisements received from LLDP neighbors.
- `show lldp local-info` – Displays the details of the LLDP advertisements that will be transmitted on each port.

This above `show` commands are described in this section.

LLDP configuration summary

To display a summary of the LLDP configuration settings on the device, enter the `show lldp` command at any level of the CLI.

The following shows an example report.

```
+ MED Extended Power via MDI
  Power Type     : PSE device
  Power Source   : Unknown Power Source
  Power Priority : Low (3)
  Power Value    : 6.5 watts (PSE equivalent: 7005 mWatts)
```
FastIron#show lldp
LLDP transmit interval : 10 seconds
LLDP transmit hold multiplier : 4 (transmit TTL: 40 seconds)
LLDP transmit delay : 1 seconds
LLDP SNMP notification interval : 5 seconds
LLDP reinitialize delay : 1 seconds
LLDP-MED fast start repeat count : 3
LLDP maximum neighbors : 392
LLDP maximum neighbors per port : 4

Syntax: show lldp

The following table describes the information displayed by the show lldp statistics command.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLDP transmit interval</td>
<td>The number of seconds between regular LLDP packet transmissions.</td>
</tr>
<tr>
<td>LLDP transmit hold multiplier</td>
<td>The multiplier used to compute the actual time-to-live (TTL) value of an LLDP advertisement. The TTL value is the transmit interval multiplied by the transmit hold multiplier.</td>
</tr>
<tr>
<td>LLDP transmit delay</td>
<td>The number of seconds the LLDP agent will wait after transmitting an LLDP frame and before transmitting another LLDP frame.</td>
</tr>
<tr>
<td>LLDP SNMP notification interval</td>
<td>The number of seconds between transmission of SNMP LLDP traps (lldpRemTablesChange) and SNMP LLDP-MED traps (lldpXMedTopologyChangeDetected).</td>
</tr>
<tr>
<td>LLDP reinitialize delay</td>
<td>The minimum number of seconds the device will wait from when LLDP is disabled on a port, until a request to re-enable LLDP on that port will be honored.</td>
</tr>
<tr>
<td>LLDP-MED fast start repeat count</td>
<td>The number of seconds between LLDP frame transmissions when an LLDP-MED Endpoint is newly detected.</td>
</tr>
<tr>
<td>LLDP maximum neighbors</td>
<td>The maximum number of LLDP neighbors for which LLDP data will be retained, per device.</td>
</tr>
<tr>
<td>LLDP maximum neighbors per port</td>
<td>The maximum number of LLDP neighbors for which LLDP data will be retained, per port.</td>
</tr>
</tbody>
</table>

**LLDP statistics**

The **show lldp statistics** command displays an overview of LLDP neighbor detection on the device, as well as packet counters and protocol statistics. The statistics are displayed on a global basis.

The following shows an example report.
LLDP-MED attributes advertised by the Brocade device

FastIron#show lldp statistics
Last neighbor change time: 23 hours 50 minutes 40 seconds ago

Neighbor entries added : 14
Neighbor entries deleted : 5
Neighbor entries aged out : 4
Neighbor advertisements dropped : 0

Port   Tx Pkts Total Rx Pkts Total Rx Pkts w/Errors Discarded Unrecognized Discarded Aged Out
1       60963 75179     0       0       0       0       0       4
2       0       0       0       0       0       0       0       0

12      0       0       0       0       0       0       0       0
13      0       0       0       0       0       0       0       0
14      0       0       0       0       0       0       0       0

Syntax: show lldp statistics

NOTE
You can reset LLDP statistics using the CLI command clear LLDP statistics. Refer to “Resetting LLDP statistics” on page 973.

The following table describes the information displayed by the show lldp statistics command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Last neighbor change time</td>
<td>The elapsed time (in hours, minutes, and seconds) since a neighbor last advertised information. For example, the elapsed time since a neighbor was last added, deleted, or its advertised information changed.</td>
</tr>
<tr>
<td>Neighbor entries added</td>
<td>The number of new LLDP neighbors detected since the last reboot or since the last time the clear lldp statistics all command was issued.</td>
</tr>
<tr>
<td>Neighbor entries deleted</td>
<td>The number of LLDP neighbors deleted since the last reboot or since the last time the clear lldp statistics all command was issued.</td>
</tr>
<tr>
<td>Neighbor entries aged out</td>
<td>The number of LLDP neighbors dropped on all ports after the time-to-live expired. Note that LLDP entries age out naturally when a port cable or module is disconnected or when a port becomes disabled. However, if a disabled port is re-enabled, the system will delete the old LLDP entries.</td>
</tr>
<tr>
<td>Neighbor advertisements dropped</td>
<td>The number of valid LLDP neighbors the device detected, but could not add. This can occur, for example, when a new neighbor is detected and the device is already supporting the maximum number of neighbors possible. This can also occur when an LLDPDU is missing a mandatory TLV or is not formatted correctly.</td>
</tr>
<tr>
<td>Port</td>
<td>The local port number.</td>
</tr>
<tr>
<td>Tx Pkts Total</td>
<td>The number of LLDP packets the port transmitted.</td>
</tr>
<tr>
<td>Rx Pkts Total</td>
<td>The number of LLDP packets the port received.</td>
</tr>
</tbody>
</table>
LLDP-MED attributes advertised by the Brocade device

The following shows an example report.

**Syntax:** show lldp neighbors

The following table describes the information displayed by the show lldp neighbors command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rx Pkts w/Errors</td>
<td>The number of LLDP packets the port received that have one or more detectable errors.</td>
</tr>
<tr>
<td>Rx Pkts Discarded</td>
<td>The number of LLDP packets the port received then discarded.</td>
</tr>
<tr>
<td>Rx TLVs Unrecognz</td>
<td>The number of TLVs the port received that were not recognized by the LLDP local agent. Unrecognized TLVs are retained by the system and can be viewed in the output of the show LLDP neighbors detail command or retrieved through SNMP.</td>
</tr>
<tr>
<td>Rx TLVs Discarded</td>
<td>The number of TLVs the port received then discarded.</td>
</tr>
<tr>
<td>Neighbors Aged Out</td>
<td>The number of times a neighbor information was deleted because its TTL timer expired.</td>
</tr>
</tbody>
</table>

**LLDP neighbors**

The show lldp neighbors command displays a list of the current LLDP neighbors per port.

The following shows an example report.

FastIron#show lldp neighbors

<table>

LLDP neighbors detail

The **show lldp neighbors detail** command displays the LLDP advertisements received from LLDP neighbors.

The following shows an example **show lldp neighbors detail** report.

```
NOTE
The **show lldp neighbors detail** output will vary depending on the data received. Also, values that are not recognized or do not have a recognizable format, may be displayed in hexadecimal binary form.

FastIron#show lldp neighbors detail ports e 1/9
Local port: 1/9
Neighbor: 0800.0f18.cc03, TTL 101 seconds
  + Chassis ID (network address): 10.43.39.151
  + Port ID (MAC address): 0800.0f18.cc03
  + Time to live: 120 seconds
  + Port description : "LAN port"
  + System name : "regDN 1015,MITEL 5235 DM"
  + System description : "regDN 1015,MITEL 5235 DM, h/w rev 2,ASIC rev 1, f/w\n    Boot 02.01.00.11, f/w Main 02.01.00.11"

A backslash (\) at the end of a line indicates that the text continues on the next line.

Except for the following field, the fields in the above output are described in the individual TLV advertisement sections in this chapter.
LLDP-MED attributes advertised by the Brocade device

### Syntax: `show lldp neighbors detail [ports ethernet <port-list> | all]`

If you do not specify any ports or use the keyword `all`, by default, the report will show the LLDP neighbor details for all ports.

For `port-list`, specify the ports in one of the following formats:

- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`

You can list all of the ports individually, use the keyword `all` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword `all` instead of listing the ports individually.

#### LLDP configuration details

The `show lldp local-info` command displays the local information advertisements (TLVs) that will be transmitted by the LLDP agent.

**NOTE**
The `show lldp local-info` output will vary based on LLDP configuration settings.

The following shows an example report.

```
FastIron#show lldp local-info ports e 20
Local port: 20
  + Chassis ID (MAC address): 0012.f233.e2c0
  + Port ID (MAC address): 0012.f233.e2d3
  + Time to live: 40 seconds
  + System name: "FESX424_POE"
  + Port description: "GigabitEthernet20"
  + System description : "Brocade Communications, Inc. FESX424-PREM-PoE, IronWare Version 04.0.00b256T3e1 Compiled on Sep 04 2007 at 03:54:29 labeled as SX5040000b256"
  + System capabilities : bridge
     Enabled capabilities: bridge
     802.3 MAC/PHY : auto-negotiation enabled
     Advertised capabilities: 10BaseT-HD, 10BaseT-FD, 100BaseTX-HD, 100BaseTX-FD, fdxSPause, fdxB Pause, 1000BaseT-HD, 1000BaseT-FD
     Operational MAU type: 100BaseTX-FD
  + 802.3 Power via MDI: PSE port, power enabled, class 2
     Power Pair : A (not controllable)
     Link aggregation: not capable
  + Maximum frame size: 1522 octets
  + MED capabilities: capabilities, networkPolicy, location, extendedPSE
    MED device type : Network Connectivity
    MED Network Policy
    Application Type : Voice
```

NOTE
The contents of the show output will vary depending on which TLVs are configured to be advertised.

A backslash (\) at the end of a line indicates that the text continues on the next line.

The fields in the above output are described in the individual TLV advertisement sections in this chapter.

Syntax: show lldp local-info [ports ethernet <port-list> | all]
If you do not specify any ports or use the keyword **all**, by default, the report will show the local information advertisements for all ports.

For **port-list**, specify the ports in one of the following formats:

- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword **all** instead of listing the ports individually.

### Resetting LLDP statistics

To reset LLDP statistics, enter the `clear lldp statistics` command at the Global CONFIG level of the CLI. The Brocade device will clear the global and per-port LLDP neighbor statistics on the device (refer to **“LLDP statistics”** on page 967).

```
FastIron#clear lldp statistics
```

**Syntax:** `clear lldp statistics [ports ethernet <port-list> | all]`

If you do not specify any ports or use the keyword **all**, by default, the system will clear lldp statistics on all ports.

For **port-list**, specify the ports in one of the following formats:

- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`

You can list all of the ports individually, use the keyword `to` to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword **all** instead of listing the ports individually.

### Clearing cached LLDP neighbor information

The Brocade device clears cached LLDP neighbor information after a port becomes disabled and the LLDP neighbor information ages out. However, if a port is disabled then re-enabled before the neighbor information ages out, the device will clear the cached LLDP neighbor information when the port is re-enabled.

If desired, you can manually clear the cache. For example, to clear the cached LLDP neighbor information for port `e 20`, enter the following command at the Global CONFIG level of the CLI.

```
FastIron#clear lldp neighbors ports e 20
```

**Syntax:** `clear lldp neighbors [ports ethernet <port-list> | all]`

If you do not specify any ports or use the keyword **all**, by default, the system will clear the cached LLDP neighbor information for all ports.
Clearing cached LLDP neighbor information

For **port-list**, specify the ports in one of the following formats:

- FastIron chassis devices – `slotnum/portnum`
- FESX, and FWSX compact switches – `portnum`

You can list all of the ports individually, use the keyword **to** to specify ranges of ports, or a combination of both. To apply the configuration to all ports on the device, use the keyword **all** instead of listing the ports individually.
Basic configuration

NOTE
References to chassis-based Layer 3 Switches apply to the FastIron SuperX Switch.

NOTE
The terms Layer 3 Switch and router are used interchangeably in this chapter and mean the same thing.

IP is enabled by default. Basic configuration consists of adding IP addresses and, for Layer 3 Switches, enabling a route exchange protocol, such as Routing Information Protocol (RIP).

If you are configuring a Layer 3 Switch, refer to “Configuring IP addresses” on page 993 to add IP addresses, then refer to one or more of the following to enable and configure the route exchange protocols:

- Chapter 33, “Configuring RIP”
- Chapter 35, “Configuring OSPF Version 2 (IPv4)”
- Chapter 38, “Configuring BGP4”

If you are configuring a Layer 2 Switch, refer to “Configuring the management IP address and specifying the default gateway” on page 1060 to add an IP address for management access through the network and to specify the default gateway.

The rest of this chapter describes IP and how to configure it in more detail. Use the information in this chapter if you need to change some of the IP parameters from their default values or you want to view configuration information or statistics.

Overview

Brocade Layer 2 Switches and Layer 3 Switches support Internet Protocol (IP) version 4. IP support on Brocade Layer 2 Switches consists of basic services to support management access and access to a default gateway. IP support on Brocade Layer 3 Switches includes all of the following, in addition to a highly configurable implementation of basic IP services including Address Resolution Protocol (ARP), ICMP Router Discovery Protocol (IRDP), and Reverse ARP (RARP):

- Route exchange protocols:
  - Routing Information Protocol (RIP)
  - Open Shortest Path First (OSPF)
  - Border Gateway Protocol version 4 (BGP4)
- Multicast protocols:
  - Internet Group Membership Protocol (IGMP)
Overview

- Protocol Independent Multicast Dense (PIM-DM)
- Protocol Independent Multicast Sparse (PIM-SM)
- Distance Vector Multicast Routing Protocol (DVMRP)
- Router redundancy protocols:
  - Virtual Router Redundancy Protocol Extended (VRRPE)
  - Virtual Router Redundancy Protocol (VRRP)

IP interfaces

Brocade Layer 3 Switches and Layer 2 Switches allow you to configure IP addresses. On Layer 3 Switches, IP addresses are associated with individual interfaces. On Layer 2 Switches, a single IP address serves as the management access address for the entire device.

All Brocade Layer 3 Switches and Layer 2 Switches support configuration and display of IP address in classical subnet format (example: 192.168.1.1 255.255.255.0) and Classless Interdomain Routing (CIDR) format (example: 192.168.1.1/24). You can use either format when configuring IP address information. IP addresses are displayed in classical subnet format by default but you can change the display format to CIDR. Refer to “Changing the network mask display to prefix format” on page 1084.

Layer 3 Switches

Brocade Layer 3 Switches allow you to configure IP addresses on the following types of interfaces:
- Ethernet ports
- Virtual routing interfaces (used by VLANs to route among one another)
- Loopback interfaces

Each IP address on a Layer 3 Switch must be in a different subnet. You can have only one interface that is in a given subnet. For example, you can configure IP addresses 192.168.1.1/24 and 192.168.2.1/24 on the same Layer 3 Switch, but you cannot configure 192.168.1.1/24 and 192.168.1.2/24 on the same Layer 3 Switch.

You can configure multiple IP addresses on the same interface.

The number of IP addresses you can configure on an individual interface depends on the Layer 3 Switch model. To display the maximum number of IP addresses and other system parameters you can configure on a Layer 3 Switch, refer to the section “Displaying and modifying system parameter default settings” on page 380.

You can use any of the IP addresses you configure on the Layer 3 Switch for Telnet, Web management, or SNMP access.

Layer 2 Switches

You can configure an IP address on a Brocade Layer 2 Switch for management access to the Layer 2 Switch. An IP address is required for Telnet access, Web management access, and SNMP access.

You also can specify the default gateway for forwarding traffic to other subnets.
IP packet flow through a Layer 3 Switch

Figure 130 shows how an IP packet moves through a Brocade Layer 3 Switch.

**FIGURE 130** IP Packet Flow through a Brocade Layer 3 Switch

Figure 130 shows the following packet flow:

1. When the Layer 3 Switch receives an IP packet, the Layer 3 Switch checks for filters on the receiving interface. If a deny filter on the interface denies the packet, the Layer 3 Switch discards the packet and performs no further processing, except generating a Syslog entry and SNMP message, if logging is enabled for the filter.

2. If the packet is not denied at the incoming interface, the Layer 3 Switch looks in the session table for an entry that has the same source IP address and TCP or UDP port as the packet. If the session table contains a matching entry, the Layer 3 Switch immediately forwards the packet, by addressing it to the destination IP address and TCP or UDP port listed in the session table entry and sending the packet to a queue on the outgoing ports listed in the session table. The Layer 3 Switch selects the queue based on the Quality of Service (QoS) level associated with the session table entry.

1. The filter can be an Access Control List (ACL) or an IP access policy.
3. If the session table does not contain an entry that matches the packet source address and TCP or UDP port, the Layer 3 Switch looks in the IP forwarding cache for an entry that matches the packet destination IP address. If the forwarding cache contains a matching entry, the Layer 3 Switch forwards the packet to the IP address in the entry. The Layer 3 Switch sends the packet to a queue on the outgoing ports listed in the forwarding cache. The Layer 3 Switch selects the queue based on the Quality of Service (QoS) level associated with the forwarding cache entry.

4. If the IP forwarding cache does not have an entry for the packet, the Layer 3 Switch checks the IP route table for a route to the packet destination. If the IP route table has a route, the Layer 3 Switch makes an entry in the session table or the forwarding cache, and sends the route to a queue on the outgoing ports:
   • If the running-config contains an IP access policy for the packet, the software makes an entry in the session table. The Layer 3 Switch uses the new session table entry to forward subsequent packets from the same source to the same destination.
   • If the running-config does not contain an IP access policy for the packet, the software creates a new entry in the forwarding cache. The Layer 3 Switch uses the new cache entry to forward subsequent packets to the same destination.

The following sections describe the IP tables and caches:
   • ARP cache and static ARP table
   • IP route table
   • IP forwarding cache
   • IP session table

The software enables you to display these tables. You also can change the capacity of the tables on an individual basis if needed by changing the memory allocation for the table.

**ARP cache and static ARP table**

The ARP cache contains entries that map IP addresses to MAC addresses. Generally, the entries are for devices that are directly attached to the Layer 3 Switch.

An exception is an ARP entry for an interface-based static IP route that goes to a destination that is one or more router hops away. For this type of entry, the MAC address is either the destination device MAC address or the MAC address of the router interface that answered an ARP request on behalf of the device, using proxy ARP.

**ARP cache**

The ARP cache can contain dynamic (learned) entries and static (user-configured) entries. The software places a dynamic entry in the ARP cache when the Layer 3 Switch learns a device MAC address from an ARP request or ARP reply from the device.

The software can learn an entry when the Layer 2 Switch or Layer 3 Switch receives an ARP request from another IP forwarding device or an ARP reply. Here is an example of a dynamic entry:

<table>
<thead>
<tr>
<th>IP Address</th>
<th>MAC Address</th>
<th>Type</th>
<th>Age</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>207.95.6.102</td>
<td>0800.5afc.ea21</td>
<td>Dynamic</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>

Each entry contains the destination device IP address and MAC address.
Static ARP table
In addition to the ARP cache, Layer 3 Switches have a static ARP table. Entries in the static ARP table are user-configured. You can add entries to the static ARP table regardless of whether the device the entry is for is connected to the Layer 3 Switch.

NOTE
Layer 3 Switches have a static ARP table. Layer 2 Switches do not.

The software places an entry from the static ARP table into the ARP cache when the entry interface comes up.

Here is an example of a static ARP entry.

<table>
<thead>
<tr>
<th>Index</th>
<th>IP Address</th>
<th>MAC Address</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>207.95.6.111</td>
<td>0800.093b.d210</td>
<td>1/1</td>
</tr>
</tbody>
</table>

Each entry lists the information you specified when you created the entry.

To display ARP entries, refer to the following:

- “Displaying the ARP cache” on page 1091 – Layer 3 Switch
- “Displaying the static ARP table” on page 1092 – Layer 3 Switch only
- “Displaying ARP entries” on page 1101 – Layer 2 Switch

To configure other ARP parameters, refer to the following:

- “Configuring ARP parameters” on page 1005 – Layer 3 Switch only

To increase the size of the ARP cache and static ARP table, refer to the following:

- For dynamic entries, refer to the section “Displaying and modifying system parameter default settings” on page 380. The ip-arp parameter controls the ARP cache size.
- Static entries, “Changing the maximum number of entries the static ARP table can hold” on page 1010 – Layer 3 Switches only. The ip-static-arp parameter controls the static ARP table size.

IP route table
The IP route table contains paths to IP destinations.

NOTE
Layer 2 Switches do not have an IP route table. A Layer 2 Switch sends all packets addressed to another subnet to the default gateway, which you specify when you configure the basic IP information on the Layer 2 Switch.

The IP route table can receive the paths from the following sources:

- A directly-connected destination, which means there are no router hops to the destination
- A static IP route, which is a user-configured route
- A route learned through RIP
- A route learned through OSPF
- A route learned through BGP4

The IP route table contains the best path to a destination:
• When the software receives paths from more than one of the sources listed above, the software compares the administrative distance of each path and selects the path with the lowest administrative distance. The administrative distance is a protocol-independent value from 1 – 255.

• When the software receives two or more best paths from the same source and the paths have the same metric (cost), the software can load share traffic among the paths based on destination host or network address (based on the configuration and the Layer 3 Switch model).

Here is an example of an entry in the IP route table.

<table>
<thead>
<tr>
<th>Destination</th>
<th>NetMask</th>
<th>Gateway</th>
<th>Port</th>
<th>Cost</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.1.0.0</td>
<td>255.255.0.0</td>
<td>99.1.1.2</td>
<td>1/1</td>
<td>2</td>
<td>R</td>
</tr>
</tbody>
</table>

Each IP route table entry contains the destination IP address and subnet mask and the IP address of the next-hop router interface to the destination. Each entry also indicates the port attached to the destination or the next-hop to the destination, the route IP metric (cost), and the type. The type indicates how the IP route table received the route.

To display the IP route table, refer to “Displaying the IP route table” on page 1094 (Layer 3 Switch only)

To configure a static IP route, refer to “Configuring static routes” on page 1015 (Layer 3 Switch only)

To clear a route from the IP route table, refer to “Clearing IP routes” on page 1097 (Layer 3 Switch only)

To increase the size of the IP route table for learned and static routes, refer to the section “Displaying and modifying system parameter default settings” on page 380:

• For learned routes, modify the ip-route parameter.
• For static routes, modify the ip-static-route parameter.

**IP forwarding cache**

The IP forwarding cache provides a fast-path mechanism for forwarding IP packets. The cache contains entries for IP destinations. When a Brocade Layer 3 Switch has completed processing and addressing for a packet and is ready to forward the packet, the device checks the IP forwarding cache for an entry to the packet destination:

• If the cache contains an entry with the destination IP address, the device uses the information in the entry to forward the packet out the ports listed in the entry. The destination IP address is the address of the packet final destination. The port numbers are the ports through which the destination can be reached.

• If the cache does not contain an entry and the traffic does not qualify for an entry in the session table instead, the software can create an entry in the forwarding cache.

Each entry in the IP forwarding cache has an age timer. If the entry remains unused for ten minutes, the software removes the entry. The age timer is not configurable.
Here is an example of an entry in the IP forwarding cache.

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Next Hop</th>
<th>MAC Address</th>
<th>Type</th>
<th>Port</th>
<th>VLAN</th>
<th>Pri</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.1.11</td>
<td>DIRECT</td>
<td>0000.0000.0000</td>
<td>PU</td>
<td>n/a</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Each IP forwarding cache entry contains the IP address of the destination, and the IP address and MAC address of the next-hop router interface to the destination. If the destination is actually an interface configured on the Layer 3 Switch itself, as shown here, then next-hop information indicates this. The port through which the destination is reached is also listed, as well as the VLAN and Layer 4 QoS priority associated with the destination if applicable.

To display the IP forwarding cache, refer to “Displaying the forwarding cache” on page 1093.

**NOTE**

You cannot add static entries to the IP forwarding cache, although you can increase the number of entries the cache can contain. Refer to the section “Displaying and modifying system parameter default settings” on page 380.

To increase the size of the IP forwarding cache, refer to the section “Displaying and modifying system parameter default settings” on page 380.

**Layer 4 session table**

The Layer 4 session provides a fast path for forwarding packets. A session is an entry that contains complete Layer 3 and Layer 4 information for a flow of traffic. Layer 3 information includes the source and destination IP addresses. Layer 4 information includes the source and destination TCP and UDP ports. For comparison, the IP forwarding cache contains the Layer 3 destination address but does not contain the other source and destination address information of a Layer 4 session table entry.

The Layer 2 Switch or Layer 3 Switch selects the session table instead of the IP forwarding table for fast-path forwarding for the following features:

- Layer 4 Quality-of-Service (QoS) policies
- IP access policies

To increase the size of the session table, refer to the section “Displaying and modifying system parameter default settings” on page 380. The ip-qos-session parameter controls the size of the session table.

**IP route exchange protocols**

Brocade Layer 3 Switches support the following IP route exchange protocols:

- Routing Information Protocol (RIP)
- Open Shortest Path First (OSPF)
- Border Gateway Protocol version 4 (BGP4)

**NOTE**

TurboIron devices do not support BGP4.

All these protocols provide routes to the IP route table. You can use one or more of these protocols, in any combination. The protocols are disabled by default. For configuration information, refer to the following:
IP multicast protocols

Brocade Layer 3 Switches also support the following Internet Group Membership Protocol (IGMP) based IP multicast protocols:

- Protocol Independent Multicast – Dense mode (PIM-DM)
- Protocol Independent Multicast – Sparse mode (PIM-SM)
- Distance Vector Multicast Routing Protocol (DVMRP)

For configuration information, refer to Chapter 28, “Configuring IP Multicast Protocols”.

NOTE
Brocade Layer 2 Switches support IGMP and can forward IP multicast packets. Refer to Chapter 27, “Configuring IP Multicast Traffic Reduction for FastIron X Series and Turbolron Series Switches”.

IP interface redundancy protocols

You can configure a Brocade Layer 3 Switch to back up an IP interface configured on another Brocade Layer 3 Switch. If the link for the backed up interface becomes unavailable, the other Layer 3 Switch can continue service for the interface. This feature is especially useful for providing a backup to a network default gateway.

Brocade Layer 3 Switches support the following IP interface redundancy protocols:

- Virtual Router Redundancy Protocol (VRRP) – A standard router redundancy protocol based on RFC 2338. You can use VRRP to configure Brocade Layer 3 Switches and third-party routers to back up IP interfaces on other Brocade Layer 3 Switches or third-party routers.
- Virtual Router Redundancy Protocol Extended (VRRPE) – A Brocade extension to standard VRRP that adds additional features and overcomes limitations in standard VRRP. You can use VRRPE only on Brocade Layer 3 Switches.

For configuration information, refer to the following:

- Virtual Router Redundancy Protocol Extended (VRRPE) – refer to Chapter 37, “Configuring VRRP and VRRPE”.
- Virtual Router Redundancy Protocol (VRRP) – refer to Chapter 37, “Configuring VRRP and VRRPE”.

Access Control Lists and IP access policies

Brocade Layer 3 Switches provide two mechanisms for filtering IP traffic:

- Access Control Lists (ACLs)
- IP access policies

Both methods allow you to filter packets based on Layer 3 and Layer 4 source and destination information.
ACLs also provide great flexibility by providing the input to various other filtering mechanisms such as route maps, which are used by BGP4.

IP access policies allow you to configure QoS based on sessions (Layer 4 traffic flows).

Only one of these filtering mechanisms can be enabled on a Brocade device at a time. Brocade devices can store forwarding information for both methods of filtering in the session table.

For configuration information, Chapter 17, “Configuring Rule-Based IP Access Control Lists (ACLs)”

Basic IP parameters and defaults – Layer 3 Switches

IP is enabled by default. The following IP-based protocols are all disabled by default:

- Routing protocols:
  - Routing Information Protocol (RIP) – refer to Chapter 33, “Configuring RIP”
  - Open Shortest Path First (OSPF) – refer to Chapter 35, “Configuring OSPF Version 2 (IPv4)”
  - Border Gateway Protocol version 4 (BGP4) – refer to Chapter 38, “Configuring BGP4”

- Multicast protocols:
  - Internet Group Membership Protocol (IGMP) – refer to “Changing global IP multicast parameters” on page 835
  - Protocol Independent Multicast Dense (PIM-DM) – refer to “PIM Dense” on page 840
  - Protocol Independent Multicast Sparse (PIM-SM) – refer to “PIM Sparse” on page 849
  - Distance Vector Multicast Routing Protocol (DVMRP) – refer to “DVMRP overview” on page 896

- Router redundancy protocols:
  - Virtual Router Redundancy Protocol Extended (VRRPE) – refer to Chapter 37, “Configuring VRRP and VRRPE”.
  - Virtual Router Redundancy Protocol (VRRP) – refer to Chapter 37, “Configuring VRRP and VRRPE”.

The following tables list the Layer 3 Switch IP parameters, their default values, and where to find configuration information.

**NOTE**

For information about parameters in other protocols based on IP, such as RIP, OSPF, and so on, refer to the configuration chapters for those protocols.

When parameter changes take effect

Most IP parameters described in this chapter are dynamic. They take effect immediately, as soon as you enter the CLI command or select the Web Management Interface option. You can verify that a dynamic change has taken effect by displaying the running-config. To display the running-config, enter the `show running-config` or `write terminal` command at any CLI prompt. (You cannot display the running-config from the Web Management Interface.)

To save a configuration change permanently so that the change remains in effect following a system reset or software reload, save the change to the startup-config file:
• To save configuration changes to the startup-config file, enter the write memory command from the Privileged EXEC level of any configuration level of the CLI.

• To save the configuration changes using the Web Management Interface, select the Save link at the bottom of the dialog. Select Yes when prompted to save the configuration change to the startup-config file on the device flash memory. You also can access the dialog for saving configuration changes by clicking on Command in the tree view, then clicking on Save to Flash.

Changes to memory allocation require you to reload the software after you save the changes to the startup-config file. When reloading the software is required to complete a configuration change described in this chapter, the procedure that describes the configuration change includes a step for reloading the software.
Table 166 lists the IP global parameters for Layer 3 Switches.

### TABLE 166  IP global parameters – Layer 3 Switches

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>

</tr>
</thead>
<tbody>
<tr>
<td>IP state</td>
<td>The Internet Protocol, version 4</td>
<td>Enabled</td>
<td>n/a</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> You cannot disable IP.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| IP address and mask notation | Format for displaying an IP address and its network mask information. You can enable one of the following:  
• Class-based format; example: 192.168.1.1 255.255.255.0  
• Classless Interdomain Routing (CIDR) format; example: 192.168.1.1/24 | Class-based  | page 1084   |
|                         | **NOTE:** Changing this parameter affects the display of IP addresses, but you can enter addresses in either format regardless of the display setting. |              |             |
| Router ID               | The value that routers use to identify themselves to other routers when exchanging route information. OSPF and BGP4 use router IDs to identify routers. RIP does not use the router ID. | The IP address configured on the lowest-numbered loopback interface. If no loopback interface is configured, then the lowest-numbered IP address configured on the device. | page 1002   |
| Maximum Transmission Unit (MTU) | The maximum length an Ethernet packet can be without being fragmented. | 1500 bytes for Ethernet II encapsulation  
1492 bytes for SNAP encapsulation | page 1000   |
| Address Resolution Protocol (ARP) | A standard IP mechanism that routers use to learn the Media Access Control (MAC) address of a device on the network. The router sends the IP address of a device in the ARP request and receives the device MAC address in an ARP reply. | Enabled      | page 1005   |
| ARP rate limiting       | Lets you specify a maximum number of ARP packets the device will accept each second. If the device receives more ARP packets than you specify, the device drops additional ARP packets for the remainder of the one-second interval. | Disabled     | page 1006   |
| ARP age                 | The amount of time the device keeps a MAC address learned through ARP in the device ARP cache. The device resets the timer to zero each time the ARP entry is refreshed and removes the entry if the timer reaches the ARP age. | Ten minutes  | page 1007   |
|                         | **NOTE:** You also can change the ARP age on an individual interface basis. Refer to Table 167 on page 989. |              |             |
## TABLE 166  IP global parameters – Layer 3 Switches (Continued)

<table>
<thead>
<tr>

<td>Disabled</td>
<td>page 1008</td>
</tr>
<tr>
<td>Static ARP entries</td>
<td>An ARP entry you place in the static ARP table. Static entries do not age out.</td>
<td>No entries</td>
<td>page 1009</td>
</tr>
<tr>
<td>Time to Live (TTL)</td>
<td>The maximum number of routers (hops) through which a packet can pass before being discarded. Each router decreases a packet TTL by 1 before forwarding the packet. If decreasing the TTL causes the TTL to be 0, the router drops the packet instead of forwarding it.</td>
<td>64 hops</td>
<td>page 1011</td>
</tr>
<tr>
<td>Directed broadcast forwarding</td>
<td>A directed broadcast is a packet containing all ones (or in some cases, all zeros) in the host portion of the destination IP address. When a router forwards such a broadcast, it sends a copy of the packet out each of its enabled IP interfaces. NOTE: You also can enable or disable this parameter on an individual interface basis. Refer to Table 167 on page 989.</td>
<td>Disabled</td>
<td>page 1011</td>
</tr>
</tbody>
</table>
| Directed broadcast mode             | The packet format the router treats as a directed broadcast. The following formats can be directed broadcast:  
  • All ones in the host portion of the packet destination address.  
  • All zeroes in the host portion of the packet destination address.   

  NOTE: If you enable all-zeroes directed broadcasts, all-ones directed broadcasts remain enabled. | All ones  | page 1013   |
| Source-routed packet forwarding     | A source-routed packet contains a list of IP addresses through which the packet must pass to reach its destination.                                                                                           | Enabled  | page 1012   |
| Internet Control Message Protocol (ICMP) messages | The Brocade Layer 3 Switch can send the following types of ICMP messages:  
  • Echo messages (ping messages)  
  • Destination Unreachable messages | Enabled  | page 1013   |
| ICMP Router Discovery Protocol (IRDP) | An IP protocol a router can use to advertise the IP addresses of its router interfaces to directly attached hosts. You can enable or disable the protocol, and change the following protocol parameters:  
  • Forwarding method (broadcast or multicast)  
  • Hold time  
  • Maximum advertisement interval  
  • Minimum advertisement interval  
  • Router preference level  

  NOTE: You also can enable or disable IRDP and configure the parameters on an individual interface basis. Refer to Table 167 on page 989. | Disabled | page 1029   |
### Basic IP parameters and defaults – Layer 3 Switches (Continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>See page...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reverse ARP (RARP)</td>
<td>An IP mechanism a host can use to request an IP address from a directly attached router when the host boots.</td>
<td>Enabled</td>
<td>page 1031</td>
</tr>
<tr>
<td>Static RARP entries</td>
<td>An IP address you place in the RARP table for RARP requests from hosts.</td>
<td>No entries</td>
<td>page 1032</td>
</tr>
</tbody>
</table>
|                               | **NOTE:** You must enter the RARP entries manually.  
The Layer 3 Switch does not have a mechanism for learning or dynamically generating RARP entries. |          |             |
| Maximum BootP relay hops      | The maximum number of hops away a BootP server can be located from a router and still be used by the router clients for network booting. | Four     | page 1037   |
| Domain name for Domain Name Server (DNS) resolver | A domain name (example: brocade.router.com) you can use in place of an IP address for certain operations such as IP pings, trace routes, and Telnet management connections to the router. | None configured | page 996   |
| DNS default gateway addresses | A list of gateways attached to the router through which clients attached to the router can reach DNSs. | None configured | page 996   |
| IP load sharing               | A Brocade feature that enables the router to balance traffic to a specific destination across multiple equal-cost paths.  
On FastIron X Series devices, IP load sharing uses a hashing algorithm based on the source IP address, destination IP address, and protocol field in the IP header.  
**NOTE:** Load sharing is sometimes called Equal Cost Multi Path (ECMP). | Enabled  | page 1025   |
| Maximum IP load sharing paths | The maximum number of equal-cost paths across which the Layer 3 Switch is allowed to distribute traffic. | Four     | page 1028   |
| Origination of default routes | You can enable a router to originate default routes for the following route exchange protocols, on an individual protocol basis:  
- RIP  
- OSPF  
- BGP4 | Disabled | page 1150, page 1202, page 1323 |
<p>| Default network route         | The router uses the default network route if the IP route table does not contain a route to the destination and also does not contain an explicit default route (0.0.0.0 0.0.0.0 or 0.0.0.0/0). | None configured | page 1024   |</p>

<th>See page...</th>
</tr>
</thead>
</table>
| IP address and mask notation                        | Format for displaying an IP address and its network mask information. You can enable one of the following:  
  - Class-based format; example: 192.168.1.1 255.255.255.0  
  - Classless Interdomain Routing (CIDR) format; example: 192.168.1.1/24 | Class-based      | page 1084    |
| IP address                                          | A Layer 3 network interface address                                           | None configured  | page 1060   |
| Default gateway                                      | The IP address of a locally attached router (or a router attached to the Layer 2 Switch by bridges or other Layer 2 Switches). The Layer 2 Switch and clients attached to it use the default gateway to communicate with devices on other subnets. | None configured  | page 1060   |
| Address Resolution Protocol (ARP)                   | A standard IP mechanism that networking devices use to learn the Media Access Control (MAC) address of another device on the network. The Layer 2 Switch sends the IP address of a device in the ARP request and receives the device MAC address in an ARP reply. | Enabled          | n/a         |
| ARP age                                              | The amount of time the device keeps a MAC address learned through ARP in the device ARP cache. The device resets the timer to zero each time the ARP entry is refreshed and removes the entry if the timer reaches the ARP age. | Ten minutes      | n/a         |
| Time to Live (TTL)                                  | The maximum number of routers (hops) through which a packet can pass before being discarded. Each router decreases a packet TTL by 1 before forwarding the packet. If decreasing the TTL causes the TTL to be 0, the router drops the packet instead of forwarding it. | 64 hops          | page 1062   |
| Domain name for Domain Name Server (DNS) resolver    | A domain name (example: brocade.router.com) you can use in place of an IP address for certain operations such as IP pings, trace routes, and Telnet management connections to the router. | None configured  | page 1061   |
| DNS default gateway addresses                        | A list of gateways attached to the router through which clients attached to the router can reach DNSs. | None configured  | page 1061   |

</tr>
</tbody>
</table>
Configuring IP addresses

You can configure an IP address on the following types of Layer 3 Switch interfaces:

- Ethernet port
- Virtual routing interface (also called a Virtual Ethernet or “VE”)
- Loopback interface

By default, you can configure up to 24 IP addresses on each interface.

On Compact Layer 3 Switches, you can increase this amount to up to 64 IP subnet addresses per port by increasing the size of the subnet-per-interface table.

On FWS devices, you can increase this to 128 IP addresses on each interface.

Refer to the section “Displaying and modifying system parameter default settings” on page 380.

NOTE

Once you configure a virtual routing interface on a VLAN, you cannot configure Layer 3 interface parameters on individual ports. Instead, you must configure the parameters on the virtual routing interface itself.

Brocade devices support both classical IP network masks (Class A, B, and C subnet masks, and so on) and Classless Interdomain Routing (CIDR) network prefix masks:

- To enter a classical network mask, enter the mask in IP address format. For example, enter “209.157.22.99 255.255.255.0” for an IP address with a Class-C subnet mask.
- To enter a prefix network mask, enter a forward slash ( / ) and the number of bits in the mask immediately after the IP address. For example, enter “209.157.22.99/24” for an IP address that has a network mask with 24 significant bits (ones).

By default, the CLI displays network masks in classical IP address format (example: 255.255.255.0). You can change the display to prefix format. Refer to “Changing the network mask display to prefix format” on page 1084.

Assigning an IP address to an Ethernet port

To assign an IP address to port 1/1, enter the following commands.

```bash
FastIron(config)#interface ethernet 1/1
FastIron(config-if-1/1)#ip address 192.45.6.1 255.255.255.0
```

You also can enter the IP address and mask in CIDR format, as follows.

```bash
FastIron(config-if-1/1)#ip address 192.45.6.1/24
```

Syntax: `[no] ip address <ip-addr> <ip-mask> [ospf-ignore | ospf-passive | secondary]

or

Syntax: `[no] ip address <ip-addr>/<mask-bits> [ospf-ignore | ospf-passive | secondary]

The `ospf-ignore` | `ospf-passive` parameters modify the Layer 3 Switch defaults for adjacency formation and interface advertisement. Use one of these parameters if you are configuring multiple IP subnet addresses on the interface but you want to prevent OSPF from running on some of the subnets:
• **ospf-passive** – This option disables adjacency formation with OSPF neighbors. By default, when OSPF is enabled on an interface, the software forms OSPF router adjacencies between each primary IP address on the interface and the OSPF neighbor attached to the interface.

• **ospf-ignore** – This option disables OSPF adjacency formation and also disables advertisement of the interface into OSPF. The subnet is completely ignored by OSPF.

**NOTE**
The **ospf-passive** option disables adjacency formation but does not disable advertisement of the interface into OSPF. To disable advertisement in addition to disabling adjacency formation, you must use the **ospf-ignore** option.

Use the **secondary** parameter if you have already configured an IP address within the same subnet on the interface.

**NOTE**
When you configure more than one address in the same subnet, all but the first address are secondary addresses and do not form OSPF adjacencies.

**NOTE**
Starting in software release FGS 05.0.00, all physical IP interfaces on IronStack devices share the same MAC address. For this reason, if more than one connection is made between two devices, one of which is an FGS-STK or FLS-STK device, Brocade recommends the use of virtual interfaces. It is not recommended to connect two or more physical IP interfaces between two routers.

**NOTE**
Starting in software release FSX 03.0.00, all physical IP interfaces on FastIron X Series Layer 3 devices share the same MAC address. For this reason, if more than one connection is made between two devices, one of which is a FastIron X Series Layer 3 device, Brocade recommends the use of virtual interfaces. It is not recommended to connect two or more physical IP interfaces between two routers.

### Assigning an IP address to a loopback interface

Loopback interfaces are always up, regardless of the states of physical interfaces. They can add stability to the network because they are not subject to route flap problems that can occur due to unstable links between a Layer 3 Switch and other devices. You can configure up to eight loopback interfaces on a Chassis Layer 3 Switch and FWS devices. You can configure up to four loopback interfaces on a Compact Layer 3 Switch.

You can add up to 24 IP addresses to each loopback interface.

**NOTE**
If you configure the Brocade Layer 3 Switch to use a loopback interface to communicate with a BGP4 neighbor, you also must configure a loopback interface on the neighbor and configure the neighbor to use that loopback interface to communicate with the Brocade Layer 3 Switch. Refer to “Adding a loopback interface” on page 1306.

To add a loopback interface, enter commands such as those shown in the following example.

```
FastIron(config-bgp-router)#exit
FastIron(config)#int loopback 1
FastIron(config-lbif-1)#ip address 10.0.0.1/24
```
Syntax:  interface loopback <num>

The <num> parameter specifies the virtual interface number. You can specify from 1 to the maximum number of virtual interfaces supported on the device. To display the maximum number of virtual interfaces supported on the device, enter the show default values command. The maximum is listed in the System Parameters section, in the Current column of the virtual-interface row.

Refer to the syntax description in “Assigning an IP address to an Ethernet port” on page 993.

Assigning an IP address to a virtual interface

A virtual interface is a logical port associated with a Layer 3 Virtual LAN (VLAN) configured on a Layer 3 Switch. You can configure routing parameters on the virtual interface to enable the Layer 3 Switch to route protocol traffic from one Layer 3 VLAN to the other, without using an external router.¹

You can configure IP routing interface parameters on a virtual interface. This section describes how to configure an IP address on a virtual interface. Other sections in this chapter that describe how to configure interface parameters also apply to virtual interfaces.

NOTE
The Layer 3 Switch uses the lowest MAC address on the device (the MAC address of port 1 or 1/1) as the MAC address for all ports within all virtual interfaces you configure on the device.

To add a virtual interface to a VLAN and configure an IP address on the interface, enter commands such as the following.

FastIron(config)#vlan 2 name IP-Subnet_1.1.2.0/24
FastIron(config-vlan-2)#untag e1 to 4
FastIron(config-vlan-2)#router-interface ve1
FastIron(config-vlan-2)#interface ve1
FastIron(config-vif-1)#ip address 1.1.2.1/24

The first two commands in this example create a Layer 3 protocol-based VLAN name “IP-Subnet_1.1.2.0/24” and add a range of untagged ports to the VLAN. The router-interface command creates virtual interface 1 as the routing interface for the VLAN. The last two commands change to the interface configuration level for the virtual interface and assign an IP address to the interface.

Syntax:  router-interface ve <num>

Syntax:  interface ve <num>

Refer to the syntax description in “Assigning an IP address to an Ethernet port” on page 993.

Configuring IP follow on a virtual routing interface

Platform Support:

- FastIron X Series devices running software release 03.2.00 and later

IP Follow allows multiple virtual routing interfaces to share the same IP address. With this feature, one virtual routing interface is configured with an IP address, while the other virtual routing interfaces are configured to use that IP address, thus, they “follow” the virtual routing interface that has the IP address. This feature is helpful in conserving IP address space.

1. The Brocade feature that allows routing between VLANs within the same device, without the need for external routers, is called Integrated Switch Routing (ISR).
Configuration limitations and feature limitations

- When configuring IP Follow, the primary virtual routing interface should not have ACL or DoS Protection configured. It is recommended that you create a dummy virtual routing interface as the primary and use the IP-follow virtual routing interface for the network.
- Global Policy Based Routing is not supported when IP Follow is configured.
- IPv6 is not supported with `ip-follow`.
- FastIron devices support `ip-follow` with OSPF and VRRP protocols only.

Configuration syntax

Configure IP Follow by entering commands such as the following.

```plaintext
FastIron(config)#vlan 2 name IP-Subnet_1.1.2.0/24
FastIron(config-vlan-2)#untag e1 to 4
FastIron(config-vlan-2)#router-interface ve1
FastIron(config-vlan-2)#interface ve1
FastIron(config-vif-1)#ip address 10.10.2.1/24
FastIron(config-vif-1)#interface ve2
FastIron(config-vif-2)#ip follow ve1
FastIron(config-vif-2)#interface ve3
FastIron(config-vif-3)#ip follow ve1
```

Syntax: `[no] ip follow ve <number>`

For `<number>` enter the ID of the virtual routing interface.

Use the `no` form of the command to disable the configuration.

Virtual routing interface 2 and 3 do not have their own IP subnet address, but are sharing the IP address of virtual routing interface 1.

Deleting an IP address

To delete an IP address, enter a command such as the following.

```plaintext
FastIron(config-if-e1000-1)#no ip address 1.1.2.1
```

This command deletes IP address 1.1.2.1. You do not need to enter the subnet mask.

To delete all IP addresses from an interface, enter the following command.

```plaintext
FastIron(config-if-e1000-1)#no ip address *
```

Syntax: `no ip address <ip-addr> | *`

Configuring Domain Name Server (DNS) resolver

Platform Support:

- FastIron X Series devices running software release 03.0.00 and later

The DNS resolver is a feature in a Layer 2 Switch or Layer 3 Switch that sends and receives queries to and from the DNS server on behalf of a client:

- In software releases prior to 03.0.00 for the FastIron X Series devices, you can use one domain name to perform Telnet, ping, traceroute and other DNS query commands. You define one domain name on a Brocade Layer 2 Switch or Layer 3 Switch and up to four DNS servers. Host names and their IP addresses are configured on the DNS servers.
• Starting in software release 03.0.00 for the FastIron X Series devices, you can create a list of domain names that can be used to resolve host names. This list can have more than one domain name. When a client performs a DNS query, all hosts within the domains in the list can be recognized and queries can be sent to any domain on the list.

When a client performs a DNS query, all hosts within that domain can be recognized. After you define a domain name, the Brocade device automatically appends the appropriate domain to a host and forwards it to the DNS servers for resolution.

For example, if the domain “ds.company.com” is defined on a Brocade Layer 2 Switch or Layer 3 Switch and you want to initiate a ping to “mary”. You need to reference only the host name instead of the host name and its domain name. For example, you could enter the following command to initiate the ping.

U:> ping mary

The Brocade Layer 2 Switch or Layer 3 Switch qualifies the host name by appending a domain name. For example, mary.ds1.company.com. This qualified name is sent to the DNS server for resolution. If there are four DNS servers configured, it is sent to the first DNS server. If the host name is not resolved, it is sent to the second DNS server. If a match is found, a response is sent back to the client with the host IP address. If no match is found, an “unknown host” message is returned. (Refer to Figure 131.)

**FIGURE 131** DNS resolution with one domain name

---

**Defining a domain name**

To define a domain to resolve host names, enter a command such as the following.
FastIron(config)#ip dns domain-name ds.company.com

Syntax: [no] ip dns domain-name <domain-name>
Enter the domain name for <domain-name>.

Defining DNS server addresses

You can configure the Brocade device to recognize up to four DNS servers. The first entry serves as the primary default address. If a query to the primary address fails to be resolved after three attempts, the next DNS address is queried (also up to three times). This process continues for each defined DNS address until the query is resolved. The order in which the default DNS addresses are polled is the same as the order in which you enter them.

To define DNS servers, enter a command such as the following.

FastIron(config)#ip dns server-address 209.157.22.199 205.96.7.15 208.95.7.25 201.98.7.15

Syntax: [no] ip dns server-address <ip-addr> [<ip-addr>] [<ip-addr>] [<ip-addr>]

In this example, the first IP address entered becomes the primary DNS address and all others are secondary addresses. Because IP address 201.98.7.15 is the last address listed, it is also the last address consulted to resolve a query.

Defining a domain list

NOTE
Domain lists are supported starting in software release 03.0.00 for the FESX, FSX, FSX 800, FSX 1600, and FWSX.

If you want to use more than one domain name to resolve host names, you can create a list of domain names. For example, enter the commands such as the following.

FastIron(config)#ip dns domain-list company.com
FastIron(config)#ip dns domain-list ds.company.com
FastIron(config)#ip dns domain-list hw_company.com
FastIron(config)#ip dns domain-list qa_company.com
FastIron(config)#

The domain names are tried in the order you enter them.

Syntax: [no] ip dns domain-list <domain-name>

Using a DNS name to initiate a trace route

Suppose you want to trace the route from a Brocade Layer 3 Switch to a remote server identified as NYC02 on domain newyork.com. Because the NYC02@ds1.newyork.com domain is already defined on the Layer 3 Switch, you need to enter only the host name, NYC02, as noted below.

FastIron#traceroute nyc02

Syntax: traceroute <host-ip-addr> [maxttl <value>] [minttl <value>] [numeric] [timeout <value>] [source-ip <ip addr>]

The only required parameter is the IP address of the host at the other end of the route.
After you enter the command, a message indicating that the DNS query is in process and the current gateway address (IP address of the domain name server) being queried appear on the screen.

Type Control-c to abort
Sending DNS Query to 209.157.22.199
Tracing Route to IP node 209.157.22.80
To ABORT Trace Route, Please use stop-traceroute command.

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Round Trip Time1</th>
<th>Round Trip Time2</th>
</tr>
</thead>
<tbody>
<tr>
<td>207.95.6.30</td>
<td>93 msec</td>
<td>121 msec</td>
</tr>
</tbody>
</table>

**NOTE**
In the above example, 209.157.22.199 is the IP address of the domain name server (default DNS gateway address), and 209.157.22.80 represents the IP address of the NYC02 host.

## Configuring packet parameters

You can configure the following packet parameters on Layer 3 Switches. These parameters control how the Layer 3 Switch sends IP packets to other devices on an Ethernet network. The Layer 3 Switch always places IP packets into Ethernet packets to forward them on an Ethernet port.

- **Encapsulation type** – The format for the Layer 2 packets within which the Layer 3 Switch sends IP packets.
- **Maximum Transmission Unit (MTU)** – The maximum length of IP packet that a Layer 2 packet can contain. IP packets that are longer than the MTU are fragmented and sent in multiple Layer 2 packets. You can change the MTU globally or an individual ports:
  - **Global MTU** – The default MTU value depends on the encapsulation type on a port and is 1500 bytes for Ethernet II encapsulation and 1492 bytes for SNAP encapsulation.
  - **Port MTU** – A port default MTU depends on the encapsulation type enabled on the port.

## Changing the encapsulation type

The Layer 3 Switch encapsulates IP packets into Layer 2 packets, to send the IP packets on the network. (A Layer 2 packet is also called a MAC layer packet or an Ethernet frame.) The source address of a Layer 2 packet is the MAC address of the Layer 3 Switch interface sending the packet. The destination address can be one of the following:

- The MAC address of the IP packet destination. In this case, the destination device is directly connected to the Layer 3 Switch.
- The MAC address of the next-hop gateway toward the packet destination.
- An Ethernet broadcast address.

The entire IP packet, including the source and destination address and other control information and the data, is placed in the data portion of the Layer 2 packet. Typically, an Ethernet network uses one of two different formats of Layer 2 packet:

- Ethernet II
- Ethernet SNAP (also called IEEE 802.3)
The control portions of these packets differ slightly. All IP devices on an Ethernet network must use the same format. Brocade Layer 3 Switches use Ethernet II by default. You can change the IP encapsulation to Ethernet SNAP on individual ports if needed.

**NOTE**
All devices connected to the Layer 3 Switch port must use the same encapsulation type.

To change the IP encapsulation type on interface 5 to Ethernet SNAP, enter the following commands.

```plaintext
FastIron(config)#int e 5
FastIron(config-if-e1000-5)#ip encapsulation snap
```

**Syntax:** ip encapsulation snap | ethernet_ii

**Changing the Maximum Transmission Unit (MTU)**

The Maximum Transmission Unit (MTU) is the maximum length of IP packet that a Layer 2 packet can contain. IP packets that are longer than the MTU are fragmented and sent in multiple Layer 2 packets. You can change the MTU globally or on individual ports.

The default MTU is 1500 bytes for Ethernet II packets and 1492 for Ethernet SNAP packets.

**MTU enhancements**

Brocade devices contain the following enhancements to jumbo packet support:

- Hardware forwarding of Layer 3 jumbo packets – Layer 3 IP unicast jumbo packets received on a port that supports the frame's MTU size and forwarded to another port that also supports the frame's MTU size are forwarded in hardware. Previous releases support hardware forwarding of Layer 2 jumbo frames only.

- ICMP unreachable message if a frame is too large to be forwarded – If a jumbo packet has the Do not Fragment (DF) bit set, and the outbound interface does not support the packet's MTU size, the Brocade device sends an ICMP unreachable message to the device that sent the packet.

**NOTE**
These enhancements apply only to transit traffic forwarded through the Brocade device.

**Configuration considerations for increasing the MTU**

- When you increase the MTU size of a port, the increase uses system resources. Increase the MTU size only on the ports that need it. For example, if you have one port connected to a server that uses jumbo frames and two other ports connected to clients that can support the jumbo frames, increase the MTU only on those three ports. Leave the MTU size on the other ports at the default value (1500 bytes). Globally increase the MTU size only if needed.

- Use the same MTU size on all ports that will be supporting jumbo frames. If the device needs to fragment a jumbo frame (and the frame does not have the DF bit set), the device fragments the frame into 1500-byte fragments, even if the outbound port has a larger MTU. For example, if a port has an MTU setting of 8000 and receives an 8000-byte frame, then must forward the frame onto a port with an MTU of 4000, the device does not fragment the 8000-byte frame into two 4000-byte frames. Instead, the device fragments the 8000-byte frame into six fragments (five 1500-byte fragments and a final, smaller fragment.)
Globally changing the Maximum Transmission Unit (MTU)
The Maximum Transmission Unit (MTU) is the maximum size an IP packet can be when 
encapsulated in a Layer 2 packet. If an IP packet is larger than the MTU allowed by the Layer 2 
packet, the Layer 3 Switch fragments the IP packet into multiple parts that will fit into the Layer 2 
packets, and sends the parts of the fragmented IP packet separately, in different Layer 2 packets. 
The device that receives the multiple fragments of the IP packet reassembles the fragments into 
the original packet.
You can increase the MTU size to accommodate jumbo packet sizes up to 10,232 bytes in an 
IronStack, or up to 9198 bytes in a TurboIron X Series device.
To globally enable jumbo support on all ports of a FastIron X Series device, enter commands such 
as the following.

```
FastIron(config)#jumbo
FastIron(config)#write memory
FastIron(config)#end
FastIron#reload
```

Syntax: `[no] jumbo`

**NOTE**
You must save the configuration change and then reload the software to enable jumbo support.

Changing the Maximum Transmission Unit on an individual port
By default, the maximum Ethernet MTU sizes are as follows:

- 1500 bytes – The maximum for Ethernet II encapsulation
- 1492 bytes – The maximum for SNAP encapsulation

When jumbo mode is enabled, the maximum Ethernet MTU sizes are as follows:

- 9198 bytes – The maximum for Ethernet II encapsulation
- 9190 bytes – The maximum for SNAP encapsulation

**NOTE**
On FastIron devices, if you set the MTU of a port to a value lower than the global MTU and from 576 – 1499, the port fragments the packets. However, if the port MTU is exactly 1500 and this is larger 
than the global MTU, the port drops the packets.

**NOTE**
On FastIron devices, you must save the configuration change and then reload the software to enable 
jumbo support.

To change the MTU for interface 1/5 to 1000, enter the following commands.

```
FastIron(config)#int e 1/5
FastIron(config-if-1/5)#ip-port-mtu 1000
FastIron(config-if-1/5)#write memory
FastIron(config-if-1/5)#end
```

Syntax: `[no] ip-port-mtu <num>`
NOTE

The new command `ip-port-mtu` replace the command `ip mtu`. On the Turbolron, the IP MTU check on egress is validated based on the physical port instead of the ip interface. Therefore, the command `ip-port-mtu` can be set only on a physical port. In the case of a VE, we can set the `ip-port-mtu` on a port member of a VE. In contrast with the `ip mtu` command, the multiple physical ports in a VE can have a different IP MTU. However, on Turbolron, all VLANs of a port would have the same IP MTU size.

The `<num>` parameter specifies the MTU. Ethernet II packets can hold IP packets from 576 – 1500 bytes long. If jumbo mode is enabled, Ethernet II packets can hold IP packets up to 9198 bytes long. Ethernet SNAP packets can hold IP packets from 576 – 1492 bytes long. If jumbo mode is enabled, SNAP packets can hold IP packets up to 9190 bytes long. The default MTU for Ethernet II packets is 1500. The default MTU for SNAP packets is 1492.

Path MTU discovery (RFC 1191) support

NOTE

IP MTU is not supported for FGS, FLS, FGS-STK, FLS-STK and FWS devices.

Most Brocade devices support the path MTU discovery method described in RFC 1191. When the Brocade device receives an IP packet that has its Do not Fragment (DF) bit set, and the packet size is greater than the MTU value of the outbound interface, then the Brocade device returns an ICMP Destination Unreachable message to the source of the packet, with the Code indicating "fragmentation needed and DF set". The ICMP Destination Unreachable message includes the MTU of the outbound interface. The source host can use this information to help determine the maximum MTU of a path to a destination.

RFC 1191 is supported on all interfaces.

Changing the router ID

In most configurations, a Layer 3 Switch has multiple IP addresses, usually configured on different interfaces. As a result, a Layer 3 Switch identity to other devices varies depending on the interface to which the other device is attached. Some routing protocols, including Open Shortest Path First (OSPF) and Border Gateway Protocol version 4 (BGP4), identify a Layer 3 Switch by just one of the IP addresses configured on the Layer 3 Switch, regardless of the interfaces that connect the Layer 3 Switches. This IP address is the router ID.

NOTE

Routing Information Protocol (RIP) does not use the router ID.

NOTE

If you change the router ID, all current BGP4 sessions are cleared.

By default, the router ID on a Brocade Layer 3 Switch is one of the following:

- If the router has loopback interfaces, the default router ID is the IP address configured on the lowest numbered loopback interface configured on the Layer 3 Switch. For example, if you configure loopback interfaces 1, 2, and 3 as follows, the default router ID is 9.9.9.9/24:
  - Loopback interface 1, 9.9.9.9/24
  - Loopback interface 2, 4.4.4.4/24
  - Loopback interface 3, 1.1.1.1/24
• If the device does not have any loopback interfaces, the default router ID is the lowest numbered IP interface configured on the device.

If you prefer, you can explicitly set the router ID to any valid IP address. The IP address cannot be in use on another device in the network.

**NOTE**
Brocade Layer 3 Switches use the same router ID for both OSPF and BGP4. If the router is already configured for OSPF, you may want to use the router ID that is already in use on the router rather than set a new one. To display the router ID, enter the `show ip cli` command at any CLI level or select the IP->General links from the Configure tree in the Web Management Interface.

To change the router ID, enter a command such as the following.

```
FastIron(config)#ip router-id 209.157.22.26
```

**Syntax:** `ip router-id <ip-addr>`

The `<ip-addr>` can be any valid, unique IP address.

**NOTE**
You can specify an IP address used for an interface on the Brocade Layer 3 Switch, but do not specify an IP address in use by another device.

---

### Specifying a single source interface for Telnet, TACACS/TACACS+, or RADIUS Packets

When the Layer 3 Switch originates a Telnet, TACACS/TACACS+, or RADIUS packet, the source address of the packet is the lowest-numbered IP address on the interface that sends the packet. You can configure the Layer 3 Switch to always use the lowest-numbered IP address on a specific interface as the source addresses for these types of packets. When you configure the Layer 3 Switch to use a single source interface for all Telnet, TACACS/TACACS+, or RADIUS packets, the Layer 3 Switch uses the same IP address as the source for all packets of the specified type, regardless of the ports that actually sends the packets.

Identifying a single source IP address for Telnet, TACACS/TACACS+, or RADIUS packets provides the following benefits:

- If your Telnet, TACACS/TACACS+, or RADIUS server is configured to accept packets only from specific IP addresses, you can use this feature to simplify configuration of the server by configuring the Brocade device to always send the packets from the same link or source address.

- If you specify a loopback interface as the single source for Telnet, TACACS/TACACS+, or RADIUS packets, servers can receive the packets regardless of the states of individual links. Thus, if a link to the server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

The software contains separate CLI commands for specifying the source interface for Telnet, TACACS/TACACS+, or RADIUS packets. You can configure a source interface for one or more of these types of packets separately.
To specify an Ethernet or a loopback or virtual interface as the source for all TACACS/TACACS+ packets from the device, use the following CLI method. The software uses the lowest-numbered IP address configured on the port or interface as the source IP address for TACACS/TACACS+ packets originated by the device.

The following sections show the syntax for specifying a single source IP address for Telnet, TACACS/TACACS+, and RADIUS packets.

**Telnet packets**
To specify the lowest-numbered IP address configured on a virtual interface as the device source for all Telnet packets, enter commands such as the following.

```plaintext
FastIron(config)#int loopback 2
FastIron(config-lbif-2)#ip address 10.0.0.2/24
FastIron(config-lbif-2)#exit
FastIron(config)#ip telnet source-interface loopback 2
```

The commands in this example configure loopback interface 2, assign IP address 10.0.0.2/24 to the interface, then designate the interface as the source for all Telnet packets from the Layer 3 Switch.

**Syntax:**  `ip telnet source-interface ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num>`

The `<num>` parameter is a loopback interface or virtual interface number. If you specify an Ethernet port, the `<portnum>` is the port number (including the slot number, if you are configuring a Chassis device).

The following commands configure an IP interface on an Ethernet port and designate the address port as the source for all Telnet packets from the Layer 3 Switch.

```plaintext
FastIron(config)#interface ethernet 1/4
FastIron(config-if-1/4)#ip address 209.157.22.110/24
FastIron(config-if-1/4)#exit
FastIron(config)#ip telnet source-interface ethernet 1/4
```

**TACACS/TACACS+ packets**
To specify the lowest-numbered IP address configured on a virtual interface as the device source for all TACACS/TACACS+ packets, enter commands such as the following.

```plaintext
FastIron(config)#int ve 1
FastIron(config-vif-1)#ip address 10.0.0.3/24
FastIron(config-vif-1)#exit
FastIron(config)#ip tacacs source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface as the source for all TACACS/TACACS+ packets from the Layer 3 Switch.

**Syntax:**  `ip tacacs source-interface ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num>`

The `<num>` parameter is a loopback interface or virtual interface number. If you specify an Ethernet port, the `<portnum>` is the port number (including the slot number, if you are configuring a Chassis device).

**RADIUS packets**
To specify the lowest-numbered IP address configured on a virtual interface as the device source for all RADIUS packets, enter commands such as the following.
FastIron(config)#int ve 1
FastIron(config-vif-1)#ip address 10.0.0.3/24
FastIron(config-vif-1)#exit
FastIron(config)#ip radius source-interface ve 1

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface as the source for all RADIUS packets from the Layer 3 Switch.

Syntax: ip radius source-interface ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num>

The <num> parameter is a loopback interface or virtual interface number. If you specify an Ethernet port, the <portnum> is the port number (including the slot number, if you are configuring a Chassis device).

Configuring ARP parameters

Address Resolution Protocol (ARP) is a standard IP protocol that enables an IP Layer 3 Switch to obtain the MAC address of another device interface when the Layer 3 Switch knows the IP address of the interface. ARP is enabled by default and cannot be disabled.

NOTE
Brocade Layer 2 Switches also support ARP. The description in “How ARP works” also applies to ARP on Brocade Layer 2 Switches. However, the configuration options described later in this section apply only to Layer 3 Switches, not to Layer 2 Switches.

How ARP works

A Layer 3 Switch needs to know a destination MAC address when forwarding traffic, because the Layer 3 Switch encapsulates the IP packet in a Layer 2 packet (MAC layer packet) and sends the Layer 2 packet to a MAC interface on a device directly attached to the Layer 3 Switch. The device can be the packet final destination or the next-hop router toward the destination.

The Layer 3 Switch encapsulates IP packets in Layer 2 packets regardless of whether the ultimate destination is locally attached or is multiple router hops away. Since the Layer 3 Switch IP route table and IP forwarding cache contain IP address information but not MAC address information, the Layer 3 Switch cannot forward IP packets based solely on the information in the route table or forwarding cache. The Layer 3 Switch needs to know the MAC address that corresponds with the IP address of either the packet locally attached destination or the next-hop router that leads to the destination.

For example, to forward a packet whose destination is multiple router hops away, the Layer 3 Switch must send the packet to the next-hop router toward its destination, or to a default route or default network route if the IP route table does not contain a route to the packet destination. In each case, the Layer 3 Switch must encapsulate the packet and address it to the MAC address of a locally attached device, the next-hop router toward the IP packet destination.

To obtain the MAC address required for forwarding a datagram, the Layer 3 Switch does the following:
First, the Layer 3 Switch looks in the ARP cache (not the static ARP table) for an entry that lists the MAC address for the IP address. The ARP cache maps IP addresses to MAC addresses. The cache also lists the port attached to the device and, if the entry is dynamic, the age of the entry. A dynamic ARP entry enters the cache when the Layer 3 Switch receives an ARP reply or receives an ARP request (which contains the sender IP address and MAC address). A static entry enters the ARP cache from the static ARP table (which is a separate table) when the interface for the entry comes up.

To ensure the accuracy of the ARP cache, each dynamic entry has its own age timer. The timer is reset to zero each time the Layer 3 Switch receives an ARP reply or ARP request containing the IP address and MAC address of the entry. If a dynamic entry reaches its maximum allowable age, the entry times out and the software removes the entry from the table. Static entries do not age out and can be removed only by you.

If the ARP cache does not contain an entry for the destination IP address, the Layer 3 Switch broadcasts an ARP request out all its IP interfaces. The ARP request contains the IP address of the destination. If the device with the IP address is directly attached to the Layer 3 Switch, the device sends an ARP response containing its MAC address. The response is a unicast packet addressed directly to the Layer 3 Switch. The Layer 3 Switch places the information from the ARP response into the ARP cache.

ARP requests contain the IP address and MAC address of the sender, so all devices that receive the request learn the MAC address and IP address of the sender and can update their own ARP caches accordingly.

**NOTE**
The ARP request broadcast is a MAC broadcast, which means the broadcast goes only to devices that are directly attached to the Layer 3 Switch. A MAC broadcast is not routed to other networks. However, some routers, including Brocade Layer 3 Switches, can be configured to reply to ARP requests from one network on behalf of devices on another network. Refer to “Enabling proxy ARP” on page 1008.

**NOTE**
If the router receives an ARP request packet that it is unable to deliver to the final destination because of the ARP timeout and no ARP response is received (the Layer 3 Switch knows of no route to the destination address), the router sends an ICMP Host Unreachable message to the source.

**Rate limiting ARP packets**

**Platform Support:**
- FastIron X Series devices running software release 03.0.01 or later
- TurboIron X Series devices running software release 04.2.00 and later

You can limit the number of ARP packets the Brocade device accepts during each second. By default, the software does not limit the number of ARP packets the device can receive. Since the device sends ARP packets to the CPU for processing, if a device in a busy network receives a high number of ARP packets in a short period of time, some CPU processing might be deferred while the CPU processes the ARP packets.
To prevent the CPU from becoming flooded by ARP packets in a busy network, you can restrict the number of ARP packets the device will accept each second. When you configure an ARP rate limit, the device accepts up to the maximum number of packets you specify, but drops additional ARP packets received during the one-second interval. When a new one-second interval starts, the counter restarts at zero, so the device again accepts up to the maximum number of ARP packets you specified, but drops additional packets received within the interval.

To limit the number of ARP packets the device will accept each second, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)#rate-limit-arp 100
```

This command configures the device to accept up to 100 ARP packets each second. If the device receives more than 100 ARP packets during a one-second interval, the device drops the additional ARP packets during the remainder of that one-second interval.

**Syntax:** `[no] rate-limit-arp <num>`

The `<num>` parameter specifies the number of ARP packets and can be from 0 – 100. If you specify 0, the device will not accept any ARP packets.

**NOTE**

If you want to change a previously configured the ARP rate limiting policy, you must remove the previously configured policy using the `no rate-limit-arp <num>` command before entering the new policy.

### Changing the ARP aging period

When the Layer 3 Switch places an entry in the ARP cache, the Layer 3 Switch also starts an aging timer for the entry. The aging timer ensures that the ARP cache does not retain learned entries that are no longer valid. An entry can become invalid when the device with the MAC address of the entry is no longer on the network.

The ARP age affects dynamic (learned) entries only, not static entries. The default ARP age is ten minutes. On Layer 3 Switches, you can change the ARP age to a value from 0 – 240 minutes. You cannot change the ARP age on Layer 2 Switches. If you set the ARP age to zero, aging is disabled and entries do not age out.

On TurboIron devices, ARP aging period is performed on route entry.

To globally change the ARP aging parameter to 20 minutes, enter the following command.

```
FastIron(config)#ip arp-age 20
```

**Syntax:** `ip arp-age <num>`

The `<num>` parameter specifies the number of minutes and can be from 0 – 240. The default is 10. If you specify 0, aging is disabled.

To override the globally configured IP ARP age on an individual interface, enter a command such as the following at the interface configuration level.

```
FastIron(config-if-e1000-1/1)#ip arp-age 30
```

**Syntax:** `[no] ip arp-age <num>`

The `<num>` parameter specifies the number of minutes and can be from 0 – 240. The default is the globally configured value, which is 10 minutes by default. If you specify 0, aging is disabled.
Enabling proxy ARP

Proxy ARP allows a Layer 3 Switch to answer ARP requests from devices on one network on behalf of devices in another network. Since ARP requests are MAC-layer broadcasts, they reach only the devices that are directly connected to the sender of the ARP request. Thus, ARP requests do not cross routers.

For example, if Proxy ARP is enabled on a Layer 3 Switch connected to two subnets, 10.10.10.0/24 and 20.20.20.0/24, the Layer 3 Switch can respond to an ARP request from 10.10.10.69 for the MAC address of the device with IP address 20.20.20.69. In standard ARP, a request from a device in the 10.10.10.0/24 subnet cannot reach a device in the 20.20.20.0 subnet if the subnets are on different network cables, and thus is not answered.

NOTE
An ARP request from one subnet can reach another subnet when both subnets are on the same physical segment (Ethernet cable), since MAC-layer broadcasts reach all the devices on the segment.

Proxy ARP is disabled by default on Brocade Layer 3 Switches. This feature is not supported on Brocade Layer 2 Switches.

In releases prior to FSX 04.0.00, you enable proxy ARP at the Global CONFIG level of the CLI. Beginning in software release FSX 04.0.00, you can enable proxy ARP at the Interface level, as well as at the Global CONFIG level, of the CLI.

NOTE
Configuring proxy ARP at the Interface level overrides the global configuration.

Enabling proxy ARP globally
To enable IP proxy ARP on a global basis, enter the following command.

```
FastIron(config)#ip proxy-arp
```

To again disable IP proxy ARP on a global basis, enter the following command.

```
FastIron(config)#no ip proxy-arp
```

Syntax:  [no] ip proxy-arp

Platform Support:
- Layer 3 devices only – BL3 and L3

Enabling IP ARP on an Interface
Platform Support:
- FastIron X Series devices running software release 04.0.00 and later

NOTE
Configuring proxy ARP at the Interface level overrides the global configuration.

To enable IP proxy ARP on an interface, enter the following command.

```
FastIron(config)#int e 5
FastIron(config-if-e1000-5)#ip proxy-arp enable
```

To again disable IP proxy ARP on an interface, enter the following command.
Configuring IP parameters – Layer 3 Switches

FastIron(config)#int e 5
FastIron(config-if-e1000-5)#ip proxy-arp disable

Syntax: [no] ip proxy-arp enable | disable

Platform Support:
- FastIron X Series devices running software release 04.0.00 and later – BL3 and L3

Enabling local proxy ARP

**NOTE**
This feature is not supported for FGS, FLS, FGS-STK, FLS-STK, and FWS devices.

Brocade devices support Proxy Address Resolution Protocol (*Proxy ARP*), a feature that enables router ports to respond to ARP requests for subnets it can reach. However, router ports will not respond to ARP requests for IP addresses in the same subnet as the incoming ports. Software release 02.3.03 resolves this issue with the introduction of Local Proxy ARP per IP interface. **Local Proxy ARP** enables router ports to reply to ARP requests for IP addresses within the same subnet and to forward all traffic between hosts in the subnet.

When Local Proxy ARP is enabled on a router port, the port will respond to ARP requests for IP addresses within the same subnet, if it has ARP entries for the destination IP addresses in the ARP cache. If it does not have ARP entries for the IP addresses, the port will attempt to resolve them by broadcasting its own ARP requests.

Local Proxy ARP is disabled by default. To use Local Proxy ARP, Proxy ARP (CLI command `ip proxy-arp`) must be enabled globally on the Brocade device. You can enter the CLI command to enable Local Proxy ARP even though Proxy ARP is not enabled, however, the configuration will not take effect until you enable Proxy ARP.

Use the `show run` command to view the ports on which Local Proxy ARP is enabled.

To enable Local Proxy ARP, enter commands such as the following.

FastIron(config)#int e 4
FastIron(config-if-e1000-4)#ip local-proxy-arp

**Syntax:** [no] ip local-proxy-arp

Use the `no` form of the command to disable Local Proxy ARP.

Creating static ARP entries

Brocade Layer 3 Switches have a static ARP table, in addition to the regular ARP cache. The static ARP table contains entries that you configure.

Static entries are useful in cases where you want to pre-configure an entry for a device that is not connected to the Layer 3 Switch, or you want to prevent a particular entry from aging out. The software removes a dynamic entry from the ARP cache if the ARP aging interval expires before the entry is refreshed. Static entries do not age out, regardless of whether the Brocade device receives an ARP request from the device that has the entry address.

**NOTE**
You cannot create static ARP entries on a Layer 2 Switch.
The maximum number of static ARP entries you can configure depends on the software version running on the device. Refer to “Changing the maximum number of entries the static ARP table can hold” on page 1010.

To display the ARP cache and static ARP table, refer to the following:

- To display the ARP table, refer to “Displaying the ARP cache” on page 1091.
- To display the static ARP table, refer to “Displaying the static ARP table” on page 1092.

To create a static ARP entry, enter a command such as the following.

```
FastIron(config)#arp 1 192.53.4.2 1245.7654.2348 e 1/2
```

**Syntax:** `arp <num> <ip-addr> <mac-addr> ethernet [<slotnum>/]<portnum>`

The `<num>` parameter specifies the entry number. You can specify a number from 1 up to the maximum number of static entries allowed on the device.

The `<ip-addr>` command specifies the IP address of the device that has the MAC address of the entry.

The `<mac-addr>` parameter specifies the MAC address of the entry.

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` command specifies the port number attached to the device that has the MAC address of the entry.

### Changing the maximum number of entries the static ARP table can hold

Table 170 on page 1011 lists the default maximum and configurable maximum number of entries in the static ARP table that are supported on a Brocade Layer 3 Switch. If you need to change the maximum number of entries supported on a Layer 3 Switch, use the method described in this section.

**NOTE**
The basic procedure for changing the static ARP table size is the same as the procedure for changing other configurable cache or table sizes. Refer to the section “Displaying and modifying system parameter default settings” on page 380.

To increase the maximum number of static ARP table entries you can configure on a Brocade Layer 3 Switch, enter commands such as the following at the global CONFIG level of the CLI.

```
FastIron(config)#system-max ip-static-arp 1000
FastIron(config)#write memory
FastIron(config)#end
FastIron#reload
```

**NOTE**
You must save the configuration to the startup-config file and reload the software after changing the static ARP table size to place the change into effect.

**Syntax:** `system-max ip-static-arp <num>`
The `<num>` parameter indicates the maximum number of static ARP entries and can be within one of the ranges shown in Table 170, depending on the software version running on the device.

**TABLE 170  Static ARP entry support**

**Configuring forwarding parameters**

The following configurable parameters control the forwarding behavior of Brocade Layer 3 Switches:

- Time-To-Live (TTL) threshold
- Forwarding of directed broadcasts
- Forwarding of source-routed packets
- Ones-based and zero-based broadcasts

All these parameters are global and thus affect all IP interfaces configured on the Layer 3 Switch.

To configure these parameters, use the procedures in the following sections.

**Changing the TTL threshold**

The TTL threshold prevents routing loops by specifying the maximum number of router hops an IP packet originated by the Layer 3 Switch can travel through. Each device capable of forwarding IP that receives the packet decrements (decreases) the packet TTL by one. If a device receives a packet with a TTL of 1 and reduces the TTL to zero, the device drops the packet.

The default TTL is 64. You can change the TTL to a value from 1–255.

To modify the TTL threshold to 25, enter the following commands.

```
FastIron(config)#ip ttl 25
```

**Syntax:** `ip ttl <1-255>`

**Enabling forwarding of directed broadcasts**

A directed broadcast is an IP broadcast to all devices within a single directly-attached network or subnet. A net-directed broadcast goes to all devices on a given network. A subnet-directed broadcast goes to all devices within a given subnet.

**NOTE**

A less common type, the all-subnets broadcast, goes to all directly-attached subnets. Forwarding for this broadcast type also is supported, but most networks use IP multicasting instead of all-subnet broadcasting.

Forwarding for all types of IP directed broadcasts is disabled by default. You can enable forwarding for all types if needed. You cannot enable forwarding for specific broadcast types.
To enable forwarding of IP directed broadcasts, enter the following command.

FastIron(config)#ip directed-broadcast

Syntax: [no] ip directed-broadcast

**NOTE**
This command is not supported on the Turbolron X Series devices.

Brocade software makes the forwarding decision based on the router's knowledge of the destination network prefix. Routers cannot determine that a message is unicast or directed broadcast apart from the destination network prefix. The decision to forward or not forward the message is by definition only possible in the last hop router.

To disable the directed broadcasts, enter the following command in the CONFIG mode.

FastIron(config)#no ip directed-broadcast

To enable directed broadcasts on an individual interface instead of globally for all interfaces, enter commands such as the following.

FastIron(config)#interface ethernet 1/1
FastIron(config-if-1/1)#ip directed-broadcast

Syntax: [no] ip directed-broadcast

---

**Disabling forwarding of IP source-routed packets**

A source-routed packet specifies the exact router path for the packet. The packet specifies the path by listing the IP addresses of the router interfaces through which the packet must pass on its way to the destination. The Layer 3 Switch supports both types of IP source routing:

- Strict source routing – requires the packet to pass through only the listed routers. If the Layer 3 Switch receives a strict source-routed packet but cannot reach the next hop interface specified by the packet, the Layer 3 Switch discards the packet and sends an ICMP Source-Route-Failure message to the sender.

  **NOTE**
  The Layer 3 Switch allows you to disable sending of the Source-Route-Failure messages. Refer to “Disabling ICMP messages” on page 1013.

- Loose source routing – requires that the packet pass through all of the listed routers but also allows the packet to travel through other routers, which are not listed in the packet.

  The Layer 3 Switch forwards both types of source-routed packets by default. To disable the feature, use either of the following methods. You cannot enable or disable strict or loose source routing separately.

To disable forwarding of IP source-routed packets, enter the following command.

FastIron(config)#no ip source-route

Syntax: [no] ip source-route

To re-enable forwarding of source-routed packets, enter the following command.

FastIron(config)#ip source-route
Enabling support for zero-based IP subnet broadcasts

By default, the Layer 3 Switch treats IP packets with all ones in the host portion of the address as IP broadcast packets. For example, the Layer 3 Switch treats IP packets with 209.157.22.255/24 as the destination IP address as IP broadcast packets and forwards the packets to all IP hosts within the 209.157.22.x subnet (except the host that sent the broadcast packet to the Layer 3 Switch).

Most IP hosts are configured to receive IP subnet broadcast packets with all ones in the host portion of the address. However, some older IP hosts instead expect IP subnet broadcast packets that have all zeros instead of all ones in the host portion of the address. To accommodate this type of host, you can enable the Layer 3 Switch to treat IP packets with all zeros in the host portion of the destination IP address as broadcast packets.

NOTE
When you enable the Layer 3 Switch for zero-based subnet broadcasts, the Layer 3 Switch still treats IP packets with all ones the host portion as IP subnet broadcasts too. Thus, the Layer 3 Switch can be configured to support all ones only (the default) or all ones and all zeroes.

NOTE
This feature applies only to IP subnet broadcasts, not to local network broadcasts. The local network broadcast address is still expected to be all ones.

To enable the Layer 3 Switch for zero-based IP subnet broadcasts in addition to ones-based IP subnet broadcasts, enter the following command.

```
FastIron(config)#ip broadcast-zero
FastIron(config)#write memory
FastIron(config)#end
FastIron#reload
```

NOTE
You must save the configuration and reload the software to place this configuration change into effect.

Syntax: `[no] ip broadcast-zero`

NOTE
This command is not supported on the TurboIron X Series devices.

Disabling ICMP messages

Brocade devices are enabled to reply to ICMP echo messages and send ICMP Destination Unreachable messages by default.

You can selectively disable the following types of Internet Control Message Protocol (ICMP) messages:

- Echo messages (ping messages) – The Layer 3 Switch replies to IP pings from other IP devices.
- Destination Unreachable messages – If the Layer 3 Switch receives an IP packet that it cannot deliver to its destination, the Layer 3 Switch discards the packet and sends a message back to the device that sent the packet to the Layer 3 Switch. The message informs the device that the destination cannot be reached by the Layer 3 Switch.
Disabling replies to broadcast ping requests
By default, Brocade devices are enabled to respond to broadcast ICMP echo packets, which are ping requests.

To disable response to broadcast ICMP echo packets (ping requests), enter the following command.

```
FastIron(config)#no ip icmp echo broadcast-request
```

Syntax: `[no] ip icmp echo broadcast-request`

If you need to re-enable response to ping requests, enter the following command.

```
FastIron(config)#ip icmp echo broadcast-request
```

Disabling ICMP destination unreachable messages
By default, when a Brocade device receives an IP packet that the device cannot deliver, the device sends an ICMP Unreachable message back to the host that sent the packet. You can selectively disable a Brocade device response to the following types of ICMP Unreachable messages:

- Administration – The packet was dropped by the Brocade device due to a filter or ACL configured on the device.
- Fragmentation-needed – The packet has the Do not Fragment bit set in the IP Flag field, but the Brocade device cannot forward the packet without fragmenting it.
- Host – The destination network or subnet of the packet is directly connected to the Brocade device, but the host specified in the destination IP address of the packet is not on the network.
- Port – The destination host does not have the destination TCP or UDP port specified in the packet. In this case, the host sends the ICMP Port Unreachable message to the Brocade device, which in turn sends the message to the host that sent the packet.
- Protocol – The TCP or UDP protocol on the destination host is not running. This message is different from the Port Unreachable message, which indicates that the protocol is running on the host but the requested protocol port is unavailable.
- Source-route-failure – The device received a source-routed packet but cannot locate the next-hop IP address indicated in the packet Source-Route option.

You can disable the Brocade device from sending these types of ICMP messages on an individual basis. To do so, use the following CLI method.

**NOTE**
Disabling an ICMP Unreachable message type does not change the Brocade device ability to forward packets. Disabling ICMP Unreachable messages prevents the device from generating or forwarding the Unreachable messages.

To disable all ICMP Unreachable messages, enter the following command.

```
FastIron(config)#no ip icmp unreachable
```

Syntax: `[no] ip icmp unreachable [host | protocol | administration | fragmentation-needed | port | source-route-fail]`

- If you enter the command without specifying a message type (as in the example above), all types of ICMP Unreachable messages listed above are disabled. If you want to disable only specific types of ICMP Unreachable messages, you can specify the message type. To disable more than one type of ICMP message, enter the `no ip icmp unreachable` command for each messages type.
- The **administration** parameter disables ICMP Unreachable (caused by Administration action) messages.
- The **fragmentation-needed** parameter disables ICMP Fragmentation-Needed But Do not-Fragment Bit Set messages.
- The **host** parameter disables ICMP Host Unreachable messages.
- The **port** parameter disables ICMP Port Unreachable messages.
- The **protocol** parameter disables ICMP Protocol Unreachable messages.
- The **source-route-fail** parameter disables ICMP Unreachable (caused by Source-Route-Failure) messages.

To disable ICMP Host Unreachable messages but leave the other types of ICMP Unreachable messages enabled, enter the following commands instead of the command shown above.

```
FastIron(config)#no ip icmp unreachable host
```

If you have disabled all ICMP Unreachable message types but you want to re-enable certain types, for example ICMP Host Unreachable messages, you can do so by entering the following command.

```
FastIron(config)#ip icmp unreachable host
```

### Configuring static routes

The IP route table can receive routes from the following sources:

- **Directly-connected networks** – When you add an IP interface, the Layer 3 Switch automatically creates a route for the network the interface is in.
- **RIP** – If RIP is enabled, the Layer 3 Switch can learn about routes from the advertisements other RIP routers send to the Layer 3 Switch. If the route has a lower administrative distance than any other routes from different sources to the same destination, the Layer 3 Switch places the route in the IP route table.
- **OSPF** – Refer to RIP, but substitute “OSPF” for “RIP”.
- **BGP4** – Refer to RIP, but substitute “BGP4” for “RIP”.
- **Default network route** – A statically configured default route that the Layer 3 Switch uses if other default routes to the destination are not available. Refer to “Configuring a default network route” on page 1024.
- **Statically configured route** – You can add routes directly to the route table. When you add a route to the IP route table, you are creating a static IP route. This section describes how to add static routes to the IP route table.

**NOTE**

On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

### Static route types

You can configure the following types of static IP routes:

- **Standard** – the static route consists of the destination network address and network mask, and the IP address of the next-hop gateway. You can configure multiple standard static routes with the same metric for load sharing or with different metrics to provide a primary route and backup routes.
• Interface-based – the static route consists of the destination network address and network mask, and the Layer 3 Switch interface through which you want the Layer 3 Switch to send traffic for the route. Typically, this type of static route is for directly attached destination networks.

• Null – the static route consists of the destination network address and network mask, and the “null0” parameter. Typically, the null route is configured as a backup route for discarding traffic if the primary route is unavailable.

**Static IP route parameters**

When you configure a static IP route, you must specify the following parameters:

• The IP address and network mask for the route destination network.

• The route path, which can be one of the following:
  • The IP address of a next-hop gateway
  • An Ethernet port
  • A virtual interface (a routing interface used by VLANs for routing Layer 3 protocol traffic among one another)
  • A “null” interface. The Layer 3 Switch drops traffic forwarded to the null interface.

You also can specify the following optional parameters:

• The metric for the route – The value the Layer 3 Switch uses when comparing this route to other routes in the IP route table to the same destination. The metric applies only to routes that the Layer 3 Switch has already placed in the IP route table. The default metric for static IP routes is 1.

• The administrative distance for the route – The value that the Layer 3 Switch uses to compare this route with routes from other route sources to the same destination before placing a route in the IP route table. This parameter does not apply to routes that are already in the IP route table. The default administrative distance for static IP routes is 1.

The default metric and administrative distance values ensure that the Layer 3 Switch always prefers static IP routes over routes from other sources to the same destination.

**Multiple static routes to the same destination provide load sharing and redundancy**

You can add multiple static routes for the same destination network to provide one or more of the following benefits:

• IP load balancing – When you add multiple IP static routes for the same destination to different next-hop gateways, and the routes each have the same metric and administrative distance, the Layer 3 Switch can load balance traffic to the routes’ destination. For information about IP load balancing, refer to “Configuring IP load sharing” on page 1025.

• Path redundancy – When you add multiple static IP routes for the same destination, but give the routes different metrics or administrative distances, the Layer 3 Switch uses the route with the lowest administrative distance by default, but uses another route to the same destination if the first route becomes unavailable.

Refer to the following sections for examples and configuration information:

• “Configuring load balancing and redundancy using multiple static routes to the same destination” on page 1019
• “Configuring standard static IP routes and interface or null static routes to the same destination” on page 1020

**Static route states follow port states**

IP static routes remain in the IP route table only so long as the port or virtual interface used by the route is available. If the port or virtual routing interface becomes unavailable, the software removes the static route from the IP route table. If the port or virtual routing interface becomes available again later, the software adds the route back to the route table.

This feature allows the Layer 3 Switch to adjust to changes in network topology. The Layer 3 Switch does not continue trying to use routes on unavailable paths but instead uses routes only when their paths are available.

**Figure 132** shows an example of a network containing a static route. The static route is configured on Switch A, as shown in the CLI example following the figure.

**FIGURE 132  Example of a static route**

The following command configures a static route to 207.95.7.0, using 207.95.6.157 as the next-hop gateway.

```
FastIron(config)# ip route 207.95.7.0/24 207.95.6.157
```

When you configure a static IP route, you specify the destination address for the route and the next-hop gateway or Layer 3 Switch interface through which the Layer 3 Switch can reach the route. The Layer 3 Switch adds the route to the IP route table. In this case, Switch A knows that 207.95.6.157 is reachable through port 1/2, and also assumes that local interfaces within that subnet are on the same port. Switch A deduces that IP interface 207.95.7.188 is also on port 1/2.

The software automatically removes a static IP route from the IP route table if the port used by that route becomes unavailable. When the port becomes available again, the software automatically re-adds the route to the IP route table.

**Configuring a static IP route**

To configure an IP static route with a destination address of 192.0.0.0 255.0.0.0 and a next-hop router IP address of 195.1.1.1, enter the following commands.

```
FastIron(config)# ip route 192.0.0.0 255.0.0.0 195.1.1.1
```

To configure a static IP route with an Ethernet port instead of a next-hop address, enter a command such as the following.

```
FastIron(config)# ip route 192.128.2.69 255.255.255.0 ethernet 4/1
```

The command in the example above configures a static IP route for destination network 192.128.2.69/24. Since an Ethernet port is specified instead of a gateway IP address as the next hop, the Layer 3 Switch always forwards traffic for the 192.128.2.69/24 network to port 4/1. The command in the following example configures an IP static route that uses virtual interface 3 as its next hop.
FastIron(config)# ip route 192.128.2.71 255.255.255.0 ve 3

The command in the following example configures an IP static route that uses port 2/2 as its next hop.

FastIron(config)# ip route 192.128.2.73 255.255.255.0 ethernet 2/2

**Syntax:**

```
ip route <dest-ip-addr> <dest-mask>
  <next-hop-ip-addr> [ethernet [<slotnum>]/<portnum> | ve <num>
  [<metric>] [distance <num>]]
```

or

```
ip route <dest-ip-addr>/<mask-bits>
  <next-hop-ip-addr> [ethernet [<slotnum>]/<portnum> | ve <num>
  [<metric>] [distance <num>]]
```

The `<dest-ip-addr>` is the route destination. The `<dest-mask>` is the network mask for the route destination IP address. Alternatively, you can specify the network mask information by entering a forward slash followed by the number of bits in the network mask. For example, you can enter 192.0.0.0 255.255.255.0 as 192.0.0.0/24.

The `<next-hop-ip-addr>` is the IP address of the next-hop router (gateway) for the route.

If you do not want to specify a next-hop IP address, you can instead specify a port or interface number on the Layer 3 Switch. The `<num>` parameter is a virtual interface number. If you instead specify an Ethernet port, the `<portnum>` is the port number (including the slot number, if you are configuring a Chassis device). In this case, the Layer 3 Switch forwards packets destined for the static route destination network to the specified interface. Conceptually, this feature makes the destination network like a directly connected network, associated with a specific Layer 3 Switch interface.

**NOTE**
The port or virtual interface you use for the static route next hop must have at least one IP address configured on it. The address does not need to be in the same subnet as the destination network.

The `<metric>` parameter can be a number from 1 – 16. The default is 1.

**NOTE**
If you specify 16, RIP considers the metric to be infinite and thus also considers the route to be unreachable.

The `distance <num>` parameter specifies the administrative distance of the route. When comparing otherwise equal routes to a destination, the Layer 3 Switch prefers lower administrative distances over higher ones, so make sure you use a low value for your default route. The default is 1.

**NOTE**
The Layer 3 Switch will replace the static route if it receives a route with a lower administrative distance. Refer to "Changing administrative distances" on page 1327 for a list of the default administrative distances for all types of routes.

**NOTE**
You can also assign the default router as the destination by entering 0.0.0.0 0.0.0.0 xxx.xxx.xxx.xxx.
**Configuring a “Null” route**

You can configure the Layer 3 Switch to drop IP packets to a specific network or host address by configuring a “null” (sometimes called “null0”) static route for the address. When the Layer 3 Switch receives a packet destined for the address, the Layer 3 Switch drops the packet instead of forwarding it.

To configure a null static route, use the following CLI method.

To configure a null static route to drop packets destined for network 209.157.22.x, enter the following commands.

```
FastIron(config)# ip route 209.157.22.0 255.255.255.0 null0
FastIron(config)# write memory
```

**Syntax:** `ip route <ip-addr> <ip-mask> null0 [metric] [distance <num>]`

or

**Syntax:** `ip route <ip-addr>/<mask-bits> null0 [metric] [distance <num>]`

To display the maximum value for your device, enter the `show default values` command. The maximum number of static IP routes the system can hold is listed in the `ip-static-route` row in the System Parameters section of the display. To change the maximum value, use the `system-max` `ip-static-route <num>` command at the global CONFIG level.

The `<ip-addr>` parameter specifies the network or host address. The Layer 3 Switch will drop packets that contain this address in the destination field instead of forwarding them.

The `<ip-mask>` parameter specifies the network mask. Ones are significant bits and zeros allow any value. For example, the mask 255.255.255.0 matches on all hosts within the Class C subnet address specified by `<ip-addr>`. Alternatively, you can specify the number of bits in the network mask. For example, you can enter `209.157.22.0/24` instead of `209.157.22.0 255.255.255.0`.

The `null0` parameter indicates that this is a null route. You must specify this parameter to make this a null route.

The `<metric>` parameter adds a cost to the route. You can specify from `1 – 16`. The default is `1`.

The distance `<num>` parameter configures the administrative distance for the route. You can specify a value from `1 – 255`. The default is `1`. The value `255` makes the route unusable.

**NOTE**
The last two parameters are optional and do not affect the null route, unless you configure the administrative distance to be `255`. In this case, the route is not used and the traffic might be forwarded instead of dropped.

---

**Configuring load balancing and redundancy using multiple static routes to the same destination**

You can configure multiple static IP routes to the same destination, for the following benefits:

- **IP load sharing** – If you configure more than one static route to the same destination, and the routes have different next-hop gateways but have the same metrics, the Layer 3 Switch load balances among the routes using basic round-robin. For example, if you configure two static routes with the same metrics but to different gateways, the Layer 3 Switch alternates between the two routes. For information about IP load balancing, refer to “Configuring IP load sharing” on page 1025.
• **Backup Routes** – If you configure multiple static IP routes to the same destination, but give the routes different next-hop gateways and different metrics, the Layer 3 Switch will always use the route with the lowest metric. If this route becomes unavailable, the Layer 3 Switch will fail over to the static route with the next-lowest metric, and so on.

**NOTE**
You also can bias the Layer 3 Switch to select one of the routes by configuring them with different administrative distances. However, make sure you do not give a static route a higher administrative distance than other types of routes, unless you want those other types to be preferred over the static route. For a list of the default administrative distances, refer to “Changing administrative distances” on page 1327.

The steps for configuring the static routes are the same as described in the previous section. The following sections provide examples.

To configure multiple static IP routes, enter commands such as the following.

```plaintext
FastIron(config)# ip route 192.128.2.69 255.255.255.0 209.157.22.1
FastIron(config)# ip route 192.128.2.69 255.255.255.0 192.111.10.1
```

The commands in the example above configure two static IP routes. The routes go to different next-hop gateways but have the same metrics. These commands use the default metric value (1), so the metric is not specified. These static routes are used for load sharing among the next-hop gateways.

The following commands configure static IP routes to the same destination, but with different metrics. The route with the lowest metric is used by default. The other routes are backups in case the first route becomes unavailable. The Layer 3 Switch uses the route with the lowest metric if the route is available.

```plaintext
FastIron(config)# ip route 192.128.2.69 255.255.255.0 209.157.22.1
FastIron(config)# ip route 192.128.2.69 255.255.255.0 192.111.10.1 2
FastIron(config)# ip route 192.128.2.69 255.255.255.0 201.1.1.1 3
```

In this example, each static route has a different metric. The metric is not specified for the first route, so the default (1) is used. A metric is specified for the second and third static IP routes. The second route has a metric of two and the third route has a metric of 3. Thus, the second route is used only if the first route (which has a metric of 1) becomes unavailable. Likewise, the third route is used only if the first and second routes (which have lower metrics) are both unavailable.

For complete syntax information, refer to “Configuring a static IP route” on page 1017.

**Configuring standard static IP routes and interface or null static routes to the same destination**

You can configure a null0 or interface-based static route to a destination and also configure a normal static route to the same destination, so long as the route metrics are different.

When the Layer 3 Switch has multiple routes to the same destination, the Layer 3 Switch always prefers the route with the lowest metric. Generally, when you configure a static route to a destination network, you assign the route a low metric so that the Layer 3 Switch prefers the static route over other routes to the destination.

This feature is especially useful for the following configurations. These are not the only allowed configurations but they are typical uses of this enhancement:
• When you want to ensure that if a given destination network is unavailable, the Layer 3 Switch drops (forwards to the null interface) traffic for that network instead of using alternate paths to route the traffic. In this case, assign the normal static route to the destination network a lower metric than the null route.

• When you want to use a specific interface by default to route traffic to a given destination network, but want to allow the Layer 3 Switch to use other interfaces to reach the destination network if the path that uses the default interface becomes unavailable. In this case, give the interface route a lower metric than the normal static route.

**NOTE**
You cannot add a null or interface-based static route to a network if there is already a static route of any type with the same metric you specify for the null or interface-based route.
Figure 133 shows an example of two static routes configured for the same destination network. In this example, one of the routes is a standard static route and has a metric of 1. The other static route is a null route and has a higher metric than the standard static route. The Layer 3 Switch always prefers the static route with the lower metric. In this example, the Layer 3 Switch always uses the standard static route for traffic to destination network 192.168.7.0/24, unless that route becomes unavailable, in which case the Layer 3 Switch sends traffic to the null route instead.

**FIGURE 133  Standard and null static routes to the same destination network**

Two static routes to 192.168.7.0/24:

- Standard static route through gateway 192.168.6.157, with metric 1
- Null route, with metric 2

---

Figure 134 shows another example of two static routes. In this example, a standard static route and an interface-based static route are configured for destination network 192.168.6.0/24. The interface-based static route has a lower metric than the standard static route. As a result, the Layer 3 Switch always prefers the interface-based route when the route is available. However, if the interface-based route becomes unavailable, the Layer 3 Switch still forwards the traffic toward the destination using an alternate route through gateway 192.168.8.11/24.

**FIGURE 134  Standard and interface routes to the same destination network**

---
To configure a standard static IP route and a null route to the same network as shown in Figure 133 on page 1022, enter commands such as the following.

```
FastIron(config)# ip route 192.168.7.0/24 192.168.6.157/24 1
FastIron(config)# ip route 192.168.7.0/24 null0 3
```

The first command configures a standard static route, which includes specification of the next-hop gateway. The command also gives the standard static route a metric of 1, which causes the Layer 3 Switch to always prefer this route when the route is available.

The second command configures another static route for the same destination network, but the second route is a null route. The metric for the null route is 3, which is higher than the metric for the standard static route. If the standard static route is unavailable, the software uses the null route.

For complete syntax information, refer to “Configuring a static IP route” on page 1017.

To configure a standard static route and an interface-based route to the same destination, enter commands such as the following.

```
FastIron(config)# ip route 192.168.6.0/24 ethernet 1/1 1
FastIron(config)# ip route 192.168.6.0/24 192.168.8.11/24 3
```

The first command configured an interface-based static route through Ethernet port 1/1. The command assigns a metric of 1 to this route, causing the Layer 3 Switch to always prefer this route when it is available. If the route becomes unavailable, the Layer 3 Switch uses an alternate route through the next-hop gateway 192.168.8.11/24.
Configuring a default network route

The Layer 3 Switch enables you to specify a candidate default route without the need to specify the next hop gateway. If the IP route table does not contain an explicit default route (for example, 0.0.0.0/0) or propagate an explicit default route through routing protocols, the software can use the default network route as a default route instead.

When the software uses the default network route, it also uses the default network route’s next hop gateway as the gateway of last resort.

This feature is especially useful in environments where network topology changes can make the next hop gateway unreachable. This feature allows the Layer 3 Switch to perform default routing even if the default network route's default gateway changes.

The feature thus differs from standard default routes. When you configure a standard default route, you also specify the next hop gateway. If a topology change makes the gateway unreachable, the default route becomes unusable.

For example, if you configure 10.10.10.0/24 as a candidate default network route, if the IP route table does not contain an explicit default route (0.0.0.0/0), the software uses the default network route and automatically uses that route's next hop gateway as the default gateway. If a topology change occurs and as a result the default network route’s next hop gateway changes, the software can still use the default network route. To configure a default network route, use the following CLI method.

If you configure more than one default network route, the Layer 3 Switch uses the following algorithm to select one of the routes.

1. Use the route with the lowest administrative distance.
2. If the administrative distances are equal:
   • Are the routes from different routing protocols (RIP, OSPF, or BGP4)? If so, use the route with the lowest IP address.
   • If the routes are from the same routing protocol, use the route with the best metric. The meaning of “best” metric depends on the routing protocol:
     • RIP – The metric is the number of hops (additional routers) to the destination. The best route is the route with the fewest hops.
     • OSPF – The metric is the path cost associated with the route. The path cost does not indicate the number of hops but is instead a numeric value associated with each route. The best route is the route with the lowest path cost.
     • BGP4 – The metric is the Multi-exit Discriminator (MED) associated with the route. The MED applies to routes that have multiple paths through the same AS. The best route is the route with the lowest MED.

Configuring a default network route

You can configure up to four default network routes.

To configure a default network route, enter commands such as the following.

```
FastIron(config)# ip default-network 209.157.22.0
FastIron(config)# write memory
```

Syntax: `ip default-network <ip-addr>`

The `<ip-addr>` parameter specifies the network address.
To verify that the route is in the route table, enter the following command at any level of the CLI.

```
FastIron# show ip route
Total number of IP routes: 2
```

<table>
<thead>
<tr>
<th>Destination</th>

</table>

This example shows two routes. Both of the routes are directly attached, as indicated in the Type column. However, one of the routes is shown as type “*D”, with an asterisk (*). The asterisk indicates that this route is a candidate default network route.

### Configuring IP load sharing

#### Platform Support:

- All FESX, FSX, FSX 800, FSX 1600, and FWSX devices
- FGS, FLS, and FWS devices running software release 04.3.01 and later
- TurboIron X Series devices running software release 04.2.00 and later

The IP route table can contain more than one path to a given destination. When this occurs, the Layer 3 Switch selects the path with the lowest cost as the path for forwarding traffic to the destination. If the IP route table contains more than one path to a destination and the paths each have the lowest cost, then the Layer 3 Switch uses **IP load sharing** to select a path to the destination.¹

On FastIron X Series devices, IP load sharing uses a hashing algorithm based on the source IP address, destination IP address, and protocol field in the IP header.

In software releases 02.1.00 and later, you can enable a Layer 3 Switch to load balance across up to six equal-cost paths. In software releases prior to 02.1.00, you can enable a Layer 3 Switch to load balance across up to eight equal-cost paths. The default maximum number of equal-cost load sharing paths is four.

---

**NOTE**

IP load sharing is based on next-hop routing, and not on source routing.

---

**NOTE**

The term “path” refers to the next-hop router to a destination, not to the entire route to a destination. Thus, when the software compares multiple equal-cost paths, the software is comparing paths that use different next-hop routers, with equal costs, to the same destination.

In many contexts, the terms “route” and “path” mean the same thing. Most of the user documentation uses the term “route” throughout. The term “path” is used in this section to refer to an individual next-hop router to a destination, while the term “route” refers collectively to the multiple paths to the destination. Load sharing applies when the IP route table contains multiple, equal-cost paths to a destination.

---

**NOTE**

Brocade devices also perform load sharing among the ports in aggregate links. Refer to “Trunk group load sharing” on page 553.

---

1. IP load sharing is also called “Equal-Cost Multi-Path (ECMP)” load sharing or just “ECMP”
How multiple equal-cost paths enter the IP route table

IP load sharing applies to equal-cost paths in the IP route table. Routes that are eligible for load sharing can enter the table from any of the following sources:

- IP static routes
- Routes learned through RIP
- Routes learned through OSPF
- Routes learned through BGP4

Administrative distance

The administrative distance is a unique value associated with each type (source) of IP route. Each path has an administrative distance. The administrative distance is not used when performing IP load sharing, but the administrative distance is used when evaluating multiple equal-cost paths to the same destination from different sources, such as RIP, OSPF and so on.

The value of the administrative distance is determined by the source of the route. The Layer 3 Switch is configured with a unique administrative distance value for each IP route source.

When the software receives multiple paths to the same destination and the paths are from different sources, the software compares the administrative distances of the paths and selects the path with the lowest distance. The software then places the path with the lowest administrative distance in the IP route table. For example, if the Layer 3 Switch has a path learned from OSPF and a path learned from RIP for a given destination, only the path with the lower administrative distance enters the IP route table.

Here are the default administrative distances on the Brocade Layer 3 Switch:

- Directly connected – 0 (this value is not configurable)
- Static IP route – 1 (applies to all static routes, including default routes and default network routes)
- Exterior Border Gateway Protocol (EBGP) – 20
- OSPF – 110
- RIP – 120
- Interior Gateway Protocol (IBGP) – 200
- Local BGP – 200
- Unknown – 255 (the router will not use this route)

Lower administrative distances are preferred over higher distances. For example, if the router receives routes for the same network from OSPF and from RIP, the router will prefer the OSPF route by default.

NOTE

You can change the administrative distances individually. Refer to the configuration chapter for the route source for information.

Since the software selects only the path with the lowest administrative distance, and the administrative distance is determined by the path source, IP load sharing does not apply to paths from different route sources. IP load sharing applies only when the IP route table contains multiple paths to the same destination, from the same IP route source.

IP load sharing does not apply to paths that come from different sources.
Path cost

The cost parameter provides a common basis of comparison for selecting from among multiple paths to a given destination. Each path in the IP route table has a cost. When the IP route table contains multiple paths to a destination, the Layer 3 Switch chooses the path with the lowest cost. When the IP route table contains more than one path with the lowest cost to a destination, the Layer 3 Switch uses IP load sharing to select one of the lowest-cost paths.

The source of a path cost value depends on the source of the path:

- IP static route – The value you assign to the metric parameter when you configure the route. The default metric is 1. Refer to “Configuring load balancing and redundancy using multiple static routes to the same destination” on page 1019.
- RIP – The number of next-hop routers to the destination.
- OSPF – The Path Cost associated with the path. The paths can come from any combination of inter-area, intra-area, and external Link State Advertisements (LSAs).
- BGP4 – The path Multi-Exit Discriminator (MED) value.

**NOTE**

If the path is redistributed between two or more of the above sources before entering the IP route table, the cost can increase during the redistribution due to settings in redistribution filters.

Static route, OSPF, and BGP4 load sharing

IP load sharing and load sharing for static routes, OSPF routes, and BGP4 routes are individually configured. Multiple equal-cost paths for a destination can enter the IP route table only if the source of the paths is configured to support multiple equal-cost paths. For example, if BGP4 allows only one path with a given cost for a given destination, the BGP4 route table cannot contain equal-cost paths to the destination. Consequently, the IP route table will not receive multiple equal-cost paths from BGP4.

**Table 171** lists the default and configurable maximum numbers of paths for each IP route source that can provide equal-cost paths to the IP route table. The table also lists where to find configuration information for the route source load sharing parameters.
The load sharing state for all the route sources is based on the state of IP load sharing. Since IP load sharing is enabled by default on all Brocade Layer 3 Switches, load sharing for static IP routes, RIP routes, OSPF routes, and BGP4 routes also is enabled by default.

### How IP load sharing works

When the Layer 3 Switch receives traffic for a destination and the IP route table contains multiple, equal-cost paths to that destination, the device checks the IP forwarding cache for a forwarding entry for the destination. The IP forwarding cache provides a fast path for forwarding IP traffic, including load-balanced traffic. The cache contains entries that associate a destination host or network with a path (next-hop router).

- If the IP forwarding sharing cache contains a forwarding entry for the destination, the device uses the entry to forward the traffic.
- If the IP load forwarding cache does not contain a forwarding entry for the destination, the software selects a path from among the available equal-cost paths to the destination, then creates a forwarding entry in the cache based on the calculation. Subsequent traffic for the same destination uses the forwarding entry.

### Response to path state changes

If one of the load-balanced paths to a cached destination becomes unavailable, or the IP route table receives a new equal-cost path to a cached destination, the software removes the unavailable path from the IP route table. Then the software selects a new path.

### Disabling or re-enabling load sharing

To disable IP load sharing, enter the following commands.

```
FastIron(config)# no ip load-sharing
```

**Syntax:** [no] ip load-sharing

### Changing the maximum number of load sharing paths

By default, IP load sharing allows IP traffic to be balanced across up to four equal paths. You can change the maximum number of paths the Layer 3 Switch supports to a value from 2 – 8.

**NOTE**

FSX devices support up to 6 paths. FCX devices support up to 8 paths.

---

**TABLE 171** Default load sharing parameters for route sources

<table>
<thead>
<tr>
<th>Route source</th>
<th>Default maximum number of paths</th>
<th>Maximum number of paths</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>FSX</td>
<td>FCX</td>
</tr>
<tr>
<td>Static IP route</td>
<td>4</td>
<td>6</td>
<td>8</td>
</tr>
<tr>
<td>RIP</td>
<td>4</td>
<td>6</td>
<td>8</td>
</tr>
<tr>
<td>OSPF</td>
<td>4</td>
<td>6</td>
<td>8</td>
</tr>
<tr>
<td>BGP4</td>
<td>1</td>
<td>4</td>
<td>4</td>
</tr>
</tbody>
</table>

1. This value depends on the value for IP load sharing, and is not separately configurable.
For optimal results, set the maximum number of paths to a value at least as high as the maximum number of equal-cost paths your network typically contains. For example, if the Layer 3 Switch you are configuring for IP load sharing has six next-hop routers, set the maximum paths value to six.

**NOTE**
If the setting for the maximum number of paths is lower than the actual number of equal-cost paths, the software does not use all the paths for load sharing.

To change the number of IP load sharing paths, enter a command such as the following.

```
FastIron(config)# ip load-sharing 6
```

Syntax: `[no] ip load-sharing [<num>]`

The `<num>` parameter specifies the number of paths and can be from 2 – 8.

**NOTE**
FSX devices support up to 6 paths. FCX devices support up to 8 paths.

### Configuring IRDP

The ICMP Router Discovery Protocol (IRDP) is used by Brocade Layer 3 Switches to advertise the IP addresses of its router interfaces to directly attached hosts. IRDP is disabled by default. You can enable the feature on a global basis or on an individual port basis:

- If you enable the feature globally, all ports use the default values for the IRDP parameters.
- If you leave the feature disabled globally but enable it on individual ports, you also can configure the IRDP parameters on an individual port basis.

**NOTE**
You can configure IRDP parameters only on an individual port basis. To do so, IRDP must be disabled globally and enabled only on individual ports. You cannot configure IRDP parameters if the feature is globally enabled.

When IRDP is enabled, the Layer 3 Switch periodically sends Router Advertisement messages out the IP interfaces on which the feature is enabled. The messages advertise the Layer 3 Switch IP addresses to directly attached hosts who listen for the messages. In addition, hosts can be configured to query the Layer 3 Switch for the information by sending Router Solicitation messages. Some types of hosts use the Router Solicitation messages to discover their default gateway. When IRDP is enabled on the Brocade Layer 3 Switch, the Layer 3 Switch responds to the Router Solicitation messages. Some clients interpret this response to mean that the Layer 3 Switch is the default gateway. If another router is actually the default gateway for these clients, leave IRDP disabled on the Brocade Layer 3 Switch.

IRDP uses the following parameters. If you enable IRDP on individual ports instead of enabling the feature globally, you can configure these parameters on an individual port basis:

- **Packet type** – The Layer 3 Switch can send Router Advertisement messages as IP broadcasts or as IP multicasts addressed to IP multicast group 224.0.0.1. The packet type is IP broadcast.
- **Maximum message interval and minimum message interval** – When IRDP is enabled, the Layer 3 Switch sends the Router Advertisement messages every 450 – 600 seconds by default. The time within this interval that the Layer 3 Switch selects is random for each message and is not affected by traffic loads or other network factors. The random interval
minimizes the probability that a host will receive Router Advertisement messages from other routers at the same time. The interval on each IRDP-enabled Layer 3 Switch interface is independent of the interval on other IRDP-enabled interfaces. The default maximum message interval is 600 seconds. The default minimum message interval is 450 seconds.

- **Hold time** – Each Router Advertisement message contains a hold time value. This value specifies the maximum amount of time the host should consider an advertisement to be valid until a newer advertisement arrives. When a new advertisement arrives, the hold time is reset. The hold time is always longer than the maximum advertisement interval. Therefore, if the hold time for an advertisement expires, the host can reasonably conclude that the router interface that sent the advertisement is no longer available. The default hold time is three times the maximum message interval.

- **Preference** – If a host receives multiple Router Advertisement messages from different routers, the host selects the router that sent the message with the highest preference as the default gateway. The preference can be a number from 0-4294967296 to 0-4294967295. The default is 0.

**Enabling IRDP globally**

To globally enable IRDP, enter the following command.

```plaintext
FastIron(config)# ip irdp
```

This command enables IRDP on the IP interfaces on all ports. Each port uses the default values for the IRDP parameters. The parameters are not configurable when IRDP is globally enabled.

**Enabling IRDP on an individual port**

To enable IRDP on an individual interface and change IRDP parameters, enter commands such as the following.

```plaintext
FastIron(config)# interface ethernet 1/3
FastIron(config-if-1/3)# ip irdp maxadvertinterval 400
```

This example shows how to enable IRDP on a specific port and change the maximum advertisement interval for Router Advertisement messages to 400 seconds.

**NOTE**

To enable IRDP on individual ports, you must leave the feature globally disabled.

**Syntax:**

```plaintext
[no] ip irdp [broadcast | multicast] [holdtime <seconds>] [maxadvertinterval <seconds>]
[minadvertinterval <seconds>] [preference <number>]
```

The `broadcast | multicast` parameter specifies the packet type the Layer 3 Switch uses to send Router Advertisement:

- **broadcast** – The Layer 3 Switch sends Router Advertisement as IP broadcasts. This is the default.
- **multicast** – The Layer 3 Switch sends Router Advertisement as multicast packets addressed to IP multicast group 224.0.0.1.

The `holdtime <seconds>` parameter specifies how long a host that receives a Router Advertisement from the Layer 3 Switch should consider the advertisement to be valid. When a host receives a new Router Advertisement message from the Layer 3 Switch, the host resets the hold time for the Layer 3 Switch to the hold time specified in the new advertisement. If the hold time of
an advertisement expires, the host discards the advertisement, concluding that the router
interface that sent the advertisement is no longer available. The value must be greater than the
value of the `maxadvertinterval` parameter and cannot be greater than 9000. The default is three
times the value of the `maxadvertinterval` parameter.

The `maxadvertinterval` parameter specifies the maximum amount of time the Layer 3 Switch waits
between sending Router Advertisements. You can specify a value from 1 to the current value of the
`holdtime` parameter. The default is 600 seconds.

The `minadvertinterval` parameter specifies the minimum amount of time the Layer 3 Switch can
wait between sending Router Advertisements. The default is three-fourths (0.75) the value of the
`maxadvertinterval` parameter. If you change the `maxadvertinterval` parameter, the software
automatically adjusts the `minadvertinterval` parameter to be three-fourths the new value of the
`maxadvertinterval` parameter. If you want to override the automatically configured value, you can
specify an interval from 1 to the current value of the `maxadvertinterval` parameter.

The `preference <number>` parameter specifies the IRDP preference level of this Layer 3 Switch. If
a host receives Router Advertisements from multiple routers, the host selects the router interface
that sent the message with the highest interval as the host default gateway. The valid range is
0-4294967296 to 0-4294967295. The default is 0.

### Configuring RARP

The Reverse Address Resolution Protocol (RARP) provides a simple mechanism for
directly-attached IP hosts to boot over the network. RARP allows an IP host that does not have a
means of storing its IP address across power cycles or software reloads to query a directly-attached
router for an IP address.

RARP is enabled by default. However, you must create a RARP entry for each host that will use the
Layer 3 Switch for booting. A RARP entry consists of the following information:

- The entry number – the entry sequence number in the RARP table.
- The MAC address of the boot client.
- The IP address you want the Layer 3 Switch to give to the client.

When a client sends a RARP broadcast requesting an IP address, the Layer 3 Switch responds to
the request by looking in the RARP table for an entry that contains the client MAC address:

- If the RARP table contains an entry for the client, the Layer 3 Switch sends a unicast response
to the client that contains the IP address associated with the client MAC address in the RARP
table.
- If the RARP table does not contain an entry for the client, the Layer 3 Switch silently discards
the RARP request and does not reply to the client.

### How RARP Differs from BootP/DHCP

RARP and BootP/DHCP are different methods for providing IP addresses to IP hosts when they
boot. These methods differ in the following ways:

- Location of configured host addresses:
  - RARP requires static configuration of the host IP addresses on the Layer 3 Switch. The
    Layer 3 Switch replies directly to a host request by sending an IP address you have
    configured in the RARP table.
• The Layer 3 Switch forwards BootP and DHCP requests to a third-party BootP/DHCP server that contains the IP addresses and other host configuration information.

• Connection of host to boot source (Layer 3 Switch or BootP/DHCP server):
  • RARP requires the IP host to be directly attached to the Layer 3 Switch.
  • An IP host and the BootP/DHCP server can be on different networks and on different routers, so long as the routers are configured to forward (“help”) the host boot request to the boot server.
  • You can centrally configure other host parameters on the BootP/DHCP server, in addition to the IP address, and supply those parameters to the host along with its IP address.

To configure the Layer 3 Switch to forward BootP/DHCP requests when boot clients and the boot servers are on different subnets on different Layer 3 Switch interfaces, refer to “Configuring BootP/DHCP relay parameters” on page 1035.

**Disabling RARP**

RARP is enabled by default. To disable RARP, enter the following command at the global CONFIG level.

```
FastIron(config)# no ip rarp
```

**Syntax:** `[no] ip rarp`

To re-enable RARP, enter the following command.

```
FastIron(config)# ip rarp
```

**Creating static RARP entries**

You must configure the RARP entries for the RARP table. The Layer 3 Switch can send an IP address in reply to a client RARP request only if create a RARP entry for that client.

To assign a static IP RARP entry for static routes on a Brocade router, enter a command such as the following.

```
FastIron(config)# rarp 1 1245.7654.2348 192.53.4.2
```

This command creates a RARP entry for a client with MAC address 1245.7654.2348. When the Layer 3 Switch receives a RARP request from this client, the Layer 3 Switch replies to the request by sending IP address 192.53.4.2 to the client.

**Syntax:** `rarp <number> <mac-addr> <ip-addr>`

The `<number>` parameter identifies the RARP entry number. You can specify an unused number from 1 to the maximum number of RARP entries supported on the device. To determine the maximum number of entries supported on the device, refer to the section “Displaying and modifying system parameter default settings” on page 380.

The `<mac-addr>` parameter specifies the MAC address of the RARP client.

The `<ip-addr>` parameter specifies the IP address the Layer 3 Switch will give the client in response to the client RARP request.
Changing the maximum number of static RARP entries supported

The number of RARP entries the Layer 3 Switch supports depends on how much memory the Layer 3 Switch has. To determine how many RARP entries your Layer 3 Switch can have, display the system default information using the procedure in the section “Displaying and modifying system parameter default settings” on page 380.

If your Layer 3 Switch allows you to increase the maximum number of RARP entries, you can use a procedure in the same section to do so.

**NOTE**
You must save the configuration to the startup-config file and reload the software after changing the RARP cache size to place the change into effect.

Configuring UDP broadcast and IP helper parameters

Some applications rely on client requests sent as limited IP broadcasts addressed to the UDP application port. If a server for the application receives such a broadcast, the server can reply to the client. Routers do not forward subnet directed broadcasts, so the client and server must be on the same network for the broadcast to reach the server. If the client and server are on different networks (on opposite sides of a router), the client request cannot reach the server.

You can configure the Layer 3 Switch to forward clients’ requests to UDP application servers. To do so:

- Enable forwarding support for the UDP application port, if forwarding support is not already enabled.
- Configure a helper address on the interface connected to the clients. Specify the helper address to be the IP address of the application server or the subnet directed broadcast address for the IP subnet the server is in. A helper address is associated with a specific interface and applies only to client requests received on that interface. The Layer 3 Switch forwards client requests for any of the application ports the Layer 3 Switch is enabled to forward to the helper address.

Forwarding support for the following application ports is enabled by default:

- bootps (port 67)
- dns (port 53)
- tftp (port 69)
- time (port 37)
- netbios-ns (port 137)
- netbios-dgm (port 138)
- tacacs (port 65)

**NOTE**
The application names are the names for these applications that the Layer 3 Switch software recognizes, and might not match the names for these applications on some third-party devices. The numbers listed in parentheses are the UDP port numbers for the applications. The numbers come from RFC 1340.
NOTE
Forwarding support for BootP/DHCP is enabled by default. If you are configuring the Layer 3 Switch to forward BootP/DHCP requests, refer to “Configuring BootP/DHCP relay parameters” on page 1035.

You can enable forwarding for other applications by specifying the application port number.

You also can disable forwarding for an application.

NOTE
If you disable forwarding for a UDP application, forwarding of client requests received as broadcasts to helper addresses is disabled. Disabling forwarding of an application does not disable other support for the application. For example, if you disable forwarding of Telnet requests to helper addresses, other Telnet support on the Layer 3 Switch is not also disabled.

Enabling forwarding for a UDP application

If you want the Layer 3 Switch to forward client requests for UDP applications that the Layer 3 Switch does not forward by default, you can enable forwarding support for the port. To enable forwarding support for a UDP application, use the following method. You also can disable forwarding for an application using this method.

NOTE
You also must configure a helper address on the interface that is connected to the clients for the application. The Layer 3 Switch cannot forward the requests unless you configure the helper address. Refer to “Configuring an IP helper address” on page 1036.

To enable the forwarding of SNMP trap broadcasts, enter the following command.

```
FastIron(config)# ip forward-protocol udp snmp-trap
```

Syntax: [no] ip forward-protocol udp <udp-port-name> | <udp-port-num>

The <udp-port-name> parameter can have one of the following values. For reference, the corresponding port numbers from RFC 1340 are shown in parentheses. If you specify an application name, enter the name only, not the parentheses or the port number shown here:

- bootpc (port 68)
- bootps (port 67)
- discard (port 9)
- dns (port 53)
- dnsix (port 90)
- echo (port 7)
- mobile-ip (port 434)
- netbios-dgm (port 138)
- netbios-ns (port 137)
- ntp (port 123)
- tacacs (port 65)
- talk (port 517)
- time (port 37)
• tftp (port 69)

In addition, you can specify any UDP application by using the application UDP port number.

The `<udp-port-num>` parameter specifies the UDP application port number. If the application you want to enable is not listed above, enter the application port number. You also can list the port number for any of the applications listed above.

To disable forwarding for an application, enter a command such as the following.

```
FastIron(config)# no ip forward-protocol udp snmp
```

This command disables forwarding of SNMP requests to the helper addresses configured on Layer 3 Switch interfaces.

**Configuring an IP helper address**

To forward a client broadcast request for a UDP application when the client and server are on different networks, you must configure a helper address on the interface connected to the client. Specify the server IP address or the subnet directed broadcast address of the IP subnet the server is in as the helper address.

You can configure up to 16 helper addresses on each interface. You can configure a helper address on an Ethernet port or a virtual interface.

To configure a helper address on interface 2 on chassis module 1, enter the following commands.

```
FastIron(config)# interface e 1/2
FastIron(config-if-1/2)# ip helper-address 1 207.95.7.6
```

The commands in this example change the CLI to the configuration level for port 1/2, then add a helper address for server 207.95.7.6 to the port. If the port receives a client request for any of the applications that the Layer 3 Switch is enabled to forward, the Layer 3 Switch forwards the client request to the server.

**Syntax:** `ip helper-address <num> <ip-addr>`

The `<num>` parameter specifies the helper address number and can be from 1 – 16.

The `<ip-addr>` command specifies the server IP address or the subnet directed broadcast address of the IP subnet the server is in.

**Configuring BootP/DHCP relay parameters**

A host on an IP network can use BootP/DHCP to obtain its IP address from a BootP/DHCP server. To obtain the address, the client sends a BootP/DHCP request. The request is a subnet directed broadcast and is addressed to UDP port 67. A limited IP broadcast is addressed to IP address 255.255.255.255 and is not forwarded by the Brocade Layer 3 Switch or other IP routers.

When the BootP/DHCP client and server are on the same network, the server receives the broadcast request and replies to the client. However, when the client and server are on different networks, the server does not receive the client request, because the Layer 3 Switch does not forward the request.

You can configure the Layer 3 Switch to forward BootP/DHCP requests. To do so, configure a helper address on the interface that receives the client requests, and specify the BootP/DHCP server IP address as the address you are helping the BootP/DHCP requests to reach. Instead of the server IP address, you can specify the subnet directed broadcast address of the IP subnet the server is in.
BootP/DHCP relay parameters

The following parameters control the Layer 3 Switch forwarding of BootP/DHCP requests:

- **Helper address** – The BootP/DHCP server IP address. You must configure the helper address on the interface that receives the BootP/DHCP requests from the client. The Layer 3 Switch cannot forward a request to the server unless you configure a helper address for the server.

- **Gateway address** – The Layer 3 Switch places the IP address of the interface that received the BootP/DHCP request in the request packet Gateway Address field (sometimes called the Router ID field). When the server responds to the request, the server sends the response as a unicast packet to the IP address in the Gateway Address field. (If the client and server are directly attached, the Gateway ID field is empty and the server replies to the client using a unicast or broadcast packet, depending on the server.)

By default, the Layer 3 Switch uses the lowest-numbered IP address on the interface that receives the request as the Gateway address. You can override the default by specifying the IP address you want the Layer 3 Switch to use.

- **Hop count** – Each router that forwards a BootP/DHCP packet increments the hop count by 1. Routers also discard a forwarded BootP/DHCP request instead of forwarding the request if the hop count is greater than the maximum number of BootP/DHCP hops allows by the router. By default, a Brocade Layer 3 Switch forwards a BootP/DHCP request if its hop count is four or less, but discards the request if the hop count is greater than four. You can change the maximum number of hops the Layer 3 Switch will allow to a value from 1 – 15.

**NOTE**
The BootP/DHCP hop count is not the TTL parameter.

Configuring an IP helper address

The procedure for configuring a helper address for BootP/DHCP requests is the same as the procedure for configuring a helper address for other types of UDP broadcasts. Refer to “Configuring an IP helper address” on page 1035.

Configuring the BOOTP/DHCP reply source address

You can configure the Brocade device so that a BOOTP/DHCP reply to a client contains the server IP address as the source address instead of the router IP address. To do so, enter the following command at the Global CONFIG level of the CLI.

```
FastIron(config)# ip helper-use-responder-ip
```

**Syntax:** [no] ip helper-use-responder-ip

Changing the IP address used for stamping BootP/DHCP requests

**NOTE**
This feature is not supported in TurboIron devices.

When the Layer 3 Switch forwards a BootP/DHCP request, the Layer 3 Switch “stamps” the Gateway Address field. The default value the Layer 3 Switch uses to stamp the packet is the lowest-numbered IP address configured on the interface that received the request. If you want the Layer 3 Switch to use a different IP address to stamp requests received on the interface, use either of the following methods to specify the address.
The BootP/DHCP stamp address is an interface parameter. Change the parameter on the interface that is connected to the BootP/DHCP client.

To change the IP address used for stamping BootP/DHCP requests received on interface 1/1, enter commands such as the following.

```bash
FastIron(config)# int e 1/1
FastIron(config-if-1/1)# ip bootp-gateway 109.157.22.26
```

These commands change the CLI to the configuration level for port 1/1, then change the BootP/DHCP stamp address for requests received on port 1/1 to 192.157.22.26. The Layer 3 Switch will place this IP address in the Gateway Address field of BootP/DHCP requests that the Layer 3 Switch receives on port 1/1 and forwards to the BootP/DHCP server.

**Syntax:** `ip bootp-gateway <ip-addr>`

### Changing the maximum number of hops to a BootP relay server

Each BootP/DHCP request includes a field Hop Count field. The Hop Count field indicates how many routers the request has passed through. When the Layer 3 Switch receives a BootP/DHCP request, the Layer 3 Switch looks at the value in the Hop Count field:

- If the hop count value is equal to or less than the maximum hop count the Layer 3 Switch allows, the Layer 3 Switch increments the hop count by one and forwards the request.
- If the hop count is greater than the maximum hop count the Layer 3 Switch allows, the Layer 3 Switch discards the request.

To change the maximum number of hops the Layer 3 Switch allows for forwarded BootP/DHCP requests, use either of the following methods.

**NOTE**
The BootP/DHCP hop count is not the TTL parameter.

To modify the maximum number of BootP/DHCP hops, enter the following command.

```bash
FastIron(config)# bootp-relay-max-hops 10
```

This command allows the Layer 3 Switch to forward BootP/DHCP requests that have passed through ten previous hops before reaching the Layer 3 Switch. Requests that have traversed 11 hops before reaching the switch are dropped. Since the hop count value initializes at zero, the hop count value of an ingressing DHCP Request packet is the number of Layer 3 routers that the packet has already traversed.

**Syntax:** `bootp-relay-max-hops <1 through 15>`

### DHCP Server

**Platform Support:**

- FastIron GS, LS, and WS devices running software version 04.3.03 and later
Overview

The Dynamic Host Configuration Protocol (DHCP) is a computer networking protocol used by devices (DHCP clients) to obtain leased (or permanent) IP addresses. DHCP is an extension of the Bootstrap Protocol (BOOTP). The differences between DHCP and BOOTP are the address allocation and renewal process.

DHCP introduces the concept of a lease on an IP address. See “How DHCP Client-based Auto-Configuration works” on page 1052. The DHCP server can allocate an IP address for a specified amount of time, or can extend a lease for an indefinite amount of time. DHCP provides greater control of address distribution within a subnet. This feature is crucial if the subnet has more devices than available IP address. In contrast to BOOTP, which has two types of messages that can be used for leased negotiation, DHCP provides 7 types of messages. See “Supported Options for DHCP Servers” on page 1056.

DHCP allocates temporary or permanent network IP addresses to clients. When a client requests the use of an address for a time interval, the DHCP server guarantees not to reallocate that address within the requested time and tries to return the same network address each time the client makes a request. The period of time for which a network address is allocated to a client is called a lease. The client may extend the lease through subsequent requests. When the client is done with the address, they can release the address back to the server. By asking for an indefinite lease, clients may receive a permanent assignment.

In some environments, it may be necessary to reassign network addresses due to exhaustion of the available address pool. In this case, the allocation mechanism reuses addresses with expired leases.

DHCP Option 82 Support

The DHCP relay agent information option (DHCP option 82) enables a DHCP relay agent to include information about itself when forwarding client-originated DHCP packets to a DHCP server. The DHCP server uses this information to implement IP address or other parameter-assignment policies.

In a metropolitan Ethernet-access environment, the DHCP server can centrally manage IP address assignments for a large number of subscribers. If DHCP option 82 is disabled, a DHCP policy can only be applied per subnet, rather than per physical port. When DHCP option 82 is enabled, a subscriber is identified by the physical port through which it connects to the network.

DHCP Server Options

A FastIron configured as a DHCP server can support up to 1000 DHCP clients, offering them the following options:

- **NetBIOS over TCP/IP Name Server** - Specifies a list of RFC1001/1002 NBNS name servers listed in order of preference.
- **Domain Name Server** - Specifies a list of Domain Name System (RFC 1035) name servers available to the client. Servers are listed in order of preference.
- **Domain Name** - Specifies the domain name the client should use when resolving hostnames using the Domain Name system.
- **Router Option** - Specifies a list of IP addresses for routers on the client subnet. Routers are listed in order of preference.
- **Subnet Mask** - Specifies the client subnet mask (per RFC950).
- **Vendor Specific Information** - Allows clients and servers to exchange vendor-specific information.
- **Boot File** - Specifies a boot image to be used by the client
- **Next Bootstrap Server** - Configures the IP address of the next server to be used for startup by the client.
- **TFTP Server** - Configures the address of the TFTP server available to the client.
A DHCP server assigns and manages IPv4 addresses from a multiple address pools, using dynamic address allocation. The DHCP server also contains the relay agent to forward DHCP broadcast messages to network segments that do not support these types of messages.

**FIGURE 135** DHCP Server configuration flow chart
Configuring DHCP Server on a device

Perform the following steps to configure the DHCP Server feature on your FastIron device.

1. Classify incoming message.
2. DHCP enabled?
   - Yes: Previous allocation in DB for this host?
     - Yes: Reserve the previous allocated address.
     - No: Route Portnum, Ciaddr field, and Giaddr field to select proper address pool.
   - No: Use RX Portnum, Ciaddr field, and Giaddr field to select proper address pool.
3. Available address in the pool?
   - Yes: Host options requested address?
     - Yes: Check for requested address from host options parameters (Requested IP Address).
     - No: Reserve an address from the address pool.
   - No: Reserve the address.
4. Requested address available?
   - Yes: Requested address available.
   - No: Log error in system log and send DHCP NAK to host.
5. Host responds?
   - Yes: Send offer to host and listen for response.
   - No: Reserve the previous allocated address.
6. Host options requested address?
   - Yes: Send offer to host and listen for response.
   - No: Reserve an address from the address pool.
7. Available address in the pool?
   - Yes: Use RX Portnum, Ciaddr field, and Giaddr field to select proper address pool.
   - No: Reserve the address.
8. Check host decline address against address pool.
   - Yes: Mark address as available to another host.
   - No: Log error to system log.
9. DHCP release?
   - Yes: Mark address as no available and log config error in system log.
   - No: Check for requested address from host options parameters (Requested IP Address).
10. DHCP decline?
    - Yes: Send ACK to host with all configured options. Do not include lease expiration or yiaddr.
    - No: Log warning to system log.
11. DHCP inform?
    - Yes: Send ACK to host and listen for request to extend, renew, or release lease.
    - No: Request to extend or renew lease.
12. DHCP request?
    - Yes: Accepting assigned address/lease parameters.
    - No: Renew or extend the lease.

End.
1. Enable DHCP Server by entering a command similar to the following:

   FWS624 Switch(config)# ip dhcp-server enable

2. Create a DHCP Server address pool by entering a command similar to the following:

   FWS624 Switch(config)# ip dhcp-server pool cabo

3. Configure the DHCP Server address pool by entering commands similar to the following:

   FWS624 Switch(config-dhcp-cabo)# network 172.16.1.0/24
   FWS624 Switch(config-dhcp-cabo)# domain-name brocade.com
   FWS624 Switch(config-dhcp-cabo)# dns-server 172.16.1.2 172.16.1.3
   FWS624 Switch(config-dhcp-cabo)# netbios-name-server 172.16.1.2
   FWS624 Switch(config-dhcp-cabo)# lease 0 0 5

4. To disable DHCP, enter a command similar to the following:

   FWS624 Switch(config)# no ip dhcp-server enable

The following sections describe the default DHCP settings, CLI commands and the options you can configure for the DHCP Server feature.
Default DHCP Server Settings

Table 172 shows the default DHCP server settings.

<table>
<thead>
<tr>
<th>TABLE 172</th>
<th>DHCP Server default settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Default Value</td>

DHCP Server CLI commands

This section describes the CLI commands that are available in the DHCP Server feature.

<table>
<thead>
<tr>
<th>TABLE 173</th>
<th>DHCP Server CLI commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>ip dhcp-server arp-ping-timeout &lt;#&gt;</td>
<td>Specifies the time (in seconds) the server will wait for a response to an arp-ping packet before deleting the client from the binding database. The minimum setting is 5 seconds and the maximum time is 30 seconds.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td>Do not alter the default value unless it is necessary. Increasing the value of this timer may increase the time to get console access after a reboot.</td>
</tr>
<tr>
<td>clear ip dhcp-server binding</td>
<td>Deletes a specific, or all leases from the binding database. See &quot;Removing DHCP leases&quot; on page 1044.</td>
</tr>
<tr>
<td>ip dhcp-server enable</td>
<td>Enables the DHCP server feature. See &quot;Enabling DHCP Server&quot; on page 1045.</td>
</tr>
<tr>
<td>ip dhcp-server pool &lt;name&gt;</td>
<td>Switches to pool configuration mode (config-dhcp-name# prompt) and creates an address pool. See &quot;Creating an address pool&quot; on page 1045.</td>
</tr>
<tr>
<td>ip dhcp-server relay-agent-echo enable</td>
<td>Enables relay agent echo (Option 82). See &quot;Enabling relay agent echo (Option 82)&quot; on page 1045.</td>
</tr>
<tr>
<td>ip dhcp-server &lt;server-id&gt; &lt;address&gt;</td>
<td>Specifies the IP address of the selected DHCP server. See &quot;Configuring the IP address of the DHCP server&quot; on page 1045.</td>
</tr>
<tr>
<td>show ip dhcp-server binding [&lt;address&gt;]</td>
<td>Displays a specific lease entry, or all lease entries. See &quot;Display active lease entries&quot; on page 1048.</td>
</tr>
</tbody>
</table>
Removing DHCP leases

The clear ip dhcp-server binding command can be used to delete a specific lease, or all lease entries from the lease binding database.

FWS624 Switch(config)# clear ip dhcp-server binding *

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip dhcp-server address-pool &lt;name&gt;</td>
<td>Displays a specific address pool or all address pools. See “Display address-pool information” on page 1048.</td>
</tr>
<tr>
<td>show ip dhcp-server flash</td>
<td>Displays the lease binding database that is stored in flash memory. See “Display lease-binding information in flash memory” on page 1049.</td>
</tr>
<tr>
<td>show ip dhcp-server summary</td>
<td>Displays a summary of active leases, deployed address pools, undeployed address pools, and server uptime. “Display summary DHCP information” on page 1050.</td>
</tr>
<tr>
<td>bootfile &lt;name&gt;</td>
<td>Specifies a boot image to be used by the client. See “Configure the boot image” on page 1046.</td>
</tr>
<tr>
<td>deploy</td>
<td>Deploys an address pool configuration to the server. See “Deploy an address pool configuration to the server” on page 1046.</td>
</tr>
<tr>
<td>dhcp-default-router &lt;addresses&gt;</td>
<td>Specifies the IP address of the default router or routers for a client. See “Specify default routers available to the client” on page 1046.</td>
</tr>
<tr>
<td>dns-server &lt;addresses&gt;</td>
<td>Specifies the IP addresses of a DNS server or servers available to the client. See “Specify DNS servers available to the client” on page 1046.</td>
</tr>
<tr>
<td>domain-name &lt;domain&gt;</td>
<td>Configures the domain name for the client. See “Configure the domain name for the client” on page 1046.</td>
</tr>
<tr>
<td>lease &lt;days&gt;&lt;hours&gt;&lt;minutes&gt;</td>
<td>Specifies the lease duration for an address pool. The default is a one-day lease. See “Configure the lease duration for the address pool” on page 1046.</td>
</tr>
<tr>
<td>excluded-address [&lt;address&gt;</td>
<td>Secifies an address or range of addresses to be excluded from the address pool. See “Specify addresses to exclude from the address pool” on page 1047.</td>
</tr>
<tr>
<td>netbios-name-server &lt;address&gt;</td>
<td>Specifies the IP address of a NetBIOS WINS server or servers that are available to Microsoft DHCP clients. See “Configure the NetBIOS server for DHCP clients” on page 1047.</td>
</tr>
<tr>
<td>network &lt;subnet&gt;/&lt;mask&gt;</td>
<td>Configures the subnet network and mask of the DHCP address pool. See “Configure the subnet and mask of a DHCP address pool” on page 1047.</td>
</tr>
<tr>
<td>next-bootstrap-server &lt;address&gt;</td>
<td>Configures the IP address of the next server to be used for startup by the client. See “Configure a next-bootstrap server” on page 1047.</td>
</tr>
<tr>
<td>tftp-server &lt;address&gt;</td>
<td>Configures the address of the TFTP server available to the client. See “Configure the TFTP server” on page 1047.</td>
</tr>
<tr>
<td>vendor-class [\ascii]</td>
<td>Specifies the vendor type and configuration value for the DHCP client. See “Configure a vendor type and configuration value for a DHCP client” on page 1047.</td>
</tr>
</tbody>
</table>
**Syntax:** clear ip dhcp-server binding [<address> | <*>]
- `<address>` - The IP address to be deleted
- `<*>` - Clears all IP addresses

**Enabling DHCP Server**

The `dhcp server` command enables DHCP Server, which is disabled by default.

**Syntax:** [no] ip dhcp-server enable
- Enables the DHCP server feature. The `no` version of this command disables DHCP server.

**Setting the wait time for ARP-ping response**

At startup, the server reconciles the lease-binding database by sending an ARP-ping packet out to every client. If there is no response to the ARP-ping packet within a set amount of time (set in seconds), the server deletes the client from the lease-binding database. The minimum setting is 5 seconds and the maximum is 30 seconds.

**Syntax:** ip dhcp-server arp-ping-timeout <#>
- `<#>` - The number of seconds to wait for a response to an ARP-ping packet.

**NOTE**
Do not alter the default value unless it is necessary. Increasing the value of this timer may increase the time to get console access after a reboot.

**Creating an address pool**

The `dhcp-server pool` command puts you in pool configuration mode, and allows you to create an address pool.

```
FWS624 Switch(config)# dhcp-server pool
FWS624 Switch(config-dhcp-name)# dhcp-server pool monterey
FWS624 Switch(config-dhcp-monterey)#
```

These commands have created an address pool named monterey.

**Syntax:** dhcp-server pool <name>

**Enabling relay agent echo (Option 82)**

The `ip dhcp-server relay-agent-echo enable` command activates DHCP Option 82, and enables the DHCP server to echo relay agent information in all replies.

```
FWS624 Switch(config)# ip dhcp-server relay-agent-echo enable
```

**Syntax:** ip dhcp-server relay-agent-echo enable

**Configuring the IP address of the DHCP server**

The `ip dhcp-server` command specifies the IP address of the selected DHCP server, as shown in this example:

```
FWS624 Switch(config)# ip dhcp-server cabo 102.1.1.144
```
Syntax:  `ip dhcp-server <server-identifier> <address>`

- `<server-identifier>` - The name of the DHCP server
- `<address>` - The IP address of the DHCP server

This command assigns an IP address to the selected DHCP server.

**Configure the boot image**

The `bootfile` command specifies a boot image name to be used by the DHCP client.

```
FWS624 Switch(config-dhcp-cabo)# bootfile foxhound
```

In this example, the DHCP client should use the boot image called “foxhound”.

Syntax:  `bootfile <name>`

**Deploy an address pool configuration to the server**

The `deploy` command sends an address pool configuration to the DHCP server.

```
FWS624 Switch(config-dhcp-cabo)# deploy
```

Syntax:  `deploy`

**Specify default routers available to the client**

The `dhcp-default-router` command specifies the IP addresses of the default routers for a client.

Syntax:  `dhcp-default-router <address> [<address>, <address>]`

**Specify DNS servers available to the client**

The `dns-server` command specifies DNS servers that are available to DHCP clients.

```
FWS624 Switch(config-dhcp-cabo)# dns-server 102.2.1.143, 101.2.2.142
```

Syntax:  `dns-server <address> [<address>, <address>]`

**Configure the domain name for the client**

- The `domain-name` command configures the domain name for the client.

```
FWS624 Switch(config-dhcp-cabo)# domain-name sierra
```

Syntax:  `domain-name <domain>`

**Configure the lease duration for the address pool**

The `lease` command specifies the lease duration for the address pool. The default is a one-day lease.

```
FWS624 Switch(config-dhcp-cabo)# lease 1 4 32
```

In this example, the lease duration has been set to one day, four hours, and 32 minutes. You can set a lease duration for just days, just hours, or just minutes, or any combination of the three.
Syntax: lease <days> <hours> <minutes>

Specify addresses to exclude from the address pool

The excluded-address command specifies either a single address, or a range of addresses that are to be excluded from the address pool.

FWS624 Switch(config-dhcp-cabo)# excluded-address 101.2.3.44

Syntax: excluded-address <[<address> | <address-low address-high>]> 
- <address> - Specifies a single address 
- <address-low address-high> - Specifies a range of addresses

Configure the NetBIOS server for DHCP clients

The netbios-name-server command specifies the IP address of a NetBIOS WINS server or servers that are available to Microsoft DHCP clients.

FWS624 Switch(config-dhcp-cabo)# netbios-name-server 192.168.1.55

Syntax: netbios-name-server <address> [<address2>, <address3>]

Configure the subnet and mask of a DHCP address pool

This network command configures the subnet network and mask of the DHCP address pool.

FWS624 Switch(config-dhcp-cabo)# network 101.2.3.44/24

Syntax: network <subnet>/<mask>

Configure a next-bootstrap server

The next-bootstrap-server command specifies the IP address of the next server the client should use for boot up.

FWS624 Switch(config-dhcp-cabo)# next-bootstrap-server 101.2.5.44

Syntax: next-bootstrap-server <address>

Configure the TFTP server

This tftp-server command specifies the address of the TFTP server to be used by the DHCP clients.

FWS624 Switch(config-dhcp-cabo)# tftp-server 101.7.5.48

Syntax: tftp-server <address>

Configure a vendor type and configuration value for a DHCP client

The vendor-class command specifies the vendor-type and configuration value for a DHCP client.

FWS624 Switch(config-dhcp-cabo)# vendor class ascii waikiki

Syntax: vendor-class {[<ascii> | <ip> | <hex> ]} <value>
Displaying DHCP information

The following DHCP show commands may be entered from any level of the CLI.

Display active lease entries

The show ip dhcp-server binding command displays a specific active lease, or all active leases, as shown in this example:

FWS624 Switch# show ip dhcp-server binding

The following output is displayed:

SW-FWS624 Switch# show ip dhcp-server bind

Bindings from all pools:

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Client-ID/</th>
<th>Lease expiration</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Hardware address</td>
<td></td>
<td></td>
</tr>
<tr>
<td>192.168.1.2</td>
<td>001b.ed5d.a440</td>
<td>0d:0h:29m:31s</td>
<td>Automatic</td>
</tr>
<tr>
<td>192.168.1.3</td>
<td>0012.f2e1.26c0</td>
<td>0d:0h:29m:38s</td>
<td>Automatic</td>
</tr>
</tbody>
</table>

SW-FWS624 Switch#

Syntax:  show ip dhcp-server binding [<address>]

- <address> - Displays entries for this address only

The following table describes this output.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address</td>
<td>The IP addresses currently in the binding database</td>
</tr>
<tr>
<td>Client ID/Hardware address</td>
<td>The hardware address for the client</td>
</tr>
<tr>
<td>Lease expiration</td>
<td>The time when this lease will expire</td>
</tr>
<tr>
<td>Type</td>
<td>The type of lease</td>
</tr>
</tbody>
</table>

Display address-pool information

This show ip dhcp-server address-pool command displays information about a specific address pool, or for all address pools.

FWS624 Switch# show ip dhcp-server address-pools

Output similar to the following is displayed, as shown here.

Showing all address pool(s):

Pool Name:  one
Time elapsed since last save:  0d:0h:6m:52s
Total number of active leases:  2
Address Pool State:  active
IP Address Exclusions:  192.168.1.45
IP Address Exclusions:  192.168.1.99 192.168.1.103
Pool Configured Options:
  bootfile: example.bin
    dhcp-default-router:  192.168.1.1
    dns-server:  192.168.1.100
    domain-name: example.com
    lease:  0 0 30
    netbios-name-server:  192.168.1.101
    network:  192.168.1.0 255.255.255.0
    next-bootstrap-server:  192.168.1.102
    tftp-server:  192.168.1.103

Syntax:  show ip dhcp-server address-pool[s] [<name>]
  - address-pool[s] - If you enter address-pools, the display will show all address pools
  - <name> - Displays information about a specific address pool

The following table describes this output.

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pool name</td>
<td>The name of the address pool</td>
</tr>
<tr>
<td>Time elapsed since last save</td>
<td>The time that has elapsed since the last save.</td>
</tr>
<tr>
<td>Total number of active leases</td>
<td>The number of leases that are currently active.</td>
</tr>
<tr>
<td>Address pool state</td>
<td>The state of the address pool (active or inactive).</td>
</tr>
<tr>
<td>IP Address exclusions</td>
<td>IP addresses that are not included in the address pool</td>
</tr>
<tr>
<td>Pool configured options</td>
<td></td>
</tr>
<tr>
<td>bootfile</td>
<td>The name of the bootfile</td>
</tr>
<tr>
<td>dhcp-server-router</td>
<td>The address of the DHCP server router</td>
</tr>
<tr>
<td>dns-server</td>
<td>The address of the dns server</td>
</tr>
<tr>
<td>domain-name</td>
<td>The name of the domain</td>
</tr>
<tr>
<td>lease</td>
<td>The identifier for the lease</td>
</tr>
<tr>
<td>netbios-name server</td>
<td>The address of the netbios name server</td>

<td>tftp-server</td>
<td>The address of the TFTP server</td>
</tr>
</tbody>
</table>

**Display lease-binding information in flash memory**

The show ip dhcp-server flash command displays the lease-binding database that is stored in flash memory.

FWS624 Switch# show ip dhcp-server flash

The following information is displayed.

SW-FWS624 Switch# show ip dhcp-server flash
Address Pool Binding:
### DHCP Server

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Client-ID/Hardware address</th>
<th>Lease expiration</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.1.2</td>
<td>001b.ed5d.a440</td>
<td>0d:0h:18m:59s</td>
<td>Automatic</td>
</tr>
<tr>
<td>192.168.1.3</td>
<td>0012.f2e1.26c0</td>
<td>0d:0h:19m:8s</td>
<td>Automatic</td>
</tr>
</tbody>
</table>

**Syntax:** `show ip dhcp-server flash`

The following table describes this output.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>

<td>The time when the lease will expire</td>
</tr>
<tr>
<td>Type</td>
<td>The type of lease</td>
</tr>
</tbody>
</table>

### Display summary DHCP information

The `show ip dhcp-server summary` command displays information about active leases, deployed address-pools, undeployed address-pools, and server uptime.

FWS624 Switch# show ip dhcp-server summary

The following information is displayed.

**DHCP Server Summary:**

- Total number of active leases: 2
- Total number of deployed address-pools: 1
- Total number of undeployed address-pools: 0
- Server uptime: 0d:0h:8m:27s

**Syntax:** `show ip dhcp-server summary`

The following table describes this output.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total number of active leases</td>
<td>Indicates the number of leases that are currently active</td>
</tr>
<tr>
<td>Total number of deployed address-pools</td>
<td>The number of address pools currently in use.</td>
</tr>
<tr>
<td>Total number of undeployed address-pools</td>
<td>The number of address-pools being held in reserve.</td>
</tr>
<tr>
<td>Server uptime</td>
<td>The amount of time that the server has been active.</td>
</tr>
</tbody>
</table>
DHCP Client-Based Auto-Configuration

DHCP Client-Based Auto-Configuration allows FGS, FLS, FWS and FCX Layer 2 and Base Layer 3 devices to automatically obtain leased IP addresses through a DHCP server, negotiate address lease renewal, and obtain configuration files.

DHCP Client-Based Auto-Configuration occurs in two steps:

- In the first step, the IP address validation and lease negotiation enables the DHCP client (an FGS, FLS, FWS and FCX Layer 2 or Base-Layer 3 device) to automatically obtain and configure an IP address, as follows:
  - One lease is granted for each Layer 2 device. if the device is configured with a static IP address, the DHCP Auto-Configuration feature is automatically disabled.
  - For a Base Layer 3 devices, one leased address is granted (per device) to the interface that first receives a response from the DHCP server.
- In the second step, TFTP configuration download and update, the device downloads a configuration file from a TFTP server and saves it as the running configuration.
**Figure 136** shows how DHCP Client-Based Auto Configuration works.

**FIGURE 136  DHCP Client-Based Auto-Configuration**

---

**How DHCP Client-based Auto-Configuration works**

Auto-Configuration is enabled by default. To disable this feature, refer to “Disabling or re-enabling Auto-Configuration” on page 1056.

The steps of the Auto-Configuration process are described in Figure 137, and in the description that follows the flowchart.

**NOTE**

For Base Layer 3 devices, this feature is available for the default VLAN only. For Layer 2 devices, this feature is available for default VLANs and management VLANs. This feature is not supported on virtual interfaces (VEs), trunked ports, or LACP ports.
NOTE
Although the DHCP server may provide multiple addresses, only one IP address is installed at a time.

FIGURE 137  The DHCP Client-Based Auto-Configuration steps

The IP address validation and lease negotiation step
1. At boot-up, the device automatically checks its configuration for an IP address.
2. If the device does not have a static IP address, it requests the lease of an address from the DHCP server:
• If the server responds, it leases an IP address to the device for the specified lease period.
• If the server does not respond (after four tries) the DHCP Client process is ended.

3. If the device has a dynamic address, the device asks the DHCP server to validate that address. If the server does not respond, the device will continue to use the existing address until the lease expires. If the server responds, and the IP address is outside of the DHCP address pool or has been leased to another device, it is automatically rejected, and the device receives a new IP address from the server. If the existing address is valid, the lease continues.

**NOTE**
The lease time interval is configured on the DHCP server, not on the client device. The `ip dhcp-client lease` command is set by the system, and is non-operational to a user.

4. If the existing address is static, the device keeps it and the DHCP Client process is ended.

5. For a leased IP address, when the lease interval reaches the renewal point, the device requests a renewal from the DHCP server:
   • If the device is able to contact the DHCP server at the renewal point in the lease, the DHCP server extends the lease. This process can continue indefinitely.
   • If the device is unable to reach the DHCP server after four attempts, it continues to use the existing IP address until the lease expires. When the lease expires, the dynamic IP address is removed and the device contacts the DHCP server for a new address. If the device is still unable to contact the DHCP server after four attempts, the process is ended.

### The IP address validation and lease negotiation step

1. At boot-up, the device automatically checks its configuration for an IP address.

2. If the device does not have a static IP address, it requests the lease of an address from the DHCP server:
   • If the server responds, it leases an IP address to the device for the specified lease period.
   • If the server does not respond (after four tries) the DHCP Client process is ended.

3. If the device has a dynamic address, the device asks the DHCP server to validate that address. If the server does not respond, the device will continue to use the existing address until the lease expires. If the server responds, and the IP address is outside of the DHCP address pool or has been leased to another device, it is automatically rejected, and the device receives a new IP address from the server. If the existing address is valid, the lease continues.

**NOTE**
The lease time interval is configured on the DHCP server, not on the client device. The `ip dhcp-client lease` command is set by the system, and is non-operational to a user.

4. If the existing address is static, the device keeps it and the DHCP Client process is ended.

5. For a leased IP address, when the lease interval reaches the renewal point, the device requests a renewal from the DHCP server:
   • If the device is able to contact the DHCP server at the renewal point in the lease, the DHCP server extends the lease. This process can continue indefinitely.
   • If the device is unable to reach the DHCP server after four attempts, it continues to use the existing IP address until the lease expires. When the lease expires, the dynamic IP address is removed and the device contacts the DHCP server for a new address. If the device is still unable to contact the DHCP server after four attempts, the process is ended.
The TFTP Flash image download and update step

NOTE
This process only occurs when the client device reboots, or when DHCP-client has been disabled and then re-enabled.

Once a lease is obtained from the server (described in “The IP address validation and lease negotiation step” on page 1053), the device compares the filename of the requested flash image with the image stored in flash. In a stacking configuration, the device compares the filename with the image stored in the Active controller only.

- If the .bin filenames match, then the DHCP client skips the flash image download. If auto-configuration is enabled, the DHCP client proceeds with downloading the configuration files as described in “The TFTP configuration download and update step”.

- If the .bin filenames are different, then the DHCP client downloads the new image from a TFTP server, then writes the downloaded image to flash. In a stacking configuration, the device copies the flash image to flash in all stack member units.

The code determines which flash (i.e., primary or secondary) to use based on how the device is booted. In a stacking configuration, the member units use the same flash as the Active controller. Once the flash is updated with the newer flash image, the device is reloaded and any member units in a stacking configuration are reloaded as well. If auto-configuration is enabled, the DHCP client then proceeds to download the configuration files described in “The TFTP configuration download and update step”.

NOTE
In a stacking environment, the DHCP client flash image download waits 5 minutes for all member units to join and update. Then the DHCP client downloads the new image from the TFTP server using the TFTP server IP address (option 150), if it is available. If the TFTP server IP address is not available, the DHCP client requests the TFTP file from the DHCP server.

The TFTP configuration download and update step

NOTE
This process only occurs when the client device reboots, or when Auto-Configuration has been disabled and then re-enabled.

1. When the device reboots, or the Auto-Configuration feature has been disabled and then re-enabled, the device uses information from the DHCP server to contact the TFTP server to update the running-configuration file:
   - If the DHCP server provides a TFTP server name or IP address, the device uses this information to request files from the TFTP server.
   - If the DHCP server does not provide a TFTP server name or IP address, the device requests the configuration files from the DHCP server.

2. The device requests the configuration files from the TFTP server by asking for filenames in the following order:
   - bootfile name provided by the DHCP server (if configured)
   - hostnameMAC-config.cfg, for example:
     FGS624p-Switch001b.ed5e.4d00-config.cfg
   - hostnameMAC.cfg, for example:
• **foundry.cfg** (applies to FGS and FLS devices), for example:
  foundry.cfg

• **brocade.cfg** (applies to all devices, for example:
  brocade.cfg

• **<fcx | fgs | fls>-<switch | router>.cfg** (applies to Layer 2 or base Layer 3 devices), for example:
  
  - fgs-switch.cfg (FGS Layer 2)
  - fls-switch.cfg (FLS Layer 2)
  - fgs-router.cfg (FGS Base-Layer 3)
  - fls-router.cfg (FLS Base Layer 3)
  - fcx-switch.cfg (FCX Layer 2)
  - fcx-router.cfg (FCX Layer 3)

• **hostnameMAC.cfg**, for example:

  FGS624p-Switch001b.ed5e.4d00.cfg

• **foundry.cfg** (applies to both FGS and FLS devices), for example:

  foundry.cfg

• **<fgs | fls>-<switch | router>.cfg** (applies to Layer 2 or base Layer 3 devices), for example:

  - fgs-switch.cfg (FGS Layer 2)
  - fls-switch.cfg (FLS Layer 2)
  - fgs-router.cfg (FGS Base-Layer 3)
  - fls-router.cfg (FLS Base Layer 3)

If the device is successful in contacting the TFTP server and the server has the configuration file, the files are merged. If there is a conflict, the server file takes precedence.

If the device is **unable** to contact the TFTP server or if the files are not found on the server, the TFTP part of the configuration download process ends.

### Supported Options for DHCP Servers

DHCP Client supports the following options:

- 001 - subnetmask
- 003 - router ip
- 015 - domain name
- 006 - domain name server
- 012 - hostname (optional)
- 066 - TFTP server name (only used for Client-Based Auto Configuration)
- 067 - bootfile name
- 150 - TFTP server IP address (private option, datatype = IP Address)

### Disabling or re-enabling Auto-Configuration

For a switch, you can disable or enable this feature using the following commands.

```
FGS Switch(config)# ip dhcp-client enable
FGS Switch(config)# no ip dhcp-client enable
```
For a router, you can disable or enable this feature using the following commands.

FGS Router(config-if-e1000-0/1/1)# ip dhcp-client enable
FGS Router(config-if-e1000-0/1/1)# no ip dhcp-client enable

Syntax: [no] ip dhcp-client enable

Configuration notes

• When using DHCP on a router, if you have a DHCP address for one interface, and you want to connect to the DHCP server from another interface, you must disable DHCP on the first interface, then enable DHCP on the second interface.

• When DHCP is disabled, and then re-enabled, or if the system is rebooted, the TFTP process requires approximately three minutes to run in the background before file images can be downloaded manually.

• Once a port is assigned a leased IP address, it is bound by the terms of the lease regardless of the link state of the port.
### Displaying DHCP configuration information

The following example shows output from the `show ip` command for Layer 2 devices.

```
FGS Switch(config)# show ip

Switch IP address: 10.44.16.116
Subnet mask: 255.255.255.0
Default router address: 10.44.16.1
TFTP server address: 10.44.16.41
Configuration filename: foundry.cfg
Image filename: None
```

The following example shows output from the `show ip address` command for a Layer 2 device.

```
FGS Switch(config)# show ip address

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Type</th>
<th>Lease Time</th>
<th>Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.44.16.116</td>
<td>Dynamic</td>
<td>174</td>
<td>0/1/1</td>
</tr>
</tbody>
</table>
```

The following example shows output from the `show ip address` command for a Base Layer 3 device.

```
FGS Router(config)# show ip address

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Type</th>
<th>Lease Time</th>
<th>Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.44.3.233</td>
<td>Dynamic</td>
<td>672651</td>
<td>0/1/2</td>
</tr>
<tr>
<td>1.0.0.1</td>
<td>Static</td>
<td>N/A</td>
<td>0/1/15</td>
</tr>
</tbody>
</table>
```

The following example shows a Layer 2 device configuration as a result of the `show run` command.

```
FGS Switch(config)# show run

Current configuration:
!
ver 04.2.00b4777e1
!
module 1 fls-24-port-copper-base-module
!
ip address 10.44.16.116 255.255.255.0 dynamic
ip dns server-address 10.44.16.41
ip dhcp-client lease 174
ip default-gateway 10.44.16.1
!
end
```

The following example shows a Base Layer 3 device configuration as a result of the `show run` command.
DHCP Log messages

The following DHCP notification messages are sent to the log file.

2d01h48m21s:I: DHCP: existing ip address found, no further action needed by DHCP
2d01h48m21s:I: DHCP: Starting DHCP Client service
2d01h48m21s:I: DHCP: Stopped DHCP Client service
2d01h48m21s:I: DHCP: FGS624P Switch running-configuration changed
2d01h48m21s:I: DHCP: sending TFTP request for bootfile name fgs-switch.cfg
2d01h48m21s:I: DHCP: TFTP unable to download running-configuration
2d01h48m21s:I: DHCP: Found static IP Address 1.1.1.1 subnet mask 255.255.255.0 on port 0/1/5
2d01h48m21s:I: DHCP: Client service found no DHCP server(s) on 3 possible subnet
2d01h48m21s:I: DHCP: changing 0/1/3 protocol from stopped to running

Configuring IP parameters – Layer 2 Switches

The following sections describe how to configure IP parameters on a Brocade Layer 2 Switch.

NOTE
This section describes how to configure IP parameters for Layer 2 Switches. For IP configuration information for Layer 3 Switches, refer to “Configuring IP parameters – Layer 3 Switches” on page 992.
Configuring the management IP address and specifying the default gateway

To manage a Layer 2 Switch using Telnet or Secure Shell (SSH) CLI connections or the Web Management Interface, you must configure an IP address for the Layer 2 Switch. Optionally, you also can specify the default gateway.

Brocade devices support both classical IP network masks (Class A, B, and C subnet masks, and so on) and Classless Interdomain Routing (CIDR) network prefix masks:

- To enter a classical network mask, enter the mask in IP address format. For example, enter “209.157.22.99 255.255.255.0” for an IP address with a Class-C subnet mask.
- To enter a prefix network mask, enter a forward slash (/) and the number of bits in the mask immediately after the IP address. For example, enter “209.157.22.99/24” for an IP address that has a network mask with 24 significant bits (ones).

By default, the CLI displays network masks in classical IP address format (example: 255.255.255.0). You can change the display to prefix format. Refer to “Changing the network mask display to prefix format” on page 1084.

To assign an IP address to a Brocade Layer 2 Switch, enter a command such as the following at the global CONFIG level.

```
FastIron(config)# ip address 192.45.6.110 255.255.255.0
```

Syntax: `ip address <ip-addr> <ip-mask>`

or

Syntax: `ip address <ip-addr>/<mask-bits>`

**NOTE**
You also can enter the IP address and mask in CIDR format, as follows.

```
FastIron(config)# ip address 192.45.6.1/24
```

To specify the Layer 2 Switch default gateway, enter a command such as the following.

```
FastIron(config)# ip default-gateway 192.45.6.1 255.255.255.0
```

```
ip default-gateway <ip-addr>
```

or

```
ip default-gateway <ip-addr>/<mask-bits>
```

**NOTE**
When configuring an IP address on a Layer 2 switch that has multiple VLANs, make sure the configuration includes a designated management VLAN that identifies the VLAN to which the global IP address belongs. Refer to “Designated VLAN for Telnet management sessions to a Layer 2 Switch” on page 1421.
Configuring Domain Name Server (DNS) resolver

The Domain Name Server (DNS) resolver feature lets you use a host name to perform Telnet, ping, and traceroute commands. You can also define a DNS domain on a Brocade Layer 2 Switch or Layer 3 Switch and thereby recognize all hosts within that domain. After you define a domain name, the Brocade Layer 2 Switch or Layer 3 Switch automatically appends the appropriate domain to the host and forwards it to the domain name server.

For example, if the domain “newyork.com” is defined on a Brocade Layer 2 Switch or Layer 3 Switch and you want to initiate a ping to host “NYC01” on that domain, you need to reference only the host name in the command instead of the host name and its domain name. For example, you could enter either of the following commands to initiate the ping.

FastIron# ping nyc01
FastIron# ping nyc01.newyork.com

Defining a DNS entry

You can define up to four DNS servers for each DNS entry. The first entry serves as the primary default address. If a query to the primary address fails to be resolved after three attempts, the next gateway address is queried (also up to three times). This process continues for each defined gateway address until the query is resolved. The order in which the default gateway addresses are polled is the same as the order in which you enter them.

Suppose you want to define the domain name of newyork.com on a Layer 2 Switch and then define four possible default DNS gateway addresses. To do so, enter the following commands.

FastIron(config)# ip dns domain-name newyork.com
FastIron(config)# ip dns server-address 209.157.22.199 205.96.7.15 208.95.7.25 201.98.7.15

Syntax: ip dns server-address <ip-addr> [...]

In this example, the first IP address in the ip dns server-address... command becomes the primary gateway address and all others are secondary addresses. Because IP address 201.98.7.15 is the last address listed, it is also the last address consulted to resolve a query.

Using a DNS name To initiate a trace route

Example

Suppose you want to trace the route from a Brocade Layer 2 Switch to a remote server identified as NYC02 on domain newyork.com. Because the newyork.com domain is already defined on the Layer 2 Switch, you need to enter only the host name, NYC02, as noted below.

FastIron# traceroute nyc02

Syntax: traceroute <host-ip-addr> [maxttl <value>] [minttl <value>] [numeric] [timeout <value>]

[source-ip <ip addr>]

The only required parameter is the IP address of the host at the other end of the route.
After you enter the command, a message indicating that the DNS query is in process and the current gateway address (IP address of the domain name server) being queried appear on the screen.

Type Control-c to abort
Sending DNS Query to 209.157.22.199
Tracing Route to IP node 209.157.22.80
To ABORT Trace Route, Please use stop-traceroute command.
Traced route to target IP node 209.157.22.80:
<table>
<thead>
<tr>
<th>IP Address</th>
<th>Round Trip Time1</th>
<th>Round Trip Time2</th>
</tr>
</thead>
<tbody>
<tr>
<td>207.95.6.30</td>
<td>93 msec</td>
<td>121 msec</td>
</tr>
</tbody>
</table>

**NOTE**
In the above example, 209.157.22.199 is the IP address of the domain name server (default DNS gateway address), and 209.157.22.80 represents the IP address of the NYC02 host.

**FIGURE 138** Querying a Host on the newyork.com Domain

Changing the TTL threshold

The TTL threshold prevents routing loops by specifying the maximum number of router hops an IP packet originated by the Layer 2 Switch can travel through. Each device capable of forwarding IP that receives the packet decrements (decreases) the packet TTL by one. If a router receives a packet with a TTL of 1 and reduces the TTL to zero, the router drops the packet.

The default TTL is 64. You can change the TTL to a value from 1 – 255.

To modify the TTL threshold to 25, enter the following commands.

```plaintext
FastIron(config)# ip ttl 25
FastIron(config)# exit
```

**Syntax:** `ip ttl <1-255>`
Configuring DHCP Assist

Platform Support:
- FastIron X Series devices – all software releases
- FGS and FLS devices running software release 03.0.00 and later
- FWS devices running software release 04.3.00 or later
- Turbolron X Series devices running software release 04.1.00 and later

DHCP Assist allows a Brocade Layer 2 Switch to assist a router that is performing multi-netting on its interfaces as part of its DHCP relay function.

DHCP Assist ensures that a DHCP server that manages multiple IP subnets can readily recognize the requester IP subnet, even when that server is not on the client local LAN segment. The Brocade Layer 2 Switch does so by stamping each request with its IP gateway address in the DHCP discovery packet.

**NOTE**
Brocade Layer 3 Switches provide BootP/DHCP assistance by default on an individual port basis. Refer to “Changing the IP address used for stamping BootP/DHCP requests” on page 1036.

By allowing multiple subnet DHCP requests to be sent on the same wire, you can reduce the number of router ports required to support secondary addressing as well as reduce the number of DHCP servers required, by allowing a server to manage multiple subnet address assignments.

**FIGURE 139**  DHCP requests in a network without DHCP Assist on the Layer 2 Switch
In a network operating without DHCP Assist, hosts can be assigned IP addresses from the wrong subnet range because a router with multiple subnets configured on an interface cannot distinguish among DHCP discovery packets received from different subnets.

For example, in Figure 139, a host from each of the four subnets supported on a Layer 2 Switch requests an IP address from the DHCP server. These requests are sent transparently to the router. Because the router is unable to determine the origin of each packet by subnet, it assumes the lowest IP address or the ‘primary address’ is the gateway for all ports on the Layer 2 Switch and stamps the request with that address.

When the DHCP request is received at the server, it assigns all IP addresses within that range only. With DHCP Assist enabled on a Brocade Layer 2 Switch, correct assignments are made because the Layer 2 Switch provides the stamping service.
**How DHCP Assist works**

Upon initiation of a DHCP session, the client sends out a DHCP discovery packet for an address from the DHCP server as seen in Figure 140. When the DHCP discovery packet is received at a Brocade Layer 2 Switch with the DHCP Assist feature enabled, the gateway address configured on the receiving interface is inserted into the packet. This address insertion is also referred to as stamping.

FIGURE 140  DHCP requests in a network with DHCP Assist operating on a FastIron Switch

When the stamped DHCP discovery packet is then received at the router, it is forwarded to the DHCP server. The DHCP server then extracts the gateway address from each request and assigns an available IP address within the corresponding IP subnet (Figure 141). The IP address is then forwarded back to the workstation that originated the request.

**NOTE**

When DHCP Assist is enabled on any port, Layer 2 broadcast packets are forwarded by the CPU. Unknown unicast and multicast packets are still forwarded in hardware, although selective packets such as IGMP, are sent to the CPU for analysis. When DHCP Assist is not enabled, Layer 2 broadcast packets are forwarded in hardware.
**NOTE**
The DHCP relay function of the connecting router must be turned on.

**FIGURE 141** DHCP Offers are forwarded back toward the requestors

Step 4:
DHCP Server extracts the gateway address from each packet and assigns IP addresses for each host within the appropriate range.

DHCP response with IP addresses for Subnets 1, 2, 3 and 4

- 192.95.5.10
- 200.95.6.15
- 202.95.1.35
- 202.95.5.25

Step 5:
IP addresses are distributed to the appropriate hosts.

- 192.95.5.10
- 200.95.6.15
- 202.95.1.35
- 202.95.5.25

**NOTE**
When DHCP Assist is enabled on any port, Layer 2 broadcast packets are forwarded by the CPU. Unknown unicast and multicast packets are still forwarded in hardware, although selective packets such as IGMP are sent to the CPU for analysis. When DHCP Assist is not enabled, Layer 2 broadcast packets are forwarded in hardware.

**Configuring DHCP Assist**

You can associate a gateway list with a port. You must configure a gateway list when DHCP Assist is enabled on a Brocade Layer 2 Switch. The gateway list contains a gateway address for each subnet that will be requesting addresses from a DHCP server. The list allows the stamping process to occur. Each gateway address defined on the Layer 2 Switch corresponds to an IP address of the Brocade router interface or other router involved.
Up to eight addresses can be defined for each gateway list in support of ports that are multi-homed. When multiple IP addresses are configured for a gateway list, the Layer 2 Switch inserts the addresses into the discovery packet in a round robin fashion.

Up to 32 gateway lists can be defined for each Layer 2 Switch.

Example
To create the configuration indicated in Figure 140 and Figure 141, enter commands such as the following.

```
FastIron(config)# dhcp-gateway-list 1 192.95.5.1
FastIron(config)# dhcp-gateway-list 2 200.95.6.1
FastIron(config)# dhcp-gateway-list 3 202.95.1.1 202.95.5.1
FastIron(config)# int e 2
FastIron(config-if-e1000-2)# dhcp-gateway-list 1
FastIron(config-if-e1000-2)# int e8
FastIron(config-if-e1000-8)# dhcp-gateway-list 3
FastIron(config-if-e1000-8)# int e 14
FastIron(config-if-e1000-14)# dhcp-gateway-list 2
```

**Syntax:** `dhcp-gateway-list <num> <ip-addr>`

### IPv4 point-to-point GRE tunnels

**Platform Support:** FESX, FSX and SX IPv6 devices running software release FSX 05.1.00 and later

This section describes support for point-to-point Generic Routing Encapsulation (GRE) tunnels and how to configure them on a Brocade device.

GRE tunnels support includes, but is not limited to, the following:

- IPv4 over GRE tunnels. IPv6 over GRE tunnels is not supported.
- Static and dynamic unicast routing over GRE tunnels
- Multicast routing over GRE tunnels
- Hardware forwarding of IP data traffic across a GRE tunnel.
- Path MTU Discovery (PMTUD)

**Overview**

Generic Routing Encapsulation is described in RFC 2784. Generally, GRE provides a way to encapsulate arbitrary packets (payload packet) inside of a transport protocol, and transmit them from one tunnel endpoint to another. The payload is encapsulated in a GRE packet. The resulting GRE packet is then encapsulated in a delivery protocol, then forwarded to the tunnel destination. At the tunnel destination, the packet is de-encapsulated to reveal the payload. The payload is then forwarded to its final destination.

FESX, FSX, and SX IPv6 devices allow the tunneling of packets of the following protocols over an IP network using GRE:

- OSPF V2
- BGP4
- RIP V1 and V2
GRE packet structure and header format

Figure 142 shows the structure of a GRE encapsulated packet.

**FIGURE 142**  GRE encapsulated packet structure

![GRE packet structure](image)

Figure 143 shows the GRE header format.

Path MTU Discovery (PMTUD) support

Brocade IronWare software supports the following RFCs for handling large packets over a GRE tunnel:

- RFC 1191, Path MTU Discovery
- RFC 4459, MTU and Fragmentation Issues with In-the-Network Tunneling
RFC 1191 describes a method for dynamically discovering the maximum transmission unit (MTU) of an arbitrary internet path. When the FastIron receives an IP packet that has its Do not Fragment (DF) bit set, and the packet size is greater than the MTU value of the outbound interface, then the FastIron returns an ICMP Destination Unreachable message to the source of the packet, with the code indicating "fragmentation needed and DF set". The ICMP Destination Unreachable message includes the MTU of the outbound interface. The source host can use this information to help determine the maximum MTU of a path to a destination.

RFC 4459 describes solutions for issues with large packets over a tunnel. The following methods, from RFC 4459, are supported in Brocade IronWare software:

- If a source attempts to send packets that are larger than the lowest MTU value along the path, PMTUD can signal to the source to send smaller packets so that they can be encapsulated. This method is described in Section 3.2 of RFC 4459.
- Inner packets can be fragmented before encapsulation, in such a manner that the encapsulated packet fits in the tunnel path MTU, which is discovered using PMTUD. This method is described in Section 3.4 of RFC 4459.

PMTUD is enabled by default.

Tunnel loopback ports for GRE tunnels

A physical tunnel loopback port is required for routing a de-encapsulated packet. When a GRE-encapsulated packet is received on a tunnel interface, and the packet needs to be de-encapsulated, the packet is de-encapsulated and sent to the tunnel loopback port. The packet is then looped back and forwarded based on the payload packets.

If a tunnel loopback port is not configured, tunnel termination is performed by the CPU. Each GRE tunnel interface can have one assigned tunnel loopback port and the same tunnel loopback port can be used for multiple tunnels.

Tunnel loopback ports for GRE tunnels are supported on:

- untagged ports
- ports that are enabled by default
- 10 Gbps and 1 Gbps copper and fiber ports

Note the following hardware limitations for these port types:

- On 10 Gbps ports, the port LEDs will be ON (green) when the ports are configured as tunnel loopback ports for GRE tunnels. Also, the LEDs will blink when data packets are forwarded.
- On 1 Gbps fiber and copper ports, port LEDs will not be ON when the ports are configured as tunnel loopback ports for GRE tunnels, nor will the LEDs blink when data packets are forwarded.

Tunnel loopback ports for GRE tunnels are not supported on:

- tagged ports
- trunk ports
- ports that are members of a VE
- ports that are disabled
- ports that have an IP address
- flow control
Support for IPv4 multicast routing over GRE tunnels

PIM-DM and PIM-SM Layer 3 multicast protocols and multicast data traffic are supported over GRE tunnels. When a multicast protocol is enabled on both ends of a GRE tunnel, multicast packets can be sent from one tunnel endpoint to another. To accomplish this, the packets are encapsulated using the GRE unicast tunneling mechanism and forwarded like any other IPv4 unicast packet to the destination endpoint of the tunnel. The router that terminates the tunnel (i.e., the router where the tunnel endpoint is an ingress interface) de-encapsulates the GRE tunneled packet to retrieve the native multicast data packets. After de-encapsulation, data packets are forwarded in the direction of its receivers, and control packets may be consumed. This creates a PIM-enabled virtual or logical link between the two GRE tunnel endpoints.

Strict RPF check for multicast protocols

IronWare software enforces strict Reverse Path Forwarding (RPF) check rules on an (s,g) entry on a GRE tunnel interface. The (s,g) entry uses the GRE tunnel as an RPF interface. During unicast routing transit, GRE tunnel packets may arrive at different physical interfaces. The strict RPF check limits GRE PIM tunnel interfaces to accept the (s,g) GRE tunnel traffic.

When the GRE-encapsulated multicast packet is received, the unicast GRE mechanism takes care of de-encapsulating the packet. The packet then egresses and re-enters the tunnel interface loopback port as the native multicast packet. The hardware RPF check is done, not on the tunnel interface directly, but on the loopback port – the hardware compares this port number with the port number configured in the Multicast table (s,g) entry. If they match, the packet is routed. Otherwise it is sent to the CPU for error processing.

In unicast, it is permissible for multiple tunnel interfaces to use a single loopback port. However, in multicast, this will not allow the hardware to determine the tunnel interface that the packet was received on in order to do an RPF check. Therefore, when IPv4 Multicast Routing is enabled on a GRE tunnel, the tunnel interface must have a dedicated loopback port.

GRE support with other features

This section describes how GRE tunnels may affect other features on FESX, FSX, and SX IPv6 devices.

Support for ECMP for routes through a GRE tunnel

Equal-Cost Multi-Path (ECMP) load sharing allows for load distribution of traffic among available routes. When GRE is enabled, a mix of GRE tunnels and normal IP routes is supported. If multiple routes are using GRE tunnels to a destination, packets are automatically load-balanced between tunnels, or between tunnels and normal IP routes.

ACL, QoS, and PBR support for traffic through a GRE tunnel

Traffic coming from a tunnel can be filtered by an ACL or redirected by PBR both before and after the tunnel is terminated. An ACL classifies and sets QoS for GRE traffic. PBR routes GRE traffic that matches an ACL, according to instructions in the route map. If the ACL or PBR is applied to the tunnel loopback port, it would apply to the inner IP packet header (the payload packet) after the tunnel is terminated. If the ACL or PBR is applied to the tunnel ingress port, then the delivery header (outer header) would be classified or filtered before the tunnel is terminated.
NOTE
Restrictions for using ACLs in conjunction with GRE are noted in the section “Configuration considerations” on page 1071. PBR can be configured on tunnel loopback ports for tunnel interfaces with no restrictions.

Syslog messages
Syslog messages provide management applications with information related to GRE IP tunnels. The following Syslog message is supported.

Tunnel: TUN-RECURSIVE-DOWN tnnl 1, Tnnl disabled due to recursive routing

Configuration considerations
Before configuring GRE tunnels and tunnel options, consider the configuration notes in this section.

• When GRE is enabled on a Layer 3 switch, the following features are not supported on Virtual Ethernet (VE) ports, VE member ports (ports that have IP addresses), and GRE tunnel loopback ports:
  • ACL logging
  • ACL statistics (also called ACL counting)
  • MAC filters
  • IPv6 filters

NOTE
The above features are supported on VLANs that do not have VE ports.

• Whenever multiple IP addresses are configured on a tunnel source, the primary address of the tunnel is always used for forming the tunnel connections. Therefore, carefully check the configurations when configuring the tunnel destination.

• When a GRE tunnel is configured, you cannot configure the same routing protocol on the tunnel through which you learn the route to the tunnel destination. For example, if the FastIron learns the tunnel destination route through the OSPF protocol, you cannot configure the OSPF protocol on the same tunnel and vice-versa. When a tunnel has OSPF configured, the FastIron cannot learn the tunnel destination route through OSPF. This could cause the system to become unstable.

• The tunnel destination cannot be resolved to the tunnel itself or any other local tunnel. This is called recursive routing. This scenario would cause the tunnel interface to flap and the Syslog message TUN-RECURSIVE-DOWN to be logged. To resolve this issue, create a static route for the tunnel destination.

Configuration considerations for tunnel loopback ports
Consider the following when configuring tunnel loopback ports for GRE tunnels:

• For multicast traffic over a GRE tunnel, each PIM-enabled tunnel interface must have a dedicated tunnel loopback port.
IPv4 point-to-point GRE tunnels

- For unicast traffic, a tunnel loopback port can be oversubscribed, meaning multiple GRE tunnels (up to the maximum supported) can use the same tunnel loopback port for traffic. When oversubscribed, proper traffic classification on the tunnel loopback port is necessary in order to avoid traffic congestion. In this case, Brocade recommends that you configure the trust level at the DSCP level for QoS by adding an ACL that maps DSCP 46 to priority 5. Otherwise, loss of loopback packets may flap the tunnel interface.
- By default, when you create a tunnel loopback port for a GRE tunnel on a port that is part of the default VLAN, the port will stay in the default VLAN. Before configuring a port as a tunnel loopback port for a GRE tunnel, if the port is in the default VLAN (VLAN 1), first create a VLAN, then add the port to the VLAN. Otherwise, an error message such as the following will appear on the console when you attempt to configure a router interface for the default VLAN.

```
ERROR: Router-interface cannot be applied because of GRE loopback port 1/2
```

**GRE MTU configuration considerations**

The default Maximum Transmission Unit (MTU) value for packets in a GRE tunnel is 1476 bytes, or 10194 bytes for jumbo packets. The MTU of the GRE tunnel is compared with the outgoing packet before the packet is encapsulated. After encapsulation, the packet size increases by 24 bytes. Therefore, when changing the GRE tunnel MTU, set the MTU to at least 24 bytes less than the IP MTU of the outgoing interface. Otherwise, the size of the encapsulated packet will exceed the IP MTU, the outgoing interface and the packet will be dropped if the DF (Do-Not-Fragment) bit is set in the original IP packet, and an ICMP message will be sent. Otherwise, the packet will be sent to the CPU for fragmentation.

**Configuration tasks**

Brocade recommends that you perform the configuration tasks in the order listed in Table 178.

```
<table>
<thead>
<tr>
<th>Configuration tasks</th>
<th>Default behavior</th>
<th>See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required tasks</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1  Create a tunnel interface</td>
<td>Not assigned</td>
<td>“Creating a tunnel interface” on page 1073</td>
</tr>
<tr>
<td>2  Configure the source address or source interface for the tunnel interface</td>
<td>Not assigned</td>
<td>“Configuring the source address or source interface for a tunnel interface” on page 1073</td>
</tr>
<tr>
<td>3  Configure the destination address of the tunnel interface</td>
<td>Not assigned</td>
<td>“Configuring the destination address for a tunnel interface” on page 1074</td>
</tr>
<tr>
<td>4  Enable GRE encapsulation on the tunnel interface</td>
<td>Disabled</td>
<td>“Enabling GRE encapsulation on a tunnel interface” on page 1074</td>
</tr>
<tr>
<td>5  If packets need to be terminated in hardware, configure a tunnel loopback port for the tunnel interface</td>
<td>Not assigned</td>
<td>“Tunnel loopback ports for GRE tunnels” on page 1069</td>
</tr>
<tr>
<td>6  Configure an IP address for the tunnel interface</td>
<td>Not assigned</td>
<td>“Configuring an IP address for a tunnel interface” on page 1075</td>
</tr>
<tr>
<td>7  If a route to the tunnel destination (configured in Step 3) does not already exist, create a static route and specify that the route is through the tunnel interface.</td>
<td>Not assigned</td>
<td>“Configuring a static route to a tunnel destination” on page 1075</td>
</tr>
</tbody>
</table>
```
The following features are also supported on GRE tunnel interfaces:

- Naming the tunnel interface (CLI command `port-name`) – for configuration details, see “Assigning a port name” on page 56.
- Changing the Maximum Transmission Unit (MTU) (CLI command `ip mtu`) – for configuration details, see “Changing the Maximum Transmission Unit on an individual port” on page 1001.
- Increasing the cost of routes learned on the port (CLI command `ip metric`) – for configuration details, see “Changing the cost of routes learned on a port” on page 1146.

After performing the configuration steps listed in Table 178, you can view the GRE configuration and observe the routes that use GRE tunnels. For details, see “Displaying GRE tunneling information” on page 1080.

### Creating a tunnel interface

To create a tunnel interface, enter the following command at the Global CONFIG level of the CLI.

```
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)#
```

**Syntax:** `[no] interface tunnel `<tunnel-number>`

The `<tunnel-number>` is a numerical value that identifies the tunnel being configured.

**NOTE**

You can also use the `port-name` command to name the tunnel. To do so, follow the configuration instructions in “Assigning a port name” on page 56.

### Configuring the source address or source interface for a tunnel interface

To configure the source for a tunnel interface, specify either a source address or a source interface.

**NOTE**

If the destination address for a tunnel interface is not resolved, Brocade recommends that you either configure `source interface` (instead of `source address`) as the source for a tunnel interface, or enable GRE link keepalive on the tunnel interface.
The tunnel **source address** should be one of the router IP addresses configured on a physical or VE interface, through which the other end of the tunnel is reachable.

To configure the source address for a specific tunnel interface, enter commands such as the following.

```plaintext
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# tunnel source 36.0.8.108
```

The **source interface** should be the port number of the interface configured on a physical or VE interface. The source interface should have at least one IP address configured on it. Otherwise, the interface will not be added to the tunnel configuration and an error message similar to the following will be displayed:

```
ERROR - Tunnel source interface 3/1 has no configured IP address.
```

To configure the source interface for a specific tunnel interface, enter commands such as the following.

```plaintext
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# tunnel source ethernet 3/1
```

**Syntax:**

```
[no] tunnel source <ip-address> | ethernet <port-number> | ve <number>
```

The `<ip-address>` variable is the source IP address being configured for the specified tunnel.

The ethernet `<port-number>` variable is the source slot (chassis devices only) and port number of the physical interface being configured for the specified tunnel, for example 3/1.

The ve `<number>` variable is the VE interface number being configured for the specified tunnel.

### Configuring the destination address for a tunnel interface

The destination address should be the address of the IP interface of the device on the other end of the tunnel.

To configure the destination address for a specific tunnel interface, enter commands such as the following.

```plaintext
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# tunnel destination 131.108.5.2
```

**Syntax:**

```
[no] tunnel destination <ip-address>
```

The `<ip-address>` variable is the destination IP address being configured for the specified tunnel.

**NOTE**

Ensure a route to the tunnel destination exists on the tunnel source device. Create a static route if necessary. For configuration details, see “Configuring a static route to a tunnel destination” on page 1075.

### Enabling GRE encapsulation on a tunnel interface

To enable GRE encapsulation on a tunnel interface, enter commands such as the following.

```plaintext
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# tunnel mode gre ip
```

**Syntax:**

```
[no] tunnel mode gre ip
```

**gre** specifies that the tunnel will use GRE encapsulation (IP protocol 47).

**ip** specifies that the tunneling protocol is IPv4.
Configuring a tunnel loopback port for a tunnel interface

For details and important configuration considerations regarding tunnel loopback ports for GRE tunnels, see “Tunnel loopback ports for GRE tunnels” on page 1069 and “Configuration considerations for tunnel loopback ports” on page 1071.

To configure a tunnel loopback port, enter commands such as the following:

FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# tunnel loopback 3/1

Syntax: [no] tunnel loopback <port-number>

The <port-number> is the slot (chassis devices) and port number of the tunnel loopback port for the specified tunnel interface, for example 3/1.

Configuring an IP address for a tunnel interface

An IP address sets a tunnel interface as an IP port and allows the configuration of Layer 3 protocols, such as OSPF, BGP, and Multicast (PIM-DM and PIM-SM) on the port. Note that the subnet cannot overlap other subnets configured on other routing interfaces, and both ends of the tunnel should be in the same subnet, as illustrated in the GRE tunnel configuration example in Figure 144 on page 1079.

To configure an IP address for a specified tunnel interface, enter commands such as the following:

FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# ip address 10.10.3.1/24

Syntax: [no] ip address <ip-address>

The <ip-address> is the IP address being configured for the specified tunnel interface.

Configuring a static route to a tunnel destination

If a route to the tunnel destination does not already exist on the tunnel source, create a static route and set the route to go through the tunnel interface.

FastIron(config)# ip route 131.108.5.0/24 36.0.8.1
FastIron(config)# ip route 10.10.2.0/24 tunnel 1

Syntax: [no] ip route <ip-address> tunnel <tunnel-ID>

The <ip-address> variable is the IP address of the tunnel interface.
The <tunnel-ID> variable is a valid tunnel number or name.

Changing the MTU value for a tunnel interface

For important configuration considerations regarding this feature, see “GRE MTU configuration considerations” on page 1072.

You can set an MTU value for packets entering the tunnel. Packets that exceed either the default MTU value of 1476 bytes or the value that you set using this command, are fragmented and encapsulated with IP/GRE headers for transit through the tunnel. Jumbo packets are supported, although they may be fragmented based on the configured MTU value.

The following command allows you to change the MTU value for packets transiting “tunnel 1”:

FESX Router(config)# interface tunnel 1
FESX Router(config-tnif-1)# tunnel mtu 1200

Syntax: tunnel mtu <packet-size>
The `<packet-size>` variable specifies the maximum MTU size in bytes for the packets transiting the tunnel. Enter a value from 576 – 1476. The default value is 1476.

**NOTE**
To prevent packet loss after the 24 byte GRE header is added, make sure that any physical interface that is carrying GRE tunnel traffic has an IP MTU setting at least 24 bytes greater than the tunnel MTU setting.

### Changing the maximum number of tunnels supported

By default, FastIron IPv6 devices support up to 16 GRE tunnels. You can configure the device to support 16 – 64 GRE tunnels. To change the maximum number of tunnels supported, enter commands such as the following.

```
FastIron(config)# system-max gre-tunnels 32
Reload required. Please write memory and then reload or power cycle.
FastIron(config)# write mem
FastIron(config)# exit
FastIron# reload
```

**NOTE**
You must save the configuration (write mem) and reload the software to place the change into effect.

**Syntax:** `system-max gre-tunnels <number>`

The `<number>` variable specifies the number of GRE tunnels that can be supported on the device. The permissible range is 16 – 64. The default is 16.

### Configuring GRE link keepalive

When GRE tunnels are used in combination with static routing or policy-based routing, and a dynamic routing protocol such as RIP, BGP, or OSPF is not deployed over the GRE tunnel, a configured tunnel does not have the ability to bring down the line protocol of either tunnel endpoint, if the far end becomes unreachable. Traffic sent on the tunnel cannot follow alternate paths because the tunnel is always UP. To avoid this scenario, enable GRE link keepalive, which will maintain or place the tunnel in an UP or DOWN state based upon the periodic sending of keepalive packets and the monitoring of responses to the packets. If the packets fail to reach the tunnel far end more frequently than the configured number of retries, the tunnel is placed in the DOWN state.

To enable GRE link keepalive, configure it on one end of the tunnel and ensure the other end of the tunnel has GRE enabled.

To configure GRE link keepalive, enter commands such as the following.

```
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# keepalive 12 4
```

These commands configure the device to wait for 4 consecutive lost keepalive packets before bringing the tunnel down. There will be a 12 second interval between each packet. Note that when the tunnel comes up, it would immediately (within one second) send the first keepalive packet.

**Syntax:** `[no] keepalive <seconds> <retries>`

Use the `no` form of the command to disable the keepalive option.

The `<seconds>` variable specifies the number of seconds between each initiation of a keepalive message. The range for this interval is 2 – 32767 seconds. The default value is 10 seconds.
The <retries> variable specifies the number of times that a packet is sent before the system places the tunnel in the DOWN state. Possible values are from 1 – 255. The default number of retries is 3.

Use the show interface tunnel and show ip tunnel traffic commands to view the GRE link keepalive configuration. For details, see “Displaying GRE tunneling information” on page 1080.

**Configuring Path MTU Discovery (PMTUD)**

Path MTU Discovery (PMTUD) support is described in the section “Path MTU Discovery (PMTUD) support” on page 1068. PMTUD is enabled by default on tunnel interfaces. This section describes how to disable and re-enable PMTUD on a tunnel interface, change the PMTUD age timer, manually clear the tunnel PMTUD, and view the PMTUD configuration.

**Disabling and re-enabling PMTUD**

PMTUD is enabled by default. To disable it, enter the following command:

```
FastIron(config-tnif-1)# tunnel path-mtu-discovery disable
```

To re-enable PMTUD after it has been disabled, enter the following command:

```
FastIron(config-tnif-1)# no tunnel path-mtu-discovery disable
```

**Changing the age timer for PMTUD**

By default, when PMTUD is enabled on a tunnel interface, the path MTU is reset to its original value every 10 minutes. If desired, you can change the reset time (default age timer) to a value of up to 30 minutes. To do so, enter a command such as the following on the GRE tunnel interface.

```
FastIron(config-tnif-1)# tunnel path-mtu-discovery age-timer 20
```

This command configures the device to wait for 20 minutes before resetting the path MTU to its original value.

**Syntax:**

```
[no] tunnel path-mtu-discovery age-timer  <minutes> | infinite
```

For <minutes>, enter a value from 10 to 30.

Enter **infinite** to disable the timer.

**Clearing the PMTUD dynamic value**

To reset a dynamically-configured MTU on a tunnel interface back to the configured value, enter the following command.

```
FastIron(config)# clear ip tunnel pmtud 1
```

**Syntax:**

```
clear ip tunnel pmtud <tunnel-ID>
```

The <tunnel-ID> variable is a valid tunnel number or name.

**Viewing PMTUD configuration details**

use the `show interface tunnel` command to view the PMTUD configuration and to determine whether PMTUD has reduced the size of the MTU. For details about the `show interface tunnel` command, see “Displaying GRE tunneling information” on page 1080.

**Enabling IPv4 multicast routing over a GRE tunnel**

This section describes how to enable IPv4 multicast protocols, PIM Sparse (PIM-SM) and PIM Dense (PIM-DM), on a GRE tunnel. Perform the procedures in this section after completing the required tasks in Table 178 on page 1072.
IPv4 point-to-point GRE tunnels

For an overview of multicast routing support over a GRE tunnel, see “Support for IPv4 multicast routing over GRE tunnels” on page 1070. To view information about multicast protocols and GRE tunnel-specific information, see “Displaying multicast protocols and GRE tunneling information” on page 1082.

**NOTE**
Each PIM-enabled tunnel interface must have a *dedicated* tunnel loopback port. This differs from GRE tunnels that support unicast traffic only. For unicast traffic, multiple GRE tunnels can use the same tunnel loopback port for traffic.

**Enabling PIM-SM on a GRE tunnel**
To enable PIM-SM on a GRE tunnel interface, enter commands such as the following:

```
FastIron(config)# interface tunnel 10
FastIron(config-tnif-10)# ip pim-sparse
```
Syntax: Syntax: `[no] ip pim-sparse`

Use the `no` form of the command to disable PIM-SM on the tunnel interface.

**Enabling PIM-DM on a GRE tunnel interface**
To enable PIM-DM on a GRE tunnel interface, enter commands such as the following:

```
FastIron(config)# interface tunnel 10
FastIron(config-tnif-10)# ip pim
```
Syntax: Syntax: `[no] ip pim`

Use the `no` form of the command to disable PIM-DM on the tunnel interface.
Example point-to-point GRE tunnel configuration

In the configuration example shown in Figure 144, a GRE Tunnel is configured between FastIron A and FastIron B. Traffic between networks 10.10.1.0/24 and 10.10.2.0/24 is encapsulated in a GRE packet sent through the tunnel on the 10.10.3.0 network, and unpacked and sent to the destination network. A static route is configured at each Layer 3 switch to go through the tunnel interface to the target network.

**FIGURE 144  Point-to-point GRE tunnel configuration example**

The following shows the configuration commands for the example shown in Figure 144.

**Configuration example for FastIron A**

```
FastIron (config)# interface ethernet 3/1
FastIron (config-if-e1000-3/1)# ip address 36.0.8.108/24
FastIron (config)# exit
FastIron (config)# interface tunnel 1
FastIron(config-tnif-1)# tunnel source 36.0.8.108
FastIron(config-tnif-1)# tunnel destination 131.108.5.2
FastIron(config-tnif-1)# tunnel mode gre ip
FastIron(config-tnif-1)# tunnel loopback 4/1
FastIron(config-tnif-1)# ip address 10.10.3.1/24
FastIron(config-tnif-1)# exit
FastIron (config)# ip route 131.108.5.0/24 36.0.8.1
FastIron(config)# ip route 10.10.2.0/24 tunnel 1
```

**Configuration example for FastIron B**

```
FastIron(config)# interface ethernet 5/1
FastIron(config-if-e1000-5/1)# ip address 131.108.5.2/24
FastIron(config)# exit
FastIron(config)# interface tunnel 1
FastIron(config-tnif-1)# tunnel source 131.108.5.2
FastIron(config-tnif-1)# tunnel destination 36.0.8.108
FastIron(config-tnif-1)# tunnel mode gre ip
```
Displaying GRE tunneling information

This section describes the `show` commands that display the GRE tunnels configuration, the link status of the GRE tunnels, and the routes that use GRE tunnels. To display information about multicast protocols and GRE tunnels, see “Displaying multicast protocols and GRE tunneling information” on page 1082.

To display GRE tunneling Information, use the following commands:

- `show ip interface`
- `show ip route`
- `show ip interface tunnel`
- `show ip tunnel traffic`
- `show interface tunnel`

The following shows an example output of the `show ip interface` command, which includes information about GRE tunnels.

```
FastIron# show ip interface
Interface       IP-Address     OK?  Method    Status   Protocol
Tunnel 1        10.10.3.1      YES  NVRAM     up       up
```

For field definitions, see Table 182 on page 1090.

**Syntax:** `show ip interface`

The `show ip route` command displays routes that are pointing to a GRE tunnel as shown in the following example.

```
FastIron# show ip route
Total number of IP routes: 3, avail: 79996 (out of max 80000)
B:BGP D:Connected  R:RIP  S:Static  O:OSPF *:Candidate default
    Destination     NetMask         Gateway         Port       Cost   Type
 1       7.1.1.0         255.255.255.0   0.0.0.0         7          1      D
 2       7.1.2.0         255.255.255.0   7.1.1.3         7          1      S
 3       10.34.3.0       255.255.255.0   0.0.0.0         tn3        1      D
```

For field definitions, see Table 186 on page 1097.

**Syntax:** `show ip route`

The `show ip interface tunnel` command displays the link status and IP address configuration for an IP tunnel interface as shown in the following example.

```
FastIron# show ip interface tunnel 1
Interface Tunnel 1
    port state: UP
    ip address: 21.21.21.2     subnet mask: 255.255.255.0
    encapsulation: GRE, mtu: 1476, metric: 1
    directed-broadcast-forwarding: disabled
    proxy-arp: disabled
```
ip arp-age: 10 minutes
No Helper Addresses are configured
No inbound ip access-list is set
No outgoing ip access-list is set

Syntax: show ip interface tunnel [<tunnel-ID>]

The <tunnel-ID> variable is a valid tunnel number or name.

The show interface tunnel command displays the GRE tunnel configuration.

FastIron# show int tunnel 3
Tunnel3 is up, line protocol is up
Hardware is Tunnel
Tunnel source 7.1.1.1
Tunnel destination is 7.1.2.3
Tunnel loopback is not configured
Port name is customer1001
Internet address is 10.34.3.2/24, MTU 1476 bytes, encapsulation GRE
Keepalive is Enabled: Interval 10, No.of Retries 3
Total Keepalive Pkts Tx: 2, Rx: 2
Path MTU Discovery: Enabled, MTU is 1476 bytes

Syntax: show interface tunnel [<tunnel-ID>]

This display shows the following information.

**TABLE 179** CLI Display of show interface tunnel command

<table>

**Displaying multicast protocols and GRE tunneling information**

The following `show` commands display information about multicast protocols and GRE tunnels:

- `show ip pim interface`
- `show ip pim nbr`
- `show ip mcache`
- `show ip pim flow`
- `show statistics`

**NOTE**

All other `show` commands that are supported currently for Ethernet, VE, and IP loopback interfaces, are also supported for tunnel interfaces. To display information for a tunnel interface, specify the tunnel in the format `tunnel <num>`. For example, `show ip pim interface tunnel 1`. In the show output, the tunnel interface will display in the format `tn<num>`. In some cases, the Ethernet port that the tunnel is using will also display in the format `tn<num>:e<port>`.

The following shows an example output of the `show ip pim interface` command. The lines in bold highlight the GRE tunnel-specific information.

```
FastIron# show ip pim interface
```
Interface e1
PIM Dense: V2
TTL Threshold: 1, Enabled, DR: itself
Local Address: 10.10.10.10

Interface tn1
PIM Dense: V2
TTL Threshold: 1, Enabled, DR: 1.1.1.20 on tn1:e2
Local Address: 1.1.1.10
Neighbor: 1.1.1.20

Syntax: `show ip pim interface`

The following shows an example output of the `show ip pimnbr` command. The line in bold shows the GRE tunnel-specific information.

FastIron# show ip pim nbr
Total number of neighbors: 1 on 1 ports
Port   Phy_p      Neighbor        Holdtime Age   UpTime
tn1    tn1:e2     1.1.1.20        180      60    1740

Syntax: `show ip pim nbr`

The following shows an example output of the `show ip pim mcache` command. The line in bold shows the GRE tunnel-specific information.

FastIron# show ip pim mcache 230.1.1.1
1    (10.10.10.1 230.1.1.1) in e1 (e1), cnt=629
Source is directly connected
L3 (HW) 1: tn1:e2(VL1)  
fast=1 slow=0 pru=1 graft
age=120s up-time=8m HW=1 L2-vidx=8191 has mll

Syntax: `show ip pim mcache <ip-address>`

The following shows an example output of the `show ip pim flow` command. The text in bold highlights the GRE tunnel-specific information.

FastIron# show ip pim flow 230.1.1.1
Multicast flow (10.10.10.1 230.1.1.1):
Vidx for source vlan forwarding: 8191 (Blackhole, no L2 clients)
Hardware MC Entry hit on devices: 0 1 2 3
MC Entry[0x0c08040]: 00014001 000022ee 0ff0001 00000000
--- MLL contents read from Device 0 ---
MLL Data[0x018c0010]: 0021ff8d 00000083 00000000 00000000
First : Last:1, outlif:60043ff1 00000000, TNL:1(e2)

1 flow printed

Syntax: `show ip pim flow`

The following shows an example output of the `show statistics` command. The below statistics demonstrate an example where the encapsulated multicast traffic ingresses a tunnel endpoint on port e 2, egresses and re-ingresses as native multicast traffic on the loopback port e 4, and is then forwarded to the outbound interface e 1.
Displaying IP configuration information and statistics

The following sections describe IP display options for Layer 3 Switches and Layer 2 Switches:

- To display IP information on a Layer 3 Switch, refer to “Displaying IP information – Layer 3 Switches” on page 1085.
- To display IP information on a Layer 2 Switch, refer to “Displaying IP information – Layer 2 Switches” on page 1100.

Changing the network mask display to prefix format

By default, the CLI displays network masks in classical IP address format (example: 255.255.255.0). You can change the displays to prefix format (example: /18) on a Layer 3 Switch or Layer 2 Switch using the following CLI method.

**NOTE**
This option does not affect how information is displayed in the Web Management Interface.

To enable CIDR format for displaying network masks, entering the following command at the global CONFIG level of the CLI.

```
FastIron(config)# ip show-subnet-length
```

**Syntax:** [no] ip show-subnet-length
Displaying IP information – Layer 3 Switches

You can display the following IP configuration information statistics on Layer 3 Switches:

- Global IP parameter settings and IP access policies – refer to “Displaying global IP configuration information” on page 1085.
- IP interfaces – refer to “Displaying IP interface information” on page 1089.
- ARP entries – refer to “Displaying ARP entries” on page 1090.
- Static ARP entries – refer to “Displaying ARP entries” on page 1090.
- IP forwarding cache – refer to “Displaying the forwarding cache” on page 1093.
- IP route table – refer to “Displaying the IP route table” on page 1094.
- IP traffic statistics – refer to “Displaying IP traffic statistics” on page 1098.

The sections below describe how to display this information.

In addition to the information described below, you can display the following IP information. This information is described in other parts of this guide:

- RIP
- OSPF
- BGP4
- DVMRP
- PIM
- VRRP or VRRPE

Displaying global IP configuration information

To display IP configuration information, enter the following command at any CLI level.

```
FastIron# show ip
```

### Global Settings

- **ttl**: 64, **arp-age**: 10, **bootp-relay-max-hops**: 4
- **router-id**: 207.95.11.128
- **enabled**: UDP-Broadcast-Forwarding IRDP Proxy-ARP RARP OSPF
- **disabled**: BGP4 Load-Sharing RIP DVMRP FSRP VRRP

### Static Routes

<table>
<thead>
<tr>

<td>any</td>
<td>any</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Syntax:** show ip

**NOTE**

This command has additional options, which are explained in other sections in this guide, including the sections below this one.
This display shows the following information.

**TABLE 181**  CLI Display of global IP configuration information – Layer 3 Switch

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Global settings</strong></td>
<td></td>
</tr>
<tr>
<td>ttl</td>
<td>The Time-To-Live (TTL) for IP packets. The TTL specifies the maximum number of router hops a packet can travel before reaching the Brocade router. If the packet TTL value is higher than the value specified in this field, the Brocade router drops the packet. To change the maximum TTL, refer to “Changing the TTL threshold” on page 1011.</td>
</tr>
<tr>
<td>arp-age</td>
<td>The ARP aging period. This parameter specifies how many minutes an inactive ARP entry remains in the ARP cache before the router ages out the entry. To change the ARP aging period, refer to “Changing the ARP aging period” on page 1007.</td>
</tr>
<tr>
<td>bootp-relay-max-hops</td>
<td>The maximum number of hops away a BootP server can be located from the Brocade router and still be used by the router clients for network booting. To change this value, refer to “Changing the maximum number of hops to a BootP relay server” on page 1037.</td>
</tr>
<tr>
<td>router-id</td>
<td>The 32-bit number that uniquely identifies the Brocade router. By default, the router ID is the numerically lowest IP interface configured on the router. To change the router ID, refer to “Changing the router ID” on page 1002.</td>
</tr>
<tr>
<td>enabled</td>
<td>The IP-related protocols that are enabled on the router.</td>
</tr>
<tr>
<td>disabled</td>
<td>The IP-related protocols that are disabled on the router.</td>
</tr>
</tbody>
</table>

**Static routes**

<table>
<thead>
<tr>
<th>Index</th>
<th>The row number of this entry in the IP route table.</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Address</td>
<td>The IP address of the route destination.</td>
</tr>
<tr>
<td>Subnet Mask</td>
<td>The network mask for the IP address.</td>
</tr>
<tr>
<td>Next Hop Router</td>
<td>The IP address of the router interface to which the Brocade router sends packets for the route.</td>
</tr>
<tr>
<td>Metric</td>
<td>The cost of the route. Usually, the metric represents the number of hops to the destination.</td>
</tr>
<tr>
<td>Distance</td>
<td>The administrative distance of the route. The default administrative distance for static IP routes in Brocade routers is 1. To list the default administrative distances for all types of routes or to change the administrative distance of a static route, refer to “Changing administrative distances” on page 1327.</td>
</tr>
</tbody>
</table>

**Policies**

<table>
<thead>
<tr>
<th>Index</th>
<th>The policy number. This is the number you assigned the policy when you configured it.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>The action the router takes if a packet matches the comparison values in the policy. The action can be one of the following: • deny – The router drops packets that match this policy. • permit – The router forwards packets that match this policy.</td>
</tr>
<tr>
<td>Source</td>
<td>The source IP address the policy matches.</td>
</tr>
<tr>
<td>Destination</td>
<td>The destination IP address the policy matches.</td>
</tr>
</tbody>
</table>
Displaying CPU utilization statistics

You can display CPU utilization statistics for IP protocols using the `show process cpu` command.

The `show process cpu` command includes CPU utilization statistics for ACL, 802.1x, and L2VLAN. L2VLAN contains any packet transmitted to a VLAN by the CPU, including unknown unicast, multicast, broadcast, and CPU forwarded Layer 2 traffic.

### TABLE 181  CLI Display of global IP configuration information – Layer 3 Switch (Continued)

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>

<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
</tbody>
</table>

To display utilization statistics for a specific number of seconds, enter a command such as the following.

```
FastIron# show process cpu 2
Statistics for last 1 sec and 80 ms
```

<table>
<thead>
<tr>
<th>Process Name</th>
<th>Sec(%)</th>
<th>Time(ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACL</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>ARP</td>
<td>1.01</td>
<td>0.01</td>
</tr>
<tr>
<td>BGP</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>DOT1X</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>GVRP</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>ICMP</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>IP</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>L2VLAN</td>
<td>1.01</td>
<td>0.01</td>
</tr>
<tr>
<td>OSPF</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>RIP</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>STP</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>VRRP</td>
<td>0.00</td>
<td>0.00</td>
</tr>
</tbody>
</table>

When you specify how many seconds’ worth of statistics you want to display, the software selects
the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

Syntax: show process cpu [<num>]

The <num> parameter specifies the number of seconds and can be from 1 – 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.

**Displaying IP Interface information**

To display IP interface information, enter the following command at any CLI level.

FastIron# show ip interface

<table>
<thead>
<tr>
<th>Interface</th>
<th>IP-Address</th>
<th>OK? Method</th>
<th>Status</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet 1/1</td>
<td>207.95.6.173</td>
<td>YES NVRAM</td>
<td>up</td>
<td>up</td>
</tr>
<tr>
<td>Ethernet 1/2</td>
<td>3.3.3.3</td>
<td>YES manual</td>
<td>up</td>
<td>up</td>
</tr>
<tr>
<td>Loopback 1</td>
<td>1.2.3.4</td>
<td>YES NVRAM</td>
<td>down</td>
<td>down</td>
</tr>
</tbody>
</table>

Syntax: show ip interface [ethernet [<slotnum>/]<portnum>] | [loopback <num>] | [ve <num>]
This display shows the following information.

**TABLE 182**  CLI display of interface IP configuration information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
<td>The type and the slot and port number of the interface.</td>
</tr>
<tr>
<td>IP-Address</td>
<td>The IP address of the interface. <strong>NOTE:</strong> If an “s” is listed following the address, this is a secondary address. When the address was configured, the interface already had an IP address in the same subnet, so the software required the “secondary” option before the software could add the interface.</td>
</tr>
<tr>
<td>OK?</td>
<td>Whether the IP address has been configured on the interface.</td>
</tr>
<tr>
<td>Method</td>
<td>Whether the IP address has been saved in NVRAM. If you have set the IP address for the interface in the CLI or Web Management Interface, but have not saved the configuration, the entry for the interface in the Method field is “manual”.</td>
</tr>
<tr>
<td>Status</td>
<td>The link status of the interface. If you have disabled the interface with the disable command, the entry in the Status field will be “administratively down”. Otherwise, the entry in the Status field will be either “up” or “down”.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Whether the interface can provide two-way communication. If the IP address is configured, and the link status of the interface is up, the entry in the protocol field will be “up”. Otherwise the entry in the protocol field will be “down”.</td>
</tr>
</tbody>
</table>

To display detailed IP information for a specific interface, enter a command such as the following.

```plaintext
FastIron# show ip interface ethernet 1/1
Interface Ethernet 1/1
  port state: UP
  ip address: 192.168.9.51      subnet mask: 255.255.255.0
  encapsulation: ETHERNET, mtu: 1500, metric: 1
  directed-broadcast-forwarding: disabled
  proxy-arp: disabled
  ip arp-age: 10 minutes
  Ip Flow switching is disabled
  No Helper Addresses are configured.
  No inbound ip access-list is set
  No outgoing ip access-list is set
```

**Displaying ARP entries**

You can display the ARP cache and the static ARP table. The ARP cache contains entries for devices attached to the Layer 3 Switch. The static ARP table contains the user-configured ARP entries. An entry in the static ARP table enters the ARP cache when the entry interface comes up.

The tables require separate display commands or Web management options.
Displaying the ARP cache
To display the contents of the ARP cache, enter the following command at any CLI level.

FastIron# show arp

Total number of ARP entries: 5

<table>
<thead>
<tr>
<th>IP Address</th>
<th>MAC Address</th>
<th>Type</th>
<th>Age</th>
<th>Port</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>207.95.6.102</td>
<td>0800.5afc.ea21</td>
<td>Dynamic</td>
<td>0</td>
<td>6</td>
<td>Valid</td>
</tr>
<tr>
<td>207.95.6.18</td>
<td>00a0.24d2.04ed</td>
<td>Dynamic</td>
<td>3</td>
<td>6</td>
<td>Pend</td>
</tr>
<tr>
<td>207.95.6.54</td>
<td>00a0.24ab.cd2b</td>
<td>Dynamic</td>
<td>0</td>
<td>6</td>
<td>Pend</td>
</tr>
<tr>
<td>207.95.6.101</td>
<td>0800.207c.a7fa</td>
<td>Dynamic</td>
<td>0</td>
<td>6</td>
<td>Valid</td>
</tr>
<tr>
<td>207.95.6.211</td>
<td>00c0.2638.ac9c</td>
<td>Dynamic</td>
<td>0</td>
<td>6</td>
<td>Valid</td>
</tr>
</tbody>
</table>

Syntax: show arp [ethernet [<slotnum>/]<portnum> | mac-address <xxxx.xxxx.xxxx> [<mask>] | <ip-addr> [<ip-mask>] [num>

The <slotnum> parameter is required on chassis devices.

The <portnum> parameter lets you restrict the display to entries for a specific port.

The mac-address <xxxx.xxxx.xxxx> parameter lets you restrict the display to entries for a specific MAC address.

The <mask> parameter lets you specify a mask for the mac-address <xxxx.xxxx.xxxx> parameter, to display entries for multiple MAC addresses. Specify the MAC address mask as “f”s and “0”s, where “f”s are significant bits.

The <ip-addr> and <ip-mask> parameters let you restrict the display to entries for a specific IP address and network mask. Specify the IP address masks in standard decimal mask format (for example, 255.255.0.0).

NOTE
The <ip-mask> parameter and <mask> parameter perform different operations. The <ip-mask> parameter specifies the network mask for a specific IP address, whereas the <mask> parameter provides a filter for displaying multiple MAC addresses that have specific values in common.

The <num> parameter lets you display the table beginning with a specific entry number.

NOTE
The entry numbers in the ARP cache are not related to the entry numbers for static ARP table entries.
This display shows the following information. The number in the left column of the CLI display is the row number of the entry in the ARP cache. This number is not related to the number you assign to static MAC entries in the static ARP table.

**TABLE 183** CLI display of ARP cache

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Address</td>
<td>The IP address of the device.</td>
</tr>
<tr>
<td>MAC Address</td>
<td>The MAC address of the device.</td>
</tr>
<tr>
<td>Type</td>
<td>The ARP entry type, which can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Dynamic – The Layer 3 Switch learned the entry from an incoming packet.</td>
</tr>
<tr>
<td></td>
<td>• Static – The Layer 3 Switch loaded the entry from the static ARP table when the device for the entry was connected to the Layer 3 Switch.</td>
</tr>
<tr>
<td></td>
<td>• DHCP – The Layer 3 Switch learned the entry from the DHCP binding address table.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> If the type is DHCP, the port number will not be available until the entry gets resolved through ARP.</td>
</tr>
<tr>
<td>Age</td>
<td>The number of minutes the entry has remained unused. If this value reaches the ARP aging period, the entry is removed from the table.</td>
</tr>
<tr>
<td></td>
<td>To display the ARP aging period, refer to “Displaying global IP configuration information” on page 1085. To change the ARP aging interval, refer to “Changing the ARP aging period” on page 1007.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> Static entries do not age out.</td>
</tr>
<tr>
<td>Port</td>
<td>The port on which the entry was learned.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> If the ARP entry type is DHCP, the port number will not be available until the entry gets resolved through ARP.</td>
</tr>
<tr>
<td>Status</td>
<td>The status of the entry, which can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Valid – This a valid ARP entry.</td>
</tr>
<tr>
<td></td>
<td>• Pend – The ARP entry is not yet resolved.</td>
</tr>
</tbody>
</table>

**Displaying the static ARP table**

To display the static ARP table instead of the ARP cache, enter the following command at any CLI level.

`FastIron# show ip static-arp`

**Static ARP table size: 512, configurable from 512 to 1024**

<table>
<thead>
<tr>
<th>Index</th>
<th>IP Address</th>
<th>MAC Address</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>207.95.6.111</td>
<td>0800.093b.d210</td>
<td>1/1</td>
</tr>
<tr>
<td>3</td>
<td>207.95.6.123</td>
<td>0800.093b.d211</td>
<td>1/1</td>
</tr>
</tbody>
</table>

This example shows two static entries. Note that since you specify an entry index number when you create the entry, it is possible for the range of index numbers to have gaps, as shown in this example.

**NOTE**

The entry number you assign to a static ARP entry is not related to the entry numbers in the ARP cache.

**Syntax:** `show ip static-arp [ethernet [<slotnum>/]<portnum>] | mac-address <xxxx.xxxx.xxxx> [mask:] | ip-addr [<ip-mask>] [<num>]`

The `<slotnum>` parameter is required on chassis devices.
The `<portnum>` parameter lets you restrict the display to entries for a specific port.

The `mac-address <xxxx.xxxx.xxxx>` parameter lets you restrict the display to entries for a specific MAC address.

The `<mask>` parameter lets you specify a mask for the `mac-address <xxxx.xxxx.xxxx>` parameter, to display entries for multiple MAC addresses. Specify the MAC address mask as “f”s and “0”s, where “f”s are significant bits.

The `<ip-addr>` and `<ip-mask>` parameters let you restrict the display to entries for a specific IP address and network mask. Specify the IP address masks in standard decimal mask format (for example, 255.255.0.0).

**NOTE**

The `<ip-mask>` parameter and `<mask>` parameter perform different operations. The `<ip-mask>` parameter specifies the network mask for a specific IP address, whereas the `<mask>` parameter provides a filter for displaying multiple MAC addresses that have specific values in common.

The `<num>` parameter lets you display the table beginning with a specific entry number.

**TABLE 184** CLI display of static ARP table

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static ARP table size</td>
<td>The maximum number of static entries that can be configured on the device using the current memory allocation. The range of valid memory allocations for static ARP entries is listed after the current allocation. To change the memory allocation for static ARP entries, refer to “Changing the maximum number of entries the static ARP table can hold” on page 1010.</td>
</tr>
<tr>
<td>Index</td>
<td>The number of this entry in the table. You specify the entry number when you create the entry.</td>
</tr>
<tr>
<td>IP Address</td>
<td>The IP address of the device.</td>
</tr>
<tr>
<td>MAC Address</td>
<td>The MAC address of the device.</td>
</tr>
<tr>
<td>Port</td>
<td>The port attached to the device the entry is for.</td>
</tr>
</tbody>
</table>

**Displaying the forwarding cache**

To display the IP forwarding cache, enter the following command at any CLI level.

FastIron# show ip cache

Total number of cache entries: 3

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Next Hop</th>
<th>MAC Address</th>
<th>Type</th>
<th>Port</th>
<th>Vlan</th>
<th>Pri</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 192.168.1.11</td>
<td>DIRECT</td>
<td>0000.0000.0000</td>
<td>PU</td>
<td>n/a</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>2 192.168.1.1255</td>
<td>DIRECT</td>
<td>0000.0000.0000</td>
<td>PU</td>
<td>n/a</td>
<td>0</td>
<td></td>

<tr>
<td>3 255.255.255.255</td>
<td>DIRECT</td>
<td>0000.0000.0000</td>
<td>PU</td>
<td>n/a</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

**Syntax: show ip cache [ <ip-addr> ] | [ <num> ]**

The `<ip-addr>` parameter displays the cache entry for the specified IP address.

The `<num>` parameter displays the cache beginning with the row following the number you enter. For example, to begin displaying the cache at row 10, enter the following command.
show ip cache 9

The **show ip cache** command displays the following information.

**TABLE 185** CLI display of IP forwarding cache – Layer 3 Switch

<table>
<thead>
<tr>
<th>This field…</th>
<th>Displays…</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Address</td>
<td>The IP address of the destination.</td>
</tr>
<tr>
<td>Next Hop</td>
<td>The IP address of the next-hop router to the destination. This field contains either an IP address or the value DIRECT. DIRECT means the destination is either directly attached or the destination is an address on this Brocade device. For example, the next hop for loopback addresses and broadcast addresses is shown as DIRECT.</td>
</tr>
<tr>
<td>MAC</td>
<td>The MAC address of the destination.</td>

<td>2</td>
<td>R</td>
</tr>
</tbody>
</table>

**Syntax:** `show ip route [ip-addr] [ip-mask] [longer] [none-bgp] | <num> | bgp | direct | ospf | rip | static`

The `<ip-addr>` parameter displays the route to the specified IP address.
The `<ip-mask>` parameter lets you specify a network mask or, if you prefer CIDR format, the number of bits in the network mask. If you use CIDR format, enter a forward slash immediately after the IP address, then enter the number of mask bits (for example: 209.157.22.0/24 for 209.157.22.0 255.255.255.0).

The `longer` parameter applies only when you specify an IP address and mask. This option displays only the routes for the specified IP address and mask. See the example below.

The `none-bgp` parameter displays only the routes that did not come from BGP4.

The `<num>` option displays the route table entry whose row number corresponds to the number you specify. For example, if you want to display the tenth row in the table, enter “10”.

The `bgp` option displays the BGP4 routes.

The `direct` option displays only the IP routes that are directly attached to the Layer 3 Switch.

The `ospf` option displays the OSPF routes.

The `rip` option displays the RIP routes.

The `static` option displays only the static IP routes.

The `default` routes are displayed first.

Here is an example of how to use the `direct` option. To display only the IP routes that go to devices directly attached to the Layer 3 Switch, enter the following command.

```
FastIron# show ip route direct
Start index: 1  B:BGP D:Connected  R:RIP  S:Static  O:OSPF *:Candidate default

   Destination       NetMask           Gateway           Port   Cost   Type
     209.157.22.0      255.255.255.0     0.0.0.0           4/11   1      D
```

Notice that the route displayed in this example has “D” in the Type field, indicating the route is to a directly connected device.

Here is an example of how to use the `static` option. To display only the static IP routes, enter the following command.

```
FastIron# show ip route static
Start index: 1  B:BGP D:Connected  R:RIP  S:Static  O:OSPF *:Candidate default

   Destination       NetMask           Gateway           Port   Cost   Type
     192.144.33.11     255.255.255.0     209.157.22.12     1/1    2      S
```

Notice that the route displayed in this example has “S” in the Type field, indicating the route is static.
Here is an example of how to use the `longer` option. To display only the routes for a specified IP address and mask, enter a command such as the following.

```
FastIron# show ip route 209.159.0.0/16 longer
Starting index: 1 B:BGP D:Directly-Connected R:RIP S:Static O:OSPF
Destination NetMask Gateway Port Cost Type
```

```
52 209.159.38.0 255.255.255.0 207.95.6.101 1/1 1 S
53 209.159.39.0 255.255.255.0 207.95.6.101 1/1 1 S
54 209.159.40.0 255.255.255.0 207.95.6.101 1/1 1 S
55 209.159.41.0 255.255.255.0 207.95.6.101 1/1 1 S
56 209.159.42.0 255.255.255.0 207.95.6.101 1/1 1 S
57 209.159.43.0 255.255.255.0 207.95.6.101 1/1 1 S
58 209.159.44.0 255.255.255.0 207.95.6.101 1/1 1 S
59 209.159.45.0 255.255.255.0 207.95.6.101 1/1 1 S
60 209.159.46.0 255.255.255.0 207.95.6.101 1/1 1 S
```

This example shows all the routes for networks beginning with 209.159. The mask value and `longer` parameter specify the range of network addresses to be displayed. In this example, all routes within the range 209.159.0.0 – 209.159.255.255 are listed.

The `summary` option displays a summary of the information in the IP route table. The following is an example of the output from this command.

Example

```
FastIron# show ip route summary
IP Routing Table - 35 entries:
 6 connected, 28 static, 0 RIP, 1 OSPF, 0 BGP, 0 ISIS, 0 MPLS
Number of prefixes:
 /0: 1 /16: 27 /22: 1 /24: 5 /32: 1
```

Syntax: show ip route summary

In this example, the IP route table contains 35 entries. Of these entries, 6 are directly connected devices, 28 are static routes, and 1 route was calculated through OSPF. One of the routes has a zero-bit mask (this is the default route), 27 have a 22-bit mask, 5 have a 24-bit mask, and 1 has a 32-bit mask.
The following table lists the information displayed by the `show ip route` command.

**TABLE 186  CLI display of IP route table**

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Destination</td>
<td>The destination network of the route.</td>
</tr>
<tr>
<td>NetMask</td>
<td>The network mask of the destination address.</td>
</tr>
<tr>
<td>Gateway</td>
<td>The next-hop router.</td>
</tr>
<tr>
<td>Port</td>
<td>The port through which this router sends packets to reach the route's destination.</td>
</tr>
<tr>
<td>Cost</td>
<td>The route's cost.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>The route type, which can be one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>The route was learned from BGP.</td>
</tr>
<tr>
<td>D</td>
<td>The destination is directly connected to this Layer 3 Switch.</td>
</tr>
<tr>
<td>R</td>
<td>The route was learned from RIP.</td>
</tr>
<tr>
<td>S</td>
<td>The route is a static route.</td>
</tr>
<tr>
<td>*</td>
<td>The route is a candidate default route.</td>
</tr>
<tr>
<td>O</td>
<td>The route is an OSPF route. Unless you use the <code>ospf</code> option to display the route table, “O” is used for all OSPF routes. If you do use the <code>ospf</code> option, the following type codes are used:</td>
</tr>
<tr>
<td>IA</td>
<td>The route is an OSPF inter area route (a route that passes from one area into another).</td>
</tr>
<tr>
<td>E1</td>
<td>The route is an OSPF external type 1 route.</td>
</tr>
<tr>
<td>E2</td>
<td>The route is an OSPF external type 2 route.</td>
</tr>
</tbody>
</table>

**Clearing IP routes**

If needed, you can clear the entire route table or specific individual routes.

To clear all routes from the IP route table, enter the following command.

```
FastIron# clear ip route
```

To clear route 209.157.22.0/24 from the IP routing table, enter the following command.

```
FastIron# clear ip route 209.157.22.0/24
```

**Syntax:** clear ip route [\langle ip-addr \rangle \langle ip-mask \rangle]

or

**Syntax:** clear ip route [\langle ip-addr \rangle/\langle mask-bits \rangle]
Displaying IP traffic statistics

To display IP traffic statistics, enter the following command at any CLI level.

FastIron# show ip traffic
IP Statistics
  139 received, 145 sent, 0 forwarded
  0 filtered, 0 fragmented, 0 reassembled, 0 bad header
  0 no route, 0 unknown proto, 0 no buffer, 0 other errors

ICMP Statistics
Received:
  0 total, 0 errors, 0 unreachable, 0 time exceed
  0 parameter, 0 source quench, 0 redirect, 0 echo,
  0 echo reply, 0 timestamp, 0 timestamp reply, 0 addr mask
  0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation
Sent:
  0 total, 0 errors, 0 unreachable, 0 time exceed
  0 parameter, 0 source quench, 0 redirect, 0 echo,
  0 echo reply, 0 timestamp, 0 timestamp reply, 0 addr mask
  0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation

UDP Statistics
  1 received, 0 sent, 1 no port, 0 input errors

TCP Statistics
  0 active opens, 0 passive opens, 0 failed attempts
  0 active resets, 0 passive resets, 0 input errors
  138 in segments, 141 out segments, 4 retransmission

RIP Statistics
  0 requests sent, 0 requests received
  0 responses sent, 0 responses received
  0 unrecognized, 0 bad version, 0 bad addr family, 0 bad req format
  0 bad metrics, 0 bad resp format, 0 resp not from rip port
  0 resp from loopback, 0 packets rejected

The show ip traffic command displays the following information.

**TABLE 187**  CLI display of IP traffic statistics – Layer 3 Switch

<table>

<tr>
<td>no buffer</td>
<td>This information is used by Brocade customer support.</td>
</tr>
<tr>
<td>other errors</td>
<td>The number of packets dropped due to error types other than those listed above.</td>
</tr>
</tbody>
</table>

**ICMP statistics**

The ICMP statistics are derived from RFC 792, “Internet Control Message Protocol”, RFC 950, “Internet Standard Subnetting Procedure”, and RFC 1256, “ICMP Router Discovery Messages”. Statistics are organized into Sent and Received. The field descriptions below apply to each.

| total      | The total number of ICMP messages sent or received by the device.            |
| errors     | This information is used by Brocade customer support.                      |
| unreachable| The number of Destination Unreachable messages sent or received by the device. |
| time exceed| The number of Time Exceeded messages sent or received by the device.        |
| parameter  | The number of Parameter Problem messages sent or received by the device.    |
| source quench| The number of Source Quench messages sent or received by the device.      |
| redirect   | The number of Redirect messages sent or received by the device.             |
| echo       | The number of Echo messages sent or received by the device.                 |
| echo reply | The number of Echo Reply messages sent or received by the device.           |
| timestamp  | The number of Timestamp messages sent or received by the device.            |
| timestamp reply| The number of Timestamp Reply messages sent or received by the device.   |
| addr mask  | The number of Address Mask Request messages sent or received by the device. |
| addr mask reply| The number of Address Mask Replies messages sent or received by the device. |
| irdp advertisement| The number of ICMP Router Discovery Protocol (IRDP) Advertisement messages sent or received by the device. |
| irdp solicitation| The number of IRDP Solicitation messages sent or received by the device.    |

**UDP statistics**

| received | The number of UDP packets received by the device. |
| sent     | The number of UDP packets sent by the device.     |
| no port  | The number of UDP packets dropped because they did not have a valid UDP port number. |
| input errors | This information is used by Brocade customer support. |

**TCP statistics**

The TCP statistics are derived from RFC 793, “Transmission Control Protocol”.

| active opens | The number of TCP connections opened by sending a TCP SYN to another device. |
| passive opens| The number of TCP connections opened by this device in response to connection requests (TCP SYN) received from other devices. |
| failed attempts | This information is used by Brocade customer support. |
| active resets | The number of TCP connections this device reset by sending a TCP RESET message to the device at the other end of the connection. |
Displaying IP configuration information and statistics

**TABLE 187** CLI display of IP traffic statistics – Layer 3 Switch (Continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>passive resets</td>
<td>The number of TCP connections this device reset because the device at the other end of the connection sent a TCP RESET message.</td>
</tr>
<tr>
<td>input errors</td>
<td>This information is used by Brocade customer support.</td>
</tr>
<tr>
<td>in segments</td>
<td>The number of TCP segments received by the device.</td>
</tr>
<tr>
<td>out segments</td>
<td>The number of TCP segments sent by the device.</td>
</tr>
<tr>
<td>retransmission</td>
<td>The number of segments that this device retransmitted because the retransmission timer for the segment had expired before the device at the other end of the connection had acknowledged receipt of the segment.</td>
</tr>
</tbody>
</table>

**RIP statistics**

The RIP statistics are derived from RFC 1058, “Routing Information Protocol”.

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>requests sent</td>
<td>The number of requests this device has sent to another RIP router for all or part of its RIP routing table.</td>

<td>The number of responses to RIP request packets dropped because the format was bad.</td>
</tr>
<tr>
<td>resp not from rip port</td>
<td>This information is used by Brocade customer support.</td>
</tr>
<tr>
<td>resp from loopback</td>
<td>The number of RIP responses received from loopback interfaces.</td>
</tr>
<tr>
<td>packets rejected</td>
<td>This information is used by Brocade customer support.</td>
</tr>
</tbody>
</table>

**Displaying IP information – Layer 2 Switches**

You can display the following IP configuration information statistics on Layer 2 Switches:

- Global IP settings – refer to “Displaying global IP configuration information” on page 1101.
- ARP entries – refer to “Displaying ARP entries” on page 1101.
- IP traffic statistics – refer to “Displaying IP traffic statistics” on page 1102.
Displaying global IP configuration information

To display the Layer 2 Switch IP address and default gateway, enter the following command.

FastIron# show ip

    Switch IP address: 192.168.1.2
    Subnet mask: 255.255.255.0

Default router address: 192.168.1.1
TFTP server address: None
Configuration filename: None
Image filename: None

Syntax: show ip

This display shows the following information.

TABLE 188  CLI display of global IP configuration information – Layer 2 Switch

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IP configuration</strong></td>
<td></td>
</tr>
<tr>
<td>Switch IP address</td>
<td>The management IP address configured on the Layer 2 Switch. Specify this</td>
</tr>
<tr>
<td></td>
<td>address for Telnet or Web management access.</td>
</tr>
<tr>
<td>Subnet mask</td>
<td>The subnet mask for the management IP address.</td>
</tr>
<tr>
<td>Default router address</td>
<td>The address of the default gateway, if you specified one.</td>
</tr>
<tr>
<td><strong>Most recent TFTP access</strong></td>
<td></td>
</tr>
<tr>
<td>TFTP server address</td>
<td>The IP address of the most-recently contacted TFTP server, if the switch</td>
</tr>
<tr>
<td></td>
<td>has contacted a TFTP server since the last time the software was reloaded</td>
</tr>
<tr>
<td></td>
<td>or the switch was rebooted.</td>
</tr>
<tr>
<td>Configuration filename</td>
<td>The name under which the Layer 2 Switch startup-config file was uploaded</td>
</tr>
<tr>
<td></td>
<td>or downloaded during the most recent TFTP access.</td>
</tr>
<tr>
<td>Image filename</td>
<td>The name of the Layer 2 Switch flash image (system software file) that</td>
</tr>
<tr>
<td></td>
<td>was uploaded or downloaded during the most recent TFTP access.</td>
</tr>
</tbody>
</table>

Displaying ARP entries

To display the entries the Layer 2 Switch has placed in its ARP cache, enter the following command from any level of the CLI.

FastIron# show arp

    IP       Mac    Port Age VlanId
    192.168.1.170 0010.5a11.d042    7   0   1

Total Arp Entries : 1

Syntax: show arp
This display shows the following information.

**TABLE 189** CLI display of ARP cache

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>The IP address of the device.</td>
</tr>
<tr>
<td>Mac</td>
<td>The MAC address of the device.</td>
</tr>
<tr>
<td><strong>NOTE:</strong></td>
<td>If the MAC address is all zeros, the entry is for the default gateway, but the Layer 2 Switch does not have a link to the gateway.</td>
</tr>
<tr>
<td>Port</td>
<td>The port on which the entry was learned.</td>
</tr>
<tr>
<td>Age</td>
<td>The number of minutes the entry has remained unused. If this value reaches the ARP aging period, the entry is removed from the cache.</td>
</tr>
<tr>
<td>Vlanid</td>
<td>The VLAN the port that learned the entry is in.</td>
</tr>
<tr>
<td><strong>NOTE:</strong></td>
<td>If the MAC address is all zeros, this field shows a random VLAN ID, since the Layer 2 Switch does not yet know which port the device for this entry is attached to.</td>
</tr>
<tr>
<td>Total ARP Entries</td>
<td>The number of entries in the ARP cache.</td>
</tr>
</tbody>
</table>

**Displaying IP traffic statistics**

To display IP traffic statistics on a Layer 2 Switch, enter the following command at any CLI level.

FastIron# show ip traffic

**IP Statistics**

- 27 received, 24 sent
- 0 fragmented, 0 reassembled, 0 bad header
- 0 no route, 0 unknown proto, 0 no buffer, 0 other errors

**ICMP Statistics**

Received:

- 0 total, 0 errors, 0 unreachable, 0 time exceed
- 0 parameter, 0 source quench, 0 redirect, 0 echo,
- 0 echo reply, 0 timestamp, 0 timestamp rely, 0 addr mask
- 0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation

Sent:

- 0 total, 0 errors, 0 unreachable, 0 time exceed
- 0 parameter, 0 source quench, 0 redirect, 0 echo,
- 0 echo reply, 0 timestamp, 0 timestamp rely, 0 addr mask
- 0 addr mask reply, 0 irdp advertisement, 0 irdp solicitation

**UDP Statistics**

- 0 received, 0 sent, 0 no port, 0 input errors

**TCP Statistics**

- 1 current active tcbs, 4 tcbs allocated, 0 tcbs freed 0 tcbs protected
- 0 active opens, 0 passive opens, 0 failed attempts
- 0 active resets, 0 passive resets, 0 input errors
- 27 in segments, 24 out segments, 0 retransmission

**Syntax:** show ip traffic
The `show ip traffic` command displays the following information.

**TABLE 190** CLI display of IP traffic statistics – Layer 2 Switch

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IP statistics</strong></td>
<td></td>

Disabling IP checksum check

**Platform Support:** FESX, FSX and SX IPv6 devices running software release FSX 05.1.00 and later

The **disable-hw-ip-checksum-check** command traps a packet with bad checksum to the CPU. Previously, if the packet processor detected a packet with, for example, the checksum 0xFFFF, it would treat it as a bad checksum even if it was correct and it would drop the packet. Now, the command, **disable-hw-ip-checksum-check** traps the packet at the CPU and if the checksum is correct, it forwards the packet.

To set disable hardware ip checksum check for all ports, enter the following command.

FastIron# ))disable-hw-ip-checksum-check
disable-ip-header-check set for all ports

To clear disable hardware ip checksum check on all ports, enter the following command.

FastIron# ))no disable-hw-ip-checksum-check ethernet 13
disable-hw-ip-checksum-check cleared for ports the 13 to 24

To set disable hardware ip checksum check on for example, port range 0-12, enter the following command.

FastIron# ))disable-hw-ip-checksum-check ethernet 2
disable-ip-header-check set for ports ethe 1 to 12

To set disable hardware ip checksum check on, for example, port range 13-24, enter the following command.

FastIron# ))disable-hw-ip-checksum-check ethernet 22
disable-ip-header-check set for ports ethe 13 to 24

To clear disable hardware ip checksum check on, for example, port range 13-24, enter the following command.

FastIron# )#no disable-hw-ip-checksum-check ethernet 13
disable-hw-ip-checksum-check cleared for ports the 13 to 24

NOTE
The port range could be any consecutive range, it may not nescesarily be a decimal number.

Syntax: [no] disable-hw-ip-checksum-check <ethernet> <port number>

NOTE
This command only functions on the IPv4 platform.
Disabling IP checksum check
Chapter 31

Configuring Multicast Listening Discovery (MLD) Snooping on FGS, FGS-STK, FLS, FLS-STK, FWS, and FCX devices

Overview

The default method a FastIron uses to process an IPv6 multicast packet is to broadcast it to all ports except the incoming port of a VLAN. Packets are flooded by hardware without going to CPU, which may result in some clients receiving unwanted traffic.

MLD Snooping provides multicast containment by forwarding traffic only to those clients that have MLD receivers for a specific multicast group (destination address). The FastIron maintains the MLD group membership information by processing MLD reports and generating messages so traffic can be forwarded to ports receiving MLD reports. This is analogous to IGMP Snooping on the Brocade Layer3 switches.

An IPv6 multicast address is a destination address in the range of FF00::/8. A limited number of multicast addresses are reserved. Since packets destined for the reserved addresses may require VLAN flooding, these devices do not snoop in the FF0X::000X range (where X is from 0 to F). Data packets destined to these addresses are flooded to the entire VLAN by hardware, and mirrored to CPU. Multicast data packets destined to addresses outside the FF0X::000X range are snooped. A client must send MLD reports in order to receive traffic. If an application outside the FF0X::000X range requires VLAN flooding, you must configure a static group for the entire VLAN.

An MLD device periodically broadcasts general queries, and sends group queries upon receiving a leave message to ensure no other clients at the same port still want this specific traffic before removing it. MLDv1 allows clients to specify which group (destination IPv6 address) on which to receive traffic. (MLDv1 cannot choose the source of the traffic.) MLDv2 deals with source-specific multicasts, adding the capability for clients to INCLUDE or EXCLUDE specific traffic sources. An MLDv2 device's port state can either be in INCLUDE or EXCLUDE mode. There are different types of group records for client reports.

The interfaces respond to general queries by sending a membership report containing one or more of the following records associated with a specific group:

- Current-state record - Indicates the sources from which the interface wants to receive or not receive traffic. This record contains the source addresses of the interfaces and whether or not traffic will be included (IS_IN) or excluded (IS_EX) from that source address.
- Filter-mode-change record - If the interface changes its current state from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if an interface current state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.
- MLDv1 leave report - Equivalent to a TO_IN (empty) record in MLDv2. This record means that no traffic from this group will be received regardless of the source.
- An MLDv1 group report - Equivalent to an IS_EX (empty) record in MLDv2. This record means that all traffic from this group will be received regardless of source.
• Source-list-change record - If the interface wants to add or remove traffic sources from its membership report, the report can include an ALLOW record, which contains a list of new sources from which the interface wishes to receive traffic. The report can also contain a BLOCK record, which lists current traffic sources from which the interface wants to stop receiving traffic.

MLD protocols provide a way for clients and a device to exchange messages, and allow the device to build a database indicating which port wants what traffic. Since the MLD protocols do not specify forwarding methods, MLD Snooping or multicast protocols such as IPv6 PIM-Sparse Mode (PIM SM) are required to handle packet forwarding. PIM SM can route multicast packets within and outside a VLAN, while MLD Snooping can switch packets only within a VLAN. These devices do not support PIM-SM routing.

If a VLAN is not MLD Snooping-enabled, it floods IPv6 multicast data and control packets to the entire VLAN in hardware. When snooping is enabled, MLD packets are trapped to the CPU. Data packets are mirrored to the CPU and VLAN flooded. The CPU then installs hardware resources so subsequent data packets can be hardware-switched to desired ports without going through the CPU. If there is no client report, the hardware resource drops the data stream. The hardware can either match group addresses only (* G), or both source and group (S G) addresses in the data stream. If MLDv2 is configured in any port of a VLAN, the VLAN uses an (S G) match, otherwise it uses (* G). Because the hardware can match only the lowest 32 bits of a 128 bit IPv6 address, the output interfaces (OIF) of a hardware resource are the superset of the OIF of all data streams sharing the same lowest 32 bits. For example, if groups ff10::1234:5678:abcd and ff20::5678:abcd share the same hardware resource, then the OIF of the hardware matching (* 5678:abcd) is the superset of these two groups.

FGS, FLS, FGS-STK, FLS-STK, FWS and FCX devices allocate 16K of hardware resources for MAC learning, IGMP, and MLD snooping. If a data packet does not match any of these resources, it might be sent to the CPU, increasing the CPU burden. This can happen if the device runs out of hardware resources, or is unable to install a resource for a specific matching address due to a hashing collision. Because the hardware hashes addresses into 16K entries, some addresses may be hashed into the same entry. If the collision number in an entry is more than the hardware chain length, the resource cannot be installed. The chain length can be configured using the hash-chain-length command, as follows.

```
FastIron(config)#hash-chain-length 8
```

**Syntax:** `[no] hash-chain-length <num>`

The `<num>` parameter range is 4 to 32, in multiples of 4. If the input value is not a multiple of 4, then it will be changed to the multiple of 4 lower than then the input value (e.g. 11 will be changed to 8). The default hash chain length is 4. A chain length of more than 4 may affect line rate switching.

**NOTE**
For this command to take effect, you must save the configuration and reload the switch.

The hardware resource limit applies only to snooping-enabled VLANs. In VLANs where snooping is not enabled, multicast streams are switched in hardware without using any pre-installed resources.

The Brocade device supports up to 32K of MLD groups. They are produced by client membership reports.

**Platform support**

- FGS and FLS devices running software release 03.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 and later
- FCX-S devices running software release 06.0.00 and later

**Configuration notes**

- Servers (traffic sources) are not required to send MLD memberships.
- The default MLD version is V1.
- Hardware resources are installed only when there is data traffic. If a VLAN is configured for MLDv2, the hardware matches (S G), otherwise it matches (* G).
- You can configure the maximum number of groups and hardware-switched data streams.
- The device supports static groups applying to the entire VLAN, or to specific ports. The device acts as a proxy to send MLD reports for the static groups when receiving queries.
- A user can configure static router ports, forcing all multicast traffic to be sent to these ports.
- All devices support fast leave for MLDv1, which stops traffic immediately to any port that has received a leave message.
- All devices support tracking and fast leave for MLDv2, which tracks all MLDv2 clients. If the only client on a port leaves, traffic is stopped immediately.
- An MLD device can be configured as a querier (active) or non-querier (passive). Queriers send queries. Non-queriers listen for queries and forward them to the entire VLAN.
- Every VLAN can be independently configured as a querier or a non-querier.
- A VLAN that has a connection to an IPv6 PIM-enabled port on another router should be configured as a non-querier. When multiple snooping devices connect together and there is no connection to IPv6 PIM ports, only one device should be configured as the querier. If multiple devices are configured as active, only one will continue to send queries after the devices have exchanged queries. Refer to "Configuring queriers and non-queriers" on page 1110.
- An MLD device can be configured to rate-limit the forwarding of MLDv1 membership reports to queriers.
- Because these devices use an IPv6 link-local address as the source address when sending queries, no global address is required.

The MLD implementation allows snooping on some VLANs or on all VLANs. MLD can be enabled or disabled independently for each VLAN. In addition, individual ports of a VLAN can be configured as MSLv1 and MLDv2. In general, global configuration commands such as ipv6 mld-snooping, apply to all VLANs except those with a local mld-snooping, configuration, which supersedes the global configuration. Configuring the version on a port or a VLAN only affects the device sent query version. The device always processes all versions of client reports regardless of the version configured.

MLD Snooping requires hardware resources. If the device has insufficient resources, the data stream without a resource is mirrored to the CPU in addition to being VLAN flooded, which can cause high CPU usage. To avoid this situation, Brocade recommends that you avoid enabling snooping globally unless necessary.
When any port of a VLAN is configured for MLDv2, the VLAN matches both source and group (S G) in hardware switching. If no port is configured for MLDv2, the VLAN matches group only (* G). Matching (S G) requires more hardware resources than (* G) when there are multiple servers sharing the same group. For example, two data streams from different sources to the same group require two (S G) entries in MLDv2, compared to only one (* G) in MLDv1. Brocade recommends that you use MLDv2 only in a source-specific application. Because each VLAN can be configured for the version independently, some VLANs might match (* G) while others match (S G).

To receive data traffic, MLD Snooping requires clients to send membership reports. If a client does not send reports, you must configure a static group to force traffic to client ports. The static group can either apply to some ports or to the entire VLAN.

### Configuring queriers and non-queriers

An MLD Snooping-enabled device can be configured as a querier (active) or non-querier (passive). An MLD querier sends queries; a non-querier listens for MLD queries and forwards them to the entire VLAN. Starting with release 03.0.00, VLANs can be independently configured as queriers or non-queriers. If a VLAN has a connection to an IPv6 PIM-enabled port on another router, the VLAN should be configured as a non-querier. When multiple MLD snooping devices are connected together, and there is no connection to an IPv6 PIM-enabled port, one of the devices should be configured as a querier. If multiple devices are configured as queriers, after multiple devices exchange queries, then all devices except the winner (the device with the lowest address) stop sending queries. Although the system works when multiple devices are configured as queriers, Brocade recommends that only one device, preferably the one with the traffic source, is configured as the querier.

Because non-queriers always forward multicast data traffic and MLD messages to router ports which receive MLD queries or IPv6 PIM hellos, Brocade recommends that you configure the devices with the data traffic source (server) as queriers. If a server is attached to a non-querier, the non-querier always forwards traffic to the querier regardless of whether or not there are clients on the querier.

**NOTE**

In a topology with one or more connected devices, at least one device must be running PIM, or configured as active. Otherwise, no devices can send queries, and traffic cannot be forwarded to clients.

### VLAN specific configuration

You can configure MLD snooping on some VLANs or all VLANs. Each VLAN can be independently enabled or disabled for MLD snooping, or can be configured with MLDv1 or MLDv2. In general, the `ipv6 mld-snooping...` commands apply globally to all VLANs except those configured with `VLAN-specific mld-snooping...` commands. `VLAN-specific mld-snooping` commands supersede global `ipv6 mld-snooping` commands.

### Using MLDv1 with MLDv2

MLD snooping can be configured as MLDv1 or MLDv2 on individual ports on a VLAN. An interface or router sends queries and reports that include the MLD version with which it has been configured. The version configuration applies only to the sending of queries. The snooping device recognizes and processes MLDv1 and MLDv2 packets regardless of the version configured.
NOTE
To avoid version deadlock, when an interface receives a report with a lower version than that for which it has been configured, the interface does not automatically downgrade the running MLD version.

Configuring MLD snooping

Configuring MLD Snooping on IPv6 FGS, FLS, FGS-STK, FLS-STK, FWS and FCX devices consists of the following global and VLAN-specific tasks.

Global tasks:
• Configuring hardware and software resource limits
• Disabling transmission and receipt of MLD packets on a port
• Configuring the MLD mode: active or passive (must be enabled for MLD Snooping)
• Modifying the age interval
• Specifying the interval for query messages (active MLD mode only)
• Specifying the global MLD version
• Enabling and disabling report control (rate limiting)
• Modifying the leave-wait time
• Modifying the mcache age interval
• Disabling error and warning messages

VLAN-specific tasks:
• Configuring the MLD mode for the VLAN: active or passive
• Enabling or disabling MLD Snooping for the VLAN
• Configuring the MLD version for the VLAN
• Configuring the MLD version for individual ports
• Configuring static groups to the entire VLAN or some ports
• Configuring static router ports
• Enabling client tracking and the fast leave feature for MLDv2
• Configuring fast leave for MLDv1
• Configuring fast-convergence

Configuring the hardware and software resource limits

The system supports up to 8K of hardware-switched multicast streams. The configurable range is from 256 to 8192 and the default is 4096. Enter a command such as the following to define the maximum number of MLD Snooping cache entries.

```
FastIron(config)#system-max mld-snoop-mcache 8000
```

Syntax:  `[no] system-max mld-snoop-mcache <num>`
The system supports up to 32K of groups. The configurable range is 256 to 32768 and the default is 8192. The configured number is the upper limit of an expandable database. Client memberships exceeding the group limits are not processed.

Disabling transmission and receipt of MLD packets on a port

When a VLAN is snooping-enabled, all MLD packets are trapped to the CPU without hardware VLAN flooding. The CPU can block MLD packets to and from a multicast-disabled port, and will not add that port to the output interfaces or hardware resources, which prevents the disabled port from receiving multicast traffic. However, if static groups to the entire VLAN are defined, the traffic for these groups is flooded to the entire VLAN, including to the disabled ports. Since the hardware cannot block traffic from disabled ports, hardware traffic is switched in the same way as traffic from enabled ports.

NOTE
This command has no effect on a VLAN that is not snooping-enabled because all multicast traffic is VLAN flooded.

FastIron(config)#interface ethernet 0/1/3
FastIron(config-if-e1000-0/1/3)#ipv6-multicast-disable

Syntax: [no] ipv6-multicast-disable

Configuring the global MLD mode

You can configure a device for either active or passive (default) MLD mode. If you specify an MLD mode for a VLAN, the MLD mode overrides the global setting:

• **Active** – In active MLD mode, an FGS, FWS, or FLS device actively sends out MLD queries to identify IPv6 multicast groups on the network, and makes entries in the MLD table based on the group membership reports it receives from the network.

• **Passive** – In passive MLD mode, the device forwards reports to the router ports which receive queries. MLD Snooping in passive mode does not send queries, but does forward queries to the entire VLAN.

To globally set the MLD mode to active for the device, enter the following command.

FGS624 Switch(config)#ipv6 mld-snooping active

Syntax: [no] ipv6 mld-snooping [active | passive]

Omitting both the active and passive keywords is the same as entering ipv6 mld-snooping passive.

Modifying the age interval

When the device receives a group membership report, it makes an entry in the MLD group table for the group in the report. The age interval specifies how long the entry can remain in the table without the device receiving another group membership report. When multiple devices connect together, all devices should be configured with the same age interval. The age interval should be at least twice that of the query interval, so that missing one report will not stop traffic. For a non-querier, the query interval should equal that of the querier.

To modify the age interval, enter a command such as the following.
Configuring MLD snooping

FGS624 Switch(config)#ipv6 mld-snooping age-interval 280

**Syntax:** `[no] ipv6 mld-snooping age-interval <interval>`

The `<interval>` parameter specifies the aging time. You can specify a value from 20 – 7200 seconds. The default is 140 seconds.

**Modifying the query interval (Active MLD snooping mode only)**

If the MLD mode is set to active, you can modify the query interval, which specifies how often the device sends group membership queries. When multiple queriers connect together, all queriers should be configured with the same interval.

To modify the query interval, enter a command such as the following.

FGS624 Switch(config)#ipv6 mld-snooping query-interval 120

**Syntax:** `[no] ipv6 mld-snooping query-interval <interval>`

The `<interval>` parameter specifies the interval between queries. You can specify a value from 10 – 3600 seconds. The default is 60 seconds.

**Configuring the global MLD version**

The default version is MLDv1. You can specify the global MLD version on the device as either MLDv1 or MLDv2. For example, the following command configures the device to use MLDv2.

FGS624 Switch(config)#ipv6 mld-snooping version 2

**Syntax:** `[no] ipv6 mld-snooping version 1 | 2`

You can also specify the MLD version for individual VLANs, or individual ports within VLANs. If no MLD version is specified for a VLAN, then the globally configured MLD version is used. If an MLD version is specified for individual ports in a VLAN, those ports use that version instead of the version specified for the VLAN or the globally specified version. The default is MLDv1.

**Configuring report control**

When a device is in passive mode, it forwards reports and leave messages from clients to the upstream router ports that are receiving queries.

You can configure report control to rate-limit report forwarding for the same group to no more than once per 10 seconds. This rate limiting does not apply to the first report answering a group-specific query.

---

**NOTE**

This feature applies to MLDv1 only. The leave messages are not rate limited.

MLDv1 membership reports for the same group from different clients are considered to be the same, and are rate-limited. This alleviates the report storm caused by multiple clients answering the upstream router query. To enable report-control, use a command similar to the following.

FGS624 Switch(config)#ipv6 mld-snooping report-control

**Syntax:** `[no] ipv6 mld-snooping report-control`
Modifying the wait time before stopping traffic when receiving a leave message

You can define the wait time before stopping traffic to a port when the device receives a leave message for that port. The device sends group-specific queries once per second to determine if any client on the same port still needs the group. The value range is from 1 to 5, and the default is 2. Due to the internal timer accuracy, the actual wait time is between \( n \) and \( (n+1) \) seconds, where \( n \) is the configured value.

FGS624 Switch(config)#ipv6 mld-snooping leave-wait-time 1
Syntax: [no] ipv6 mld-snooping leave-wait-time <num>

Modifying the multicast cache (mcache) aging time

You can set the time for an mcache to age out when it does not receive traffic. The traffic is hardware-switched. One minute before an mcache is aged out, the device mirrors a packet of the mcache to the CPU to reset the age. If no data traffic arrives within one minute, the mcache is deleted. If you configure a lower value, the resource consumed by idle streams is quickly removed, but packets are mirrored to the CPU more frequently. Configure a higher value only when data streams are arriving consistently. The range is 60 to 3600 seconds, and the default is 60 seconds.

FGS624 Switch(config)#ipv6 mld-snooping mcache-age 180
Syntax: [no] ipv6 mld-snooping mcache-age <num>

Disabling error and warning messages

The device prints error or warning messages when it runs out of software resources or when it receives packets with the wrong checksum or groups. These messages are rate limited. You can turn off these messages by entering a command such as the following.

FGS624 Switch(config)#ipv6 mld-snooping verbose-off
Syntax: [no] ipv6 mld-snooping verbose-off

Configuring the MLD mode for a VLAN

You can configure a VLAN for either the active or passive (default) MLD mode. The VLAN setting overrides the global setting:

- **Active** – In active MLD mode, a device actively sends out MLD queries to identify IPv6 multicast groups on the network, and makes entries in the MLD table based on the group membership reports it receives from the network.

- **Passive** – In passive MLD mode, the device forwards reports to router ports which receive queries. MLD snooping in the passive mode does not send queries. However, it does forward queries to the entire VLAN.

To set the MLD mode for VLAN 20 to active, enter the following commands.

FGS624 Switch(config)#vlan 20
FGS624 Switch(config-vlan-20)#mld-snooping active

Syntax: [no] mld-snooping active | passive
Disabling MLD snooping for the VLAN

When MLD snooping is enabled globally, you can disable it for a specific VLAN. For example, the following commands disable MLD snooping for VLAN 20. This setting overrides the global setting for VLAN 20.

FGS624 Switch(config)#vl 20
FGS624 Switch(config-vlan-20)#mld-snooping disable-mld-snoop

Syntax: [no] mld-snooping disable-mld-snoop

Configuring the MLD version for the VLAN

You can specify the MLD version for a VLAN. For example, the following commands configure VLAN 20 to use MLDv2.

FGS624 Switch(config)#vl 20
FGS624 Switch(config-vlan-20)#mld-snooping version 2

Syntax: [no] mld-snooping version 1 | 2

When no MLD version is specified, the globally-configured MLD version is used. If an MLD version is specified for individual ports, these ports use that version, instead of the version specified for the VLAN.

Configuring the MLD version for individual ports

You can specify the MLD version for individual ports in a VLAN. For example, the following commands configure ports 0/1/4, 0/1/5, 0/1/6 and 0/2/1 to use MLDv2. The other ports use the MLD version specified with the mld-snooping version command, or the globally configured MLD version.

FGS624 Switch(config)#vl 20
FGS624 Switch(config-vlan-20)#mld-snooping port-version 2 ethe 0/2/1 ethe 0/1/4 to 0/1/6

Syntax: [no] mld-snooping port-version 1 | 2 <stack-unit/slot/port>

Configuring static groups to the entire VLAN or to individual ports

A snooping-enabled VLAN cannot forward multicast traffic to ports that do not receive MLD membership reports. To allow clients to send reports, you can configure a static group which applies to the entire VLAN, or to individual ports on the VLAN. The static group forwards packets to the static group ports even if they have no client membership reports. The static group for the entire VLAN is used in VLAN flooding because it uses fewer hardware resources than the static group for individual ports. Configure a static group for specific ports on VLAN 20 using commands similar to the following.

FGS624 Switch(config)#vl 20
FGS624 Switch(config-vlan-20)#mld-snooping static-group ff05::100 count 2 ethe 0/1/3 ethe 0/1/5 to 0/1/7
FGS624 Switch(config-vlan-20)#mld-snooping static-group ff10::200

Syntax: [no] mld-snooping static-group <ipv6-address> [count <num>] [<stack-unit/slot/port>]

Configuring MLD snooping
Configuring MLD snooping

The `ipv6-address` parameter is the IPv6 address of the multicast group.
The `count` is optional, which allows a contiguous range of groups. Omitting the count `<num>` is equivalent to the count being 1.

If there are no `<stack-unit/slot/port>` numbers, the static groups apply to the entire VLAN.

Configuring static router ports

A device always forwards all multicast control and data packets to router ports that receive queries. Although router ports are learned, you can configure static router ports to force multicast traffic to specific ports, even though these ports never receive queries. To configure static router ports, enter commands such as the following.

```
FGS624 Switch(config)#vlan 70
FGS624 Switch(config-vlan-70)#mld-snooping router-port e 0/1/4 to 0/1/5 e 0/1/8
```

Syntax: `[no] mld-snooping router-port <stack-unit/slot/port>

Turning off static group proxy

A device with static groups configured acts as a proxy and sends membership reports for its static groups when it receives general or group-specific queries. When a static group configuration is removed, the group is deleted from active group table immediately. However, the device does not send leave messages to the querier. The querier should age the group out. The proxy activity can be turned off (the default is on). For example.

```
FGS624 Switch(config)#vlan 20
FGS624 Switch(config-vlan-20)#mld-snooping proxy-off
```

Syntax: `[no] mld-snooping proxy-off

Enabling MLDv2 membership tracking and fast leave for the VLAN

MLDv2 provides membership tracking and fast leave services to clients. In MLDv1, only one client per interface must respond to a router queries; leaving some clients invisible to the router, which makes it impossible for the device to track the membership of all clients in a group. In addition, when a client leaves the group, the device sends group-specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the device waits a few seconds before stopping the traffic. You can configure the wait time with the `ipv6 mld-snooping leave-wait-time` command.

MLDv2 requires that every client respond to queries, allowing the device is able to track every client. When the tracking feature is enabled, the device immediately stops forwarding traffic to the interface if an MLDv2 client sends a leave message, and there is no other client. This feature requires the entire VLAN to be configured for MLDv2 and have no MLDv1 clients. If a client does not send a report during the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.
Configuring MLD snooping

Every group on a physical port keeps its own tracking record. However, it can track group membership only; it cannot track by (source, group). For example, Client A and Client B belong to group1 but each is receiving traffic from different sources. Client A receives a traffic stream from (source_1, group1) and Client B receives a traffic stream from (source_2, group1). The device waits for the configured leave-wait-time before it stops the traffic because the two clients are in the same group. If the clients are in different groups, the waiting period is ignored and traffic is stopped immediately.

To enable tracking and fast leave for VLAN 20, enter the following commands.

FGS624 Switch(config)#vlan 20
FGS624 Switch(config-vlan-20)#mld-snooping tracking

Syntax: [no] mld-snooping tracking

The membership tracking and fast leave features are supported for MLDv2 only. If a port or client is not configured for MLDv2, the mld-snooping tracking command is ignored.

Configuring fast leave for MLDv1

When a device receives an MLDv1 leave message, it sends out multiple group-specific queries. If no other client replies within the waiting period, the device stops forwarding traffic to this port. Configuring fast-leave-v1 allows the device to stop forwarding traffic to a port immediately upon receiving a leave message. The device does not send group-specific queries. It is important that no snooping ports have multiple clients. When two devices connect, the querier device should not be configured for fast-leave-v1 because the port to the non-querier device could have multiple clients. The number of queries and the waiting period (in seconds) can be configured using the ipv6 mld-snooping leave-wait-time command. The default is 2 seconds. To configure fast leave for MLDv1, use commands such as the following.

FGS624 Switch(config)#vlan 20
FGS624 Switch(config-vlan-20)#mld-snooping fast-leave-v1

Syntax: [no] mld-snooping fast-leave-v1

Enabling fast convergence

In addition to periodically sending general queries, an active (querier) device sends out general queries when it detects a new port. However, since it does not recognize the other device port-up event, the multicast traffic might still use the query-interval time to resume after a topology change. Configuring fast-convergence allows the device to listen to topology change events in L2 protocols, such as spanning tree, and send general queries to shorten the convergence time.

If the L2 protocol is unable to detect a topology change, the fast-convergence feature may not work. For example, if the direct connection between two devices switches from one interface to another, the rapid spanning tree protocol (802.1w) considers this an optimization action, rather than a topology change. In this case, other devices will not receive topology change notifications and will be unable to send queries to speed up the convergence. The original spanning tree protocol does not recognize optimization actions, and fast-convergence works in all cases.

To enable fast-convergence, enter commands such as the following.

FGS624 Switch(config)#vlan 70
FGS624 Switch(config-vlan-70)#mld-snooping fast-convergence

Syntax: mld-snooping fast-convergence
Displaying MLD snooping information

You can display the following MLD Snooping information:

- MLD Snooping error information
- Information about VLANs
- Group and forwarding information for VLANs
- MLD memory pool usage
- Status of MLD traffic
- MLD information by VLAN

Displaying MLD snooping error information

To display information about possible MLD errors, enter the following command.

```
FGS624 Switch#show ipv6 mld-snooping error
snoop SW processed pkt: 173, up-time 160 sec
```

Syntax: `show ipv6 mld-snooping error`

The following table describes the output from the `show ipv6 mld-snooping error` command.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW processed pkt</td>
<td>The number of IPv6 multicast packets processed by MLD snooping.</td>
</tr>
<tr>
<td>up-time</td>
<td>The time since the MLD snooping last occurred is enabled.</td>
</tr>
</tbody>
</table>

Displaying MLD group information

To display MLD group information, enter the following command.

```
FGS624 Switch#show ipv6 mld-snooping group
```

```
p: physical, ST: static, QR: querier, EX: exclude, IN: include, Y: yes, N: no
VL1 : 263 grp, 263 grp-port, tracking_enabled

<table>
<thead>
<tr>
<th>Group</th>
<th>p-port</th>
<th>ST</th>
<th>QR</th>
<th>Life</th>
<th>Mode</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0/1/7</td>
<td>N</td>
<td>Y</td>
<td>120</td>
<td>EX</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>0/1/9</td>
<td>N</td>
<td>Y</td>
<td></td>
<td>IN</td>
<td>1</td>
</tr>
</tbody>
</table>
```

**NOTE**

In this example, an MLDv1 group is in EXCLUDE mode with a source of 0. The group excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

To display detailed MLD group information, enter the following command.

```
FGS624 Switch#show ipv6 mld-snooping group ff0e::ef00:a096 detail
```

```
Display group ff0e::ef00:a096 in all interfaces in details.
p: physical, ST: static, QR: querier, EX: exclude, IN: include, Y: yes, N: no
VL1 : 1 grp, 1 grp-port, tracking_enabled

<table>
<thead>
<tr>
<th>Group</th>
<th>p-port</th>
<th>ST</th>
<th>QR</th>
<th>Life</th>
<th>Mode</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0/1/7</td>
<td>N</td>
<td>Y</td>
<td>100</td>
<td>EX</td>
<td>0</td>
</tr>
</tbody>
</table>

Group: ff0e::ef00:a096, EX, permit 0 (source, life):
  life=100, deny 0:
```
If tracking and fast leave are enabled, you can display the list of clients for a particular group by entering the following command.

FGS624 Switch#show ipv6 mld-snooping group ff0e::ef00:a096 tracking
Display group ff0e::ef00:a096 in all interfaces with tracking enabled.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1 : 1 grp, 1 grp-port, tracking_enabled

<table>
<thead>
<tr>
<th>group</th>
<th>p-port ST QR life mode source</th>
</tr>
</thead>
<tbody>
<tr>
<td>ff0e::ef00:a096</td>
<td>0/1/7 N Y 80 EX 0</td>
</tr>
</tbody>
</table>

receive reports from 1 clients: (age) (fe80::1011:1213:1415 60)

Syntax: show ipv6 mld-snooping group [<group-address>] [detail] [tracking]
To receive a report for a specific multicast group, enter that group address for <group-address>.
Enter detail to display the source list of a specific VLAN.
Enter tracking for information on interfaces that are tracking-enabled.
The following table describes the information displayed by the show ipv6 mld-snooping group command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>The address of the IPv6 group (destination IPv6 address).</td>
</tr>
<tr>
<td>p-port</td>
<td>The physical port on which the group membership was received.</td>
</tr>
<tr>
<td>ST</td>
<td>Yes indicates that the MLD group was configured as a static group; No means it was learned from reports.</td>
</tr>
<tr>
<td>QR</td>
<td>Yes means the port is a querier port; No means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the port.</td>
</tr>
<tr>
<td>life</td>
<td>The number of seconds the group can remain in EXCLUDE mode. An EXCLUDE mode changes to INCLUDE if it does not receive an IS_EX or TO_EX message during a specified period of time. The default is 140 seconds. There is no life displayed in INCLUDE mode.</td>
</tr>
<tr>
<td>mode</td>
<td>The current mode of the interface: INCLUDE or EXCLUDE. If the interface is in INCLUDE mode, it admits traffic only from the source list. If the interface is in EXCLUDE mode, it denies traffic from the source list and accepts the rest.</td>
</tr>
<tr>
<td>source</td>
<td>Identifies the source list that will be included or excluded on the interface. An MLDv1 group is in EXCLUDE mode with a source of 0. The group excludes traffic from 0 (zero) source list, which actually means that all traffic sources are included.</td>
</tr>
</tbody>
</table>

If you requested a detailed report, the following information is displayed:
• The multicast group address
• The mode of the group
• Sources from which traffic will be admitted (INCLUDE) or denied (EXCLUDE) on the interface.
• The life of each source list.

If you requested a tracking/fast leave report, the clients from which reports were received are identified.

Displaying MLD snooping mcache information
The MLD snooping mcache contains multicast forwarding information for VLANs. To display information in the multicast forwarding mcache, enter the following command.
Configuring MLD snooping

Syntax: show ipv6 mld-snooping mcache

The following table describes the output from the `ipv6 mld-snooping mcache` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>(abcd:ef50 0:100):</td>
<td>The lowest 32 bits of source and group. It is displayed in XXXX:XXXX hex format. Here XXXX is a 16-bit hex number.</td>
</tr>
<tr>
<td>cnt</td>
<td>The number of packets processed in software. IPv6 packets are switched in software in the FGS 03.0.00 release causing this number to increase slowly.</td>
</tr>
<tr>
<td>OIF</td>
<td>Output interfaces. Entire vlan means that static groups apply to the entire VLAN.</td>
</tr>
<tr>
<td>age</td>
<td>The mcache age. The mcache is reset to 0 if traffic continues to arrive, otherwise it is aged out when it reaches the time defined by <code>ipv6 mld-snooping mcache-age</code>.</td>
</tr>
<tr>
<td>uptime</td>
<td>The up time of this mcache in minutes.</td>
</tr>
<tr>
<td>vidx</td>
<td>The vidx is shared among mcaches using the same output interfaces. The vidx specifies the output port list, which shows the index. Valid range is from 4096 to 8191.</td>
</tr>
<tr>
<td>ref-cnt</td>
<td>The number of mcaches using this vidx.</td>
</tr>
</tbody>
</table>

Displaying software resource usage for VLANs

To display information about the software resources used, enter the following command.

Syntax: show ipv6 mld-snooping resource

The following table describes the output from the `ipv6 mld-snooping resource` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>alloc</td>
<td>The allocated number of units.</td>
</tr>
<tr>
<td>in-use</td>
<td>The number of units which are currently used.</td>
</tr>
<tr>
<td>avail</td>
<td>The number of available units.</td>
</tr>
</tbody>
</table>
Configuring MLD snooping

Displaying status of MLD snooping traffic

To display status information for MLD snooping traffic, enter the following command.

```
FGS624 Switch# show ipv6 mld-snooping traffic
MLD snooping: Total Recv: 32208, Xmit: 166

Q: query, Qry: general Q, G-Qry: group Q, GSQry: group-source Q, Mbr: member
Recv  QryV1  QryV2  G-Qry  GSQry  MbrV1  MbrV2  Leave
VL1    0      0      0      0     31744   208    256
VL70   0      0      0      0      0      0      0
Send  QryV1  QryV2  G-Qry  GSQry  MbrV1  MbrV2
VL1    0      0      166    0     0      0      0
VL70   0      0      0      0      0      0      0
```

**Syntax:** `show ipv6 mld-snooping traffic`

The following table describes the information displayed by the `show ipv6 mld-snooping traffic` command.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q</td>
<td>Query</td>
</tr>
<tr>
<td>Qry</td>
<td>General Query</td>
</tr>
<tr>

<td>Number of general MLDv1 queries received or sent.</td>
</tr>
<tr>
<td>QryV2</td>
<td>Number of general MLDv2 snooping queries received or sent.</td>
</tr>
<tr>
<td>G-Qry</td>
<td>Number of group specific queries received or sent.</td>
</tr>
<tr>
<td>GSQry</td>
<td>Number of group source specific queries received or sent.</td>
</tr>
<tr>
<td>MBR</td>
<td>The membership report.</td>
</tr>
<tr>
<td>MbrV1</td>
<td>The MLDv1 membership report.</td>
</tr>
<tr>
<td>MbrV2</td>
<td>The MLDv2 membership report.</td>
</tr>
<tr>
<td>IsIN</td>
<td>Number of source addresses that were included in the traffic.</td>
</tr>
</tbody>
</table>
Displaying MLD snooping information by VLAN

You can display MLD snooping information for all VLANs or for a specific VLAN. For example, to display MLD snooping information for VLAN 70, enter the following command.

```
FGS624 Switch#show ipv6 mld-snooping vlan 70
version=1, query-t=60, group-aging-t=140, max-resp-t=3, other-qr-present-t=123
VL70: cfg V2, vlan cfg passive, 2 grp, 0 (SG) cache, rtr ports,
    router ports: 0/1/36(120) fe80::2e0:52ff:fe00:9900,
0/1/26 has 2 grp, non-QR (passive), cfg V1
0/1/26 has 2 grp, non-QR (passive), cfg V1
group: ff10:1234::5679, life = 100
group: ff10:1234::5678, life = 100
0/1/35 has 0 grp, non-QR (QR=fe80::2e0:52ff:fe00:9900, age=20), dft V2 trunk
```

Syntax: `show ipv6 mld-snooping vlan [vlan-id]`

If you do not specify a vlan-id, information for all VLANs is displayed.

The following table describes information displayed by the `show ipv6 mld-snooping vlan` command.

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>The MLD version number.</td>
</tr>
<tr>
<td>query-t</td>
<td>How often a querier sends a general query on the interface.</td>
</tr>
<tr>
<td>group-aging-t</td>
<td>Number of seconds membership groups can be members of this group before aging out.</td>
</tr>
<tr>
<td>rtr-port</td>
<td>The router ports which are the ports receiving queries. The display <code>router ports</code>: 0/1/36(120) fe80::2e0:52ff:fe00:9900 means port 0/1/36 has a querier with fe80::2e0:52ff:fe00:9900 as the link-local address, and the remaining life is 120 seconds.</td>
</tr>
<tr>
<td>max-resp-t</td>
<td>The maximum number of seconds a client can wait before it replies to the query.</td>
</tr>
<tr>
<td>non-QR</td>
<td>Indicates that the port is a non-querier.</td>
</tr>
<tr>
<td>QR</td>
<td>Indicates that the port is a querier.</td>
</tr>
</tbody>
</table>

Clear MLD snooping commands

The clear commands for MLD snooping should only be used in troubleshooting situations or when recovering from error conditions.
Clear MLD counters on VLANs

To clear MLD Snooping error and traffic counters on all VLANs, enter a command similar to the following.

FGS624 Switch#clear ipv6 mld-snooping counters

Syntax: clear ipv6 mld-snooping counters

Clear MLD mcache

To clear the mcache on all VLANs, enter the following command.

FGS624 Switch#clear ipv6 mld-snooping mcache

Syntax: clear ipv6 mld-snooping mcache

Clear mcache on a specific VLAN

To clear the mcache on a specific VLAN, enter the following command.

FGS624 Switch#clear ipv6 mld-snooping vlan <vlan-id> mcache

Syntax: clear ipv6 mld-snooping vlan <vlan-id> mcache

The <vlan-id> parameter specifies the specific VLAN from which to clear the cache.

Clear Traffic on a specific VLAN

To clear the traffic counters on a specific VLAN, enter the following command.

FGS624 Switch#clear ipv6 mld-snooping vlan <vlan-id> traffic

Syntax: clear ipv6 mld-snooping vlan <vlan-id> traffic

The <vlan-id> parameter specifies the specific VLAN from which to clear the traffic counters.
Configuring MLD snooping
Chapter 32

Configuring Multicast Listening Discovery (MLD) Snooping on the FastIron X Series

Overview

The default method a FastIron uses to process an IPv6 multicast packet is to broadcast it to all ports except the incoming port of a VLAN. Packets are flooded by hardware without going to the CPU, which may result in some clients receiving unwanted traffic.

If a VLAN is not MLD snooping-enabled, it floods IPv6 multicast data and control packets to the entire VLAN in hardware. When snooping is enabled, MLD packets are trapped to the CPU. Data packets are mirrored to the CPU and flooded to the entire VLAN. The CPU then installs hardware resources so subsequent data packets can be hardware-switched to desired ports without going through the CPU. If there is no client report, the hardware resource drops the data stream.

MLD protocols provide a way for clients and a device to exchange messages, and allow the device to build a database indicating which port wants what traffic. Since the MLD protocols do not specify forwarding methods, MLD snooping or multicast protocols such as IPv6 PIM-Sparse Mode (PIM SM) are required to handle packet forwarding. PIM SM can route multicast packets within and outside a VLAN, while MLD snooping can switch packets only within a VLAN. FESX and FSX devices do not support PIM-SM routing.

MLD snooping provides multicast containment by forwarding traffic only to those clients that have MLD receivers for a specific multicast group (destination address). The FastIron maintains the MLD group membership information by processing MLD reports and generating messages so traffic can be forwarded to ports receiving MLD reports. This is analogous to IGMP Snooping on Brocade Layer 3 switches.

An IPv6 multicast address is a destination address in the range of FF00::/8. A limited number of multicast addresses are reserved. Since packets destined for the reserved addresses may require VLAN flooding, FESX and FSX devices do not snoop in the FFOX::00X range (where X is from 00 to FF). Data packets destined to these addresses are flooded to the entire VLAN by hardware and mirrored to the CPU. Multicast data packets destined to addresses outside the FFOX::00X range are snooped. A client must send MLD reports in order to receive traffic.

An MLD device periodically broadcasts general queries and sends group queries upon receiving a leave message, to ensure no other clients at the same port still want this specific traffic before removing it. MLDv1 allows clients to specify which group (destination IPv6 address) will receive traffic. (MLDv1 cannot choose the source of the traffic.) MLDv2 deals with source-specific multicasts, adding the capability for clients to INCLUDE or EXCLUDE specific traffic sources. An MLDv2 device's port state can either be in INCLUDE or EXCLUDE mode.

There are different types of group records for client reports. Clients respond to general queries by sending a membership report containing one or more of the following records associated with a specific group:

- **Current-state record** - Indicates the sources from which the client wants to receive or not receive traffic. This record contains the source addresses of the clients and indicates whether or not traffic will be included (IS_IN) or excluded (IS_EX) from that source address.
• Filter-mode-change record - If the client changes its current state from IS_IN to IS_EX, a TO_EX record is included in the membership report. Likewise, if a client current state changes from IS_EX to IS_IN, a TO_IN record appears in the membership report.

• MLDe1 leave report - Equivalent to a TO_IN (empty) record in MLDe2. This record means that no traffic from this group will be received, regardless of the source.

• An MLDe1 group report - Equivalent to an IS_EX (empty) record in MLDe2. This record means that all traffic from this group will be received, regardless of the source.

• Source-list-change record - If the client wants to add or remove traffic sources from its membership report, the report can include an ALLOW record, which contains a list of new sources from which the client wishes to receive traffic. The report can also contain a BLOCK record, which lists current traffic sources from which the client wants to stop receiving traffic.

Platform Support:
• FESX and FSX IPv6 devices running software release 04.1.00 and later - L2, BL3, L3

How MLD snooping uses MAC addresses to forward multicast packets

MLD snooping on Brocade devices is based on MAC address entries. When an IPv6 multicast data packet is received, the packet destination MAC is matched with the MAC address entries in the IPv6 multicast table. If a match is found, packets are sent to the ports associated with the MAC address. If a match is not found, packets are flooded to the VLAN and copied to the CPU.

For IPv6 multicast, the destination MAC address is in the format 0x33-33-xx-yy-zz-kk, where xx-yy-zz-kk are the 32 lowest bits of the IPv6 multicast group address. For example, the IPv6 group address 0xFF3E:40:2001:660:3007:123:1234:5678 maps to the IPv6 MAC address 0x33-33-00-00-00-12.

For two multicast traffic streams, Source_1 and Group1 (S1,G1) and Source_2 and Group2 (S2,G2), with the same or different source addresses, if the lowest 32 bits of the 128-bit IPv6 group address are the same, they would map to the same destination MAC. Because the FESX and FSX support MAC-based forwarding for MLD snooping, the final multicast MAC address entry would be a superset of all the IPv6 groups mapped to it. For example, consider the following three IPv6 multicast streams sent from port 5 of a Brocade device:

• (S1,G1) = (2060::5, ff1e::12), client port 1, port 2
• (S2,G2) = (2060::6, ff1e::12), client port 2, port 3
• (S3,G1) = (2060::7, ff1e::12), client port 4

Because the lowest 32 bits of the group address for G1 and G2 are the same, all three streams would use 0x33-33-00-00-00-12 as the destination MAC address. MLD snooping would build a MAC entry with the MAC address 0x33-33-00-00-00-12 on egress ports 1, 2, 3, and 4. As a result, all three streams would be sent to ports 1, 2, 3, and 4. Note that the above example assumes the following:

• The Brocade device is running MLD snooping on VLAN 10 and all three streams are in VLAN 10
• There are clients on port 1 and port 2 for (S1,G1)
• There are clients on port 2 and port 3 for (S2,G2)
• There are clients on port 4 for (S3,G1)
Configuration notes and feature limitations

- Servers (traffic sources) are not required to send MLD memberships.
- The default MLD version is V1, where the source address is not sensitive. In the example given in the preceding section (“How MLD snooping uses MAC addresses to forward multicast packets” on page 1126), (S1,G1) and (S3,G1) would be considered the same group as (*,G1).
- If MLDv2 is configured on any port of a VLAN, you can check the source information, but because MLD snooping is MAC based, (S,G) switching is not feasible.
- Hardware resources are installed only when there is data traffic.
- Up to 4K collective entries for IGMP Snooping, MLD snooping, and Multi-port Static MAC Addresses are supported.
- You can configure the maximum number of groups and the multicast cache (mcache) number.
- The device supports static groups applying to specific ports. The device acts as a proxy to send MLD reports for the static groups when receiving queries.
- A user can configure static router ports, forcing all multicast traffic to be sent to these ports.
- Brocade devices support fast leave for MLDv1, which stops traffic immediately to any port that has received a leave message.
- Brocade devices support tracking and fast leave for MLDv2, which tracks all MLDv2 clients. If the only client on a port leaves, traffic is stopped immediately.
- An MLD device can be configured as a querier (active) or non-querier (passive). Queriers send queries. Non-queriers listen for queries and forward them to the entire VLAN.
- Every VLAN can be independently configured as a querier or a non-querier.
- A VLAN that has a connection to an IPv6 PIM-enabled port on another router should be configured as a non-querier. When multiple snooping devices connect together and there is no connection to IPv6 PIM ports, only one device should be configured as the querier. If multiple devices are configured as active, only one will continue to send queries after the devices have exchanged queries. Refer to “Queriers and non-queriers” on page 1128.
- An MLD device can be configured to rate-limit the forwarding of MLDv1 membership reports to queriers.
- Because an IPv6 link-local address as the source address when sending queries, a global address is not required.
- The MLD implementation allows snooping on some VLANs or on all VLANs. MLD can be enabled or disabled independently for each VLAN. In addition, individual ports of a VLAN can be configured as MLDv1 and MLDv2. In general, global configuration commands such as `<ipv6 mld-snooping>` apply to all VLANs except those with a local `<mld-snooping>` configuration, which supersedes the global configuration. Configuring the version on a port or a VLAN only affects the device sent query version. The device always processes all versions of client reports regardless of the version configured.
- MLD snooping requires hardware resources. If the device has insufficient resources, the data stream without a resource is mirrored to the CPU in addition to being VLAN flooded, which can cause high CPU usage. To avoid this situation, Brocade recommends that you avoid enabling snooping globally unless necessary.
- To receive data traffic, MLD snooping requires clients to send membership reports. If a client does not send reports, you must configure a static group to force traffic to client ports.
Multicast Router Discovery (MRD) messages are useful for determining which nodes attached to a switch have multicast routing enabled. This capability is useful in a Layer 2 bridge domain with snooping switches. By utilizing MRD messages, Layer 2 switches can determine where to send multicast source data and group membership messages. Multicast source data and group membership reports must be received by all multicast routers on a segment. Using the group membership protocol Query messages to discover multicast routers is insufficient due to query suppression.

Since Brocade does not support MRD, this can lead to stream loss when non-Querier router ports age out on the Querier after the initial Query election. To avoid such stream loss, configure a static router port on the querier on each interface that connects to a non-querier snooping device.

Queriers and non-queriers

An MLD snooping-enabled device can be configured as a querier (active) or non-querier (passive). An MLD querier sends queries; a non-querier listens for MLD queries and forwards them to the entire VLAN. When multiple MLD snooping devices are connected together, and there is no connection to an IPv6 PIM-enabled port, one of the devices should be configured as a querier. If multiple devices are configured as queriers, after multiple devices exchange queries, then all devices except the winner (the device with the lowest address) stop sending queries. Although the system works when multiple devices are configured as queriers, Brocade recommends that only one device, preferably the one with the traffic source, is configured as the querier.

VLANs can also be independently configured as queriers or non-queriers. If a VLAN has a connection to an IPv6 PIM-enabled port on another router, the VLAN should be configured as a non-querier.

Because non-queriers always forward multicast data traffic and MLD messages to router ports which receive MLD queries or IPv6 PIM hellos, Brocade recommends that you configure the devices with the data traffic source (server) as queriers. If a server is attached to a non-querier, the non-querier always forwards traffic to the querier regardless of whether or not there are clients on the querier.

**NOTE**

In a topology with one or more connected devices, at least one device must be running PIM, or configured as active. Otherwise, no devices can send queries, and traffic cannot be forwarded to clients.

To configure the MLD mode (querier or non-querier) on an MLD snooping-enabled device, refer to “Configuring the global MLD mode” on page 1130. To configure the MLD mode on a VLAN, refer to “Configuring the MLD mode for a VLAN” on page 1133.

VLAN specific configuration

You can configure MLD snooping on some VLANs or all VLANs. Each VLAN can be independently enabled or disabled for MLD snooping, or can be configured with MLDv1 or MLDv2. In general, the `ipv6 mld-snooping` commands apply globally to all VLANs except those configured with VLAN-specific `mld-snooping` commands. VLAN-specific `mld-snooping` commands supersede global `ipv6 mld-snooping` commands.
Using MLDv1 with MLDv2

MLD snooping can be configured as MLDv1 or MLDv2 on individual ports on a VLAN. An interface or router sends queries and reports that include the MLD version with which it has been configured. The version configuration applies only to the sending of queries. The snooping device recognizes and processes MLDv1 and MLDv2 packets regardless of the version configured.

**NOTE**
To avoid version deadlock, when an interface receives a report with a lower version than that for which it has been configured, the interface does **not** automatically downgrade the running MLD version.

Configuring MLD snooping

Configuring MLD snooping on an IPv6 device consists of the following global and VLAN-specific tasks.

**Global tasks:**
- Configuring hardware and software resource limits
- Disabling transmission and receipt of MLD packets on a port
- Configuring the MLD mode: active or passive (must be enabled for MLD snooping)
- Modifying the age interval
- Modifying the interval for query messages (active MLD mode only)
- Specifying the global MLD version
- Enabling and disabling report control (rate limiting)
- Modifying the leave wait time
- Modifying the mcache age interval
- Disabling error and warning messages

**VLAN-specific tasks:**
- Configuring the MLD mode for the VLAN: active or passive
- Enabling or disabling MLD snooping for the VLAN
- Configuring the MLD version for the VLAN
- Configuring the MLD version for individual ports
- Configuring static groups to the entire VLAN or some ports
- Configuring static router ports
- Disabling proxy activity for a static group
- Enabling client tracking and the fast leave feature for MLDv2
- Configuring fast leave for MLDv1
- Configuring fast-convergence
Configuring the hardware and software resource limits

The system supports up to 8K of hardware-switched multicast streams. The default is 512. To define the maximum number of MLD snooping mcache entries, enter a command such as the following.

```
FastIron(config)#system-max mld-snoop-mcache 8000
```

**Syntax:**
```
[no] system-max mld-snoop-mcache <num>
```

*<num>* is a value from 256 – 8192. The default is 512.

The system supports up to 32K of multicast groups. The default is 8192. The configured number is the upper limit of an expandable database. Client memberships exceeding the group limits are not processed. To define the maximum number of multicast group addresses supported, enter a command such as the following.

```
FastIron(config)#system-max mld-max-group-addr 4000
```

**Syntax:**
```
[no] system-max mld-snoop-mcache <num>
```

*<num>* is a value from 256 – 32768. The default is 8192.

Disabling transmission and receipt of MLD packets on a port

When a VLAN is snooping-enabled, all MLD packets are trapped to the CPU without hardware VLAN flooding. The CPU can block MLD packets to and from a multicast-disabled port, and will not add that port to the output interfaces of hardware resources, which prevents the disabled port from receiving multicast traffic. However, if static groups to the entire VLAN are defined, the traffic for these groups is flooded to the entire VLAN, including to the disabled ports. Since the hardware cannot block traffic from disabled ports, hardware traffic is switched in the same way as traffic from enabled ports.

**NOTE**

This command has no effect on a VLAN that is not snooping-enabled because all multicast traffic is VLAN flooded.

```
FastIron(config)#interface ethernet 1/3
FastIron(config-if-e1000-1/3)#ipv6-multicast-disable
```

**Syntax:**
```
[no] ipv6-multicast-disable
```

Configuring the global MLD mode

You can configure a Brocade device for either active or passive (default) MLD mode. If you specify an MLD mode for a VLAN, the MLD mode overrides the global setting.

- **Active** – In active MLD mode, a device actively sends out MLD queries to identify IPv6 multicast groups on the network, and makes entries in the MLD table based on the group membership reports it receives from the network.
- **Passive** – In passive MLD mode, the device forwards reports to the router ports which receive queries. MLD snooping in passive mode does not send queries, but does forward queries to the entire VLAN.

To globally set the MLD mode to active, enter the following command.
Configuring MLD snooping

FastIron(config)#ipv6 mld-snooping active

Syntax: [no] ipv6 mld-snooping [active | passive]

Omitting both the active and passive keywords is the same as entering ipv6 mld-snooping passive.

Modifying the age interval

When the device receives a group membership report, it makes an entry in the MLD group table for the group in the report. The age interval specifies how long the entry can remain in the table without the device receiving another group membership report. When multiple devices connect together, all devices should be configured with the same age interval. The age interval should be at least twice that of the query interval, so that missing one report will not stop traffic. For a non-querier, the query interval should equal that of the querier.

To modify the age interval, enter a command such as the following.

FastIron(config)#ipv6 mld-snooping age-interval 280

Syntax: [no] ipv6 mld-snooping age-interval <interval>

The <interval> parameter specifies the aging time. You can specify a value from 20 – 7200 seconds. The default is 140 seconds.

Modifying the query interval (active MLD snooping mode only)

If the MLD mode is set to active, you can modify the query interval, which specifies how often the Brocade device sends group membership queries. By default, queries are sent every 60 seconds. When multiple queriers connect together, all queriers should be configured with the same interval.

To modify the query interval, enter a command such as the following.

FastIron(config)#ipv6 mld-snooping query-interval 120

Syntax: [no] ipv6 mld-snooping query-interval <interval>

The <interval> parameter specifies the interval between queries. You can specify a value from 10 – 3600 seconds. The default is 60 seconds.

Configuring the global MLD version

The default version is MLDv1. You can specify the global MLD version on the device as either MLDv1 or MLDv2. For example, the following command configures the device to use MLDv2.

FastIron(config)#ipv6 mld-snooping version 2

Syntax: [no] ipv6 mld-snooping version 1 | 2

You can also specify the MLD version for individual VLANs, or individual ports within VLANs. If no MLD version is specified for a VLAN, then the globally configured MLD version is used. If an MLD version is specified for individual ports in a VLAN, those ports use that version instead of the version specified for the VLAN or the globally specified version. The default is MLDv1.
Configuring report control

When a device is in passive mode, it forwards reports and leave messages from clients to the upstream router ports that are receiving queries.

You can configure report control to rate-limit report forwarding for the same group to no more than once per 10 seconds. This rate limiting does not apply to the first report answering a group-specific query.

**NOTE**
This feature applies to MLDv1 only. The leave messages are not rate limited.

MLDv1 membership reports for the same group from different clients are considered to be the same, and are rate-limited. This alleviates the report storm caused by multiple clients answering the upstream router query.

To enable report-control, enter the following command.

```plaintext
FastIron(config)#ipv6 mld-snooping report-control
```

**Syntax:** `[no] ipv6 mld-snooping report-control`

Modifying the wait time before stopping traffic when receiving a leave message

You can define the wait time before stopping traffic to a port when the device receives a leave message for that port. The device sends group-specific queries once per second to determine if any client on the same port still needs the group.

```plaintext
FastIron(config)#ipv6 mld-snooping leave-wait-time 1
```

**Syntax:** `[no] ipv6 mld-snooping leave-wait-time <num>`

where `<num>` is a value from 1 to 5. The default is 2. Because of the internal timer accuracy, the actual wait time is between `n` and `(n+1)` seconds, where `n` is the configured value.

Modifying the multicast cache (mcache) aging time

You can set the time for an mcache to age out when it does not receive traffic. Two seconds before an mcache is aged out, the device mirrors a packet of the mcache to the CPU to reset the age. If no data traffic arrives within two seconds, the mcache is deleted. Note that in FESX and FSX devices, more than one mcache can be mapped to the same destination MAC. Hence, when an mcache entry is deleted, the MAC entry may not be deleted. If you configure a lower value, the resource consumed by idle streams is quickly removed, but packets are mirrored to the CPU more frequently. Configure a higher value only when data streams are arriving consistently.

You can use the `show ipv6 mld-snooping mcache` command to view the currently configured mcache age. Refer to "Displaying MLD snooping mcache information" on page 1138.

To modify the multicast cache age out time, enter a command such as the following.

```plaintext
FastIron(config)#ipv6 mld-snooping mcache-age 180
```

**Syntax:** `[no] ipv6 mld-snooping mcache-age <num>`

where `<num>` is a value from 60 to 3600 seconds, and the default is 60 seconds.
Disabling error and warning messages

Error or warning messages are printed when the device runs out of software resources or when it receives packets with the wrong checksum or groups. These messages are rate limited. You can turn off these messages by entering a command such as the following.

```
FastIron(config)#ipv6 mld-snooping verbose-off
```

Syntax: [no] ipv6 mld-snooping verbose-off

Configuring the MLD mode for a VLAN

You can configure a VLAN for either the active or passive (default) MLD mode. The VLAN setting overrides the global setting:

- Active – In active MLD mode, the device actively sends out MLD queries to identify IPv6 multicast groups on the network, and makes entries in the MLD table based on the group membership reports it receives from the network.
- Passive – In passive MLD mode, the device forwards reports to router ports that receive queries. MLD snooping in the passive mode does not send queries. However, it does forward queries to the entire VLAN.

To set the MLD mode for VLAN 20 to active, enter the following commands.

```
FastIron(config)#vlan 20
FastIron(config-vlan-20)#mld-snooping active
```

Syntax: [no] mld-snooping active | passive

The default mode is passive.

Disabling MLD snooping for the VLAN

When MLD snooping is enabled globally, you can disable it for a specific VLAN. For example, the following commands disable MLD snooping for VLAN 20. This setting overrides the global setting for VLAN 20.

```
FastIron(config)#vlan 20
FastIron(config-vlan-20)#mld-snooping disable-mld-snoop
```

Syntax: [no] mld-snooping disable-mld-snoop

Configuring the MLD version for the VLAN

You can specify the MLD version for a VLAN. For example, the following commands configure VLAN 20 to use MLDv2.

```
FastIron(config)#vlan 20
FastIron(config-vlan-20)#mld-snooping version 2
```

Syntax: [no] mld-snooping version 1 | 2

When no MLD version is specified, the globally-configured MLD version is used. If an MLD version is specified for individual ports, these ports use that version, instead of the version specified for the VLAN.
Configuring the MLD version for individual ports

You can specify the MLD version for individual ports in a VLAN. For example, the following commands configure ports 1/4, 1/5, 1/6 and 2/1 to use MLDv2. The other ports use the MLD version specified with the `mld-snooping version` command, or the globally configured MLD version.

```
FastIron(config)#vlan 20
FastIron(config-vlan-20)#mld-snooping port-version 2 ethe 2/1 ethe 1/4 to 1/6
```

Syntax: `[no] mld-snooping port-version 1 | 2 ethernet <port-numbers>`

Configuring static groups to the entire VLAN or to individual ports

**NOTE**
On FastIron X Series devices, you can configure MLD snooping static groups for individual ports in a VLAN, but not for the entire VLAN.

A snooping-enabled VLAN cannot forward multicast traffic to ports that do not receive MLD membership reports. To allow clients to send reports, you can configure a static group which applies to the entire VLAN, or to individual ports on the VLAN. The maximum number of supported static groups in a VLAN is 512, and the maximum number of supported static groups for individual ports in a VLAN is 256. The static group forwards packets to the static group ports even if they have no client membership reports. The static group for the entire VLAN is used in VLAN flooding because it uses fewer hardware resources than the static group for individual ports. Configure a static group for specific ports on VLAN 20 using commands similar to the following.

```
FastIron(config)#vlan 20
FastIron(config-vlan-20)#mld-snooping static-group ff05::100 count 2 ethe 1/3 ethe 1/5 to 1/7
FastIron(config-vlan-20)#mld-snooping static-group ff10::200
```

Syntax: `[no] mld-snooping static-group <ipv6-address> [count <num>] [<port-numbers>]`

The `ipv6-address` parameter is the IPv6 address of the multicast group.

The `count` is optional, which allows a contiguous range of groups. Omitting the count `<num>` is equivalent to the count being 1.

Except on FastIron X Series devices, if there are no port-numbers, the static groups apply to the entire VLAN.

Configuring static router ports

All multicast control and data packets are forwarded to router ports that receive queries. Although router ports are learned, you can configure static router ports to force multicast traffic to specific ports, even though these ports never receive queries. To configure static router ports, enter commands such as the following.

```
FastIron(config)#vlan 70
FastIron(config-vlan-70)#mld-snooping router-port e 1/4 to 1/5 e 1/8
```

Syntax: `[no] mld-snooping router-port ethernet <port-numbers>`
Disabling static group proxy

A device with statically configured groups acts as a proxy and sends membership reports for its static groups when it receives general or group-specific queries. When a static group configuration is removed, the group is immediately deleted from the active group table. However, the device does not send leave messages to the querier. The querier should age out the group. The proxy activity can be disabled (the default is enabled).

Example

FastIron(config)#vlan 20
FastIron(config-vlan-20)#mld-snooping proxy-off

Syntax:  [no] mld-snooping proxy-off

By default, MLD snooping proxy is enabled.

Enabling MLDv2 membership tracking and fast leave for the VLAN

MLDv2 provides membership tracking and fast leave services to clients. In MLDv1, only one client per interface must respond to a router queries; leaving some clients invisible to the router, which makes it impossible for the device to track the membership of all clients in a group. In addition, when a client leaves the group, the device sends group-specific queries to the interface to see if other clients on that interface need the data stream of the client who is leaving. If no client responds, the device waits a few seconds before stopping the traffic. You can configure the wait time with the ipv6 mld-snooping leave-wait-time command. Refer to “Modifying the wait time before stopping traffic when receiving a leave message” on page 1132.

MLDv2 requires that every client respond to queries, allowing the device to track every client. When the tracking feature is enabled, the device immediately stops forwarding traffic to the interface if an MLDv2 client sends a leave message, and there is no other client. This feature requires the entire VLAN to be configured for MLDv2 and have no MLDv1 clients. If a client does not send a report during the specified group membership time (the default is 140 seconds), that client is removed from the tracking list.

Every group on a physical port keeps its own tracking record. However, it can track group membership only; it cannot track by (source, group). For example, Client A and Client B belong to group1 but each is receiving traffic from different sources. Client A receives a traffic stream from (source_1, group1) and Client B receives a traffic stream from (source_2, group1). The device waits for the configured leave-wait-time before it stops the traffic because the two clients are in the same group. If the clients are in different groups, the waiting period is ignored and traffic is stopped immediately.

To enable tracking and fast leave for VLAN 20, enter the following commands.

FastIron(config)#vlan 20
FastIron(config-vlan-20)#mld-snooping tracking

Syntax:  [no] mld-snooping tracking

The membership tracking and fast leave features are supported for MLDv2 only. If a port or client is not configured for MLDv2, the mld-snooping tracking command is ignored.
Configuring fast leave for MLDv1

When a FESX or FSX device receives an MLDv1 leave message, it sends out multiple group-specific queries. If no other client replies within the waiting period, the device stops forwarding traffic to this port. Configuring fast-leave-v1 allows the device to stop forwarding traffic to a port immediately upon receiving a leave message. The device does not send group-specific queries. It is important that no snooping ports have multiple clients. When two devices connect, the querier device should not be configured for fast-leave-v1 because the port to the non-querier device could have multiple clients. The number of queries and the waiting period (in seconds) can be configured using the `ipv6 mld-snooping leave-wait-time` command. Refer to “Modifying the wait time before stopping traffic when receiving a leave message” on page 1132.

To configure fast leave for MLDv1, use commands such as the following.

```
FastIron(config)#vlan 20
FastIron(config-vlan-20)#mld-snooping fast-leave-v1
```

**Syntax:** `[no] mld-snooping fast-leave-v1`

Enabling fast convergence

In addition to periodically sending general queries, an active (querier) FESX or FSX device sends out general queries when it detects a new port. However, since it does not recognize the other device port-up event, the multicast traffic might still use the query-interval time to resume after a topology change. Configuring fast-convergence allows the device to listen to topology change events in Layer 2 (L2) protocols, such as spanning tree, and send general queries to shorten the convergence time.

If the L2 protocol is unable to detect a topology change, the fast-convergence feature may not work. For example, if the direct connection between two devices switches from one interface to another, the rapid spanning tree protocol (802.1w) considers this an optimization action, rather than a topology change. In this case, other devices will not receive topology change notifications and will be unable to send queries to speed up the convergence. The original spanning tree protocol does not recognize optimization actions, and fast-convergence works in all cases.

To enable fast-convergence, enter commands such as the following.

```
FastIron(config)#vlan 70
FastIron(config-vlan-70)#mld-snooping fast-convergence
```

**Syntax:** `[no] mld-snooping fast-convergence`

Displaying MLD snooping information

You can display the following MLD snooping information:

- MLD snooping error information
- Group and forwarding information for VLANs
- Information about MLD snooping mcache
- MLD memory pool usage
- Status of MLD traffic
- MLD information by VLAN
Displaying MLD snooping error information

To display information about possible MLD errors, enter the following command.

```
FastIron#show ipv6 mld-snooping error
snoop SW processed pkt: 173, up-time 160 sec
```

**Syntax:** `show ipv6 mld-snooping error`

The following table describes the output from the `show ipv6 mld-snooping error` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW processed pkt</td>
<td>The number of IPv6 multicast packets processed by MLD snooping.</td>
</tr>
<tr>
<td>up-time</td>
<td>The MLD snooping up time.</td>
</tr>
</tbody>
</table>

Displaying MLD group information

To display MLD group information, enter the following command.

```
FastIron#show ipv6 mld-snooping group
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1: 263 grp, 263 grp-port, tracking_enabled
```

```
group                                      p-port  ST  QR  life  mode source
1   ff0e::ef00:a0e3                         1/7    N  Y  120  EX   0
2   ff01::1::f123::f567                    1/9    N  Y      IN   1
```

**NOTE**

In this example, an MLDv1 group is in EXCLUDE mode with a source of 0. The group excludes traffic from the 0 (zero) source list, which actually means that all traffic sources are included.

To display detailed MLD group information, enter the following command.

```
FastIron#show ipv6 mld-snooping group ff0e::ef00:a096 detail
Display group ff0e::ef00:a096 in all interfaces in details.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1: 1 grp, 1 grp-port, tracking_enabled
```

```
group                                      p-port  ST  QR  life  mode source
1   ff0e::ef00:a096                         1/7    N  Y  100  EX   0
```

```
group: ff0e::ef00:a096, EX, permit 0 (source, life):
    life=100, deny 0:
```

If tracking and fast leave are enabled, you can display the list of clients for a particular group by entering the following command.

```
FastIron#show ipv6 mld-snooping group ff0e::ef00:a096 tracking
Display group ff0e::ef00:a096 in all interfaces with tracking enabled.
p-:physical, ST:static, QR:querier, EX:exclude, IN:include, Y:yes, N:no
VL1: 1 grp, 1 grp-port, tracking_enabled
```

```
group                                      p-port  ST  QR  life  mode source
1   ff0e::ef00:a096                         1/7    N  Y  80   EX   0
```

```
receive reports from 1 clients: (age)
   (fe80::1011:1213:1415 60)
```

**Syntax:** `show ipv6 mld-snooping group [group-address] [detail] [tracking]`
To receive a report for a specific multicast group, enter that group address for `<group-address>`.

Enter **detail** to display the source list of a specific VLAN.

Enter **tracking** for information on interfaces that are tracking-enabled.

The following table describes the information displayed by the `show ipv6 mld-snooping group` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>The address of the IPv6 group (destination IPv6 address).</td>
</tr>
<tr>
<td>p-port</td>
<td>The physical port on which the group membership was received.</td>
</tr>
<tr>
<td>ST</td>
<td><strong>Yes</strong> indicates that the MLD group was configured as a static group; <strong>No</strong> means it was learned from reports.</td>
</tr>
<tr>
<td>QR</td>
<td><strong>Yes</strong> means the port is a querier port; <strong>No</strong> means it is not. A port becomes a non-querier port when it receives a query from a source with a lower source IP address than the port.</td>
</tr>
<tr>
<td>life</td>
<td>The number of seconds the group can remain in EXCLUDE mode. An EXCLUDE mode changes to INCLUDE if it does not receive an IS_EX or TO_EX message during a specified period of time. The default is 140 seconds. There is no life displayed in INCLUDE mode.</td>
</tr>
<tr>
<td>mode</td>
<td>The current mode of the interface: INCLUDE or EXCLUDE. If the interface is in INCLUDE mode, it admits traffic only from the source list. If the interface is in EXCLUDE mode, it denies traffic from the source list and accepts the rest.</td>
</tr>
<tr>
<td>source</td>
<td>Identifies the source list that will be included or excluded on the interface. An MLDv1 group is in EXCLUDE mode with a source of 0. The group excludes traffic from 0 (zero) source list, which actually means that all traffic sources are included.</td>
</tr>
</tbody>
</table>
| group         | If you requested a **detailed** report, the following information is displayed:  
  • The multicast group address
  • The mode of the group
  • Sources from which traffic will be admitted (INCLUDE) or denied (EXCLUDE) on the interface.
  • The life of each source list.  
  If you requested a **tracking/fast leave** report, the clients from which reports were received are identified. |

**Displaying MLD snooping mcache information**

The MLD snooping mcache contains multicast forwarding information for VLANs. To display information in the multicast forwarding mcache, enter the following command.

```
FastIron#show ipv6 mld-snooping mcache
Example: (S G) cnt=: (S G) are the lowest 32 bits, cnt: SW proc. count 
  OIF: 1/22 TR(1/32,1/33), TR is trunk, 1/32 primary, 1/33 output 
  vlan 1, has 2 cache 
  1 (abcd:ef50 0:100), cnt=121 
    OIF: 1/11 1/9 
    age=0s up-time=120s vidx=4130 (ref-cnt=1) 
  2 (abcd:ef50 0:101), cnt=0 
    OIF: entire vlan 
    age=0s up-time=0s vidx=8191 (ref-cnt=1) 
  vlan 70, has 0 cache
```

**Syntax: show ipv6 mld-snooping mcache**

The following table describes the output from the `ipv6 mld-snooping mcache` command.
Configuring MLD snooping

Displaying software resource usage for VLANs

To display information about the software resources used, enter the following command.

```
FastIron#show ipv6 mld-snooping resource
```

```
alloc in-use avail get-fail limit get-mem size init
mld group 512 9 503 0 32000 272 28 256
mld phy port 1024 16 1008 0 200000 279 21 1024
snoop group hash 512 9 503 0 59392 272 20 256
... Entries deleted
total pool memory 194432 bytes
has total 1 forwarding hash
Available vidx: 4061
```

Syntax: `show ipv6 mld-snooping resource`

The following table describes the output from the `show ipv6 mld-snooping resource` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>alloc</td>
<td>The allocated number of units.</td>
</tr>
<tr>
<td>in-use</td>
<td>The number of units which are currently used.</td>
</tr>
<tr>
<td>avail</td>
<td>The number of available units.</td>

Displaying MLD snooping information by VLAN

You can display MLD snooping information for all VLANs or for a specific VLAN. For example, to display MLD snooping information for VLAN 70, enter the following command.
Configuring MLD snooping

Syntax: show ipv6 mld-snooping vlan [<vlan-id>]

If you do not specify a vlan-id, information for all VLANs is displayed.

The following table describes information displayed by the show ipv6 mld-snooping vlan command.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>The MLD version number.</td>
</tr>
<tr>
<td>query-t</td>
<td>How often a querier sends a general query on the interface.</td>
</tr>
<tr>
<td>group-aging-t</td>
<td>Number of seconds membership groups can be members of this group before aging out.</td>
</tr>
<tr>
<td>rtr-port</td>
<td>The router ports which are the ports receiving queries. The display router ports: 1/36(120) fe80::2e0:52ff:fe00:9900, 1/26 has 2 grp, non-QR (passive), cfg V1 1/26 has 2 grp, non-QR (passive), cfg V1 group: ff10:1234::5679, life = 100 group: ff10:1234::5678, life = 100 1/35 has 0 grp, non-QR (QR=fe80::2e0:52ff:fe00:9900, age=20), dft V2 trunk</td>
</tr>
<tr>

</tbody>
</table>

Clearing MLD snooping counters and mcach

The clear commands for MLD snooping should only be used in troubleshooting situations or when recovering from error conditions.

Clearing MLD counters on all VLANs

To clear MLD snooping error and traffic counters on all VLANs, enter the following command.

FastIron#clear ipv6 mld-snooping counters

Syntax: clear ipv6 mld-snooping counters

Clearing the mcache on all VLANs

To clear the mcache on all VLANs, enter the following command.

FastIron#clear ipv6 mld-snooping mcache

Syntax: clear ipv6 mld-snooping mcache

Clearing the mcache on a specific VLAN

To clear the mcache on a specific VLAN, enter the following command.

FastIron#clear ipv6 mld-snooping vlan 10 mcache
Syntax: clear ipv6 mld-snooping vlan <vlan-id> mcache
The <vlan-id> parameter specifies the specific VLAN from which to clear the cache.

Clearing traffic counters on a specific VLAN

To clear the traffic counters on a specific VLAN, enter the following command.

FastIron#clear ipv6 mld-snooping vlan 10 traffic

Syntax: clear ipv6 mld-snooping vlan <vlan-id> traffic
The <vlan-id> parameter specifies the specific VLAN from which to clear the traffic counters.
Configuring RIP

RIP overview

Routing Information Protocol (RIP) is an IP route exchange protocol that uses a distance vector (a number representing distance) to measure the cost of a given route. The cost is a distance vector because the cost often is equivalent to the number of router hops between the Brocade Layer 3 Switch and the destination network.

A Brocade Layer 3 Switch can receive multiple paths to a destination. The software evaluates the paths, selects the best path, and saves the path in the IP route table as the route to the destination. Typically, the best path is the path with the fewest hops. A hop is another router through which packets must travel to reach the destination. If the Brocade Layer 3 Switch receives a RIP update from another router that contains a path with fewer hops than the path stored in the Brocade Layer 3 Switch route table, the Layer 3 Switch replaces the older route with the newer one. The Layer 3 Switch then includes the new path in the updates it sends to other RIP routers, including Brocade Layer 3 Switches.

RIP routers, including the Brocade Layer 3 Switch, also can modify a route cost, generally by adding to it, to bias the selection of a route for a given destination. In this case, the actual number of router hops may be the same, but the route has an administratively higher cost and is thus less likely to be used than other, lower-cost routes.

A RIP route can have a maximum cost of 15. Any destination with a higher cost is considered unreachable. Although limiting to larger networks, the low maximum hop count prevents endless loops in the network.

Brocade Layer 3 Switches support the following RIP versions:

- Version 1
- V1 compatible with V2
- Version 2 (the default)

Platform Support:

- FastIron X Series devices running software release 02.0.00 and later
- FGS-STK and FLS-STK devices running software release 05.0.00 and later (Base Layer 3)
- FWS devices running software release 04.3.00 and later (Edge Layer 3)
- FGS and FLS devices running software release 04.3.01 and later
- TurboIron X Series devices running software release 04.2.00 and later

ICMP host unreachable message for undeliverable ARPs

If the router receives an ARP request packet that it is unable to deliver to the final destination because of the ARP timeout and no ARP response is received (router knows of no route to the destination address), the router sends an ICMP Host Unreachable message to the source.
RIP parameters and defaults

The following tables list the RIP parameters, their default values, and where to find configuration information.

RIP global parameters

Table 191 lists the global RIP parameters and their default values, and indicates where you can find configuration information.

</tbody>
</table>

Configuring RIP parameters

Use the following procedures to configure RIP parameters on a system-wide and individual interface basis.

Enabling RIP

RIP is disabled by default. To enable it, use the following method.

NOTE
You must enable the protocol globally and also on individual interfaces on which you want to advertise RIP. Globally enabling the protocol does not enable it on individual interfaces.

To enable RIP globally, enter the following command.

```
FastIron(config)# router rip
```

Syntax: [no] router rip
Configuring RIP parameters

After globally enabling the protocol, you must enable it on individual interfaces. You can enable the protocol on physical interfaces as well as virtual routing interfaces. To enable RIP on an interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 0/1/1
FastIron(config-if-0/1/1)# ip rip v1-only
```

Syntax: [no] ip rip v1-only | v1-compatible-v2 | v2-only

**NOTE**
You must specify the RIP version.

Configuring metric parameters

By default, a Brocade Layer 3 Switch port increases the cost of a RIP route that is learned on the port by one. You can configure individual ports to add more than one to a learned route cost. In addition, you can configure a RIP offset list to increase the metric for learned or advertised routes based on network address.

**Changing the cost of routes learned on a port**

By default, a Brocade Layer 3 Switch port increases the cost of a RIP route that is learned on the port. The Layer 3 Switch increases the cost by adding one to the route metric before storing the route.

You can change the amount that an individual port adds to the metric of RIP routes learned on the port. To do so, use the following method.

**NOTE**
RIP considers a route with a metric of 16 to be unreachable. Use this metric only if you do not want the route to be used. In fact, you can prevent the Layer 3 Switch from using a specific port for routes learned though that port by setting its metric to 16.

To increase the cost a port adds to RIP routes learned in that port, enter commands such as the following.

```
FastIron(config)# interface ethernet 0/6/1
FastIron(config-if-0/6/1)# ip metric 5
```

These commands configure port 6/1 to add 5 to the cost of each route learned on the port.

Syntax: ip metric <1-16>

**Configuring a RIP offset list**

A RIP offset list allows you to add to the metric of specific inbound or outbound routes learned or advertised by RIP. RIP offset lists provide a simple method for adding to the cost of specific routes and therefore biasing the Layer 3 Switch route selection away from those routes.

An offset list consists of the following parameters:

- An ACL that specifies the routes to which to add the metric.
- The direction:
  - In applies to routes the Layer 3 Switch learns from RIP neighbors.
  - Out applies to routes the Layer 3 Switch is advertising to its RIP neighbors.
Configuring RIP parameters

- The type and number of a specific port to which the offset list applies (optional).

The software adds the offset value to the routing metric (cost) of the routes that match the ACL. If a route matches both a global offset list and an interface-based offset list, the interface-based offset list takes precedence. The interface-based offset list metric is added to the route in this case.

You can configure up to 24 global RIP offset lists and up to 24 RIP offset lists on each interface.

To configure a global RIP offset list, enter commands such as the following.

```
FastIron(config)# access-list 21 deny 160.1.0.0 0.0.255.255
FastIron(config)# access-list 21 permit any
FastIron(config)# router rip
FastIron(config-rip-router)# offset-list 21 out 10
```

The commands in this example configure a standard ACL. The ACL matches on all IP networks except 160.1.x.x. When the Layer 3 Switch advertises a route that matches ACL 21, the offset list adds 10 to the route metric.

**Syntax:**
```
[no] offset-list <ACL-number-or-name> in | out offset [ethernet [
[<stack-unit>]/<slotnum>/]<portnum>]
```

In the following example, the Layer 3 Switch uses ACL 21 to add 10 to the metric of routes received on Ethernet port 2/1.

```
FastIron(config-rip-router)# offset-list 21 in 10 ethernet 0/2/1
```

**Changing the administrative distance**

By default, the Layer 3 Switch assigns the default RIP administrative distance (120) to RIP routes. When comparing routes based on administrative distance, the Layer 3 Switch selects the route with the lower distance. You can change the administrative distance for RIP routes.

**NOTE**
Refer to “Changing administrative distances” on page 1327 for the default distances for all route sources.

To change the administrative distance for RIP routes, enter a command such as the following.

```
FastIron(config-rip-router)# distance 140
```

This command changes the administrative distance to 140 for all RIP routes.

**Syntax:**
```
[no] distance <num>
```

**Configuring redistribution**

You can configure the Layer 3 Switch to redistribute routes learned through Open Shortest Path First (OSPF) or Border Gateway Protocol version 4 (BGP4) into RIP. When you redistribute a route from one of these other protocols into RIP, the Layer 3 Switch can use RIP to advertise the route to its RIP neighbors.

To configure redistribution, perform the following tasks:

- Configure redistribution filters (optional). You can configure filters to permit or deny redistribution for a route based on its origin (OSPF, BGP4, and so on), the destination network address, and the route metric. You also can configure a filter to set the metric based on these criteria.
Configuring RIP parameters

- Change the default redistribution metric (optional). The Layer 3 Switch assigns a RIP metric of one to each redistributed route by default. You can change the default metric to a value up to 16.
- Enable redistribution.

**NOTE**
Do not enable redistribution until you configure the other redistribution parameters.

**Configuring redistribution filters**

RIP redistribution filters apply to all interfaces. The software uses the filters in ascending numerical order and immediately takes the action specified by the filter. Thus, if filter 1 denies redistribution of a given route, the software does not redistribute the route, regardless of whether a filter with a higher ID would permit redistribution of that route.

**NOTE**
The default redistribution action is permit, even after you configure and apply redistribution filters to the virtual routing interface. If you want to tightly control redistribution, apply a filter to deny all routes as the last filter (the filter with the highest ID), then apply filters with lower filter IDs to allow specific routes.

To configure a redistribution filter, enter a command such as the following.

```plaintext
FastIron(config-rip-router)# deny redistribute 2 all address 207.92.0.0 255.255.0.0
```

This command denies redistribution for all types of routes to the 207.92.x.x network.

**Syntax:**
```
[no] permit | deny redistribute <filter-num> all | bgp | ospf | static address <ip-addr> [match-metric <value> | set-metric <value>]
```

The `<filter-num>` specifies the redistribution filter ID. The software uses the filters in ascending numerical order. Thus, if filter 1 denies a route from being redistributed, the software does not redistribute that route even if a filter with a higher ID permits redistribution of the route.

The `all` parameter applies redistribution to all route types.

The `bgp` parameter applies redistribution to BGP4 routes only.

The `ospf` parameter applies redistribution to OSPF routes only.

The `static` parameter applies redistribution to IP static routes only.

The `address` `<ip-addr>` `<ip-mask>` parameters apply redistribution to the specified network and subnet address. Use 0 to specify “any”. For example, “207.92.0.0 255.255.0.0” means “any 207.92.x.x subnet”. However, to specify any subnet (all subnets match the filter), enter “address 255.255.255.255 255.255.255.255”.

The `match-metric` `<value>` parameter applies the redistribution filter only to those routes with the specified metric value; possible values are from 1 – 15.

The `set-metric` `<value>` parameter sets the RIP metric value that will be applied to those routes imported into RIP.

The following command denies redistribution into RIP for all OSPF routes.

```plaintext
FastIron(config-rip-router)# deny redistribute 3 ospf address 207.92.0.0 255.255.0.0
```
The following command denies redistribution for all OSPF routes that have a metric of 10.

```
FastIron(config-rip-router)# deny redistribute 3 ospf address 207.92.0.0 255.255.0.0 match-metric 10
```

The following commands deny redistribution of all routes except routes for 10.10.10.x and 20.20.20.x.

```
FastIron(config-rip-router)# deny redistribute 64 static address 255.255.255.255 255.255.255.255
FastIron(config-rip-router)# permit redistribute 1 static address 10.10.10.0 255.255.255.0
FastIron(config-rip-router)# permit redistribute 2 static address 20.20.20.0 255.255.255.0
```

**NOTE**
This example assumes that the highest RIP redistribution filter ID configured on the device is 64.

**Changing the redistribution metric**

When the Layer 3 Switch redistributes a route into RIP, the software assigns a RIP metric (cost) to the route. By default, the software assigns a metric of one to each route that is redistributed into RIP. You can increase the metric that the Layer 3 Switch assigns, up to 15.

To change the RIP metric the Layer 3 Switch assigns to redistributed routes, enter a command such as the following.

```
FastIron(config-rip-router)# default-metric 10
```

This command assigns a RIP metric of 10 to each route that is redistributed into RIP.

**Syntax:** `[no] default-metric <1-15>`

**Enabling redistribution**

After you configure redistribution parameters, you need to enable redistribution.

To enable RIP redistribution, enter the following command.

```
FastIron(config-rip-router)# redistribution
```

**Syntax:** `[no] redistribution`

**Removing a RIP redistribution deny filter**

To remove a previously configured RIP redistribution deny filter, do the following.

1. Remove the RIP redistribution deny filter.
2. Disable the redistribution function.
3. Re-enable redistribution.

The following shows an example of how to remove a RIP redistribution deny filter.
Configuring route learning and advertising parameters

By default, a Brocade Layer 3 Switch learns routes from all its RIP neighbors and advertises RIP routes to those neighbors.

You can configure the following learning and advertising parameters:

- **Update interval** – The update interval specifies how often the Layer 3 Switch sends RIP route advertisements to its neighbors. The default is 30 seconds. You can change the interval to a value from 1 – 1000 seconds.
- **Learning and advertising of RIP default routes** – The Layer 3 Switch learns and advertises RIP default routes by default. You can disable learning and advertising of default routes on a global or individual interface basis.
- **Learning of standard RIP routes** – By default, the Layer 3 Switch can learn RIP routes from all its RIP neighbors. You can configure RIP neighbor filters to explicitly permit or deny learning from specific neighbors.

Changing the update interval for route advertisements

The update interval specifies how often the Layer 3 Switch sends route advertisements to its RIP neighbors. You can specify an interval from 1 – 1000 seconds. The default is 30 seconds.

To change the RIP update interval, enter a command such as the following.

```
FastIron(config-rip-router)# update 120
```

This command configures the Layer 3 Switch to send RIP updates every 120 seconds.

**Syntax:** `update-time <1-1000>`

Enabling learning of RIP default routes

By default, the Layer 3 Switch does not learn RIP default routes. You can enable learning of RIP default routes on a global or interface basis.

To enable learning of default RIP routes on a global basis, enter the following command.

```
FastIron(config-rip-router)# learn-default
```

**Syntax:** `[no] learn-default`

To enable learning of default RIP routes on an interface basis, enter commands such as the following.

```
FastIron(config)# interface ethernet 0/1/1
FastIron(config-if-0/1/1)# ip rip learn-default
```

**Syntax:** `[no] ip rip learn-default`
Configuring RIP parameters

Configuring a RIP neighbor filter

By default, a Brocade Layer 3 Switch learns RIP routes from all its RIP neighbors. Neighbor filters allow you to specify the neighbor routers from which the Brocade device can receive RIP routes. Neighbor filters apply globally to all ports.

To configure a RIP neighbor filters, enter a command such as the following.

```
FastIron(config-rip-router)# neighbor 1 deny any
```

**Syntax:** `[no] neighbor <filter-num> permit | deny <source-ip-address> | any`

This command configures the Layer 3 Switch so that the device does not learn any RIP routes from any RIP neighbors.

The following commands configure the Layer 3 Switch to learn routes from all neighbors except 192.168.1.170. Once you define a RIP neighbor filter, the default action changes from learning all routes from all neighbors to denying all routes from all neighbors except the ones you explicitly permit. To deny learning from a specific neighbor but allow all other neighbors, you must add a filter that allows learning from all neighbors. Be sure to add the filter to permit all neighbors last (the one with the highest filter number). Otherwise, the software can match on the permit all filter instead of a filter that denies a specific neighbor, and learn routes from that neighbor.

```
FastIron(config-rip-router)# neighbor 2 deny 192.16.1.170
FastIron(config-rip-router)# neighbor 1024 permit any
```

Changing the route loop prevention method

RIP can use the following methods to prevent routing loops:

- **Split horizon** – The Layer 3 Switch does not advertise a route on the same interface as the one on which the router learned the route.
- **Poison reverse** – The Layer 3 Switch assigns a cost of 16 (“infinite” or “unreachable”) to a route before advertising it on the same interface as the one on which the router learned the route. This is the default.

These loop prevention methods are configurable on an individual interface basis. One of the methods is always in effect on an interface enabled for RIP. If you disable one method, the other method is enabled.

**NOTE**

These methods may be used in addition to RIP maximum valid route cost of 15.

To disable poison reverse and enable split horizon on an interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 0/1/1
FastIron(config-if-0/1/1)# no ip rip poison-reverse
```

**Syntax:** `[no] ip rip poison-reverse`

To disable split horizon and enable poison reverse on an interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 0/1/1
FastIron(config-if-0/1/1)# ip rip poison-reverse
```
Suppressing RIP route advertisement on a VRRP or VRRPE backup interface

**NOTE**
This section applies only if you configure the Layer 3 Switch for Virtual Router Redundancy Protocol (VRRP) or VRRP Extended (VRRPE). Refer to Chapter 37, “Configuring VRRP and VRRPE”.

Normally, a VRRP or VRRPE Backup includes route information for the virtual IP address (the backed up interface) in RIP advertisements. As a result, other routers receive multiple paths for the backed up interface and might sometimes unsuccessfully use the path to the Backup rather than the path to the Master.

You can prevent the Backups from advertising route information for the backed up interface by enabling suppression of the advertisements.

To suppress RIP advertisements for the backed up interface, enter the following commands.

```plaintext
FastIron(config)# router rip
FastIron(config-rip-router)# use-vrrp-path
```

**Syntax:** `[no] use-vrrp-path
The syntax is the same for VRRP and VRRPE.

Configuring RIP route filters

You can configure RIP route filters to permit or deny learning or advertising of specific routes. Configure the filters globally, then apply them to individual interfaces. When you apply a RIP route filter to an interface, you specify whether the filter applies to learned routes (in) or advertised routes (out).

**NOTE**
A route is defined by the destination IP address and network mask.

**NOTE**
By default, routes that do not match a route filter are learned or advertised. To prevent a route from being learned or advertised, you must configure a filter to deny the route.

To configure RIP filters, enter commands such as the following.

```plaintext
FastIron(config-rip-router)# filter 1 permit 192.53.4.1 255.255.255.0
FastIron(config-rip-router)# filter 2 permit 192.53.5.1 255.255.255.0
FastIron(config-rip-router)# filter 3 permit 192.53.6.1 255.255.255.0
FastIron(config-rip-router)# filter 4 deny 192.53.7.1 255.255.255.0
```

These commands explicitly permit RIP routes to three networks, and deny the route to one network.

Since the default action is permit, all other routes (routes not explicitly permitted or denied by the filters) can be learned or advertised.

**Syntax:** `filter <filter-num> permit | deny <source-ip-address> | any <source-mask> | any [log]`
Applying a RIP route filter to an interface

Once you define RIP route filters, you must assign them to individual interfaces. The filters do not take effect until you apply them to interfaces. When you apply a RIP route filter, you also specify whether the filter applies to learned routes or advertised routes:

- Out filters apply to routes the Layer 3 Switch advertises to its neighbor on the interface.
- In filters apply to routes the Layer 3 Switch learns from its neighbor on the interface.

To apply RIP route filters to an interface, enter commands such as the following.

```
FastIron(config)# interface ethernet 0/1/2
FastIron(config-if-0/1/2)# ip rip filter-group in 2 3 4
```

Syntax: `[no] ip rip filter-group in | out <filter-list>`

These commands apply RIP route filters 2, 3, and 4 to all routes learned from the RIP neighbor on port 1/2.

Displaying RIP filters

To display the RIP filters configured on the router, enter the following command at any CLI level.

```
FastIron# show ip rip
```

This display shows the following information.

<table>
<thead>
<tr>
<th>TABLE 193 CLI display of RIP filter information</th>
</tr>
</thead>
<tbody>
<tr>
<td>This field...</td>
</tr>
<tr>
<td>Route filters</td>
</tr>
<tr>
<td>The rows underneath “RIP Route Filter Table” list the RIP route filters. If no RIP route filters are configured on the device, the following message is displayed instead: “No Filters are configured in RIP Route Filter Table”.</td>
</tr>
<tr>
<td>Index</td>
</tr>
<tr>
<td>Action</td>
</tr>
<tr>
<td>deny</td>
</tr>
<tr>
<td>permit</td>
</tr>
<tr>
<td>Route IP Address</td>
</tr>
</tbody>
</table>
Displaying CPU utilization statistics

You can display CPU utilization statistics for RIP and other IP protocols.

To display CPU utilization statistics for RIP for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI.

```
FastIron# show process cpu
```

<table>
<thead>
<tr>
<th>Process Name</th>
<th>5Sec(%)</th>
<th>1Min(%)</th>
<th>5Min(%)</th>
<th>15Min(%)</th>
<th>Runtime (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARP</td>
<td>0.01</td>
<td>0.03</td>
<td>0.09</td>
<td>0.22</td>
<td>9</td>
</tr>
<tr>
<td>BGP</td>
<td>0.04</td>
<td>0.06</td>
<td>0.08</td>
<td>0.14</td>
<td>13</td>
</tr>
<tr>
<td>GVRP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>ICMP</td>

<td>0.00</td>
<td>0</td>
</tr>
</tbody>
</table>

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.
To display utilization statistics for a specific number of seconds, enter a command such as the following.

FastIron# show process cpu

The system has only been up for 6 seconds.

<table>
<thead>
<tr>
<th>Process Name</th>
<th>5Sec(%)</th>
<th>1Min(%)</th>
<th>5Min(%)</th>
<th>15Min(%)</th>
<th>Runtime(ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARP</td>
<td>0.01</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>

</tr>
</tbody>
</table>

When you specify how many seconds’ worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

Syntax: show process cpu [<num>]

The <num> parameter specifies the number of seconds and can be from 1 – 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.
Displaying CPU utilization statistics
Configuring RIPng

RIPng overview

Routing Information Protocol (RIP) is an IP route exchange protocol that uses a distance vector (a number representing a distance) to measure the cost of a given route. RIP uses a hop count as its cost or metric.

IPv6 RIP, known as Routing Information Protocol Next Generation or RIPng functions similarly to IPv4 RIP Version 2. RIPng supports IPv6 addresses and prefixes and introduces some new commands that are specific to RIPng. This chapter describes the commands that are specific to RIPng. This section does not describe commands that apply to both IPv4 RIP and RIPng.

RIPng maintains a Routing Information Database (RIB), which is a local route table. The local RIB contains the lowest-cost IPv6 routes learned from other RIP routers. In turn, RIPng attempts to add routes from its local RIB into the main IPv6 route table.

NOTE
Brocade IPv6 devices support up to 10000 RiPng routes.

This section describes the following:

- How to configure RIPng
- How to clear RIPng information from the RIPng route table
- How to display RIPng information and statistics

Platform Support:
- FESX and FSX IPv6 devices running software release 04.1.00 and later – L3

Summary of configuration tasks

To configure RIPng, you must enable RIPng globally on the Brocade device and on individual router interfaces. The following configuration tasks are optional:

- Change the default settings of RIPng timers.
- Configure how the Brocade device learns and advertises routes.
- Configure which routes are redistributed into RIPng from other sources.
- Configure how the Brocade device distributes routes through RIPng.
- Configure poison reverse parameters.

Enabling RIPng

Before configuring the Brocade device to run RIPng, you must do the following:
Enable the forwarding of IPv6 traffic on the Brocade device using the `ipv6 unicast-routing` command.

Enable IPv6 on each interface over which you plan to enable RIPng. You enable IPv6 on an interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface.

For more information about performing these configuration tasks, refer to the chapter “Configuring IPv6 Connectivity” on page 207.

By default, RIPng is disabled. To enable RIPng, you must enable it globally on the Brocade device and also on individual router interfaces.

**NOTE**
You are required to configure a router ID when running only IPv6 routing protocols.

**NOTE**
Enabling RIPng globally on the Brocade device does not enable it on individual router interfaces.

To enable RIPng globally, enter the following command.

```
FastIron(config)#ipv6 router rip
FastIron(config-ripng-router)#
```

After you enter this command, the Brocade device enters the RIPng configuration level, where you can access several commands that allow you to configure RIPng.

**Syntax:** `[no] ipv6 router rip`

To disable RIPng globally, use the `no` form of this command.

After enabling RIPng globally, you must enable it on individual router interfaces. You can enable it on physical as well as virtual routing interfaces. For example, to enable RIPng on Ethernet interface 3/1, enter the following commands.

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# ipv6 rip enable
```

**Syntax:** `[no] ipv6 rip enable`

To disable RIPng on an individual router interface, use the `no` form of this command.

---

### Configuring RIPng timers

**Table 194** describes the RIPng timers and provides their defaults.

<table>
<thead>
<tr>
<th>Timer</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update</td>
<td>Amount of time (in seconds) between RIPng routing updates.</td>
<td>30 seconds.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Amount of time (in seconds) after which a route is considered unreachable.</td>
<td>180 seconds.</td>
</tr>
<tr>
<td>Hold-down</td>
<td>Amount of time (in seconds) during which information about other paths is ignored.</td>
<td>180 seconds.</td>
</tr>
<tr>
<td>Garbage-collection</td>
<td>Amount of time (in seconds) after which a route is removed from the routing table.</td>
<td>120 seconds.</td>
</tr>
</tbody>
</table>

You can adjust these timers for RIPng. Before doing so, keep the following caveats in mind:
If you adjust these RIPng timers, Brocade strongly recommends setting the same timer values for all routers and access servers in the network.

Setting the update timer to a shorter interval can cause the routers to spend excessive time updating the IPv6 route table.

Brocade recommends setting the timeout timer value to at least three times the value of the update timer.

Brocade recommends a shorter hold-down timer interval, because a longer interval can cause delays in RIPng convergence.

The following example sets updates to be broadcast every 45 seconds. If a route is not heard from in 135 seconds, the route is declared unusable. Further information is suppressed for an additional 10 seconds. Assuming no updates, the route is flushed from the routing table 20 seconds after the end of the hold-down period.

```
FastIron(config)# ipv6 router rip
FastIron(config-ripng-router)# timers 45 135 10 20
```

**Syntax:**  
```
[no] timers <update-timer> <timeout-timer> <hold-down-timer> <garbage-collection-timer>
```

Possible values for the timers are as follows:

- Update timer: 3 – 65535 seconds.
- Timeout timer: 9 – 65535 seconds.
- Hold-down timer: 9 – 65535 seconds.

NOTE

You must enter a value for each timer, even if you want to retain the current setting of a particular timer.

To return to the default values of the RIPng timers, use the `no` form of this command.

---

### Configuring route learning and advertising parameters

You can configure the following learning and advertising parameters:

- Learning and advertising of RIPng default routes.
- Advertising of IPv6 address summaries.
- Metric of routes learned and advertised on a router interface.

### Configuring default route learning and advertising

By default, the Brocade device does not learn IPv6 default routes (::/0). You can originate default routes into RIPng, which causes individual router interfaces to include the default routes in their updates. When configuring the origination of the default routes, you can also do the following:

- Suppress all other routes from the updates.
- Include all other routes in the updates.

For example, to originate default routes in RIPng and suppress all other routes in updates sent from Ethernet interface 3/1, enter the following commands.
Configuring route learning and advertising parameters

FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# ipv6 rip default-information only

To originate IPv6 default routes and include all other routes in updates sent from Ethernet interface 3/1, enter the following commands.

FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# ipv6 rip default-information originate

Syntax: [no] ipv6 rip default-information only | originate

The **only** keyword originates the default routes and suppresses all other routes from the updates.

The **originate** keyword originates the default routes and includes all other routes in the updates.

To remove the explicit default routes from RIPng and suppress advertisement of these routes, use the **no** form of this command.

Advertising IPv6 address summaries

You can configure RIPng to advertise a summary of IPv6 addresses from a router interface and to specify an IPv6 prefix that summarizes the routes.

If a route prefix length matches the value specified in the `ipv6 rip summary-address` command, RIPng advertises the prefix specified in the `ipv6 rip summary-address` command instead of the original route.

For example, to advertise the summarized prefix 2001:469e::/36 instead of the IPv6 address 2001:469e:0:adff:8935:e838:78:e0ff with a prefix length of 64 bits from Ethernet interface 3/1, enter the following commands.

FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# ipv6 address 2001:469e:0:adff:8935:e838:78:e0ff /64
FastIron(config-if-e100-3/1)# ipv6 rip summary-address 2001:469e::/36

Syntax: [no] ipv6 rip summary-address <ipv6-prefix>/<prefix-length>

You must specify the `<ipv6-prefix>` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

You must specify the `<prefix-length>` parameter as a decimal value. A slash mark (/) must follow the `<ipv6-prefix>` parameter and precede the `<prefix-length>` parameter.

To stop the advertising of the summarized IPv6 prefix, use the **no** form of this command.

Changing the metric of routes learned and advertised on an interface

A router interface increases the metric of an incoming RIPng route it learns by an offset (the default is one). The Brocade device then places the route in the route table. When the Brocade device sends an update, it advertises the route with the metric plus the default offset of zero in an outgoing update message.

You can change the metric offset an individual interface adds to a route learned by the interface or advertised by the interface. For example, to change the metric offset for incoming routes learned by Ethernet interface 3/1 to one and the metric offset for outgoing routes advertised by the interface to three, enter the following commands.
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# ipv6 rip metric-offset 1
FastIron(config-if-e100-3/1)# ipv6 rip metric-offset out 3

In this example, if Ethernet interface 3/1 learns about an incoming route, it will increase the incoming metric by two (the default offset of 1 and the additional offset of 1 as specified in this example). If Ethernet interface 3/1 advertises an outgoing route, it will increase the metric by 3 as specified in this example.

Syntax: [no] ipv6 rip metric-offset <1 –– 16>
Syntax: [no] ipv6 rip metric-offset out <1 –– 15>

To return the metric offset to its default value, use the no form of this command.

**Redistributing routes into RIPng**

You can configure the Brocade device to redistribute routes from the following sources into RIPng:

- IPv6 static routes
- Directly connected IPv6 networks
- OSPF V3

When you redistribute a route from IPv6 or OSPF V3 into RIPng, the Brocade device can use RIPng to advertise the route to its RIPng neighbors.

When configuring the Brocade device to redistribute routes, you can optionally specify a metric for the redistributed routes. If you do not explicitly configure a metric, the default metric value of one is used.

For example, to redistribute OSPF V3 routes into RIPng, enter the following command.

FastIron(config)# ipv6 router rip
FastIron(config-ripng-router)# redistribute ospf

Syntax: redistribute bgp | connected | isis | ospf | static [metric <number>]

For the metric, specify a numerical value that is consistent with RIPng.

**Controlling distribution of routes through RIPng**

You can create a prefix list and then apply it to RIPng routing updates that are received or sent on a router interface. Performing this task allows you to control the distribution of routes through RIPng.

For example, to permit the inclusion of routes with the prefix 2001::/16 in RIPng routing updates sent from Ethernet interface 3/1, enter the following commands.

FastIron(config)# ipv6 prefix-list routesfor2001 permit 2001::/16
FastIron(config)# ipv6 router rip
FastIron(config-ripng-router)# distribute-list prefix-list routesfor2001 out ethernet 3/1

To deny prefix lengths greater than 64 bits in routes that have the prefix 3EE0:A99::/64 and allow all other routes received on tunnel interface 3/1, enter the following commands.
Configuring poison reverse parameters

By default, poison reverse is disabled on a RIPng router. If poison reverse is enabled, RIPng advertises routes it learns from a particular interface over that same interface with a metric of 16, which means that the route is unreachable.

If poison reverse is enabled on the RIPng router, it takes precedence over split horizon (if it is also enabled).

To enable poison reverse on the RIPng router, enter the following commands.

```
FastIron(config)# ipv6 router rip
FastIron(config-ripng-router)# poison-reverse
```

Syntax: `[no] poison-reverse`

To disable poison-reverse, use the `no` version of this command.

By default, if a RIPng interface goes down, the Brocade device does not send a triggered update for the interface IPv6 networks.

To better handle this situation, you can configure a RIPng router to send a triggered update containing the local routes of the disabled interface with an unreachable metric of 16 to the other RIPng routers in the routing domain. You can enable the sending of a triggered update by entering the following commands.

```
FastIron(config)# ipv6 router rip
FastIron(config-ripng-router)# poison-local-routes
```

Syntax: `[no] poison-local-routes`

To disable the sending of a triggered update, use the `no` version of this command.
Clearing RIPng routes from the IPv6 route table

To clear all RIPng routes from the RIPng route table and the IPv6 main route table and reset the routes, enter the following command at the Privileged EXEC level or any of the Config levels of the CLI.

FastIron# clear ipv6 rip routes

Syntax: clear ipv6 rip routes

Displaying RIPng information

You can display the following RIPng information:

- RIPng configuration
- RIPng routing table

Displaying RIPng configuration

To display RIPng configuration information, enter the following command at any CLI level.

FastIron# show ipv6 rip
IPv6 rip enabled, port 521
   Administrative distance is 120
   Updates every 30 seconds, expire after 180
   Holddown lasts 180 seconds, garbage collect after 120
   Split horizon is on; poison reverse is off
   Default routes are not generated
   Periodic updates 0, trigger updates 0
   Distribute List, Inbound : Not set
   Distribute List, Outbound : Not set
   Redistribute: CONNECTED

Syntax: show ipv6 rip

This display shows the following information.

**TABLE 195** RIPng configuration fields

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
</table>
| IPv6 RIP status/port        | The status of RIPng on the Brocade device. Possible status is “enabled” or “disabled.”
   | The UDP port number over which RIPng is enabled.                           |
| Administrative distance     | The setting of the administrative distance for RIPng.                     |
| Updates/expiration          | The settings of the RIPng update and timeout timers.                      |
| Holddown/garbage collection | The settings of the RIPng hold-down and garbage-collection timers.        |
| Split horizon/poison reverse | The status of the RIPng split horizon and poison reverse features. Possible status is “on” or “off.” |
| Default routes              | The status of RIPng default routes.                                       |
| Periodic updates/trigger updates | The number of periodic updates and triggered updates sent by the RIPng router. |
Displaying RIPng routing table

To display the RIPng routing table, enter the following command at any CLI level.

```plaintext
FastIron# show ipv6 rip route
IPv6 RIP Routing Table - 4 entries:
2001::/64, from fe80::212:f2ff:fe87:9a40, ve 177    (314)
  RIP, metric 2, tag 0, timers: aging 11
2001:11:11::/64, from ::, null   (0)
  CONNECTED, metric 1, tag 0, timers: none
  LOCAL, metric 1, tag 0, timers: none
2001:aa:2061:31:1::/96, from fe80::2e0:52ff:fe88:8000, ve 100    (58)
  RIP, metric 2, tag 0, timers: aging 43
```

Syntax: `show ipv6 rip route [<ipv6-prefix>/<prefix-length> | <ipv6-address>]`

The `<ipv6-prefix>/<prefix-length>` parameters restrict the display to the entries for the specified IPv6 prefix. You must specify the `<ipv6-prefix>` parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373. You must specify the `<prefix-length>` parameter as a decimal value. A slash mark (/) must follow the `<ipv6-prefix>` parameter and precede the `<prefix-length>` parameter.

The `<ipv6-address>` parameter restricts the display to the entries for the specified IPv6 address. You must specify this parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.

This display shows the following information.

### TABLE 196  RIPng routing table fields

<table>
<thead>

Displaying RIPng information
This chapter describes how to configure OSPF Version 2 on Brocade Layer 3 Switches using the CLI. OSPF Version 2 is supported on devices running IPv4.

NOTE
The terms Layer 3 Switch and router are used interchangeably in this chapter and mean the same thing.

Overview of OSPF

OSPF is a link-state routing protocol. The protocol uses link-state advertisements (LSA) to update neighboring routers regarding its interfaces and information on those interfaces. The router floods these LSAs to all neighboring routers to update them regarding the interfaces. Each router maintains an identical database that describes its area topology to help a router determine the shortest path between it and any neighboring router.

Brocade Layer 3 Switches support the following types of LSAs, which are described in RFC 1583:

- Router link
- Network link
- Summary link
- Autonomous system (AS) summary link
- AS external link
- Not-So-Stubby Area (NSSA) external link

OSPF is built upon a hierarchy of network components. The highest level of the hierarchy is the Autonomous System (AS). An autonomous system is defined as a number of networks, all of which share the same routing and administration characteristics.

An AS can be divided into multiple areas as shown in Figure 145 on page 1168. Each area represents a collection of contiguous networks and hosts. Areas limit the area to which link-state advertisements are broadcast, thereby limiting the amount of flooding that occurs within the network. An area is represented in OSPF by either an IP address or a number.

You can further limit the broadcast area of flooding by defining an area range. The area range allows you to assign an aggregate value to a range of IP addresses. This aggregate value becomes the address that is advertised instead of all of the individual addresses it represents being advertised. You can assign up to 32 ranges in an OSPF area.

An OSPF router can be a member of multiple areas. Routers with membership in multiple areas are known as Area Border Routers (ABRs). Each ABR maintains a separate topological database for each area the router is in. Each topological database contains all of the LSA databases for each router within a given area. The routers within the same area have identical topological databases. The ABR is responsible for forwarding routing information or changes between its border areas.
An **Autonomous System Boundary Router (ASBR)** is a router that is running multiple protocols and serves as a gateway to routers outside an area and those operating with different protocols. The ASBR is able to import and translate different protocol routes into OSPF through a process known as **redistribution**. For more details on redistribution and configuration examples, refer to “Enable route redistribution” on page 1198.

**FIGURE 145** OSPF operating in a network

**OSPF point-to-point Links**

**Platform Support:**
- FESX devices running software release 02.2.00 and later
- FSX devices running software release 02.3.01 and later
- FCX-S devices running software release 06.0.00 and later
- Turbolron X Series devices running software release 04.2.00 and later
One important OSPF process is **Adjacency**. Adjacency occurs when a relationship is formed between neighboring routers for the purpose of exchanging routing information. Adjacent OSPF neighbor routers go beyond the simple Hello packet exchange; they exchange database information. In order to minimize the amount of information exchanged on a particular segment, one of the first steps in creating adjacency is to assign a Designated Router (DR) and a Backup Designated Router (BDR). The Designated Router ensures that there is a central point of contact, thereby improving convergence time within a multi-access segment.

In an OSPF point-to-point network, where a direct Layer 3 connection exists between a single pair of OSPF routers, there is no need for Designated and Backup Designated Routers, as is the case in OSPF multi-access networks. Without the need for Designated and Backup Designated routers, a point-to-point network establishes adjacency and converges faster. The neighboring routers become adjacent whenever they can communicate directly. In contrast, in broadcast and non-broadcast multi-access (NBMA) networks, the Designated Router and Backup Designated Router become adjacent to all other routers attached to the network.

To configure an OSPF point-to-point link, refer to “Configuring an OSPF point-to-point Link” on page 1207.

**Designated routers in multi-access networks**

In a network that has multiple routers attached, OSPF elects one router to serve as the designated router (DR) and another router on the segment to act as the backup designated router (BDR). This arrangement minimizes the amount of repetitive information that is forwarded on the network by forwarding all messages to the designated router and backup designated routers responsible for forwarding the updates throughout the network.

**Designated router election in multi-access networks**

In a network with no designated router and no backup designated router, the neighboring router with the highest priority is elected as the DR, and the router with the next largest priority is elected as the BDR, as shown in Figure 146.

**FIGURE 146  Designated and backup router election**

If the DR goes off-line, the BDR automatically becomes the DR. The router with the next highest priority becomes the new BDR. This process is shown in Figure 147.
NOTE
Priority is a configurable option at the interface level. You can use this parameter to help bias one router as the DR.

**FIGURE 147** Backup designated router becomes designated router

If two neighbors share the same priority, the router with the highest router ID is designated as the DR. The router with the next highest router ID is designated as the BDR.

NOTE
By default, the Brocade router ID is the IP address configured on the lowest numbered loopback interface. If the Layer 3 Switch does not have a loopback interface, the default router ID is the lowest numbered IP address configured on the device. For more information or to change the router ID, refer to “Changing the router ID” on page 1002.

When multiple routers on the same network are declaring themselves as DRs, then both priority and router ID are used to select the designated router and backup designated routers.

When only one router on the network claims the DR role despite neighboring routers with higher priorities or router IDs, this router remains the DR. This is also true for BDRs.

The DR and BDR election process is performed when one of the following events occurs:

- An interface is in a waiting state and the wait time expires
- An interface is in a waiting state and a hello packet is received that addresses the BDR
- A change in the neighbor state occurs, such as:
  - A neighbor state transitions from 2 or higher
  - Communication to a neighbor is lost
  - A neighbor declares itself to be the DR or BDR for the first time

**OSPF RFC 1583 and 2178 compliance**

Brocade routers are configured, by default, to be compliant with the RFC 1583 OSPF V2 specification. Brocade routers can also be configured to operate with the latest OSPF standard, RFC 2178.
NOTE
For details on how to configure the system to operate with the RFC 2178, refer to “Modify OSPF standard compliance setting” on page 1206.

Reduction of equivalent AS External LSAs

An OSPF ASBR uses AS External link advertisements (AS External LSAs) to originate advertisements of a route to another routing domain, such as a BGP4 or RIP domain. The ASBR advertises the route to the external domain by flooding AS External LSAs to all the other OSPF routers (except those inside stub networks) within the local OSPF Autonomous System (AS).

In some cases, multiple ASBRs in an AS can originate equivalent LSAs. The LSAs are equivalent when they have the same cost, the same next hop, and the same destination. Brocade devices optimize OSPF by eliminating duplicate AS External LSAs in this case. The Layer 3 Switch with the lower router ID flushes the duplicate External LSAs from its database and thus does not flood the duplicate External LSAs into the OSPF AS. AS External LSA reduction therefore reduces the size of the Layer 3 Switch link state database.

This enhancement implements the portion of RFC 2328 that describes AS External LSA reduction. This enhancement is enabled by default, requires no configuration, and cannot be disabled.

Figure 148 shows an example of the AS External LSA reduction feature. In this example, Brocade Layer 3 Switches D and E are OSPF ASBRs, and thus communicate route information between the OSPF AS, which contains Routers A, B, and C, and another routing domain, which contains Router F. The other routing domain is running another routing protocol, such as BGP4 or RIP. Routers D, E, and F, therefore, are each running both OSPF and either BGP4 or RIP.
Notice that both Router D and Router E have a route to the other routing domain through Router F. In earlier software releases, if Routers D and E have equal-cost routes to Router F, then both Router D and Router E flood AS External LSAs to Routers A, B, and C advertising the route to Router F. Since both routers are flooding equivalent routes, Routers A, B, and C receive multiple routes with the same cost to the same destination (Router F). For Routers A, B, and C, either route to Router F (through Router D or through Router E) is equally good.

OSPF eliminates the duplicate AS External LSAs. When two or more Brocade Layer 3 Switches configured as ASBRs have equal-cost routes to the same next-hop router in an external routing domain, the ASBR with the highest router ID floods the AS External LSAs for the external domain into the OSPF AS, while the other ASBRs flush the equivalent AS External LSAs from their databases. As a result, the overall volume of route advertisement traffic within the AS is reduced and the Layer 3 Switches that flush the duplicate AS External LSAs have more memory for other OSPF data. In Figure 148, since Router D has a higher router ID than Router E, Router D floods the AS External LSAs for Router F to Routers A, B, and C. Router E flushes the equivalent AS External LSAs from its database.
**Algorithm for AS External LSA reduction**

*Figure 148* shows an example in which the normal AS External LSA reduction feature is in effect. The behavior changes under the following conditions:

- There is one ASBR advertising (originating) a route to the external destination, but one of the following happens:
  - A second ASBR comes on-line
  - A second ASBR that is already on-line begins advertising an equivalent route to the same destination.

In either case above, the router with the higher router ID floods the AS External LSAs and the other router flushes its equivalent AS External LSAs. For example, if Router D is offline, Router E is the only source for a route to the external routing domain. When Router D comes on-line, it takes over flooding of the AS External LSAs to Router F, while Router E flushes its equivalent AS External LSAs to Router F.

- One of the ASBRs starts advertising a route that is no longer equivalent to the route the other ASBR is advertising. In this case, the ASBRs each flood AS External LSAs. Since the LSAs either no longer have the same cost or no longer have the same next-hop router, the LSAs are no longer equivalent, and the LSA reduction feature no longer applies.

- The ASBR with the higher router ID becomes unavailable or is reconfigured so that it is no longer an ASBR. In this case, the other ASBR floods the AS External LSAs. For example, if Router D goes off-line, then Router E starts flooding the AS with AS External LSAs for the route to Router F.

**Support for OSPF RFC 2328 Appendix E**

Brocade devices provide support for Appendix E in OSPF RFC 2328. Appendix E describes a method to ensure that an OSPF router (such as a Brocade Layer 3 Switch) generates unique link state IDs for type-5 (External) link state advertisements (LSAs) in cases where two networks have the same network address but different network masks.

**NOTE**

Support for Appendix E of RFC 2328 is enabled automatically and cannot be disabled. No user configuration is required.

Normally, an OSPF router uses the network address alone for the link state ID of the link state advertisement (LSA) for the network. For example, if the router needs to generate an LSA for network 10.1.2.3 255.0.0.0, the router generates ID 10.1.2.3 for the LSA.

However, suppose that an OSPF router needs to generate LSAs for all the following networks:

- 10.0.0.0 255.0.0.0
- 10.0.0.0 255.255.0.0
- 10.0.0.0 255.255.255.0

All three networks have the same network address, 10.0.0.0. Without support for RFC 2328 Appendix E, an OSPF router uses the same link state ID, 10.0.0.0, for the LSAs for all three networks. For example, if the router generates an LSA with ID 10.0.0.0 for network 10.0.0.0 255.0.0.0, this LSA conflicts with the LSA generated for network 10.0.0.0 255.255.0.0 or 10.0.0.0 255.255.255.0. The result is multiple LSAs that have the same ID but that contain different route information.
When appendix E is supported, the router generates the link state ID for a network as follows.

1. Does an LSA with the network address as its ID already exist?
   - No – Use the network address as the ID.
   - Yes – Go to step 2.

2. Compare the networks that have the same network address, to determine which network is more specific. The more specific network is the one that has more contiguous one bits in its network mask. For example, network 10.0.0.0 255.255.0.0 is more specific than network 10.0.0.0 255.0.0.0, because the first network has 16 ones bits (255.255.0.0) whereas the second network has only 8 ones bits (255.0.0.0):
   - For the less specific network, use the networks address as the ID.
   - For the more specific network, use the network broadcast address as the ID. The broadcast address is the network address, with all ones bits in the host portion of the address. For example, the broadcast address for network 10.0.0.0 255.255.0.0 is 10.0.0.255.

   If this comparison results in a change to the ID of an LSA that has already been generated, the router generates a new LSA to replace the previous one. For example, if the router has already generated an LSA for network with ID 10.0.0.0 for network 10.0.0.0 255.255.255.0, the router must generate a new LSA for the network, if the router needs to generate an LSA for network 10.0.0.0 255.255.0.0 or 10.0.0.0 255.0.0.0.

**Dynamic OSPF activation and configuration**

OSPF is automatically activated when you enable it. The protocol does not require a software reload.

You can configure and save the following OSPF changes without resetting the system:

- All OSPF interface-related parameters (for example: area, hello timer, router dead time cost, priority, re-transmission time, transit delay)
- All area parameters
- All area range parameters
- All virtual-link parameters
- All global parameters
- Creation and deletion of an area, interface or virtual link

In addition, you can make the following changes without a system reset by first disabling and then re-enabling OSPF operation:

- Changes to address ranges
- Changes to global values for redistribution
- Addition of new virtual links

You also can change the amount of memory allocated to various types of LSA entries. However, these changes require a system reset or reboot.
Dynamic OSPF memory

FastIron devices dynamically allocate memory for Link State Advertisements (LSAs) and other OSPF data structures. This eliminates overflow conditions and does not require a reload to change OSPF memory allocation. So long as the Layer 3 Switch has free (unallocated) dynamic memory, OSPF can use the memory.

To display the current allocations of dynamic memory, use the show memory command.

Configuring OSPF

Follow the steps given below to begin using OSPF on the router.

1. Enable OSPF on the router.
2. Assign the areas to which the router will be attached.
3. Assign individual interfaces to the OSPF areas.
4. Define redistribution filters, if desired.
5. Enable redistribution, if you defined redistribution filters.
6. Modify default global and port parameters as required.
7. Modify OSPF standard compliance, if desired.

NOTE

OSPF is automatically enabled without a system reset.

Configuration rules

• Brocade FastIron devices support a maximum of 676 OSPF interfaces.
• If a router is to operate as an ASBR, you must enable the ASBR capability at the system level.
• Redistribution must be enabled on routers configured to operate as ASBRs.
• All router ports must be assigned to one of the defined areas on an OSPF router. When a port is assigned to an area, all corresponding subnets on that port are automatically included in the assignment.

OSPF parameters

You can modify or set the following global and interface OSPF parameters.

Global parameters:

• Modify OSPF standard compliance setting.
• Assign an area.
• Define an area range.
• Define the area virtual link.
• Set global default metric for OSPF.
• Change the reference bandwidth for the default cost of OSPF interfaces.
• Disable or re-enable load sharing.
• Enable or disable default-information-originate.
• Modify Shortest Path First (SPF) timers
• Define external route summarization
• Define redistribution metric type.
• Define deny redistribution.
• Define permit redistribution.
• Enable redistribution.
• Change the LSA pacing interval.
• Modify OSPF Traps generated.
• Modify database overflow interval.

**Interface parameters:**

• Assign interfaces to an area.
• Define the authentication key for the interface.
• Change the authentication-change interval
• Modify the cost for a link.
• Modify the dead interval.
• Modify MD5 authentication key parameters.
• Modify the priority of the interface.
• Modify the retransmit interval for the interface.
• Modify the transit delay of the interface.

---

**NOTE**

When using the CLI, you set global level parameters at the OSPF CONFIG Level of the CLI. To reach that level, enter `router ospf...` at the global CONFIG Level. Interface parameters for OSPF are set at the interface CONFIG Level using the CLI command, `ip ospf...`

When using the Web Management Interface, you set OSPF global parameters using the OSPF configuration panel. All other parameters are accessed through links accessed from the OSPF configuration sheet.

---

**Enable OSPF on the router**

When you enable OSPF on the router, the protocol is automatically activated. To enable OSPF on the router, enter the following CLI command.

```
FastIron(config)# router ospf
```

This command launches you into the OSPF router level where you can assign areas and modify OSPF global parameters.
Note regarding disabling OSPF

If you disable OSPF, the Layer 3 Switch removes all the configuration information for the disabled protocol from the running-config. Moreover, when you save the configuration to the startup-config file after disabling one of these protocols, all the configuration information for the disabled protocol is removed from the startup-config file.

NOTE
If you are running software release 02.4.00 and later and do not want to delete the OSPF configuration information, use the CLI command `clear ip ospf process` instead of `no router ospf`. Refer to “Resetting OSPF” on page 1177.

When you enter the `no router ospf` command, the CLI displays a warning message such as the following.

`FastIron(config-ospf-router)# no router ospf
router ospf mode now disabled. All ospf config data will be lost when writing to flash!`

The Web Management Interface does not display a warning message.

If you have disabled the protocol but have not yet saved the configuration to the startup-config file and reloaded the software, you can restore the configuration information by re-entering the command to enable the protocol (ex: `router ospf`), or by selecting the Web management option to enable the protocol. If you have already saved the configuration to the startup-config file and reloaded the software, the information is gone.

If you are testing an OSPF configuration and are likely to disable and re-enable the protocol, you might want to make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

Resetting OSPF

Platform Support:
- FastIron X Series devices running software release 02.4.00 and later
- TurboIron X Series devices running software release 04.2.00 and later

The `clear ip ospf process all` command globally resets (disables then re-enables) OSPF without deleting the OSPF configuration information. This command is equivalent to entering the commands `no router ospf` followed by `router ospf`. Whereas the `no router ospf` command disables OSPF and removes all the configuration information for the disabled protocol from the running-config, the `router ospf` command re-enables OSPF and restores the OSPF configuration information.

The `clear ip ospf process all` command is useful if you are testing an OSPF configuration and are likely to disable and re-enable the protocol. This way, you do not have to save the configuration after disabling the protocol, and you do not have to restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

To reset OSPF without deleting the OSPF configuration, enter the following command at the Global CONFIG level or at the Router OSPF level of the CLI.

`FastIron# clear ip ospf process all`
Syntax: clear ip ospf process all

Assign OSPF areas

Once OSPF is enabled on the system, you can assign areas. Assign an IP address or number as the area ID for each area. The area ID is representative of all IP addresses (subnets) on a router port. Each port on a router can support one area.

An area can be normal, a stub, or a Not-So-Stubby Area (NSSA):

- Normal – OSPF routers within a normal area can send and receive External Link State Advertisements (LSAs).
- Stub – OSPF routers within a stub area cannot send or receive External LSAs. In addition, OSPF routers in a stub area must use a default route to the area Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) to send traffic out of the area.
- NSSA – The ASBR of an NSSA can import external route information into the area:
  - ASBRs redistribute (import) external routes into the NSSA as type 7 LSAs. Type-7 External LSAs are a special type of LSA generated only by ASBRs within an NSSA, and are flooded to all the routers within only that NSSA.
  - ABRs translate type 7 LSAs into type 5 External LSAs, which can then be flooded throughout the AS. You can configure address ranges on the ABR of an NSSA so that the ABR converts multiple type-7 External LSAs received from the NSSA into a single type-5 External LSA.

When an NSSA contains more than one ABR, OSPF elects one of the ABRs to perform the LSA translation for NSSA. OSPF elects the ABR with the highest router ID. If the elected ABR becomes unavailable, OSPF automatically elects the ABR with the next highest router ID to take over translation of LSAs for the NSSA. The election process for NSSA ABRs is automatic.

Example

To set up the OSPF areas shown in Figure 145 on page 1168, enter the following commands.

```
FastIron(config-ospf-router)# area 192.5.1.0
FastIron(config-ospf-router)# area 200.5.0.0
FastIron(config-ospf-router)# area 195.5.0.0
FastIron(config-ospf-router)# area 0.0.0.0
FastIron(config-ospf-router)# write memory
```

Syntax: area <num> | <ip-addr>

The <num> | <ip-addr> parameter specifies the area number, which can be a number or in IP address format. If you specify an number, the number can be from 0 – 2,147,483,647.

**NOTE**

You can assign one area on a router interface. For example, if the system or chassis module has 16 ports, 16 areas are supported on the chassis or module.
Assign a totally stubby area

By default, the Layer 3 Switch sends summary LSAs (LSA type 3) into stub areas. You can further reduce the number of link state advertisements (LSAs) sent into a stub area by configuring the Layer 3 Switch to stop sending summary LSAs (type 3 LSAs) into the area. You can disable the summary LSAs when you are configuring the stub area or later after you have configured the area.

This feature disables origination of summary LSAs, but the Layer 3 Switch still accepts summary LSAs from OSPF neighbors and floods them to other neighbors. The Layer 3 Switch can form adjacencies with other routers regardless of whether summarization is enabled or disabled for areas on each router.

When you enter a command or apply a Web management option to disable the summary LSAs, the change takes effect immediately. If you apply the option to a previously configured area, the Layer 3 Switch flushes all of the summary LSAs it has generated (as an ABR) from the area.

**NOTE**
This feature applies only when the Layer 3 Switch is configured as an Area Border Router (ABR) for the area. To completely prevent summary LSAs from being sent to the area, disable the summary LSAs on each OSPF router that is an ABR for the area.

This feature does not apply to Not So Stubby Areas (NSSAs).

To disable summary LSAs for a stub area, enter commands such as the following.

```
FastIron(config-ospf-router)# area 40 stub 99 no-summary
```

**Syntax:** `area <num> | <ip-addr> stub <cost> [no-summary]`

The `<num>` parameter specifies the area number, which can be a number or in IP address format. If you specify a number, the number can be from 0 – 2,147,483,647.

The `stub <cost>` parameter specifies an additional cost for using a route to or from this area and can be from 1 – 16,777,215. There is no default. Normal areas do not use the cost parameter.

The `no-summary` parameter applies only to stub areas and disables summary LSAs from being sent into the area.

**NOTE**
You can assign one area on a router interface. For example, if the system or chassis module has 16 ports, 16 areas are supported on the chassis or module.

Assign a Not-So-Stubby Area (NSSA)

The OSPF Not So Stubby Area (NSSA) feature enables you to configure OSPF areas that provide the benefits of stub areas, but that also are capable of importing external route information. OSPF does not flood external routes from other areas into an NSSA, but does translate and flood route information from the NSSA into other areas such as the backbone.

NSSAs are especially useful when you want to summarize Type-5 External LSAs (external routes) before forwarding them into an OSPF area. The OSPF specification (RFC 2328) prohibits summarization of Type-5 LSAs and requires OSPF to flood Type-5 LSAs throughout a routing domain. When you configure an NSSA, you can specify an address range for aggregating the external routes that the NSSA's ABR exports into other areas.

The Brocade implementation of NSSA is based on RFC 1587.
Figure 149 shows an example of an OSPF network containing an NSSA.

FIGURE 149 OSPF network containing an NSSA

This example shows two routing domains, a RIP domain and an OSPF domain. The ASBR inside the NSSA imports external routes from RIP into the NSSA as Type-7 LSAs, which the ASBR floods throughout the NSSA.

The ABR translates the Type-7 LSAs into Type-5 LSAs. If an area range is configured for the NSSA, the ABR also summarizes the LSAs into an aggregate LSA before flooding the Type-5 LSAs into the backbone.

Since the NSSA is partially “stubby” the ABR does not flood external LSAs from the backbone into the NSSA. To provide access to the rest of the Autonomous System (AS), the ABR generates a default Type-7 LSA into the NSSA.

**Configuring an NSSA**

To configure OSPF area 1.1.1.1 as an NSSA, enter the following commands.

```plaintext
FastIron(config)# router ospf
FastIron(config-ospf-router)# area 1.1.1.1 nssa 1
FastIron(config-ospf-router)# write memory
```

**Syntax:** `area <num> | <ip-addr> nssa <cost> | default-information-originate`

The `area <num> | <ip-addr> nssa <cost>` parameter specifies the area number, which can be a number or in IP address format. If you specify an number, the number can be from 0 – 2,147,483,647.

The `nssa <cost> | default-information-originate` parameter specifies that this is a Not-So-Stubby-Area (NSSA). The `cost` specifies an additional cost for using a route to or from this NSSA and can be from 1 – 16777215. There is no default. Normal areas do not use the cost parameter. Alternatively, you can use the `default-information-originate` parameter causes the Layer 3 Switch to inject the default route into the NSSA.
NOTE
The Layer 3 Switch does not inject the default route into an NSSA by default.

NOTE
You can assign one area on a router interface. For example, if the system or chassis module has 16 ports, 16 areas are supported on the chassis or module.

To configure additional parameters for OSPF interfaces in the NSSA, use the `ip ospf area` command at the interface level of the CLI.

Configuring a summary address for the NSSA
If you want the ABR that connects the NSSA to other areas to summarize the routes in the NSSA before translating them into Type-5 LSAs and flooding them into the other areas, configure a summary address. The ABR creates an aggregate value based on the summary address. The aggregate value becomes the address that the ABR advertises instead of advertising the individual addresses represented by the aggregate.

To configure a summary address in NSSA 1.1.1.1, enter the following commands. This example assumes that you have already configured NSSA 1.1.1.1.

```
FastIron(config)# router ospf
FastIron(config-ospf-router)# summary-address 209.157.22.1 255.255.0.0
FastIron(config-ospf-router)# write memory
```

Syntax: `[no] summary address <ip-addr> <ip-mask>

The `<ip-addr>` parameter specifies the IP address portion of the range. The software compares the address with the significant bits in the mask. All network addresses that match this comparison are summarized in a single route advertised by the router.

The `<ip-mask>` parameter specifies the portions of the IP address that a route must contain to be summarized in the summary route. In the example above, all networks that begin with 209.157 are summarized into a single route.

Assigning an area range (optional)
You can assign a range for an area, but it is not required. Ranges allow a specific IP address and mask to represent a range of IP addresses within an area, so that only that reference range address is advertised to the network, instead of all the addresses within that range. Each area can have up to 32 range addresses.

Example
To define an area range for subnets on 193.45.5.1 and 193.45.6.2, enter the following command.

```
FastIron(config)# router ospf
FastIron(config-ospf-router)# area 192.45.5.1 range 193.45.0.0 255.255.0.0
FastIron(config-ospf-router)# area 193.45.6.2 range 193.45.0.0 255.255.0.0
```

Syntax: `area <num> | <ip-addr> range <ip-addr> <ip-mask`

The `<num>` | `<ip-addr>` parameter specifies the area number, which can be in IP address format.

The `range` `<ip-addr>` parameter specifies the IP address portion of the range. The software compares the address with the significant bits in the mask. All network addresses that match this comparison are summarized in a single route advertised by the router.
The `<ip-mask>` parameter specifies the portions of the IP address that a route must contain to be summarized in the summary route. In the example above, all networks that begin with 193.45 are summarized into a single route.

**Assigning interfaces to an area**

Once you define OSPF areas, you can assign interfaces to the areas. All router ports must be assigned to one of the defined areas on an OSPF router. When a port is assigned to an area, all corresponding subnets on that port are automatically included in the assignment.

To assign interface 1/8 to area 195.5.0.0 and then save the changes, enter the following commands.

```
FastIron(config-ospf-router)# interface e 1/8
FastIron(config-if-1/8)# ip ospf area 195.5.0.0
FastIron(config-if-1/8)# write memory
```

**Modify interface defaults**

OSPF has interface parameters that you can configure. For simplicity, each of these parameters has a default value. No change to these default values is required except as needed for specific network configurations.

Port default values can be modified using the following commands at the interface configuration level of the CLI:

- `ip ospf area <ip-addr>`
- `ip ospf auth-change-wait-time <secs>`
- `ip ospf authentication-key [0 | 1] <string>`
- `ip ospf cost <num>`
- `ip ospf dead-interval <value>`
- `ip ospf hello-interval <value>`
- `ip ospf md5-authentication key-activation-wait-time <num> | key-id <num> [0 | 1] key <string>`
- `ip ospf passive`
- `ip ospf priority <value>`
- `ip ospf retransmit-interval <value>`
- `ip ospf transmit-delay <value>`

For a complete description of these parameters, see the summary of OSPF port parameters in the next section.

**OSPF interface parameters**

The following parameters apply to OSPF interfaces.

**Area**: Assigns an interface to a specific area. You can assign either an IP address or number to represent an OSPF Area ID. If you assign a number, it can be any value from 0 – 2,147,483,647.
**Auth-change-wait-time:** OSPF gracefully implements authentication changes to allow all routers to implement the change and thus prevent disruption to neighbor adjacencies. During the authentication-change interval, both the old and new authentication information is supported. The default authentication-change interval is 300 seconds (5 minutes). You change the interval to a value from 0 – 14400 seconds.

**Authentication-key:** OSPF supports three methods of authentication for each interface—none, simple password, and MD5. Only one method of authentication can be active on an interface at a time. The default authentication value is none, meaning no authentication is performed.

The simple password method of authentication requires you to configure an alphanumeric password on an interface. The simple password setting takes effect immediately. All OSPF packets transmitted on the interface contain this password. Any OSPF packet received on the interface is checked for this password. If the password is not present, then the packet is dropped. The password can be up to eight characters long.

The MD5 method of authentication requires you to configure a key ID and an MD5 key. The key ID is a number from 1 – 255 and identifies the MD5 key that is being used. The MD5 key can be up to sixteen alphanumeric characters long.

**Cost:** Indicates the overhead required to send a packet across an interface. You can modify the cost to differentiate between 100 Mbps and 1000 Mbps (1 Gbps) links. The default cost is calculated by dividing 100 million by the bandwidth. For 10 Mbps links, the cost is 10. The cost for both 100 Mbps and 1000 Mbps links is 1, because the speed of 1000 Mbps was not in use at the time the OSPF cost formula was devised.

**Dead-interval:** Indicates the number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The value can be from 1 – 65535 seconds. The default is 40 seconds.

**Hello-interval:** Represents the length of time between the transmission of hello packets. The value can be from 1 – 65535 seconds. The default is 10 seconds.

**MD5-authentication activation wait time:** The number of seconds the Layer 3 Switch waits until placing a new MD5 key into effect. The wait time provides a way to gracefully transition from one MD5 key to another without disturbing the network. The wait time can be from 0 – 14400 seconds. The default is 300 seconds (5 minutes).

**MD5-authentication key ID and key:** A method of authentication that requires you to configure a key ID and an MD5 key. The key ID is a number from 1 – 255 and identifies the MD5 key that is being used. The MD5 key consists of up to 16 alphanumeric characters. The MD5 is encrypted and included in each OSPF packet transmitted.

**Passive:** When you configure an OSPF interface to be passive, that interface does not send or receive OSPF route updates. By default, all OSPF interfaces are active and thus can send and receive OSPF route information. Since a passive interface does not send or receive route information, the interface is in effect a stub network. OSPF interfaces are active by default.

---

**NOTE**
This option affects all IP subnets configured on the interface. If you want to disable OSPF updates only on some of the IP subnets on the interface, use the `ospf-ignore` or `ospf-passive` parameter with the `ip address` command. Refer to “Assigning an IP address to an Ethernet port” on page 993.
**Priority:** Allows you to modify the priority of an OSPF router. The priority is used when selecting the designated router (DR) and backup designated routers (BDRs). The value can be from 0 – 255. The default is 1. If you set the priority to 0, the Layer 3 Switch does not participate in DR and BDR election.

**Retransmit-interval:** The time between retransmissions of link-state advertisements (LSAs) to adjacent routers for this interface. The value can be from 0 – 3600 seconds. The default is 5 seconds.

**Transit-delay:** The time it takes to transmit Link State Update packets on this interface. The value can be from 0 – 3600 seconds. The default is 1 second.

### Encrypted Display of the Authentication String or MD5 Authentication Key

The optional 0 | 1 parameter with the `authentication-key` and `md5-authentication key-id` parameters affects encryption.

For added security, FastIron devices encrypt display of the password or authentication string. Encryption is enabled by default. The software also provides an optional parameter to disable encryption of a password or authentication string, on an individual OSPF area or OSPF interface basis.

When encryption of the passwords or authentication strings is enabled, they are encrypted in the CLI regardless of the access level you are using. In the Web Management Interface, the passwords or authentication strings are encrypted at the read-only access level but are visible at the read-write access level.

The encryption option can be omitted (the default) or can be one of the following:

- **0** – Disables encryption for the password or authentication string you specify with the command. The password or string is shown as clear text in the running-config and the startup-config file. Use this option if you do not want display of the password or string to be encrypted.
- **1** – Assumes that the password or authentication string you enter is the encrypted form, and decrypts the value before using it.

### NOTE

If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter **0** or **1**. Instead, omit the encryption option and allow the software to use the default behavior.

If you specify encryption option **1**, the software assumes that you are entering the encrypted form of the password or authentication string. In this case, the software decrypts the password or string you enter before using the value for authentication. If you accidentally enter option **1** followed by the clear-text version of the password or string, authentication will fail because the value used by the software will not match the value you intended to use.

### Change the timer for OSPF authentication changes

When you make an OSPF authentication change, the software uses the authentication-change timer to gracefully implement the change. The software implements the change in the following ways:
• Outgoing OSPF packets – After you make the change, the software continues to use the old authentication to send packets, during the remainder of the current authentication-change interval. After this, the software uses the new authentication for sending packets.

• Inbound OSPF packets – The software accepts packets containing the new authentication and continues to accept packets containing the older authentication for two authentication-change intervals. After the second interval ends, the software accepts packets only if they contain the new authentication key.

The default authentication-change interval is 300 seconds (5 minutes). You change the interval to a value from 0 – 14400 seconds.

OSPF provides graceful authentication change for all the following types of authentication changes in OSPF:

• Changing authentication methods from one of the following to another of the following:
  • Simple text password
  • MD5 authentication
  • No authentication

• Configuring a new simple text password or MD5 authentication key

• Changing an existing simple text password or MD5 authentication key

To change the authentication-change interval, enter a command such as the following at the interface configuration level of the CLI.

FastIron(config-if-2/5)# ip ospf auth-change-wait-time 400

Syntax:  [no] ip ospf auth-change-wait-time <secs>

The <secs> parameter specifies the interval and can be from 0 – 14400 seconds. The default is 300 seconds (5 minutes).

NOTE
For backward compatibility, the `ip ospf md5-authentication key-activation-wait-time <seconds>` command is still supported.

Block flooding of outbound LSAs on specific OSPF interfaces

By default, the Layer 3 Switch floods all outbound LSAs on all the OSPF interfaces within an area. You can configure a filter to block outbound LSAs on an OSPF interface. This feature is particularly useful when you want to block LSAs from some, but not all, of the interfaces attached to the area.

After you apply filters to block the outbound LSAs, the filtering occurs during the database synchronization and flooding.

If you remove the filters, the blocked LSAs are automatically re-flooded. You do not need to reset OSPF to re-flood the LSAs.

NOTE
You cannot block LSAs on virtual links.

To apply a filter to an OSPF interface to block flooding of outbound LSAs on the interface, enter the following command at the Interface configuration level for that interface.

FastIron(config-if-1/1)# ip ospf database-filter all out
The command in this example blocks all outbound LSAs on the OSPF interface configured on port 1/1.

Syntax: [no] ip ospf database-filter all out
To remove the filter, enter a command such as the following.

FastIron(config-if-1/1)# no ip ospf database-filter all out

Configuring an OSPF non-broadcast interface

Platform Support:
- FESX and FSX Layer 3 devices running software release 02.3.01 and later

Layer 3 switches support Non-Broadcast Multi-Access (NBMA) networks. This feature enables you to configure an interface on a Brocade device to send OSPF traffic to its neighbor as unicast packets rather than broadcast packets.

OSPF routers generally use broadcast packets to establish neighbor relationships and broadcast route updates on Ethernet and virtual interfaces (VEs). In this release, as an alternative, you can configure the Brocade device to use unicast packets for this purpose. This can be useful in situations where multicast traffic is not feasible (for example when a firewall does not allow multicast packets).

On a non-broadcast interface, the routers at the other end of this interface must also be configured as non-broadcast and neighbor routers. There is no restriction on the number of routers sharing a non-broadcast interface (for example, through a hub or switch).

NOTE
Only Ethernet interfaces or VEs can be configured as non-broadcast interfaces.

To configure an OSPF interface as a non-broadcast interface, enable the feature on a physical interface or a VE, following the ip ospf area statement, and then specify the IP address of the neighbor in the OSPF configuration. The non-broadcast interface configuration must be done on the OSPF routers on both ends of the link.

For example, the following commands configure VE 20 as a non-broadcast interface.

FastIron(config)# int ve 20
FastIron(config-vif-20)# ip ospf area 0
FastIron(config-vif-20)# ip ospf network non-broadcast
FastIron(config-vif-20)# exit

Syntax: [no] ip ospf network non-broadcast

The following commands specify 1.1.20.1 as an OSPF neighbor address. The address specified must be in the same subnet as a non-broadcast interface.

FastIron(config)# router ospf
FastIron(config ospf-router)# neighbor 1.1.20.1

For example, to configure the feature in a network with three routers connected by a hub or switch, each router must have the linking interface configured as a non-broadcast interface, and both of the other routers must be specified as neighbors.

The output of the show ip ospf interface command has been enhanced to display information about non-broadcast interfaces and neighbors that are configured in the same subnet.
Example

FastIron# show ip ospf interface
v20,OSPF enabled
    IP Address 1.1.20.4, Area 0
    OSPF state BD, Pri 1, Cost 1, Options 2, Type non-broadcast Events 6
    Timers(sec): Transit 1, Retrans 5, Hello 10, Dead 40
    DR:   Router ID 1.1.13.1    Interface Address 1.1.20.5
    BDR:  Router ID 2.2.2.1    Interface Address 1.1.20.4
    Neighbor Count = 1, Adjacent Neighbor Count= 2
    Non-broadcast neighbor config: 1.1.20.1, 1.1.20.2, 1.1.20.3, 1.1.20.5,
    Neighbor:         1.1.20.5
    Authentication-Key:None
    MD5 Authentication: Key None, Key-Id None, Auth-change-wait-time 300

In the Type field, “non-broadcast” indicates that this is a non-broadcast interface. When the interface type is non-broadcast, the Non-broadcast neighbor config field displays the neighbors that are configured in the same subnet. If no neighbors are configured in the same subnet, a message such as the following is displayed.

***Warning! no non-broadcast neighbor config in 1.1.100.1 255.255.255.0

Assign virtual links

All ABRs (area border routers) must have either a direct or indirect link to the OSPF backbone area (0.0.0.0 or 0). If an ABR does not have a physical link to the area backbone, the ABR can configure a virtual link to another router within the same area, which has a physical connection to the area backbone.

The path for a virtual link is through an area shared by the neighbor ABR (router with a physical backbone connection), and the ABR requiring a logical connection to the backbone.

Two parameters fields must be defined for all virtual links—transit area ID and neighbor router:

- The transit area ID represents the shared area of the two ABRs and serves as the connection point between the two routers. This number should match the area ID value.
- The neighbor router field is the router ID (IP address) of the router that is physically connected to the backbone, when assigned from the router interface requiring a logical connection. When assigning the parameters from the router with the physical connection, the router ID is the IP address of the router requiring a logical connection to the backbone.

NOTE
By default, the Brocade router ID is the IP address configured on the lowest numbered loopback interface. If the Layer 3 Switch does not have a loopback interface, the default router ID is the lowest numbered IP address configured on the device. For more information or to change the router ID, refer to “Changing the router ID” on page 1002.

NOTE
When you establish an area virtual link, you must configure it on both of the routers (both ends of the virtual link).
Example

Figure 150 shows an OSPF area border router, FastIronA, that is cut off from the backbone area (area 0). To provide backbone access to FastIronA, you can add a virtual link between FastIronA and FastIronC using area 1 as a transit area. To configure the virtual link, you define the link on the router that is at each end of the link. No configuration for the virtual link is required on the routers in the transit area.

To define the virtual link on FastIronA, enter the following commands.

```
FastIronA(config-ospf-router)# area 1 virtual-link 209.157.22.1
FastIronA(config-ospf-router)# write memory
```

Enter the following commands to configure the virtual link on FastIronC.

```
FastIronC(config-ospf-router)# area 1 virtual-link 10.0.0.1
FastIronC(config-ospf-router)# write memory
```

Syntax:  
```
area <ip-addr> | <num> virtual-link <router-id>  
[authentication-key | dead-interval | hello-interval | retransmit-interval | transmit-delay <value>]
```

The `area <ip-addr> | <num>` parameter specifies the transit area.

The `<router-id>` parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a Brocade Layer 3 Switch, enter the `show ip` command.
Modify virtual link parameters

OSPF has some parameters that you can modify for virtual links. Notice that these are the same parameters as the ones you can modify for physical interfaces.

You can modify default values for virtual links using the following CLI command at the OSPF router level of the CLI, as shown in the following syntax.

```plaintext
Syntax: area <num> | <ip-addr> virtual-link <ip-addr> [authentication-key [0 | 1] <string>] [dead-interval <num>] [hello-interval <num>] [md5-authentication key-activation-wait-time <num> | key-id <num> [0 | 1] key <string>] [retransmit-interval <num>] [transmit-delay <num>]
```

The parameters are described below.

**Virtual link parameter descriptions**

You can modify the following virtual link interface parameters.

**Authentication Key:** This parameter allows you to assign different authentication methods on a port-by-port basis. OSPF supports three methods of authentication for each interface—none, simple password, and MD5. Only one method of authentication can be active on an interface at a time.

The simple password method of authentication requires you to configure an alphanumeric password on an interface. The password can be up to eight characters long. The simple password setting takes effect immediately. All OSPF packets transmitted on the interface contain this password. All OSPF packets received on the interface are checked for this password. If the password is not present, the packet is dropped.

The MD5 method of authentication encrypts the authentication key you define. The authentication is included in each OSPF packet transmitted.

**MD5 Authentication Key:** When simple authentication is enabled, the key is an alphanumeric password of up to eight characters. When MD5 is enabled, the key is an alphanumeric password of up to 16 characters that is later encrypted and included in each OSPF packet transmitted. You must enter a password in this field when the system is configured to operate with either simple or MD5 authentication.

**MD5 Authentication Key ID:** The Key ID is a number from 1 – 255 and identifies the MD5 key that is being used. This parameter is required to differentiate among multiple keys defined on a router.

**MD5 Authentication Wait Time:** This parameter determines when a newly configured MD5 authentication key is valid. This parameter provides a graceful transition from one MD5 key to another without disturbing the network. All new packets transmitted after the key activation wait time interval use the newly configured MD5 Key. OSPF packets that contain the old MD5 key are accepted for up to five minutes after the new MD5 key is in operation.

The range for the key activation wait time is from 0 – 14400 seconds. The default value is 300 seconds.

**Hello Interval:** The length of time between the transmission of hello packets. The range is 1 – 65535 seconds. The default is 10 seconds.
Configuring OSPF

Retransmit Interval: The interval between the re-transmission of link state advertisements to router adjacencies for this interface. The range is 0 – 3600 seconds. The default is 5 seconds.

Transmit Delay: The period of time it takes to transmit Link State Update packets on the interface. The range is 0 – 3600 seconds. The default is 1 second.

Dead Interval: The number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The range is 1 – 65535 seconds. The default is 40 seconds.

Encrypted display of the authentication string or MD5 authentication key
The optional 0 | 1 parameter with the authentication-key and md5-authentication key-id parameters affects encryption.

For added security, FastIron devices encrypt display of the password or authentication string. Encryption is enabled by default. The software also provides an optional parameter to disable encryption of a password or authentication string, on an individual OSPF area or OSPF interface basis.

When encryption of the passwords or authentication strings is enabled, they are encrypted in the CLI regardless of the access level you are using. In the Web Management Interface, the passwords or authentication strings are encrypted at the read-only access level but are visible at the read-write access level.

The encryption option can be omitted (the default) or can be one of the following:

• 0 – Disables encryption for the password or authentication string you specify with the command. The password or string is shown as clear text in the running-config and the startup-config file. Use this option if you do not want display of the password or string to be encrypted.

• 1 – Assumes that the password or authentication string you enter is the encrypted form, and decrypts the value before using it.

NOTE
If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter 0 or 1. Instead, omit the encryption option and allow the software to use the default behavior.

If you specify encryption option 1, the software assumes that you are entering the encrypted form of the password or authentication string. In this case, the software decrypts the password or string you enter before using the value for authentication. If you accidentally enter option 1 followed by the clear-text version of the password or string, authentication will fail because the value used by the software will not match the value you intended to use.

Changing the reference bandwidth for the cost on OSPF interfaces

Each interface on which OSPF is enabled has a cost associated with it. The Layer 3 Switch advertises its interfaces and their costs to OSPF neighbors. For example, if an interface has an OSPF cost of ten, the Layer 3 Switch advertises the interface with a cost of ten to other OSPF routers.
By default, an interface OSPF cost is based on the port speed of the interface. The cost is calculated by dividing the reference bandwidth by the port speed. The default reference bandwidth is 100 Mbps, which results in the following default costs:

- 10 Mbps port – 10
- All other port speeds – 1

You can change the reference bandwidth, to change the costs calculated by the software.

The software uses the following formula to calculate the cost.

\[
\text{Cost} = \frac{\text{reference-bandwidth}}{\text{interface-speed}}
\]

If the resulting cost is less than 1, the software rounds the cost up to 1. The default reference bandwidth results in the following costs:

- 10 Mbps port cost = \( \frac{100}{10} = 10 \)
- 100 Mbps port cost = \( \frac{100}{100} = 1 \)
- 1000 Mbps port cost = \( \frac{100}{1000} = 0.10 \), which is rounded up to 1
- 155 Mbps port cost = \( \frac{100}{155} = 0.65 \), which is rounded up to 1
- 622 Mbps port cost = \( \frac{100}{622} = 0.16 \), which is rounded up to 1
- 2488 Mbps port cost = \( \frac{100}{2488} = 0.04 \), which is rounded up to 1

For 10 Gbps OSPF interfaces, in order to differentiate the costs between 100 Mbps, 1000 Mbps, and 10,000 Mbps interfaces, you can set the auto-cost reference bandwidth to 10000, whereby each slower link is given a higher cost, as follows:

- 10 Mbps port cost = \( \frac{10000}{10} = 1000 \)
- 100 Mbps port cost = \( \frac{10000}{100} = 100 \)
- 1000 Mbps port cost = \( \frac{10000}{1000} = 10 \)
- 10000 Mbps port cost = \( \frac{10000}{10000} = 1 \)

The bandwidth for interfaces that consist of more than one physical port is calculated as follows:

- Trunk group – The combined bandwidth of all the ports.
- Virtual interface – The combined bandwidth of all the ports in the port-based VLAN that contains the virtual interface.

The default reference bandwidth is 100 Mbps. You can change the reference bandwidth to a value from 1 – 4294967.

If a change to the reference bandwidth results in a cost change to an interface, the Layer 3 Switch sends a link-state update to update the costs of interfaces advertised by the Layer 3 Switch.

**NOTE**

If you specify the cost for an individual interface, the cost you specify overrides the cost calculated by the software.

**Interface types to which the reference bandwidth does not apply**

Some interface types are not affected by the reference bandwidth and always have the same cost regardless of the reference bandwidth in use:

- The cost of a loopback interface is always 0.
The cost of a virtual link is calculated using the Shortest Path First (SPF) algorithm and is not affected by the auto-cost feature.

The bandwidth for tunnel interfaces is 9 Kbps and is not affected by the auto-cost feature.

### Changing the reference bandwidth

To change the reference bandwidth, enter a command such as the following at the OSPF configuration level of the CLI.

```
FastIron(config-ospf-router)# auto-cost reference-bandwidth 500
```

The reference bandwidth specified in this example results in the following costs:

- 10 Mbps port cost = \(\frac{500}{10} = 50\)
- 100 Mbps port cost = \(\frac{500}{100} = 5\)
- 1000 Mbps port cost = \(\frac{500}{1000} = 0.5\), which is rounded up to 1
- 155 Mbps port cost = \(\frac{500}{155} = 3.23\), which is rounded up to 4
- 622 Mbps port cost = \(\frac{500}{622} = 0.80\), which is rounded up to 1
- 2488 Mbps port cost = \(\frac{500}{2488} = 0.20\), which is rounded up to 1

The costs for 10 Mbps, 100 Mbps, and 155 Mbps ports change as a result of the changed reference bandwidth. Costs for higher-speed interfaces remain the same.

**Syntax:** `[no] auto-cost reference-bandwidth <num>`

The `<num>` parameter specifies the reference bandwidth and can be a value from 1 – 4294967. The default is 100. For 10 Gbps OSPF interfaces, in order to differentiate the costs between 100 Mbps, 1000 Mbps, and 10,000 Mbps interfaces, set the auto-cost reference bandwidth to 10000, whereby each slower link is given a higher cost.

To restore the reference bandwidth to its default value and thus restore the default costs of interfaces to their default values, enter the following command.

```
FastIron(config-ospf-router)# no auto-cost reference-bandwidth
```

### Define redistribution filters

Route redistribution imports and translates different protocol routes into a specified protocol type. On Brocade routers, redistribution is supported for static routes, OSPF, RIP, and BGP4. When you configure redistribution for RIP, you can specify that static, OSPF, or BGP4 routes are imported into RIP routes. Likewise, OSPF redistribution supports the import of static, RIP, and BGP4 routes into OSPF routes. BGP4 supports redistribution of static, RIP, and OSPF routes into BGP4.

**NOTE**

The Layer 3 Switch advertises the default route into OSPF even if redistribution is not enabled, and even if the default route is learned through an IBGP neighbor. IBGP routes (including the default route) are not redistributed into OSPF by OSPF redistribution (for example, by the OSPF `redistribute` command).

In Figure 151 on page 1193, an administrator wants to configure the FastIron Layer 3 Switch acting as the ASBR (Autonomous System Boundary Router) between the RIP domain and the OSPF domain to redistribute routes between the two domains.
**NOTE**
The ASBR must be running both RIP and OSPF protocols to support this activity.

To configure for redistribution, define the redistribution tables with deny and permit redistribution filters. Use the *deny* and *permit* redistribute commands for OSPF at the OSPF router level.

**NOTE**
Do not enable redistribution until you have configured the redistribution filters. If you enable redistribution before you configure the redistribution filters, the filters will not take affect and all routes will be distributed.

**FIGURE 151**  Redistributing OSPF and static routes to RIP routes

Example
To configure the FastIron Layer 3 Switch acting as an ASBR in **Figure 151** to redistribute OSPF, BGP4, and static routes into RIP, enter the following commands.

```
FastIronASBR(config)# router rip
FastIronASBR(config-rip-router)# permit redistribute 1 all
FastIronASBR(config-rip-router)# write memory
```

**NOTE**
Redistribution is permitted for all routes by default, so the *permit redistribute 1 all* command in the example above is shown for clarity but is not required.
You also have the option of specifying import of just OSPF, BGP4, or static routes, as well as specifying that only routes for a specific network or with a specific cost (metric) be imported, as shown in the command syntax below.

Syntax: deny | permit redistribute <filter-num> all | bgp | connected | rip | static [address <ip-addr> <ip-mask> [match-metric <value> [set-metric <value>]]]

Example

To redistribute RIP, static, and BGP4 routes into OSPF, enter the following commands on the Layer 3 Switch acting as an ASBR.

```
FastIronASBR(config)# router ospf
FastIronASBR(config-ospf-router)# permit redistribute 1 all
FastIronASBR(config-ospf-router)# write memory
```

Syntax: deny | permit redistribute <filter-num> all | bgp | connected | rip | static address <ip-addr> <ip-mask> [match-metric <value> | set-metric <value>]

NOTE
Redistribution is permitted for all routes by default, so the permit redistribute 1 all command in the example above is shown for clarity but is not required.

You also have the option of specifying import of just OSPF, BGP4, or static routes, as well as specifying that only routes for a specific network or with a specific cost (metric) be imported, as shown in the command syntax below.

Syntax: [no] redistribution bgp | connected | rip | static [route-map <map-name>]

For example, to enable redistribution of RIP and static IP routes into OSPF, enter the following commands.

```
FastIron(config)# router ospf
FastIron(config-ospf-router)# redistribution rip
FastIron(config-ospf-router)# redistribution static
FastIron(config-ospf-router)# write memory
```

NOTE
The redistribution command does not perform the same function as the permit redistribute and deny redistribute commands. The redistribute commands allow you to control redistribution of routes by filtering on the IP address and network mask of a route. The redistribution commands enable redistribution for routes of specific types (static, directly connected, and so on). Configure all your redistribution filters before enabling redistribution.

NOTE
Do not enable redistribution until you have configured the redistribution filters. If you enable redistribution before you configure the redistribution filters, the filters will not take affect and all routes will be distributed.

Prevent specific OSPF routes from being installed in the IP route table

By default, all OSPF routes in the OSPF route table are eligible for installation in the IP route table. You can configure a distribution list to explicitly deny specific routes from being eligible for installation in the IP route table.
Configuring OSPF

NOTE
This feature does not block receipt of LSAs for the denied routes. The Layer 3 Switch still receives the routes and installs them in the OSPF database. The feature only prevents the software from installing the denied OSPF routes into the IP route table.

To configure an OSPF distribution list:

- Configure a standard or extended ACL that identifies the routes you want to deny. Using a standard ACL lets you deny routes based on the destination network, but does not filter based on the network mask. To also filter based on the destination network network mask, use an extended ACL.
- Configure an OSPF distribution list that uses the ACL as input.

NOTE
If you change the ACL after you configure the OSPF distribution list, you must clear the IP route table to place the changed ACL into effect. To clear the IP route table, enter the `clear ip route` command at the Privileged EXEC level of the CLI.

The following sections show how to use the CLI to configure an OSPF distribution list. Separate examples are provided for standard and extended ACLs.

NOTE
The examples show named ACLs. However, you also can use a numbered ACL as input to the OSPF distribution list.

Using a standard ACL as input to the distribution list
To use a standard ACL to configure an OSPF distribution list for denying specific routes, enter commands such as the following:

FastIron(config)# ip access-list standard no_ip
FastIron(config-std-nACL)# deny 4.0.0.0 0.255.255.255
FastIron(config-std-nACL)# permit any any
FastIron(config-std-nACL)# exit
FastIron(config)# router ospf
FastIron(config-ospf-router)# distribute-list no_ip in

The first three commands configure a standard ACL that denies routes to any 4.x.x.x destination network and allows all other routes for eligibility to be installed in the IP route table. The last three commands change the CLI to the OSPF configuration level and configure an OSPF distribution list that uses the ACL as input. The distribution list prevents routes to any 4.x.x.x destination network from entering the IP route table. The distribution list does not prevent the routes from entering the OSPF database.

Syntax: `[no] distribute-list <ACL-name> | <ACL-id> in [interface-type] [interface-number]`
Syntax: `[no] ip access-list standard <ACL-name> | <ACL-id>`
Syntax: `deny | permit <source-ip> <wildcard>`

The `<ACL-name> | <ACL-id>` parameter specifies the ACL name or ID.

The `in` command applies the ACL to incoming route updates.

The `<interface-number>` parameter specifies the interface number on which to apply the ACL. Enter only one valid interface number. If necessary, use the `show interface brief` command to display a list of valid interfaces. If you do not specify an interface, the Brocade device applies the ACL to all incoming route updates.
If you do not specify an interface type and interface number, the device applies the OSPF distribution list to all incoming route updates.

The **deny** | **permit** parameter indicates whether packets that match the policy are dropped or forwarded.

The `<source-ip>` parameter specifies the source address for the policy. Since this ACL is input to an OSPF distribution list, the `<source-ip>` parameter actually is specifying the destination network of the route.

The `<wildcard>` parameter specifies the portion of the source address to match against. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the `<source-ip>`. Ones mean any value matches. For example, the `<source-ip>` and `<wildcard>` values 4.0.0.0 0.255.255.255 mean that all 4.x.x.x networks match the ACL.

If you want the policy to match on all destination networks, enter **any any**.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of "4.0.0.0 0.255.255.255" as "4.0.0.0/8". The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros.

**NOTE**
If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in "/<mask-bits>" format. To enable the software to display the CIDR masks, enter the `ip show-subnet-length` command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the **show ip access-list** command.

**Using an extended ACL as input to the distribution list**
You can use an extended ACL with an OSPF distribution list to filter OSPF routes based on the network mask of the destination network.

To use an extended ACL to configure an OSPF distribution list for denying specific routes, enter commands such as the following.

```
FastIron(config)# ip access-list extended no_ip
FastIron(config-ext-nACL)# deny ip 4.0.0.0 0.255.255.255 255.255.0.0 0.0.255.255
FastIron(config-ext-nACL)# permit ip any any
FastIron(config-ext-nACL)# exit
FastIron(config)# router ospf
FastIron(config-ospf-router)# distribute-list no_ip in
```
The first three commands configure an extended ACL that denies routes to any 4.x.x.x destination network with a 255.255.0.0 network mask and allows all other routes for eligibility to be installed in the IP route table. The last three commands change the CLI to the OSPF configuration level and configure an OSPF distribution list that uses the ACL as input. The distribution list prevents routes to any 4.x.x.x destination network with network mask 255.255.0.0 from entering the IP route table. The distribution list does not prevent the routes from entering the OSPF database.

**Syntax:** [no] ip access-list extended <ACL-name> | <ACL-id>

**Syntax:** deny | permit <ip-protocol> <source-ip> <wildcard> <destination-ip> <wildcard>

The <ACL-name> | <ACL-id> parameter specifies the ACL name or ID.

The deny | permit parameter indicates whether packets that match the policy are dropped or forwarded.

The <ip-protocol> parameter indicates the type of IP packet you are filtering. When using an extended ACL as input for an OSPF distribution list, specify ip.

Since this ACL is input to an OSPF distribution list, the <source-ip> parameter actually specifies the destination network of the route.

The <wildcard> parameter specifies the portion of the source address to match against. The <wildcard> is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the <source-ip>. Ones mean any value matches. For example, the <source-ip> and <wildcard> values 4.0.0.0 0.255.255.255 mean that all 4.x.x.x networks match the ACL.

If you want the policy to match on all network addresses, enter any any.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of "4.0.0.0 0.255.255.255" as "4.0.0.0/8". The CLI automatically converts the CIDR number into the appropriate ACL mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros.

**NOTE**

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in "/<mask-bits>" format. To enable the software to display the CIDR masks, enter the ip show-subnet-length command at the global CONFIG level of the CLI. You can use the CIDR format to configure the ACL entry regardless of whether the software is configured to display the masks in CIDR format.

If you use the CIDR format, the ACL entries appear in this format in the running-config and startup-config files, but are shown with subnet mask in the display produced by the show ip access-list commands.

Since this ACL is input to an OSPF distribution list, the <destination-ip> parameter actually specifies the subnet mask of the route.

The <wildcard> parameter specifies the portion of the subnet mask to match against. For example, the <destination-ip> and <wildcard> values 255.255.255.255 0.0.0.255 mean that subnet mask /24 and longer match the ACL.

If you want the policy to match on all network masks, enter any any.
Modify default metric for redistribution

The default metric is a global parameter that specifies the cost applied to all OSPF routes by default. The default value is 10. You can assign a cost from 1 – 15.

**NOTE**
You also can define the cost on individual interfaces. The interface cost overrides the default cost.

To assign a default metric of 4 to all routes imported into OSPF, enter the following commands.

```
FastIron(config)# router ospf
FastIron(config-ospf-router)# default-metric 4
```

Syntax: `default-metric <value>`

The `<value>` can be from 1 – 16,777,215. The default is 10.

Enable route redistribution

To enable route redistribution, use one of the following methods.

**NOTE**
Do not enable redistribution until you have configured the redistribution filters. Otherwise, you might accidentally overload the network with routes you did not intend to redistribute.

To enable redistribution of RIP and static IP routes into OSPF, enter the following commands.

```
FastIron(config)# router ospf
FastIron(config-ospf-router)# redistribution rip
FastIron(config-ospf-router)# redistribution static
FastIron(config-ospf-router)# write memory
```

*Example using a route map*

To configure a route map and use it for redistribution of routes into OSPF, enter commands such as the following.

```
FastIron(config)# ip route 1.1.0.0 255.255.0.0 207.95.7.30
FastIron(config)# ip route 1.2.0.0 255.255.0.0 207.95.7.30
FastIron(config)# ip route 1.3.0.0 255.255.0.0 207.95.7.30
FastIron(config)# ip route 4.1.0.0 255.255.0.0 207.95.6.30
FastIron(config)# ip route 4.2.0.0 255.255.0.0 207.95.6.30
FastIron(config)# ip route 4.3.0.0 255.255.0.0 207.95.6.30
FastIron(config)# ip route 4.4.0.0 255.255.0.0 207.95.6.30 5
FastIron(config)# route-map abc permit 1
FastIron(config-route-map abc)# match metric 5
FastIron(config-route-map abc)# set metric 8
FastIron(config-route-map abc)# router ospf
FastIron(config-ospf-router)# redistribute static route-map abc
```

The commands in this example configure some static IP routes, then configure a route map and use the route map for redistributing static IP routes into OSPF.
The `ip route` commands configure the static IP routes. The `route-map` command begins configuration of a route map called “abc”. The number indicates the route map entry (called the “instance”) you are configuring. A route map can contain multiple entries. The software compares packets to the route map entries in ascending numerical order and stops the comparison once a match is found.

The `match` command in the route map matches on routes that have 5 for their metric value (cost). The `set` command changes the metric in routes that match the route map to 8.

The `redistribute static` command enables redistribution of static IP routes into OSPF, and uses route map “abc” to control the routes that are redistributed. In this example, the route map allows a static IP route to be redistributed into OSPF only if the route has a metric of 5, and changes the metric to 8 before placing the route into the OSPF route table.

The following command shows the result of the redistribution filter. Since only one of the static IP routes configured above matches the route map, only one route is redistributed. Notice that the route metric is 5 before redistribution but is 8 after redistribution.

```
FastIron# show ip ospf database external extensive
Index Aging LS ID       Router       Netmask Metric Flag
 1   2  4.4.0.0         10.10.10.60 ffff0000 80000008 0000
```

**Syntax:**
```
[no] redistribution bgp | connected | rip | static [route-map <map-name>]
```

The `bgp | connected | rip | static` parameter specifies the route source.

The `route-map <map-name>` parameter specifies the route map name. The following match parameters are valid for OSPF redistribution:

- `match ip address | next-hop <ACL-num>`
- `match metric <num>`
- `match tag <tag-value>`

The following set parameters are valid for OSPF redistribution:

- `set ip next hop <ip-addr>`
- `set metric [+] | -<num> | none`
- `set metric-type type-1 | type-2`
- `set tag <tag-value>`

**NOTE**
You must configure the route map before you configure a redistribution filter that uses the route map.

**NOTE**
When you use a route map for route redistribution, the software disregards the permit or deny action of the route map.
**NOTE**
For an external route that is redistributed into OSPF through a route map, the metric value of the route remains the same unless the metric is set by a `set metric` command inside the route map. The `default-metric <num>` command has no effect on the route. This behavior is different from a route that is redistributed without using a route map. For a route redistributed without using a route map, the metric is set by the `default-metric <num>` command.

**Disable or re-enable load sharing**

Brocade routers can load share among up to eight equal-cost IP routes to a destination. By default, IP load sharing is enabled. The default is 4 equal-cost paths but you can specify from 2 – 6 paths.

The router software can use the route information it learns through OSPF to determine the paths and costs. **Figure 152** shows an example of an OSPF network containing multiple paths to a destination (in this case, R1).

**FIGURE 152** Example OSPF network with four equal-cost paths

In the example in **Figure 152**, the Brocade switch has four paths to R1:

- FI->R3
- FI->R4
- FI->R5
- FI->R6

Normally, the Brocade switch will choose the path to the R1 with the lower metric. For example, if R3 metric is 1400 and R4 metric is 600, the Brocade switch will always choose R4.
However, suppose the metric is the same for all four routers in this example. If the costs are the same, the switch now has four equal-cost paths to R1. To allow the switch to load share among the equal cost routes, enable IP load sharing. The software supports four equal-cost OSPF paths by default when you enable load sharing. You can specify from 2 – 6 paths.

**NOTE**
The Brocade switch is not source routing in these examples. The switch is concerned only with the paths to the next-hop routers, not the entire paths to the destination hosts.

OSPF load sharing is enabled by default when IP load sharing is enabled. To configure IP load sharing parameters, refer to “Configuring IP load sharing” on page 1025.

### Configure external route summarization

When the Layer 3 Switch is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to advertise one external route as an aggregate for all redistributed routes that are covered by a specified address range.

When you configure an address range, the range takes effect immediately. All the imported routes are summarized according to the configured address range. Imported routes that have already been advertised and that fall within the range are flushed out of the AS and a single route corresponding to the range is advertised.

If a route that falls within a configured address range is imported by the Layer 3 Switch, no action is taken if the Layer 3 Switch has already advertised the aggregate route; otherwise the Layer 3 Switch advertises the aggregate route. If an imported route that falls within a configured address range is removed by the Layer 3 Switch, no action is taken if there are other imported routes that fall with in the same address range; otherwise the aggregate route is flushed.

You can configure up to 32 address ranges. The Layer 3 Switch sets the forwarding address of the aggregate route to zero and sets the tag to zero.

If you delete an address range, the advertised aggregate route is flushed and all imported routes that fall within the range are advertised individually.

If an external LSDB overflow condition occurs, all aggregate routes are flushed out of the AS, along with other external routes. When the Layer 3 Switch exits the external LSDB overflow condition, all the imported routes are summarized according to the configured address ranges.

**NOTE**
If you use redistribution filters in addition to address ranges, the Layer 3 Switch applies the redistribution filters to routes first, then applies them to the address ranges.

**NOTE**
If you disable redistribution, all the aggregate routes are flushed, along with other imported routes.

To configure a summary address for OSPF routes, enter commands such as the following.

```
FastIron(config-ospf-router)# summary-address 10.1.0.0 255.255.0.0
```

The command in this example configures summary address 10.1.0.0, which includes addresses 10.1.1.0, 10.1.2.0, 10.1.3.0, and so on. For all of these networks, only the address 10.1.0.0 is advertised in external LSAs.

**Syntax:** `summary-address <ip-addr> <ip-mask>`
The `<ip-addr>` parameter specifies the network address.
The `<ip-mask>` parameter specifies the network mask.

To display the configured summary addresses, enter the following command at any level of the CLI.

```
FastIron# show ip ospf config
OSPF Redistribution Address Ranges currently defined:
Range-Address   Subnetmask
1.0.0.0         255.0.0.0
1.0.1.0         255.255.255.0
1.0.2.0         255.255.255.0
```

Syntax: `show ip ospf config`

## Configure default route origination

When the Layer 3 Switch is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to automatically generate a default external route into an OSPF routing domain. This feature is called “default route origination” or “default information origination”.

By default, Brocade Layer 3 Switches do not advertise the default route into the OSPF domain. If you want the Layer 3 Switch to advertise the OSPF default route, you must explicitly enable default route origination.

When you enable OSPF default route origination, the Layer 3 Switch advertises a type 5 default route that is flooded throughout the AS (except stub areas and NSSAs). In addition, internal NSSA ASBRs advertise their default routes as translatable type 7 default routes.

The Layer 3 Switch advertises the default route into OSPF even if OSPF route redistribution is not enabled, and even if the default route is learned through an IBGP neighbor.

**NOTE**

Brocade Layer 3 Switches never advertise the OSPF default route, regardless of other configuration parameters, unless you explicitly enable default route origination using the following method.

If the Layer 3 Switch is an ASBR, you can use the “always” option when you enable the default route origination. The always option causes the ASBR to create and advertise a default route if it does not already have one configured.

If default route origination is enabled and you disable it, the default route originated by the Layer 3 Switch is flushed. Default routes generated by other OSPF routers are not affected. If you re-enable the feature, the feature takes effect immediately and thus does not require you to reload the software.

**NOTE**

The ABR (Layer 3 Switch) will not inject the default route into an NSSA by default and the command described in this section will not cause the Layer 3 Switch to inject the default route into the NSSA. To inject the default route into an NSSA, use the `area <num> | <ip-addr> nssa default-information-originate` command. Refer to “Assign a Not-So-Stubby Area (NSSA)” on page 1179.

To enable default route origination, enter the following command.

```
FastIron(config-ospf-router)# default-information-originate
```

To disable the feature, enter the following command.
Configuring OSPF

FastIron(config-ospf-router)# no default-information-originate

Syntax: [no] default-information-originate [always] [metric <value>] [metric-type <type>]

The always parameter advertises the default route regardless of whether the router has a default route. This option is disabled by default.

The metric <value> parameter specifies a metric for the default route. If this option is not used, the default metric is used for the route.

The metric-type <type> parameter specifies the external link type associated with the default route advertised into the OSPF routing domain. The <type> can be one of the following:

- 1 – Type 1 external route
- 2 – Type 2 external route

If you do not use this option, the default redistribution metric type is used for the route type.

**NOTE**

If you specify a metric and metric type, the values you specify are used even if you do not use the always option.

Modify SPF timers

The Layer 3 Switch uses the following timers when calculating the shortest path for OSPF routes:

- SPF delay – When the Layer 3 Switch receives a topology change, the software waits before it starts a Shortest Path First (SPF) calculation. By default, the software waits five seconds. You can configure the SPF delay to a value from 0 – 65535 seconds. If you set the SPF delay to 0 seconds, the software immediately begins the SPF calculation after receiving a topology change.
- SPF hold time – The Layer 3 Switch waits for a specific amount of time between consecutive SPF calculations. By default, the Layer 3 Switch waits ten seconds. You can configure the SPF hold time to a value from 0 – 65535 seconds. If you set the SPF hold time to 0 seconds, the software does not wait between consecutive SPF calculations.

You can set the delay and hold time to lower values to cause the Layer 3 Switch to change to alternate paths more quickly in the event of a route failure. Note that lower values require more CPU processing time.

You can change one or both of the timers. To do so, enter commands such as the following.

FastIron(config-ospf-router)# timers spf 10 20

The command in this example changes the SPF delay to 10 seconds and changes the SPF hold time to 20 seconds.

**Syntax:** timers spf <delay> <hold-time>

The <delay> parameter specifies the SPF delay.

The <hold-time> parameter specifies the SPF hold time.

To set the timers back to their default values, enter a command such as the following.

FastIron(config-ospf-router)# no timers spf 10 20
Modify redistribution metric type

The redistribution metric type is used by default for all routes imported into OSPF unless you specify different metrics for individual routes using redistribution filters. Type 2 specifies a big metric (three bytes). Type 1 specifies a small metric (two bytes). The default value is type 2.

To modify the default value to type 1, enter the following command.

```bash
FastIron(config-ospf-router)# metric-type type1
```

**Syntax:** metric-type type1 | type2

The default is type2.

Modify administrative distance

Brocade Layer 3 Switches can learn about networks from various protocols, including Border Gateway Protocol version 4 (BGP4), RIP, and OSPF. Consequently, the routes to a network may differ depending on the protocol from which the routes were learned. The default administrative distance for OSPF routes is 110. Refer to “Changing administrative distances” on page 1327 for a list of the default distances for all route sources.

The router selects one route over another based on the source of the route information. To do so, the router can use the administrative distances assigned to the sources. You can bias the Layer 3 Switch decision by changing the default administrative distance for RIP routes.

**Configuring administrative distance based on route type**

You can configure a unique administrative distance for each type of OSPF route. For example, you can use this feature to prefer a static route over an OSPF inter-area route but you also want to prefer OSPF intra-area routes to static routes.

The distance you specify influences the choice of routes when the Layer 3 Switch has multiple routes for the same network from different protocols. The Layer 3 Switch prefers the route with the lower administrative distance.

You can specify unique default administrative distances for the following route types:

- Intra-area routes
- Inter-area routes
- External routes

The default for all these OSPF route types is 110.

**NOTE**

This feature does not influence the choice of routes within OSPF. For example, an OSPF intra-area route is always preferred over an OSPF inter-area route, even if the intra-area route distance is greater than the inter-area route distance.

To change the default administrative distances for inter-area routes, intra-area routes, and external routes, enter the following command.

```bash
FastIron(config-ospf-router)# distance external 100
FastIron(config-ospf-router)# distance inter-area 90
FastIron(config-ospf-router)# distance intra-area 80
```

**Syntax:** distance external | inter-area | intra-area <distance>
The `external` | `inter-area` | `intra-area` parameter specifies the route type for which you are changing the default administrative distance.

The `<distance>` parameter specifies the new distance for the specified route type. Unless you change the distance for one of the route types using commands such as those shown above, the default is 110.

To reset the administrative distance to its system default (110), enter a command such as the following.

```
FastIron(config-ospf-router)# no distance external 100
```

**Configure OSPF group Link State Advertisement (LSA) pacing**

The Layer 3 Switch paces LSA refreshes by delaying the refreshes for a specified time interval instead of performing a refresh each time an individual LSA refresh timer expires. The accumulated LSAs constitute a group, which the Layer 3 Switch refreshes and sends out together in one or more packets.

The pacing interval, which is the interval at which the Layer 3 Switch refreshes an accumulated group of LSAs, is configurable to a range from 10 – 1800 seconds (30 minutes). The default is 240 seconds (four minutes). Thus, every four minutes, the Layer 3 Switch refreshes the group of accumulated LSAs and sends the group together in the same packets.

**Usage guidelines**

The pacing interval is inversely proportional to the number of LSAs the Layer 3 Switch is refreshing and aging. For example, if you have approximately 10,000 LSAs, decreasing the pacing interval enhances performance. If you have a very small database (40 – 100 LSAs), increasing the pacing interval to 10 – 20 minutes might enhance performance slightly.

**Changing the LSA pacing interval**

To change the LSA pacing interval to two minutes (120 seconds), enter the following command.

```
FastIron(config-ospf-router)# timers lsa-group-pacing 120
```

**Syntax:** `[no] timers lsa-group-pacing <secs>

The `<secs>` parameter specifies the number of seconds and can be from 10 – 1800 (30 minutes). The default is 240 seconds (four minutes).

To restore the pacing interval to its default value, enter the following command.

```
FastIron(config-ospf-router)# no timers lsa-group-pacing
```

**Modify OSPF traps generated**

OSPF traps as defined by RFC 1850 are supported on Brocade routers. OSPF trap generation is enabled on the router, by default.

When using the CLI, you can disable all or specific OSPF trap generation by entering the following CLI command.

```
FastIron(config-ospf-router)# no snmp-server trap ospf
```
To later re-enable the trap feature, enter `snmp-server trap ospf`.

To disable a specific OSPF trap, enter the command as `no snmp-server trap ospf <ospf-trap>`. These commands are at the OSPF router Level of the CLI.

Here is a summary of OSPF traps supported on Brocade routers, their corresponding CLI commands, and their associated MIB objects from RFC 1850:

- `interface-state-change-trap` – [MIB object: OspfIfstateChange]
- `virtual-interface-state-change-trap` – [MIB object: OspfVirtIfStateChange]
- `neighbor-state-change-trap` – [MIB object: ospfNbrStateChange]
- `virtual-neighbor-state-change-trap` – [MIB object: ospfVirtNbrStateChange]
- `interface-config-error-trap` – [MIB object: ospfIfConfigError]
- `virtual-interface-config-error-trap` – [MIB object: ospfVirtIfConfigError]
- `interface-authentication-failure-trap` – [MIB object: ospfIfAuthFailure]
- `virtual-interface-authentication-failure-trap` – [MIB object: ospfVirtIfAuthFailure]
- `virtual-interface-receive-bad-packet-trap` – [MIB object: ospfVirtIfRxBadPacket]
- `interface-retransmit-packet-trap` – [MIB object: ospfTxRetransmit]
- `virtual-interface-retransmit-packet-trap` – [MIB object: ospfVirtIfTxRetransmit]
- `originate-lsa-trap` – [MIB object: ospfOriginateLsa]
- `originate-maxage-lsa-trap` – [MIB object: ospfMaxAgeLsa]
- `link-state-database-overflow-trap` – [MIB object: ospfLsdbOverflow]
- `link-state-database-approaching-overflow-trap` – [MIB object: ospfLsdbApproachingOverflow]

Example

To stop an OSPF trap from being collected, use the CLI command: `no trap <ospf-trap>`, at the Router OSPF level of the CLI. To disable reporting of the neighbor-state-change-trap, enter the following command.

```
FastIron(config-ospf-router)# no trap neighbor-state-change-trap
```

Example

To reinstate the trap, enter the following command.

```
FastIron(config-ospf-router)# trap neighbor-state-change-trap
```

**Syntax:** `[no] snmp-server trap ospf <ospf-trap>`

### Modify OSPF standard compliance setting

Brocade routers are configured, by default, to be compliant with the RFC 1583 OSPF V2 specification.

To configure a router to operate with the latest OSPF standard, RFC 2178, enter the following commands.

```
FastIron(config)# router ospf
FastIron(config-ospf-router)# no rfc1583-compatibility
```

**Syntax:** `[no] rfc1583-compatibility`
Modify exit overflow interval

If a database overflow condition occurs on a router, the router eliminates the condition by removing entries that originated on the router. The exit overflow interval allows you to set how often a Layer 3 Switch checks to see if the overflow condition has been eliminated. The default value is 0. The range is 0 – 86400 seconds (24 hours). If the configured value of the database overflow interval is zero, then the router never leaves the database overflow condition.

NOTE
FastIron devices dynamically allocate OSPF memory as needed. Refer to “Dynamic OSPF memory” on page 1175.

To modify the exit overflow interval to 60 seconds, enter the following command.

```
FastIron(config-ospf-router)# data-base-overflow-interval 60
```

Syntax: `data-base-overflow-interval <value>`

The `<value>` can be from 0 – 86400 seconds. The default is 0 seconds.

Configuring an OSPF point-to-point Link

Platform Support:
- FESX devices running software release 02.2.00 and later
- FSX devices running software release 02.3.01 and later

In an OSPF point-to-point link, a direct Layer 3 connection exists between a single pair of OSPF routers, without the need for Designated and Backup Designated routers. In a point-to-point link, neighboring routers become adjacent whenever they can communicate directly. In contrast, in broadcast and non-broadcast multi-access (NBMA) networks, the Designated Router and the Backup Designated Router become adjacent to all other routers attached to the network.

Configuration notes and limitations
- This feature is supported on Gbps Ethernet and 10 Gbps Ethernet interfaces.
- This feature is supported on physical interfaces. It is not supported on virtual interfaces.
- Brocade supports numbered point-to-point networks, meaning the OSPF router must have an IP interface address which uniquely identifies the router over the network. Brocade does not support unnumbered point-to-point networks.

Configuring an OSPF point-to-point link

To configure an OSPF point-to-point link, enter commands such as the following.

```
FastIron(config)# interface eth 1/5
FastIron(config-if-1/5)# ip ospf network point-to-point
```

This command configures an OSPF point-to-point link on Interface 5 in slot 1.

Syntax: `[no] ip ospf network point-to-point`
Clearing OSPF information

**Viewing configured OSPF point-to-point links**

Refer to “Displaying OSPF neighbor information” on page 1213 and “Displaying OSPF interface information” on page 1215.

**Specifying the types of OSPF Syslog messages to log**

You can specify which kinds of OSPF-related Syslog messages are logged. By default, the only OSPF messages that are logged are those indicating possible system errors. If you want other kinds of OSPF messages to be logged, you can configure the Brocade device to log them.

---

**NOTE**

This feature is not supported on FGS, FWS, or FLS devices.

For example, to specify that all OSPF-related Syslog messages be logged, enter the following commands.

```text
FastIron(config)# router ospf
FastIron(config-ospf-router)# log all
```

### Syntax: [no] log all | adjacency | bad_packet [checksum] | database | memory | retransmit

The log command has the following options:

- **The all option** causes all OSPF-related Syslog messages to be logged. If you later disable this option with the no log all command, the OSPF logging options return to their default settings.

- **The adjacency option** logs essential OSPF neighbor state changes, especially on error cases. This option is disabled by default.

- **The bad_packet checksum option** logs all OSPF packets that have checksum errors. This option is enabled by default.

- **The bad_packet option** logs all other bad OSPF packets. This option is disabled by default.

- **The database option** logs OSPF LSA-related information. This option is disabled by default.

- **The memory option** logs abnormal OSPF memory usage. This option is enabled by default.

- **The retransmit option** logs OSPF retransmission activities. This option is disabled by default.

---

**Clearing OSPF information**

**Platform Support:**

- FESX and FSX devices running software release 03.0.00 and later
- Turbolon X Series devices running software release 04.2.00 and later

The following kinds of OSPF information can be cleared from a Brocade OSPF link state database and OSPF routing table:

- Routes received from OSPF neighbors. You can clear routes from all OSPF neighbors, or an individual OSPF neighbor, specified either by the neighbor IP address or its router ID
- OSPF topology information, including all routes in the OSPF routing table
- All routes in the OSPF routing table that were redistributed from other protocols
• OSPF area information, including routes received from OSPF neighbors within an area, as well as routes imported into the area. You can clear area information for all OSPF areas, or for a specified OSPF area.

The OSPF information is cleared dynamically when you enter the command; you do not need to remove statements from the Brocade configuration or reload the software for the change to take effect.

**Clearing OSPF neighbor information**

To clear information on the Brocade device about all OSPF neighbors, enter the following command.

```
FastIron# clear ip ospf neighbor
```

**Syntax:** `clear ip ospf neighbor [ip <ip-addr> | id <ip-addr>]`

This command clears all OSPF neighbors and the OSPF routes exchanged with the neighbors in the Brocade OSPF link state database. After this information is cleared, adjacencies with all neighbors are re-established, and routes with these neighbors exchanged again.

To clear information on the Brocade device about OSPF neighbor 10.10.10.1, enter the following command.

```
FastIron# clear ip ospf neighbor ip 10.10.10.1
```

This command clears the OSPF neighbor and the OSPF routes exchanged with neighbor 10.10.10.1 in the OSPF link state database in the Brocade device. After this information is cleared, the adjacency with the neighbor is re-established, and routes are exchanged again.

The neighbor router can be specified either by its IP address or its router ID. To specify the neighbor router using its IP address, use the `ip <ip-addr>` parameter. To specify the neighbor router using its router ID, use the `id <ip-addr>` parameter.

**Clearing OSPF topology information**

To clear OSPF topology information on the Brocade device, enter the following command.

```
FastIron# clear ip ospf topology
```

**Syntax:** `clear ip ospf topology`

This command clears all OSPF routes from the OSPF routing table, including intra-area, (which includes ABR and ASBR intra-area routes), inter-area, external type 1, external type 2, OSPF default, and OSPF summary routes.

After you enter this command, the OSPF routing table is rebuilt, and valid routes are recomputed from the OSPF link state database. When the OSPF routing table is cleared, OSPF routes in the global routing table are also recalculated. If redistribution is enabled, the routes are imported again.

**Clearing redistributed routes from the OSPF routing table**

To clear all routes in the OSPF routing table that were redistributed from other protocols, enter the following command.

```
FastIron# clear ospf redistribution
```
Syntax: clear ospf redistribution

This command clears all routes in the OSPF routing table that are redistributed from other protocols, including direct connected, static, RIP, and BGP. To import redistributed routes from other protocols, use the redistribution command at the OSPF configuration level.

Clearing information for OSPF areas

To clear information on the Brocade device about all OSPF areas, enter the following command.

FastIron# clear ip ospf

This command clears all OSPF areas, all OSPF neighbors, and the entire OSPF routing table. After this information has been cleared, adjacencies with all neighbors are re-established, and all OSPF routes are re-learned.

To clear information on the Brocade device about OSPF area 1, enter the following command.

FastIron# clear ip ospf area 1

This command clears information about the specified area ID. Information about other OSPF areas is not affected. The command clears information about all OSPF neighbors belonging to the specified area, as well as all routes imported into the specified area. Adjacencies with neighbors belonging to the area are re-established, and routes imported into the area are re-learned.

Syntax: clear ip ospf [area <area-id>]

The <area-id> can be specified in decimal format or in IP address format.

Displaying OSPF information

You can use CLI commands and Web management options to display the following OSPF information:

- Trap, area, and interface information – refer to “Displaying general OSPF configuration information” on page 1211.
- Area information – refer to “Displaying OSPF area information” on page 1213.
- Neighbor information – refer to “Displaying OSPF neighbor information” on page 1213.
- Interface information – refer to “Displaying OSPF interface information” on page 1215.
- Route information – refer to “Displaying OSPF route information” on page 1217.
- External link state information – refer to “Displaying OSPF external link state information” on page 1219.
- Link state information – refer to “Displaying OSPF link state information” on page 1220.
- Virtual Neighbor information – refer to “Displaying OSPF virtual neighbor information” on page 1221.
- Virtual Link information – refer to “Displaying OSPF virtual link information” on page 1221.
- ABR and ASBR information – refer to “Displaying OSPF ABR and ASBR information” on page 1221.
- Trap state information – refer to “Displaying OSPF trap status” on page 1222.
Displaying general OSPF configuration information

To display general OSPF configuration information, enter the following command at any CLI level.

```
FastIron# show ip ospf config
Router OSPF: Enabled
Redistribution: Disabled
Default OSPF Metric: 10
OSPF Redistribution Metric: Type2
OSPF External LSA Limit: 25000
OSPF Database Overflow Interval: 0
RFC 1583 Compatibility: Enabled
Router id: 207.95.11.128

Interface State Change Trap: Enabled
Virtual Interface State Change Trap: Enabled
Neighbor State Change Trap: Enabled
Virtual Neighbor State Change Trap: Enabled
Interface Configuration Error Trap: Enabled
Virtual Interface Configuration Error Trap: Enabled
Interface Authentication Failure Trap: Enabled
Virtual Interface Authentication Failure Trap: Enabled
Interface Receive Bad Packet Trap: Enabled
Virtual Interface Receive Bad Packet Trap: Enabled
Interface Retransmit Packet Trap: Enabled
Virtual Interface Retransmit Packet Trap: Enabled
Originate LSA Trap: Enabled
Originate MaxAge LSA Trap: Enabled
Link State Database Overflow Trap: Enabled
Link State Database Approaching Overflow Trap: Enabled

OSPF Area currently defined:
Area-ID    Area-Type Cost
0          normal    0

OSPF Interfaces currently defined:
Ethernet Interface: 3/1-3/2
ip ospf md5-authentication-key-activation-wait-time 300
ip ospf cost 0
ip ospf area 0

Ethernet Interface: v1
ip ospf md5-authentication-key-activation-wait-time 300
ip ospf cost 0
ip ospf area 0
```

**Syntax:** show ip ospf config

Displaying CPU utilization statistics

You can display CPU utilization statistics for OSPF and other IP protocols.

To display CPU utilization statistics for OSPF for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI.

```
FastIron# show ip ospf config
Router OSPF: Enabled
Redistribution: Disabled
Default OSPF Metric: 10
OSPF Redistribution Metric: Type2
OSPF External LSA Limit: 25000
OSPF Database Overflow Interval: 0
RFC 1583 Compatibility: Enabled
Router id: 207.95.11.128

Interface State Change Trap: Enabled
Virtual Interface State Change Trap: Enabled
Neighbor State Change Trap: Enabled
Virtual Neighbor State Change Trap: Enabled
Interface Configuration Error Trap: Enabled
Virtual Interface Configuration Error Trap: Enabled
Interface Authentication Failure Trap: Enabled
Virtual Interface Authentication Failure Trap: Enabled
Interface Receive Bad Packet Trap: Enabled
Virtual Interface Receive Bad Packet Trap: Enabled
Interface Retransmit Packet Trap: Enabled
Virtual Interface Retransmit Packet Trap: Enabled
Originate LSA Trap: Enabled
Originate MaxAge LSA Trap: Enabled
Link State Database Overflow Trap: Enabled
Link State Database Approaching Overflow Trap: Enabled

OSPF Area currently defined:
Area-ID    Area-Type Cost
0          normal    0

OSPF Interfaces currently defined:
Ethernet Interface: 3/1-3/2
ip ospf md5-authentication-key-activation-wait-time 300
ip ospf cost 0
ip ospf area 0

Ethernet Interface: v1
ip ospf md5-authentication-key-activation-wait-time 300
ip ospf cost 0
ip ospf area 0
```

**Syntax:** show ip ospf config
If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.

```
FastIron# show process cpu
```

```
Process Name  5Sec(%)  1Min(%)  5Min(%)  15Min(%)  Runtime(ms)
ARP  0.01  0.03  0.09  0.22  9
BGP  0.04  0.06  0.08  0.14  13
GVRP  0.00  0.00  0.00  0.00  0
ICMP  0.00  0.00  0.00  0.00  0
IP  0.00  0.00  0.00  0.00  0
OSPF  0.03  0.06  0.09  0.12  11
RIP  0.00  0.00  0.00  0.00  0
STP  0.00  0.00  0.00  0.00  0
VRRP  0.00  0.00  0.00  0.00  0
```

The system has only been up for 6 seconds.

```
FastIron# show process cpu
```

```
The system has only been up for 6 seconds.
```

```
Process Name  5Sec(%)  1Min(%)  5Min(%)  15Min(%)  Runtime(ms)
ARP  0.01  0.00  0.00  0.00  0
BGP  0.00  0.00  0.00  0.00  0
GVRP  0.00  0.00  0.00  0.00  0
ICMP  0.01  0.00  0.00  0.00  1
IP  0.00  0.00  0.00  0.00  0
OSPF  0.00  0.00  0.00  0.00  0
RIP  0.00  0.00  0.00  0.00  0
STP  0.00  0.00  0.00  0.00  0
VRRP  0.00  0.00  0.00  0.00  0
```

To display utilization statistics for a specific number of seconds, enter a command such as the following.

```
FastIron# show process cpu 2
```

```
Statistics for last 1 sec and 80 ms
```

```
Process Name  Sec(%)  Time(ms)
ARP  0.00  0
BGP  0.00  0
GVRP  0.00  0
ICMP  0.01  1
IP  0.00  0
OSPF  0.00  0
RIP  0.00  0
STP  0.01  0
VRRP  0.00  0
```

When you specify how many seconds’ worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

**Syntax:** `show process cpu [<num>]`

The `<num>` parameter specifies the number of seconds and can be from 1 – 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.
Displaying OSPF area information

To display OSPF area information, enter the following command at any CLI level.

FastIron# show ip ospf area

<table>
<thead>
<tr>
<th>Indx</th>
<th>Area</th>
<th>Type</th>
<th>Cost</th>
<th>SPFR</th>
<th>ABR</th>
<th>ASBR</th>
<th>LSA</th>
<th>Chksum(Hex)</th>
</tr>
</thead>
<tbody>
<tr>

<td>stub</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>2</td>
<td>000181cd</td>
</tr>
</tbody>
</table>

Syntax:  show ip ospf area [<area-id>] [<num>]

The <area-id> parameter shows information for the specified area.

The <num> parameter displays the entry that corresponds to the entry number you enter. The entry number identifies the entry position in the area table.

This display shows the following information.

**TABLE 197 CLI display of OSPF area information**

<table>
<thead>

</tbody>
</table>

Syntax: show ip ospf neighbor [router-id <ip-addr>] | [<num>] | [detail]

The router-id <ip-addr> parameter displays only the neighbor entries for the specified router.

The <num> parameter displays only the entry in the specified index position in the neighbor table. For example, if you enter “1”, only the first entry in the table is displayed.

The detail parameter displays detailed information about the neighbor routers.

These displays show the following information.

**TABLE 198** CLI display of OSPF neighbor information

<table>

**Displaying OSPF information**

To display OSPF interface information, enter the following command at any CLI level.

### Displaying OSPF interface information

To display OSPF interface information, enter the following command at any CLI level.

#### TABLE 198 CLI display of OSPF neighbor information (Continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>State</td>
<td>The state of the conversation between the Layer 3 Switch and the neighbor. This field can have one of the following values:</td>
</tr>
<tr>
<td></td>
<td>• Down – The initial state of a neighbor conversation. This value indicates that there has been no recent information received from the neighbor.</td>
</tr>
<tr>
<td></td>
<td>• Attempt – This state is only valid for neighbors attached to non-broadcast networks. It indicates that no recent information has been received from the neighbor.</td>
</tr>
<tr>
<td></td>
<td>• Init – A Hello packet has recently been seen from the neighbor. However, bidirectional communication has not yet been established with the neighbor. (The router itself did not appear in the neighbor's Hello packet.) All neighbors in this state (or higher) are listed in the Hello packets sent from the associated interface.</td>
</tr>
<tr>
<td></td>
<td>• 2-Way – Communication between the two routers is bidirectional. This is the most advanced state before beginning adjacency establishment. The Designated Router and Backup Designated Router are selected from the set of neighbors in the 2-Way state or greater.</td>
</tr>
<tr>
<td></td>
<td>• ExStart – The first step in creating an adjacency between the two neighboring routers. The goal of this step is to decide which router is the master, and to decide upon the initial Database Description (DD) sequence number. Neighbor conversations in this state or greater are called adjacencies.</td>
</tr>
<tr>
<td></td>
<td>• Exchange – The router is describing its entire link state database by sending Database Description packets to the neighbor. Each Database Description packet has a DD sequence number, and is explicitly acknowledged. Only one Database Description packet can be outstanding at any time. In this state, Link State Request packets can also be sent asking for the neighbor's more recent advertisements. All adjacencies in Exchange state or greater are used by the flooding procedure. In fact, these adjacencies are fully capable of transmitting and receiving all types of OSPF routing protocol packets.</td>
</tr>
<tr>
<td></td>
<td>• Loading – Link State Request packets are sent to the neighbor asking for the more recent advertisements that have been discovered (but not yet received) in the Exchange state.</td>
</tr>
<tr>
<td></td>
<td>• Full – The neighboring routers are fully adjacent. These adjacencies will now appear in router links and network link advertisements.</td>
</tr>
</tbody>
</table>

<table>

</thead>
</table>
FastIron# show ip ospf interface 192.168.1.1

**Ethernet 2/1, OSPF enabled**

- IP Address 192.168.1.1, Area 0
- OSPF state ptr2ptr, Pri 1, Cost 1, Options 2, Type pt-2-pt Events 1

**Timers (sec):** Transit 1, Retrans 5, Hello 10, Dead 40

- DR: Router ID 0.0.0.0
- BDR: Router ID 0.0.0.0

**Neighbor Count = 0, Adjacent Neighbor Count = 1**

- Neighbor: 2.2.2.2
- Authentication-Key: None
- MD5 Authentication: Key None, Key-Id None, Auth-change-wait-time 300

**Syntax:** `show ip ospf interface [<ip-addr>]`

The `<ip-addr>` parameter displays the OSPF interface information for the specified IP address.

The following table defines the highlighted fields shown in the above example output of the `show ip ospf interface` command.

<table>
<thead>
<tr>
<th><strong>TABLE 199</strong></th>
<th><strong>Output of the show ip ospf interface command</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field</strong></td>
<td><strong>Displays</strong></td>
</tr>
<tr>
<td>IP Address</td>
<td>The IP address of the interface.</td>

Syntax: `show ip ospf routes [<ip-addr>]`

The `<ip-addr>` parameter specifies a destination IP address. If you use this parameter, only the route entries for that destination are shown.

This display shows the following information.

### TABLE 200 CLI Display of OSPF route information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>The row number of the entry in the router OSPF route table.</td>

</tr>
<tr>
<td>Type2_Cost</td>
<td>The type 2 cost of this path.</td>
</tr>
</tbody>
</table>
Displaying OSPF information

You can display the routes that have been redistributed into OSPF. To display the redistributed routes, enter the following command at any level of the CLI.

```
FastIron# show ip ospf redistribute route
  4.3.0.0 255.255.0.0 static
  3.1.0.0 255.255.0.0 static
  10.11.61.0 255.255.255.0 connected
  4.1.0.0 255.255.0.0 static
```

In this example, four routes have been redistributed. Three of the routes were redistributed from static IP routes and one route was redistributed from a directly connected IP route.

**Syntax:** `show ip ospf redistribute route [<ip-addr> <ip-mask>]`

The `<ip-addr> <ip-mask>` parameter specifies a network prefix and network mask. Here is an example.
Displaying OSPF external link state information

To display external link state information, enter the following command at any CLI level.

```
FastIron# show ip ospf database external-link-state
```

### Syntax
```
show ip ospf database external-link-state [advertise <num>] | [extensive] | [link-state-id <ip-addr>] | [router-id <ip-addr>] | [sequence-number <num(Hex)>] | [status <num>]
```

The `advertise <num>` parameter displays the hexadecimal data in the specified LSA packet. The `<num>` parameter identifies the LSA packet by its position in the router External LSA table. To determine an LSA packet position in the table, enter the `show ip ospf external-link-state` command to display the table. Refer to “Displaying the data in an LSA” on page 1220 for an example.

The `extensive` option displays the LSAs in decrypted format.

### NOTE
You cannot use the `extensive` option in combination with other display options. The entire database is displayed.

The `link-state-id <ip-addr>` parameter displays the External LSAs for the LSA source specified by `<IP-addr>`.

The `router-id <ip-addr>` parameter shows the External LSAs for the specified OSPF router.

The `sequence-number <num(Hex)>` parameter displays the External LSA entries for the specified hexadecimal LSA sequence number.

The `status <num>` option shows status information.

This display shows the following information.

### TABLE 201 CLI display of OSPF external link state information

<table>
<thead>
<tr>
<th>Field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area ID</td>
<td>The OSPF area the router is in.</td>
</tr>
<tr>
<td>Aging</td>
<td>The age of the LSA, in seconds.</td>
</tr>
<tr>
<td>LS ID</td>
<td>The ID of the link-state advertisement from which the Layer 3 Switch learned this route.</td>
</tr>
<tr>
<td>Router</td>
<td>The router IP address.</td>
</tr>
</tbody>
</table>
### Displaying OSPF link state information

To display link state information, enter the following command at any CLI level.

```
FastIron# show ip ospf database link-state
```

**Syntax:**

```
show ip ospf database link-state [advertise <num>] | [asbr] | [extensive] | [link-state-id <ip-addr>] | [network] | [nssa] | [opaque-area] | [router] | [router-id <ip-addr>] | [sequence-number <num(Hex)>] | [status <num>] | [summary]
```

The `advertise <num>` parameter displays the hexadecimal data in the specified LSA packet. The `<num>` parameter identifies the LSA packet by its position in the router External LSA table. To determine an LSA packet position in the table, enter the `show ip ospf external-link-state` command to display the table. Refer to “Displaying the data in an LSA” on page 1220 for an example.

The `asbr` option shows ASBR information.

The `extensive` option displays the LSAs in decrypted format.

**NOTE**
You cannot use the `extensive` option in combination with other display options. The entire database is displayed.

The `link-state-id <ip-addr>` parameter displays the External LSAs for the LSA source specified by `<ip-addr>`.

The `network` option shows network information.

The `nssa` option shows network information.

The `opaque-area` option shows information for opaque areas.

The `router-id <ip-addr>` parameter shows the External LSAs for the specified OSPF router.

The `sequence-number <num(Hex)>` parameter displays the External LSA entries for the specified hexadecimal LSA sequence number.

The `status <num>` option shows status information.

The `summary` option shows summary information.

### Displaying the data in an LSA

You can use the CLI to display the data the Layer 3 Switch received in a specific External LSA packet or other type of LSA packet. For example, to display the LSA data in entry 3 in the External LSA table, enter the following command.

---

**TABLE 201** CLI display of OSPF external link state information (Continued)

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seq(hex)</td>
<td>The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps it with a sequence number to enable the Layer 3 Switch and other OSPF routers to determine which LSA for a given route is the most recent.</td>
</tr>
<tr>
<td>Chksum</td>
<td>A checksum for the LSA packet, which is based on all the fields in the packet except the age field. The Layer 3 Switch uses the checksum to verify that the packet is not corrupted.</td>
</tr>
<tr>
<td>Type</td>
<td>The route type, which is always EXTR (external).</td>
</tr>
</tbody>
</table>

---

**Seq(hex)**

The sequence number field. This field displays the sequence number assigned to the LSA by the originating router. It is used to determine the freshness of the LSA and to detect any discrepancies in the sequence numbers. A higher sequence number indicates a more recent LSA. If the sequence number field contains a value that is not greater than the sequence number field of the LSA in the current database, the LSA is discarding.

**Chksum**

The checksum field. This field displays the checksum for the LSA packet. It is calculated by summing all the data fields of the LSA, excluding the age field. The checksum is used to verify the integrity of the LSA packet. If the checksum is not correct, the LSA is discarded.

**Type**

The type field. This field displays the route type of the LSA. The type is always `EXTR` (external) for external LSAs.
Displaying OSPF information

Syntax: show ip ospf database external-link-state [advertise <num>] | [link-state-id <ip-addr>] | [router-id <ip-addr>] | [sequence-number <num(Hex)>] | [status <num>]

To determine an external LSA or other type of LSA index number, enter one of the following commands to display the appropriate LSA table:

- show ip ospf database link-state advertise <num> – This command displays the data in the packet for the specified LSA.
- show ip ospf database external-link-state advertise <num> – This command displays the data in the packet for the specified external LSA.

For example, to determine an external LSA index number, enter the following command.

FastIron# show ip ospf external-link-state

<table>
<thead>
<tr>
<th>Index</th>
<th>Aging</th>
<th>LS ID</th>
<th>Router</th>
<th>Netmask</th>
<th>Metric</th>
<th>Flag</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Displaying OSPF virtual neighbor information

To display OSPF virtual neighbor information, enter the following command at any CLI level.

FastIron# show ip ospf virtual-neighbor

Syntax: show ip ospf virtual-neighbor [<num>]

The <num> parameter displays the table beginning at the specified entry number.

Displaying OSPF virtual link information

To display OSPF virtual link information, enter the following command at any CLI level.

FastIron# show ip ospf virtual-link

Syntax: show ip ospf virtual-link [<num>]

The <num> parameter displays the table beginning at the specified entry number.

Displaying OSPF ABR and ASBR information

To display OSPF ABR and ASBR information, enter the following command at any CLI level.

FastIron# show ip ospf border-routers
Syntax: `show ip ospf border-routers [<ip-addr>]`

The `<ip-addr>` parameter displays the ABR and ASBR entries for the specified IP address.

**Displaying OSPF trap status**

All traps are enabled by default when you enable OSPF. To disable or re-enable an OSPF trap, refer to “Modify OSPF traps generated” on page 1205.

To display the state of each OSPF trap, enter the following command at any CLI level.

```
FastIron# show ip ospf trap
Interface State Change Trap:                  Enabled
Virtual Interface State Change Trap:          Enabled
Neighbor State Change Trap:                   Enabled
Virtual Neighbor State Change Trap:           Enabled
Interface Configuration Error Trap:           Enabled
Virtual Interface Configuration Error Trap:   Enabled
Interface Authentication Failure Trap:        Enabled
Virtual Interface Authentication Failure Trap: Enabled
Interface Receive Bad Packet Trap:            Enabled
Virtual Interface Receive Bad Packet Trap:    Enabled
Interface Retransmit Packet Trap:             Enabled
Virtual Interface Retransmit Packet Trap:     Enabled
Originate LSA Trap:                           Enabled
Originate MaxAge LSA Trap:                    Enabled
Link State Database Overflow Trap:            Enabled
Link State Database Approaching Overflow Trap: Enabled
```

Syntax: `show ip ospf trap`
Overview

Open Shortest Path First (OSPF) is a link-state routing protocol. OSPF uses link-state advertisements (LSAs) to update neighboring routers about its interfaces and information on those interfaces. The switch floods LSAs to all neighboring routers to update them about the interfaces. Each router maintains an identical database that describes its area topology to help a router determine the shortest path between it and any neighboring router:

- The differences between OSPF Version 2 (OSPF V2) and OSPF Version 3 (OSPF V3).
- The link state advertisement types for OSPF Version 3.
- How to configure OSPF Version 3.
- How to display OSPF Version 3 information and statistics.

**NOTE**
The terms *Layer 3 Switch* and *router* are used interchangeably in this chapter and mean the same thing.

Differences between OSPF V2 and OSPF V3

IPv6 supports OSPF V3 functions similarly to OSPF V2 (the current version that IPv4 supports), except for the following enhancements:

- Support for IPv6 addresses and prefixes.
- While OSPF V2 runs per IP subnet, OSPF V3 runs per link. In general, you can configure several IPv6 addresses on a router interface, but OSPF V3 forms one adjacency per interface only, using the interface associated link-local address as the source for OSPF protocol packets. On virtual links, OSPF V3 uses the global IP address as the source.
- You can run one instance of OSPF Version 2 and one instance of OSPF V3 concurrently on a link.
- Support for IPv6 link state advertisements (LSAs).

In addition, Brocade implements some new commands that are specific to OSPF V3. This chapter describes the commands that are specific to OSPF V3.

**NOTE**
Although OSPF Versions 2 and 3 function similarly to each other, Brocade has implemented the user interface for each version independently of each other. Therefore, any configuration of OSPF Version 2 features will not affect the configuration of OSPF V3 features and vice versa.

**NOTE**
You are required to configure a router ID when running only IPv6 routing protocols.
Link state advertisement types for OSPF V3

OSPF V3 supports the following types of LSAs:

- Router LSAs (Type 1)
- Network LSAs (Type 2)
- Interarea-prefix LSAs for ABRs (Type 3)
- Interarea-router LSAs for ASBRs (Type 4)
- Autonomous system external LSAs (Type 5)
- Link LSAs (Type 8)
- Intra-area prefix LSAs (Type 9)

For more information about these LSAs, see RFC 2740.

Configuring OSPF V3

To configure OSPF V3, you must do the following:

1. Enable OSPF V3 globally.
2. Assign OSPF areas.
3. Assign router interfaces to an OSPF area.

The following configuration tasks are optional:

- Configure a virtual link between an ABR without a physical connection to a backbone area and the Brocade device in the same area with a physical connection to the backbone area.
- Change the reference bandwidth for the cost on OSPF V3 interfaces.
- Configure the redistribution of routes into OSPF V3.
- Configure default route origination.
- Modify the shortest path first (SPF) timers.
- Modify the administrative distances for OSPF V3 routes.
- Configure the OSPF V3 LSA pacing interval.
- Modify how often the Brocade device checks on the elimination of the database overflow condition.
- Modify the external link state database limit.
- Modify the default values of OSPF V3 parameters for router interfaces.
- Disable or re-enable OSPF V3 event logging.

Enabling OSPF V3

Before enabling the Brocade device to run OSPF V3, you must do the following:

- Enable the forwarding of IPv6 traffic on the Brocade device using the `ipv6 unicast-routing` command.
- Enable IPv6 on each interface over which you plan to enable OSPF V3. You enable IPv6 on an interface by configuring an IPv6 address or explicitly enabling IPv6 on that interface.
By default, OSPF V3 is disabled. To enable OSPF V3, you must enable it globally.

To enable OSPF V3 globally, enter the following command.

```
FastIron(config-ospf-router)#ipv6 router ospf
FastIron(config-ospf6-router)#
```

After you enter this command, the Brocade device enters the IPv6 OSPF configuration level, where you can access several commands that allow you to configure OSPF V3.

**Syntax:** `[no] ipv6 router ospf` 

To disable OSPF V3, enter the `no` form of this command. If you disable OSPF V3, the Brocade device removes all the configuration information for the disabled protocol from the running-config. Moreover, when you save the configuration to the startup-config file after disabling one of these protocols, all the configuration information for the disabled protocol is removed from the startup-config file.

The CLI displays a warning message such as the following.

```
FastIron(config-ospf6-router)#no ipv6 router ospf
ipv6 router ospf mode now disabled. All ospf config data will be lost when writing to flash!
```

If you have disabled the protocol but have not yet saved the configuration to the startup-config file and reloaded the software, you can restore the configuration information by re-entering the command to enable the protocol (for example, `ipv6 router ospf`). If you have already saved the configuration to the startup-config file and reloaded the software, the information is gone. If you are testing an OSPF configuration and are likely to disable and re-enable the protocol, you might want to make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

### Assigning OSPF V3 areas

After OSPF V3 is enabled, you can assign OSPF V3 areas. You can assign an IPv4 address or a number as the area ID for each area. The area ID is representative of all IPv6 addresses (subnets) on a router interface. Each router interface can support one area.

An area can be **normal** or a **stub**:

- **Normal** – OSPF routers within a normal area can send and receive External Link State Advertisements (LSAs).
- **Stub** – OSPF routers within a stub area cannot send or receive External LSAs. In addition, OSPF routers in a stub area must use a default route to the area Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) to send traffic out of the area.

For example, to set up OSPF V3 areas 0.0.0.0, 200.5.0.0, 192.5.1.0, and 195.5.0.0, enter the following commands.

```
FastIron(config-ospf6-router)#area 0.0.0.0
FastIron(config-ospf6-router)#area 200.5.0.0
FastIron(config-ospf6-router)#area 192.5.1.0
FastIron(config-ospf6-router)#area 195.5.0.0
```

**Syntax:** `[no] area <number> | <ipv4-address>`
Configuring OSPF V3

The `<number> | <ipv4-address>` parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 – 2,147,483,647.

**NOTE**
You can assign one area on a router interface.

### Assigning a totally stubby area

By default, the Brocade device sends summary LSAs (LSA type 3) into stub areas. You can further reduce the number of LSAs sent into a stub area by configuring the Brocade device to stop sending summary LSAs into the area. You can disable the summary LSAs when you are configuring the stub area or later after you have configured the area.

This feature disables origination of summary LSAs into a stub area, but the Brocade device still accepts summary LSAs from OSPF neighbors and floods them to other areas. The Brocade device can form adjacencies with other routers regardless of whether summarization is enabled or disabled for areas on each router.

When you disable the summary LSAs, the change takes effect immediately. If you apply the option to a previously configured area, the router flushes all of the summary LSAs it has generated (as an ABR) from the area.

**NOTE**
This feature applies only when the Brocade device is configured as an Area Border Router (ABR) for the area. To completely prevent summary LSAs from being sent to the area, disable the summary LSAs on each OSPF router that is an ABR for the area.

For example, to disable summary LSAs for stub area 40 and specify an additional metric of 99, enter the following command.

```
FastIron(config-ospf6-router)#area 40 stub 99 no-summary
```

**Syntax:** `area <number> | <ipv4-address> stub <metric> [no-summary]`

The `<number> | <ipv4-address>` parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 – 2,147,483,647.

The `stub <metric>` parameter specifies an additional cost for using a route to or from this area and can be from 1 – 16777215. There is no default. Normal areas do not use the cost parameter.

The `no-summary` parameter applies only to stub areas and disables summary LSAs from being sent into the area.

### Assigning interfaces to an area

After you define OSPF V3 areas, you must assign router interfaces to the areas. All router interfaces must be assigned to one of the defined areas on an OSPF router. When an interface is assigned to an area, all corresponding subnets on that interface are automatically included in the assignment.

For example, to assign Ethernet interface 3/1 to area 192.5.0.0, enter the following commands.

```
FastIron(config)#interface ethernet 3/1
FastIron(config-if-e100-3/1)#ipv6 ospf area 192.5.0.0
```

**Syntax:** `[no] ipv6 ospf area <number> | <ipv4-address>`
The `<number> | <ipv4-address>` parameter specifies the area number, which can be a number or in IPv4 address format. If you specify a number, the number can be from 0 – 2,147,483,647.

To remove the interface from the specified area, use the `no` form of this command.

### Configuring virtual links

All ABRs must have either a direct or indirect link to an OSPF backbone area (0.0.0.0 or 0). If an ABR does not have a physical link to a backbone area, you can configure a virtual link from the ABR to another router within the same area that has a physical connection to the backbone area.

The path for a virtual link is through an area shared by the neighbor ABR (router with a physical backbone connection) and the ABR requiring a logical connection to the backbone.

Two parameters must be defined for all virtual links—transit area ID and neighbor router:

- The transit area ID represents the shared area of the two ABRs and serves as the connection point between the two routers. This number should match the area ID value.
- When assigned from the router interface requiring a logical connection, the neighbor router field is the router ID (IPv4 address) of the router that is physically connected to the backbone. When assigned from the router interface with the physical connection, the neighbor router is the router ID (IPv4) address of the router requiring a logical connection to the backbone.

**NOTE**

By default, the Brocade router ID is the IPv4 address configured on the lowest numbered loopback interface. If the Brocade device does not have a loopback interface, the default router ID is the lowest numbered IPv4 address configured on the device.

**NOTE**

When you establish an area virtual link, you must configure it on both of the routers (both ends of the virtual link).

For example, imagine that ABR1 in areas 1 and 2 is cut off from the backbone area (area 0). To provide backbone access to ABR1, you can add a virtual link between ABR1 and ABR2 in area 1 using area 1 as a transit area. To configure the virtual link, you define the link on the router that is at each end of the link. No configuration for the virtual link is required on the routers in the transit area.

To define the virtual link on ABR1, enter the following command on ABR1.

```
FastIron(config-ospf6-router)#area 1 virtual-link 209.157.22.1
```

To define the virtual link on ABR2, enter the following command on ABR2.

```
FastIron(config-ospf6-router)#area 1 virtual-link 10.0.0.1
```

**Syntax:** `area <number> | <ipv4-address> virtual-link <router-id>`

The `area <number> | <ipv4-address>` parameter specifies the transit area.

The `<router-id>` parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a router, enter the `show ip` command.
Assigning a virtual link source address

When routers at both ends of a virtual link need to communicate with one another, the source address included in the packets must be a global IPv6 address. Therefore, you must determine the global IPv6 address to be used by the routers for communication across the virtual link. You can specify that a router uses the IPv6 global address assigned to one of its interfaces.

For example, to specify the global IPv6 address assigned to Ethernet interface 3/1 on ABR1 as the source address for the virtual link on ABR1, enter the following command on ABR1.

```
FastIron(config-ospf6-router)#virtual-link-if-address interface ethernet 3/1
```

To specify the global IPv6 address assigned to tunnel interface 1 on ABR2 as the source address for the virtual link on ABR2, enter the following command on ABR2.

```
FastIron(config-ospf6-router)#virtual-link-if-address interface tunnel 1
```

Syntax: `virtual-link-if-address interface ethernet <port> | loopback <number> | tunnel <number> | ve <number>`

The `ethernet | loopback | tunnel | ve` parameter specifies the interface from which the router derives the source IPv6 address for communication across the virtual link. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a loopback, tunnel, or VE interface, also specify the number associated with the respective interface.

To delete the source address for the virtual link, use the `no` form of this command.

Modifying virtual link parameters

You can modify the following virtual link parameters:

- **Dead-interval**: The number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router is down. The range is 1 – 65535 seconds. The default is 40 seconds.
- **Hello-interval**: The length of time between the transmission of hello packets. The range is 1 – 65535 seconds. The default is 10 seconds.
- **Retransmit-interval**: The interval between the re-transmission of link state advertisements to router adjacencies for this interface. The range is 0 – 3600 seconds. The default is 5 seconds.
- **Transmit-delay**: The period of time it takes to transmit Link State Update packets on the interface. The range is 0 – 3600 seconds. The default is 1 second.

**NOTE**

The values of the `dead-interval` and `hello-interval` parameters must be the same at both ends of a virtual link. Therefore, if you modify the values of these parameters at one end of a virtual link, you must remember to make the same modifications on the other end of the link.

The values of the other virtual link parameters do not require synchronization.

For example, to change the dead interval to 60 seconds on the virtual links defined on ABR1 and ABR2, enter the following command on ABR1.

```
FastIron(config-ospf6-router)#area 1 virtual-link 209.157.22.1 dead-interval 60
```

Enter the following command on ABR2.

```
FastIron(config-ospf6-router)#area 1 virtual-link 10.0.0.1 dead-interval 60
```
Configuring OSPF V3

Syntax: area <number> | <ipv4-address> virtual-link <router-id> [dead-interval <seconds> | hello-interval <seconds> | retransmit-interval <seconds> | transmit-delay <seconds>]

The area <number> | <ipv4-address> parameter specifies the transit area.

The <router-id> parameter specifies the router ID of the OSPF router at the remote end of the virtual link. To display the router ID on a router, enter the show ip command.

The dead-interval, hello-interval, retransmit-interval, and transmit-delay parameters are discussed earlier in this section.

Changing the reference bandwidth for the cost on OSPF V3 interfaces

Each interface on which OSPF V3 is enabled has a cost associated with it. The Brocade device advertises its interfaces and their costs to OSPF V3 neighbors. For example, if an interface has an OSPF cost of ten, the Brocade device advertises the interface with a cost of ten to other OSPF routers.

By default, an interface OSPF cost is based on the port speed of the interface. The software uses the following formula to calculate the cost.

Cost = reference-bandwidth/interface-speed

By default, the reference bandwidth is 100 Mbps. If the resulting cost is less than 1, the software rounds the cost up to 1. The default reference bandwidth results in the following costs:

- 10 Mbps port cost = 100/10 = 10
- 100 Mbps port cost = 100/100 = 1
- 1000 Mbps port cost = 100/1000 = 0.10, which is rounded up to 1
- 155 Mbps port cost = 100/155 = 0.65, which is rounded up to 1
- 622 Mbps port cost = 100/622 = 0.16, which is rounded up to 1
- 2488 Mbps port cost = 100/2488 = 0.04, which is rounded up to 1

The bandwidth for interfaces that consist of more than one physical port is calculated as follows:

- Trunk group – The combined bandwidth of all the ports.
- Virtual (Ethernet) interface – The combined bandwidth of all the ports in the port-based VLAN that contains the virtual interface.

You can change the default reference bandwidth from 100 Mbps to a value from 1 – 4294967 Mbps.

If a change to the reference bandwidth results in a cost change to an interface, the Brocade device sends a link state update to update the costs of interfaces advertised by the Brocade device.

NOTE

If you specify the cost for an individual interface, the cost you specify overrides the cost calculated by the software.

Some interface types are not affected by the reference bandwidth and always have the same cost regardless of the reference bandwidth in use:

- The cost of a loopback interface is always 0.
The cost of a virtual link is calculated using the Shortest Path First (SPF) algorithm and is not affected by the auto-cost feature.

For example, to change the reference bandwidth to 500, enter the following command.

```
FastIron(config-ospf6-router)#auto-cost reference-bandwidth 500
```

The reference bandwidth specified in this example results in the following costs:

- 10 Mbps port cost = 500/10 = 50
- 100 Mbps port cost = 500/100 = 5
- 1000 Mbps port cost = 500/1000 = 0.5, which is rounded up to 1
- 155 Mbps port cost = 500/155 = 3.23, which is rounded up to 4
- 622 Mbps port cost = 500/622 = 0.80, which is rounded up to 1
- 2488 Mbps port cost = 500/2488 = 0.20, which is rounded up to 1

The costs for 10 Mbps, 100 Mbps, and 155 Mbps ports change as a result of the changed reference bandwidth. Costs for higher-speed interfaces remain the same.

**Syntax:** `[no] auto-cost reference-bandwidth <number>`

The `<number>` parameter specifies the reference bandwidth and can be a value from 1 – 4294967. The default is 100.

To restore the reference bandwidth to its default value and thus restore the default costs of interfaces to their default values, enter the `no` form of this command.

### Redistributing routes into OSPF V3

In addition to specifying which routes are redistributed into OSPF V3, you can configure the following aspects related to route redistribution:

- Default metric
- Metric type
- Advertisement of an external aggregate route

**Configuring route redistribution into OSPF V3**

You can configure the Brocade device to redistribute routes from the following sources into OSPF V3:

- IPv6 static routes
- Directly connected IPv6 networks
- RIPng

You can redistribute routes in the following ways:

- By route types, for example, the Brocade device redistributes all IPv6 static and RIPng routes.
- By using a route map to filter which routes to redistribute, for example, the Brocade device redistributes specified IPv6 static and RIPng routes only.

For example, to configure the redistribution of all IPv6 static RIPng routes, enter the following commands.

```
FastIron(config-ospf6-router)#redistribute static
FastIron(config-ospf6-router)#redistribute rip
```
Syntax: `no` redistribute bgp | connected | rip | static [metric <number> | metric-type <type>]]

The `connected` | rip | static keywords specify the route source.

The `metric <number>` parameter specifies the metric used for the redistributed route. If a value is not specified for this option, and the value for the `default-metric` command is set to 0, its default metric, then routes redistributed from the various routing protocols will have the metric value of the protocol from which they are redistributed. For information about the `default-metric` command, refer to “Modifying default metric for routes redistributed into OSPF version 3” on page 1232

The `metric-type <type>` parameter specifies an OSPF metric type for the redistributed route. You can specify external type 1 or external type 2. If a value is not specified for this option, the Brocade device uses the value specified by the `metric-type` command. For information about modifying the default metric type using the `metric-type` command, refer to “Modifying default metric for routes redistributed into OSPF version 3” on page 1232

For example, to configure a route map and use it for redistribution of routes into OSPF V3, enter commands such as the following:

```
FastIron(config)#ipv6 route 2001:1::/32 4823:eoff:343e::23
FastIron(config)#ipv6 route 2001:2::/32 4823:eoff:343e::23
FastIron(config)#ipv6 route 2001:3::/32 4823:eoff:343e::23 metric 5
FastIron(config)#route-map abc permit 1
FastIron(config-route-map abc)#match metric 5
FastIron(config-route-map abc)#set metric 8
FastIron(config-route-map abc)#ipv6 router ospf
FastIron(config-ospf6-router)#redistribute static route-map abc
```

The commands in this example configure some static IPv6 routes and a route map, and use the route map for redistributing the static IPv6 routes into OSPF V3.

The `ipv6 route` commands configure the static IPv6 routes.

The `route-map` command begins configuration of a route map called “abc”. The number indicates the route map entry (called the “instance”) you are configuring. A route map can contain multiple entries. The software compares packets to the route map entries in ascending numerical order and stops the comparison once a match is found.

**NOTE**
The default action rule for route-map is to deny all routes that are not explicitly permitted. Refer to “Configuring an OSPF V3 redistribution list using a route map that uses a prefix list” on page 1236.

The `match` command in the route map matches on routes that have 5 for their metric value (cost). The `set` command changes the metric in routes that match the route map to 8.

The `redistribute` command configures the redistribution of static IPv6 routes into OSPF V3, and uses route map “abc” to control the routes that are redistributed. In this example, the route map allows a static IPv6 route to be redistributed into OSPF only if the route has a metric of 5, and changes the metric to 8 before placing the route into the OSPF route redistribution table.

Syntax: `[no] redistribute bgp | connected | isis | rip | static [route-map <map-name>]`

The `bgp` | connected | isis | rip | static keywords specify the route source.

The `route-map <map-name>` parameter specifies the route map name. The following match parameters are valid for OSPF V3 redistribution:

- `match metric <number>`

The following set parameters are valid for OSPF redistribution:
• set metric [+ | -] <number> | none
• set metric-type type-1 | type-2

NOTE
You must configure the route map before you configure a redistribution filter that uses the route map.

NOTE
When you use a route map for route redistribution, the software disregards the permit or deny action of the route map.

NOTE
For an external route that is redistributed into OSPF V3 through a route map, the metric value of the route remains the same unless the metric is set by a set metric command inside the route map or the default-metric <num> command. For a route redistributed without using a route map, the metric is set by the metric parameter if set or the default-metric <num> command if the metric parameter is not set.

Modify default metric for routes redistributed into OSPF version 3

The default metric is a global parameter that specifies the cost applied by default to routes redistributed into OSPF V3. The default value is 0.

If the metric parameter for the redistribute command is not set and the default-metric command is set to 0, its default value, then routes redistributed from the various routing protocols will have the metric value of the protocol from which they are redistributed. For information about the redistribute command, refer to “Configuring route redistribution into OSPF V3” on page 1230.

NOTE
You also can define the cost on individual interfaces. The interface cost overrides the default cost. For information about defining the cost on individual interfaces, refer to “Modifying OSPF V3 interface defaults” on page 1241 and “Changing the reference bandwidth for the cost on OSPF V3 interfaces” on page 1229.

To assign a default metric of 4 to all routes imported into OSPF V3, enter the following command.

FastIron(config-ospf6-router)#default-metric 4

Syntax: no| default-metric <number>

You can specify a value from 0 – 65535. The default is 0.

To restore the default metric to the default value, use the no form of this command.

Modifying metric type for routes redistributed into OSPF version 3

The Brocade device uses the metric-type parameter by default for all routes redistributed into OSPF V3 unless you specify a different metric type for individual routes using the redistribute command. (For more information about using the redistribute command, refer to “Redistributing routes into OSPF V3” on page 1230).

A type 1 route specifies a small metric (two bytes), while a type 2 route specifies a big metric (three bytes). The default value is type 2.

To modify the default value of type 2 to type 1, enter the following command.
FastIron(config-ospf6-router)#metric-type type1

Syntax: no | metric-type type1 | type2

To restore the metric type to the default value, use the no form of this command.

**Configuring external route summarization**

When the Brocade device is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to advertise one external route as an aggregate for all redistributed routes that are covered by a specified IPv6 address range.

When you configure an address range, the range takes effect immediately. All the imported routes are summarized according to the configured address range. Imported routes that have already been advertised and that fall within the range are flushed out of the AS and a single route corresponding to the range is advertised.

If a route that falls within a configured address range is imported by the Brocade device, no action is taken if the device has already advertised the aggregate route; otherwise, the device advertises the aggregate route. If an imported route that falls within a configured address range is removed by the device, no action is taken if there are other imported routes that fall within the same address range; otherwise the aggregate route is flushed.

You can configure up to 32 address ranges. The Brocade device sets the forwarding address of the aggregate route to zero and sets the tag to zero.

If you delete an address range, the advertised aggregate route is flushed and all imported routes that fall within the range are advertised individually.

If an external link state database overflow (LSDB) condition occurs, all aggregate routes are flushed out of the AS, along with other external routes. When the Brocade device exits the external LSDB overflow condition, all the imported routes are summarized according to the configured address ranges.

**NOTE**

If you use redistribution filters in addition to address ranges, the Brocade device applies the redistribution filters to routes first, then applies them to the address ranges.

**NOTE**

If you disable redistribution, all the aggregate routes are flushed, along with other imported routes.

**NOTE**

This option affects only imported, type 5 external routes. A single type 5 LSA is generated and flooded throughout the AS for multiple external routes.

To configure the summary address 2201::/24 for routes redistributed into OSPF V3, enter the following command.

FastIron(config-ospf6-router)#summary-address 2201::/24

In this example, the summary prefix 2201::/24 includes addresses 2201::/1 through 2201::/24. Only the address FEC0::/24 is advertised in an external link-state advertisement.

Syntax: summary-address <ipv6-prefix>/<prefix-length>

You must specify the <ipv6-prefix> parameter in hexadecimal using 16-bit values between colons as documented in RFC 2373.
You must specify the `<prefix-length>` parameter as a decimal value. A slash mark (/) must follow the `<ipv6-prefix>` parameter and precede the `<prefix-length>` parameter.

**Filtering OSPF V3 routes**

You can filter the routes to be placed in the OSPF V3 route table by configuring distribution lists. OSPF V3 distribution lists can be applied globally or to an interface.

The functionality of OSPF V3 distribution lists is similar to that of OSPFv2 distribution lists. However, unlike OSPFv2 distribution lists, which filter routes based on criteria specified in an Access Control List (ACL), OSPF V3 distribution lists can filter routes using information specified in an IPv6 prefix list or a route map.

**Configuration examples**

The following sections show examples of filtering OSPF V3 routes using prefix lists globally and for a specific interface, as well as filtering OSPF V3 routes using a route map.

You can configure the device to use all three types of filtering. When you do this, filtering using route maps has higher priority over filtering using global prefix lists. Filtering using prefix lists for a specific interface has lower priority than the other two filtering methods.

The example in this section assume the following routes are in the OSPF V3 route table.

**FastIron#show ipv6 ospf route**

```
Current Route count: 5
 Intra: 3 Inter: 0 External: 2 (Type1 0/Type2 2)
 Equal-cost multi-path: 0
 Destination                      Options     Area         Cost    Type2 Cost Outgoing Interface
Next Hop Router                  Area        Cost
*IA 3001::/64                  --------- 0.0.0.1    0     0
     ::                         ve 10
*E2 3010::/64                  --------- 0.0.0.0    10    0
     fe80::2e0:52ff:fe00:10     ve 10
*IA 3015::/64                  V6E---R-- 0.0.0.0    11    0
     fe80::2e0:52ff:fe00:10     ve 10
*IA 3020::/64                  --------- 0.0.0.0    10    0
     ::                         ve 11
*E2 6001:5000::/64              --------- 0.0.0.0    10    0
     fe80::2e0:52ff:fe00:10     ve 10
```

**Configuring an OSPF V3 distribution list using an IPv6 prefix list as input**

The following example illustrates how to use an IPv6 prefix list is used to filter OSPF V3 routes.

To specify an IPv6 prefix list called filterOspfRoutes that denies route 3010::/64, enter the following commands.

```
FastIron(config)#ipv6 prefix-list filterOspfRoutes seq 5 deny 3010::/64
FastIron(config)#ipv6 prefix-list filterOspfRoutes seq 7 permit ::/0 ge 1 le 128
```

**Syntax:**

```
ipv6 prefix-list <name> [seq <seq-value>] [description <string>] deny | permit <ipv6-addr>/<<mask-bits>> [ge <ge-value>] [le <le-value>]
```

To configure a distribution list that applies the filterOspfRoutes prefix list globally.
FastIron(config)#ipv6 router ospf
FastIron(config-ospf6-router)#distribute-list prefix-list filterOspfRoutes in

**Syntax:** [no] distribute-list prefix-list <name> in [<interface>]

After this distribution list is configured, route 3010::/64 would be omitted from the OSPF V3 route table.

FastIron#show ipv6 ospf route

Current Route count: 4
Intra: 3 Inter: 0 External: 1 (Type1 0/Type2 1)
Equal-cost multi-path: 0

<table>
<thead>
<tr>
<th>Destination</th>
<th>Options</th>
<th>Area</th>
<th>Cost</th>
<th>Type2</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>*IA 3001::/64</td>
<td>--------</td>
<td>0.0.0.1</td>
<td>0</td>

</tr>
<tr>
<td>fe80::2e0:52ff:fe00:10</td>
<td></td>
<td>ve 10</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following commands specify an IPv6 prefix list called filterOspfRoutesVe that denies route 3015::/64.

FastIron(config)#ipv6 prefix-list filterOspfRoutesVe seq 5 deny 3015::/64
FastIron(config)#ipv6 prefix-list filterOspfRoutesVe seq 10 permit ::/0 ge 1 le 128

The following commands configure a distribution list that applies the filterOspfRoutesVe prefix list to routes pointing to virtual interface 10.

FastIron(config)#ipv6 router ospf
FastIron(config-ospf6-router)#distribute-list prefix-list filterOspfRoutes in ve 10

After this distribution list is configured, route 3015::/64, pointing to virtual interface 10, would be omitted from the OSPF V3 route table.

FastIron#show ipv6 ospf route

Configuring an OSPF V3 distribution list using a route map as input

The following commands configure a route map that matches internal routes.

FastIron(config)#route-map allowInternalRoutes permit 10
FastIron(config-route-map allowInternalRoutes)#match route-type internal

Refer to “Policy-Based Routing” for information on configuring route maps.

The following commands configure a distribution list that applies the allowInternalRoutes route map globally to OSPF V3 routes.

FastIron(config)#ipv6 router ospf
FastIron(config-ospf6-router)#distribute-list route-map allowInternalRoutes in

Syntax: [no] distribute-list route-map <name> in

After this distribution list is configured, the internal routes would be included, and the external routes would be omitted from the OSPF V3 route table.

FastIron#show ipv6 ospf route

Configuring an OSPF V3 distribution list using a route map that uses a prefix list

When you configure route redistribution into OSPF V3 using a route map that uses a prefix list, the device supports both permit and deny statements in the route map and permit statements only in the prefix list. Therefore, the action to permit or deny is determined by the route map, and the conditions for the action are contained in the prefix list. The following shows an example configuration.

FastIron(config)#route-map v64 deny 10
FastIron(config-route-map v64)#match ipv6 next-hop prefix-list ospf-filter5
FastIron(config-route-map v64)#match ipv6 address prefix-list ospf-filter2
FastIron(config-route-map v64)#route-map v64 permit 12
FastIron(config-route-map v64)#exit
FastIron(config)#ipv6 prefix-list ospf-filter2 seq 15 permit
2001:aa:2001:102::/64 ge 65 le 96
FastIron(config)#ipv6 prefix-list ospf-filter5 seq 15 permit
fe80::2e0:52ff:fe00:100/128

In this example the prefix lists, ospf-filter2 and ospf-filter5, contain a range of IPv6 routes and one host route to be denied, and the route map v64 defines the deny action.
NOTE
The default action rule for `route-map` is to deny all routes that are not explicitly permitted. If you configure a “deny” route map but want to permit other routes that do not match the rule, configure an “empty” permit route map. For example.

```
FastIron(config)#route-map abc deny 10
FastIron(config-route-map abc)#match metric 20
FastIron(config-route-map abc)#route-map abc permit 20
```

Without the last line in the above example, all routes would be denied.

Configuring default route origination

When the Brocade device is an OSPF Autonomous System Boundary Router (ASBR), you can configure it to automatically generate a default external route into an OSPF V3 routing domain. This feature is called “default route origination” or “default information origination.”

By default, the Brocade device does not advertise the default route into the OSPF V3 domain. If you want the device to advertise the OSPF default route, you must explicitly enable default route origination.

When you enable OSPF default route origination, the device advertises a type 5 default route that is flooded throughout the AS (except stub areas).

The device advertises the default route into OSPF even if OSPF route redistribution is not enabled, and even if the default route is learned through an IBGP neighbor.

NOTE
The Brocade device does not advertise the OSPF default route, regardless of other configuration parameters, unless you explicitly enable default route origination.

If default route origination is enabled and you disable it, the default route originated by the device is flushed. Default routes generated by other OSPF routers are not affected. If you re-enable the feature, the feature takes effect immediately and thus does not require you to reload the software.

For example, to create and advertise a default route with a metric of 2 and as a type 1 external route, enter the following command.

```
FastIron(config-ospf6-router)#default-information-originate always metric 2 metric-type type1
```

**Syntax:** `[no] default-information-originate [always] [metric <value>] [metric-type <type>]`

The `always` keyword originates a default route regardless of whether the device has learned a default route. This option is disabled by default.

The `metric <value>` parameter specifies a metric for the default route. If this option is not used, the value of the `default-metric` command is used for the route. For information about this command, refer to “Modifying default metric for routes redistributed into OSPF version 3” on page 1232.

The `metric-type <type>` parameter specifies the external link type associated with the default route advertised into the OSPF routing domain. The `<type>` can be one of the following:

- 1 – Type 1 external route
- 2 – Type 2 external route

If you do not use this option, the default redistribution metric type is used for the route type.
NOTE
If you specify a metric and metric type, the values you specify are used even if you do not use the always option.

To disable default route origination, enter the no form of the command.

Modifying shortest path first timers

The Brocade device uses the following timers when calculating the shortest path for OSPF V3 routes:

- **SPF delay** – When the Brocade device receives a topology change, the software waits before it starts a Shortest Path First (SPF) calculation. By default, the software waits 5 seconds. You can configure the SPF delay to a value from 0 – 65535 seconds. If you set the SPF delay to 0 seconds, the software immediately begins the SPF calculation after receiving a topology change.

- **SPF hold time** – The Brocade device waits a specific amount of time between consecutive SPF calculations. By default, the device waits 10 seconds. You can configure the SPF hold time to a value from 0 – 65535 seconds. If you set the SPF hold time to 0 seconds, the software does not wait between consecutive SPF calculations.

You can set the SPF delay and hold time to lower values to cause the device to change to alternate paths more quickly if a route fails. Note that lower values for these parameters require more CPU processing time.

You can change one or both of the timers.

NOTE
If you want to change only one of the timers, for example, the SPF delay timer, you must specify the new value for this timer as well as the current value of the SPF hold timer, which you want to retain. The Brocade device does not accept only one timer value.

To change the SPF delay to 10 seconds and the SPF hold to 20 seconds, enter the following command.

```
FastIron(config-ospf6-router)#timers spf 10 20
```

**Syntax:** `timers spf <delay> <hold-time>`

For the `<delay>` and `<hold-time>` parameters, specify a value from 0 – 65535 seconds.

To set the timers back to their default values, enter the no version of this command.

Modifying administrative distance

The Brocade device can learn about networks from various protocols, including IPv6, RIPvng, and OSPF V3. Consequently, the routes to a network may differ depending on the protocol from which the routes were learned. By default, the administrative distance for OSPF V3 routes is 110.

The device selects one route over another based on the source of the route information. To do so, the device can use the administrative distances assigned to the sources. You can influence the device decision by changing the default administrative distance for OSPF V3 routes.
Configuring administrative distance based on route type

You can configure a unique administrative distance for each type of OSPF V3 route. For example, you can use this feature to influence the Brocade device to prefer a static route over an OSPF inter-area route and to prefer OSPF intra-area routes to static routes.

The distance you specify influences the choice of routes when the device has multiple routes to the same network from different protocols. The device prefers the route with the lower administrative distance.

You can specify unique default administrative distances for the following OSPF V3 route types:

- Intra-area routes
- Inter-area routes
- External routes

The default for all of these OSPF V3 route types is 110.

**NOTE**
This feature does not influence the choice of routes within OSPF V3. For example, an OSPF intra-area route is always preferred over an OSPF inter-area route, even if the intra-area route distance is greater than the inter-area route distance.

For example, to change the default administrative distances for intra-area routes to 80, inter-area routes to 90, and external routes to 100, enter the following commands.

```
FastIron(config-ospf6-router)#distance intra-area 80
FastIron(config-ospf6-router)#distance inter-area 90
FastIron(config-ospf6-router)#distance external 100
```

**Syntax:** `distance external | inter-area | intra-area <distance>`

The `external | inter-area | intra-area` keywords specify the route type for which you are changing the default administrative distance.

The `<distance>` parameter specifies the new distance for the specified route type. You can specify a value from 1 – 255.

To reset the administrative distance of a route type to its system default, enter the `no` form of this command.

Configuring the OSPF V3 LSA pacing interval

The Brocade device paces OSPF V3 LSA refreshes by delaying the refreshes for a specified time interval instead of performing a refresh each time an individual LSA refresh timer expires. The accumulated LSAs constitute a group, which the Brocade device refreshes and sends out together in one or more packets.

The pacing interval, which is the interval at which the Brocade device refreshes an accumulated group of LSAs, is configurable to a range from 10 – 1800 seconds (30 minutes). The default is 240 seconds (four minutes). Thus, every four minutes, the Brocade device refreshes the group of accumulated LSAs and sends the group together in the same packets.
The pacing interval is inversely proportional to the number of LSAs the Brocade device is refreshing and aging. For example, if you have approximately 10,000 LSAs, decreasing the pacing interval enhances performance. If you have a very small database (40 – 100 LSAs), increasing the pacing interval to 10 – 20 minutes might enhance performance only slightly.

To change the OSPF V3 LSA pacing interval to two minutes (120 seconds), enter the following command.

```plaintext
FastIron(config)#ipv6 router ospf
FastIron(config-ospf6-router)#timers lsa-group-pacing 120
```

**Syntax:**

```
[no] timers lsa-group-pacing <seconds>
```

The `<seconds>` parameter specifies the number of seconds and can be from 10 – 1800 (30 minutes). The default is 240 seconds (four minutes).

To restore the pacing interval to its default value, use the `no` form of the command.

### Modifying exit overflow interval

If a database overflow condition occurs on the Brocade device, the device eliminates the condition by removing entries that originated on the device. The exit overflow interval allows you to set how often a device checks to see if the overflow condition has been eliminated. The default value is 0. If the configured value of the database overflow interval is 0, then the device never leaves the database overflow condition.

For example, to modify the exit overflow interval to 60 seconds, enter the following command.

```plaintext
FastIron(config-ospf6-router)#database-overflow-interval 60
```

**Syntax:**

```
[no] auto-cost reference-bandwidth <number>
```

The `<seconds>` parameter can be a value from 0 – 86400 seconds (24 hours).

To reset the exit overflow interval to its system default, enter the `no` form of this command.

### Modifying external link state database limit

By default, the link state database can hold a maximum of 2000 entries for external (type 5) LSAs. You can change the maximum number of entries from 500 – 8000. After changing this limit, make sure to save the running-config file and reload the software. The change does not take effect until you reload or reboot the software.

For example, to change the maximum number entries from the default of 2000 to 3000, enter the following command.

```plaintext
FastIron(config-ospf6-router)#external-lsdb-limit 3000
```

**Syntax:**

```
ipv6 ospf area <number> | <ipv4-address>
```

The `<entries>` parameter can be a numerical value from 500 – 8000 seconds.

To reset the maximum number of entries to its system default, enter the `no` form of this command.
Modifying OSPF V3 interface defaults

OSPF V3 has interface parameters that you can configure. For simplicity, each of these parameters has a default value. No change to these default values is required except as needed for specific network configurations.

You can modify the default values for the following OSPF interface parameters:

- **Cost**: Indicates the overhead required to send a packet across an interface. You can modify the cost to differentiate between 100 Mbps and 1000 Mbps (1 Gbps) links. The command syntax is `ipv6 ospf cost <number>`. The default cost is calculated by dividing 100 million by the bandwidth. For 10 Mbps links, the cost is 10. The cost for both 100 Mbps and 1000 Mbps links is 1, because the speed of 1000 Mbps was not in use at the time the OSPF cost formula was devised.

- **Dead-interval**: Indicates the number of seconds that a neighbor router waits for a hello packet from the current router before declaring the router down. The command syntax is `ipv6 ospf dead-interval <seconds>`. The value can be from 1 – 2147483647 seconds. The default is 40 seconds.

- **Hello-interval**: Represents the length of time between the transmission of hello packets. The command syntax is `ipv6 ospf hello-interval <seconds>`. The value can be from 1 – 65535 seconds. The default is 10 seconds.

- **Instance**: Indicates the number of OSPF V3 instances running on an interface. The command syntax is `ipv6 ospf instance <number>`. The value can be from 0 – 255. The default is 1.

- **MTU-ignore**: Allows you to disable a check that verifies the same MTU is used on an interface shared by neighbors. The command syntax is `ipv6 ospf mtu-ignore`. By default, the mismatch detection is enabled.

- **Network**: Allows you to configure the OSPF network type. The command syntax is `ipv6 ospf network [point-to-multipoint]`. The default setting of the parameter depends on the network type.

- **Passive**: When you configure an OSPF interface to be passive, that interface does not send or receive OSPF route updates. This option affects all IPv6 subnets configured on the interface. The command syntax is `ipv6 ospf passive`. By default, all OSPF interfaces are active and thus can send and receive OSPF route information. Since a passive interface does not send or receive route information, the interface is in effect a stub network.

- **Priority**: Allows you to modify the priority of an OSPF router. The priority is used when selecting the designated router (DR) and backup designated routers (BDRs). The command syntax is `ipv6 ospf priority <number>`. The value can be from 0 – 255. The default is 1. If you set the priority to 0, the router does not participate in DR and BDR election.

- **Retransmit-interval**: The time between retransmissions of LSAs to adjacent routers for an interface. The command syntax is `ipv6 ospf retransmit-interval <seconds>`. The value can be from 0 – 3600 seconds. The default is 5 seconds.

- **Transmit-delay**: The time it takes to transmit Link State Update packets on this interface. The command syntax is `ipv6 ospf transmit-delay <seconds>`. The value can be from 0 – 3600 seconds. The default is 1 second.

Disabling or re-enabling event logging

OSPF V3 does not currently support the generation of SNMP traps. Instead, you can disable or re-enable the logging of OSPF V3-related events such as neighbor state changes and database overflow conditions. By default, the Brocade device logs these events.
To disable the logging of events, enter the following command.

```
FastIron(config-ospf6-router)#no log-status-change
```

**Syntax:** `[no] log-status-change

To re-enable the logging of events, enter the following command.

```
FastIron(config-ospf6-router)#log-status-change
```

### Displaying OSPF V3 Information

You can display the information for the following OSPF V3 parameters:

- Areas
- Link state databases
- Interfaces
- Memory usage
- Neighbors
- Redistributed routes
- Routes
- SPF
- Virtual links
- Virtual neighbors

### Displaying OSPF V3 area information

To display global OSPF V3 area information for the Brocade device, enter the following command at any CLI level.

```
FastIron#show ipv6 ospf area
```

Area 0:
  Interface attached to this area: loopback 2 ethe 3/2 tunnel 2
  Number of Area scoped LSAs is 6
  Statistics of Area 0:
    SPF algorithm executed 16 times
    SPF last updated: 335256 sec ago
    Current SPF node count: 3
      Router: 2 Network: 1
      Maximum of Hop count to nodes: 2
	...

**Syntax:** `show ipv6 ospf area [<area id>]`

You can specify the `<area-id>` parameter in the following formats:

- As an IPv4 address, for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

The `<area-id>` parameter restricts the display to the specified OSPF area.

This display shows the following information.
Displaying OSPF V3 Information

You can display a summary of the link state database or detailed information about a specified LSA type.

To display a summary of a device link state database, enter the following command at any CLI level.

```
FastIron#show ipv6 ospf database
```

**TABLE 202  OSPF V3 area information fields**

**Syntax:** `show ipv6 ospf database [advrtr <ipv4-address> | as-external | extensive | inter-prefix | inter-router | intra-prefix | link | link-id <number> | network | router [scope <area-id> | as | link]]`

The `advrtr <ipv4-address>` parameter displays detailed information about the LSAs for a specified advertising router only.

The `as-external` keyword displays detailed information about the AS externals LSAs only.

The `extensive` keyword displays detailed information about all LSAs in the database.

The `inter-prefix` keyword displays detailed information about the inter-area prefix LSAs only.

The `inter-router` keyword displays detailed information about the inter-area router LSAs only.
The \textbf{intra-prefix} keyword displays detailed information about the intra-area prefix LSAs only.
The \textbf{link} keyword displays detailed information about the link LSAs only.
The \textbf{link-id} <\textit{number}> parameter displays detailed information about the specified link LSAs only.
The \textbf{network} <\textit{number}> displays detailed information about the network LSAs only.
The \textbf{router} <\textit{number}> displays detailed information about the router LSAs only.
The \textbf{scope} <\textit{area-id}> parameter displays detailed information about the LSAs for a specified area, AS, or link.

This display shows the following information.

**TABLE 203** OSPF V3 database summary fields

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area ID</td>
<td>The OSPF area in which the Brocade device resides.</td>

<td></td>
<td>• Link – Link LSAs (Type 8).</td>
</tr>
<tr>
<td></td>
<td>• Iap – Intra-area prefix LSAs (Type 9).</td>
</tr>
<tr>
<td>LS ID</td>
<td>The ID of the LSA, in hexadecimal, from which the device learned this route.</td>
</tr>
<tr>
<td>Adv Rtr</td>
<td>The device that advertised the route.</td>
</tr>
<tr>
<td>Seq(Hex)</td>
<td>The sequence number of the LSA. The OSPF neighbor that sent the LSA stamps it with a sequence number to enable the Brocade device and other OSPF routers to determine which LSA for a given route is the most recent.</td>
</tr>
<tr>
<td>Age</td>
<td>The age of the LSA, in seconds.</td>
</tr>
<tr>
<td>Chksum</td>
<td>A checksum for the LSA packet. The checksum is based on all the fields in the packet except the age field. The Brocade device uses the checksum to verify that the packet is not corrupted.</td>
</tr>
<tr>
<td>Len</td>
<td>The length, in bytes, of the LSA.</td>
</tr>
</tbody>
</table>

For example, to display detailed information about all LSAs in the database, enter the following command at any CLI level.
NOTE

Portions of this display are truncated for brevity. The purpose of this display is to show all possible fields that might display rather than to show complete output.

The fields that display depend upon the LSA type as shown in the following table.
### TABLE 204  OSPF V3 detailed database information fields

<table>
<thead>

<td>up</td>
<td></td>
</tr>
</tbody>
</table>

**Syntax:** `show ipv6 ospf interface [ethernet <port> | loopback <number> | tunnel <number> | ve <number>]`

The `ethernet` | `loopback` | `tunnel` | `ve` parameter specifies the interface for which to display information. If you specify an Ethernet interface, also specify the port number associated with the interface. If you specify a loopback, tunnel, or VE interface, also specify the number associated with the interface.

This display shows the following information.

**TABLE 204** OSPF V3 detailed database information fields (Continued)

</tbody>
</table>
Syntax:  show ipv6 ospf redistribute route [<ipv6-prefix>]

The <ipv6-prefix> parameter specifies an IPv6 network prefix. (You do not need to specify the length of the prefix.)

For example, to display redistribution information for the prefix 2002::, enter the following command at any level of the CLI.

FastIron#show ipv6 ospf redistribute route 2002::

<table>
<thead>
<tr>
<th>Id</th>
<th>Prefix</th>
<th>Protocol</th>
<th>Metric Type</th>
<th>Metric</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2002::/16</td>
<td>Static</td>
<td>Type-2</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2002:1234::/32</td>
<td>Static</td>
<td>Type-2</td>
<td>1</td>
</tr>
</tbody>
</table>

These displays show the following information.

### TABLE 210  OSPF V3 redistribution information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>An ID for the redistributed route.</td>
</tr>
<tr>
<td>Prefix</td>
<td>The IPv6 routes redistributed into OSPF V3.</td>
</tr>
<tr>
<td>Protocol</td>
<td>The protocol from which the route is redistributed into OSPF V3. Redistributed protocols can be the following:</td>
</tr>
<tr>
<td></td>
<td>• RIP – RIPv2.</td>
</tr>
<tr>
<td></td>
<td>• Static – IPv6 static route table.</td>
</tr>
<tr>
<td></td>
<td>• Connected – A directly connected network.</td>
</tr>
<tr>
<td>Metric Type</td>
<td>The metric type used for routes redistributed into OSPF V3. The metric type can be the following:</td>
</tr>
<tr>
<td></td>
<td>• Type-1 – Specifies a small metric (2 bytes).</td>
</tr>
<tr>
<td></td>
<td>• Type-2 – Specifies a big metric (3 bytes).</td>
</tr>
<tr>
<td>Metric</td>
<td>The value of the default redistribution metric, which is the OSPF cost of redistributing the route into OSPF V3.</td>
</tr>
</tbody>
</table>

### Displaying OSPF V3 route information

You can display the entire OSPF V3 route table for the Brocade device or only the route entries for a specified destination.

To display the entire OSPF V3 route table for the device, enter the following command at any level of the CLI.

FastIron#show ipv6 ospf route
FastIron#show ipv6 ospf routes
Current Route count: 4
Intra: 4 Inter: 0 External: 0 (Type1 0/Type2 0)

<table>
<thead>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Syntax: show ipv6 ospf routes [ipv6-prefix]

The <ipv6-prefix> parameter specifies a destination IPv6 prefix. (You do not need to specify the length of the prefix.) If you use this parameter, only the route entries for this destination are shown.

For example, to display route information for the destination prefix 2000:4::, enter the following command at any level of the CLI.

These displays show the following information.

**TABLE 211 OSPF V3 route information**

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current Route Count (Displays with the entire OSPF V3 route table only)</td>
<td>The number of route entries currently in the OSPF V3 route table.</td>
</tr>
<tr>
<td>Intra/Inter/External (Type1/Type2) (Displays with the entire OSPF V3 route table only)</td>
<td>The breakdown of the current route entries into the following route types:</td>
</tr>
<tr>
<td>Equal-cost multi-path (Displays with the entire OSPF V3 route table only)</td>
<td>The number of equal-cost routes to the same destination in the OSPF V3 route table. If load sharing is enabled, the router equally distributes traffic among the routes.</td>
</tr>
<tr>
<td>Destination</td>
<td>The IPv6 prefixes of destination networks to which the Brocade device can forward IPv6 packets. &quot;*IA&quot; indicates the next router is an intra-area router.</td>
</tr>
<tr>
<td>Options</td>
<td>A 24-bit field that enables IPv6 OSPF routers to support the optional capabilities. When set, the following bits indicate the following:</td>
</tr>
</tbody>
</table>
  - V6 – The device should be included in IPv6 routing calculations. |
  - E – The device floods AS-external-LSAs as described in RFC 2740. |
  - MC – The device forwards multicast packets as described in RFC 1586. |
  - N – The device handles type 7 LSAs as described in RFC 1584. |
  - R – The originator is an active router. |
  - DC –The device handles demand circuits. |
Displaying OSPF V3 SPF information

You can display the following OSPF V3 SPF information:

- SPF node information for a specified area.
- SPF table for a specified area.
- SPF tree for a specified area.

For example, to display information about SPF nodes in area 0, enter the following command at any level of the CLI:

```
FastIron#show ipv6 ospf spf node area 0
SPF node for Area 0
SPF node 223.223.223.223,  cost: 0,  hops: 0
    nexthops to node:
        parent nodes: 223.223.223.223
        child nodes: 223.223.223.223:88

SPF node 223.223.223.223:88,  cost: 1,  hops: 1
    nexthops to node: :: ethe 3/2
        parent nodes: 223.223.223.223
        child nodes: 1.1.1.1:0

SPF node 1.1.1.1:0,  cost: 1,  hops: 2
    nexthops to node: fe80::2e0:52ff:fe91:bb37 ethe 3/2
        parent nodes: 223.223.223.223:88
        child nodes:
```

Syntax: `show ipv6 ospf spf node area [<area-id>]`

The `node` keyword displays SPF node information.

The `area <area-id>` parameter specifies a particular area. You can specify the `<area-id>` in the following formats:

- As an IPv4 address; for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

This display shows the following information.
For example, to display the SPF table for area 0, enter the following command at any level of the CLI:

```
FastIron#show ipv6 ospf spf table area 0
```

### TABLE 212 OSPF V3 SPF node information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPF node</td>
<td>Each SPF node is identified by its router ID (IPv4 address). If the node is a child node, it is additionally identified by an interface on which the node can be reached appended to the router ID in the format &lt;router-id&gt;:&lt;interface-id&gt;.</td>
</tr>
<tr>
<td>Cost</td>
<td>The cost of traversing the SPF node to reach the destination.</td>
</tr>
<tr>
<td>Hops</td>
<td>The number of hops needed to reach the parent SPF node.</td>
</tr>
<tr>
<td>Next Hops to Node</td>
<td>The IPv6 address of the next hop-router or the router interface, or both, through which to access the next-hop router.</td>
</tr>
<tr>
<td>Parent Nodes</td>
<td>The SPF node parent nodes. A <strong>parent node</strong> is an SPF node at the highest level of the SPF tree, which is identified by its router ID.</td>
</tr>
<tr>
<td>Child Nodes</td>
<td>The SPF node child nodes. A <strong>child node</strong> is an SPF node at a lower level of the SPF tree, which is identified by its router ID and interface on which the node can be reached.</td>
</tr>
</tbody>
</table>

### TABLE 213 OSPF V3 SPF table

<table>
<thead>
<tr>
<th>Destination</th>

</tr>
</tbody>
</table>

**Syntax:** `show ipv6 ospf spf table area <area-id>`

The **table** parameter displays the SPF table.

The **area** `<area-id>` parameter specifies a particular area. You can specify the `<area-id>` in the following formats:

- As an IPv4 address, for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

This display shows the following information.

### TABLE 213 OSPF V3 SPF table

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Destination</td>
<td>The destination of a route, which is identified by the following:</td>
</tr>
<tr>
<td></td>
<td>• “R”, which indicates the destination is a router. “N”, which indicates the destination is a network.</td>
</tr>
<tr>
<td></td>
<td>• An SPF node router ID (IPv4 address). If the node is a child node, it is additionally identified by an interface on which the node can be reached appended to the router ID in the format &lt;router-id&gt;:&lt;interface-id&gt;.</td>
</tr>
<tr>
<td>Bits</td>
<td>A bit that indicates the capability of the Brocade device. The bit can be set to one of the following:</td>
</tr>
<tr>
<td></td>
<td>• B – The device is an area border router.</td>
</tr>
<tr>
<td></td>
<td>• E – The device is an AS boundary router.</td>
</tr>
<tr>
<td></td>
<td>• V – The device is a virtual link endpoint.</td>
</tr>
<tr>
<td></td>
<td>• W – The device is a wildcard multicast receiver.</td>
</tr>
</tbody>
</table>
For example, to display the SPF tree for area 0, enter the following command at any level of the CLI.

```
FastIron#show ipv6 ospf spf tree area 0
SPF tree for Area 0
  +- 223.223.223.223 cost 0
      +- 223.223.223.223:88 cost 1
      +- 1.1.1.1:0 cost 1
```

**Syntax:** `show ipv6 ospf spf tree area <area-id>`

The `tree` keyword displays the SPF table.

The `<area-id>` parameter specifies a particular area. You can specify the `<area-id>` in the following formats:

- As an IPv4 address; for example, 192.168.1.1.
- As a numerical value from 0 – 2,147,483,647.

In this sample output, consider the SPF node with the router ID 223.223.223.223 to be the top (root) of the tree and the local router. Consider all other layers of the tree (223.223.223.223:88 and 1.1.1.1:0) to be destinations in the network. Therefore, traffic destined from router 223.223.223.223 to router 1.1.1.1:0 must first traverse router 223.223.223.223:88.

**Displaying IPv6 OSPF virtual link information**

To display OSPF V3 virtual link information for the Brocade device, enter the following command at any level of the CLI.

```
FastIron#show ipv6 ospf virtual-link
Index Transit Area ID  Router ID  Interface Address  State
 1     1             1.1.1.1  3003::2        P2P
```

**Syntax:** `show ipv6 ospf virtual-link`

This display shows the following information.

---

**TABLE 213** OSPF V3 SPF table (Continued)

• Init  
• 2-Way  
• ExStart  
• Exchange  
• Loading  
• Full |
| Interface     | The IPv6 address of the virtual neighbor. |
This chapter describes how to configure Brocade Layer 3 Switches with the following router redundancy protocols:

- **VRRP Extended (VRRPE)** – An enhanced version of VRRP that overcomes limitations in the standard protocol.

**NOTE**

VRRP and VRRPE are separate protocols. You cannot use them together. VRRPE is not supported on FWS devices.

**NOTE**

You can use a Brocade Layer 3 Switch configured for VRRP with another Brocade Layer 3 Switch or a third-party router that is also configured for VRRP. However, you can use a Brocade Layer 3 Switch configured for VRRPE only with another Brocade Layer 3 Switch that also is configured for VRRPE.

For a summary of how these two router redundancy protocols differ, refer to “Comparison of VRRP and VRRPE” on page 1269.

**Overview**

The following sections describe VRRP and VRRPE. The protocols both provide redundant paths for IP addresses. However, the protocols differ in a few important ways. For clarity, each protocol is described separately.

**Overview of VRRP**

**Platform Support:**

- FESX and FSX running pre-release 02.4.00 software – L3
- FESX and FSX running software release 02.4.00 and later – BL3, L3
- FGS and FLS devices running software release 04.0.00 and later – BL3
- FGS-STK and FLS-STK devices running software release 05.0.00 and later
- FWS devices running software release 04.3.00 or later
- FGS and FLS devices running software release 04.3.01 and later
- FCX-S devices running software release 06.0.00 and later
- Turbolron X Series devices running software release 04.2.00 and later

**NOTE**

VRRP support in the base Layer 3 code is the same as in the full Layer 3 code.
VRRP is a protocol that provides redundancy to routers within a LAN. VRRP allows you to provide alternate router paths for a host without changing the IP address or MAC address by which the host knows its gateway. Consider the situation shown in Figure 153.

**FIGURE 153**  Switch 1 is Host1 default gateway but is a single point of failure

Switch 1 as the host default gateway out of the subnet. If this interface goes down, Host1 is cut off from the rest of the network. Switch 1 is thus a single point of failure for Host1 access to other networks.

If Switch 1 fails, you could configure Host1 to use Switch 2. Configuring one host with a different default gateway might not require too much extra administration. However, consider a more realistic network with dozens or even hundreds of hosts per subnet; reconfiguring the default gateways for all the hosts is impractical. It is much simpler to configure a VRRP virtual router on Switch 1 and Switch 2 to provide a redundant path for the hosts.

**Figure 154** shows the same example network shown in **Figure 153**, but with a VRRP virtual router configured on Switch 1 and Switch 2.
FIGURE 154 Switch 1 and Switch 2 are configured as a VRRP virtual router for redundant network access for Host1

The dashed box in Figure 154 represents a VRRP virtual router. When you configure a virtual router, one of the configuration parameters is the virtual router ID (VRID), which can be a number from 1 – 255. In this example, the VRID is 1.

NOTE
You can provide more redundancy by also configuring a second VRID with Switch 2 as the Owner and Switch 1 as the Backup. This type of configuration is sometimes called Multigroup VRRP.

Virtual Router ID (VRID)

A VRID consists of one Master router and one or more Backup routers. The Master router is the router that owns the IP address(es) you associate with the VRID. For this reason, the Master router is sometimes called the “Owner”. Configure the VRID on the router that owns the default gateway interface. The other router in the VRID does not own the IP address(es) associated with VRID but provides the backup path if the Master router becomes unavailable.

Virtual router MAC address

Notice the MAC address associated with VRID1. The first five octets of the address are the standard MAC prefix for VRRP packets, as described in RFC 2338. The last octet is the VRID. The VRID number becomes the final octet in the virtual MAC address associated with the virtual router.
When you configure a VRID, the software automatically assigns its MAC address. When a VRID becomes active, the Master router broadcasts a gratuitous ARP request containing the virtual router MAC address for each IP address associated with the virtual router. In Figure 154, Switch 1 sends a gratuitous ARP with MAC address 00-00-5e-00-01-01 and IP address 192.53.5.1. Hosts use the virtual router MAC address in routed traffic they send to their default IP gateway (in this example, 192.53.5.1).

**Virtual router IP address**

VRRP does not use virtual IP addresses. Thus, there is no virtual IP address associated with a virtual router. Instead, you associate the virtual router with one or more real interface IP addresses configured on the router that owns the real IP address(es). In Figure 154, the virtual router with VRID1 is associated with real IP address 192.53.5.1, which is configured on interface e1/6 on Switch 1. VRIDs are interface-level parameters, not system-level parameters, so the IP address you associate with the VRID must already be a real IP address configured on the Owner interface.

**NOTE**

You also can associate a virtual router with a virtual interface. A virtual interface is a named set of physical interfaces.

When you configure the Backup router for the VRID, specify the same IP address as the one you specify on the Owner. This is the IP address used by the host as its default gateway. The IP address cannot also exist on the Backup router. The interface on which you configure the VRID on the Backup router must have an IP address in the same subnet.

**NOTE**

If you delete a real IP address used by a VRRP entry, the VRRP entry also is deleted automatically.

**NOTE**

When a Backup router takes over forwarding responsibilities from a failed Master router, the Backup forwards traffic addressed to the VRID MAC address, which the host believes is the MAC address of the router interface for its default gateway. However, the Backup cannot reply to IP pings sent to the IP address(es) associated with the VRID. Because the IP address(es) are owned by the Owner, if the Owner is unavailable, the IP addresses are unavailable as packet destinations.

**Master negotiation**

The routers within a VRID use the VRRP priority values associated with each router to determine which router becomes the Master. When you configure the VRID on a router interface, you specify whether the router is the Owner of the IP addresses you plan to associate with the VRID or a Backup. If you indicate that the router is the Owner of the IP addresses, the software automatically sets the router VRRP priority for the VRID to 255, the highest VRRP priority. The router with the highest priority becomes the Master.

Backup routers can have a priority from 3 – 254, which you assign when you configure the VRID on the Backup router interfaces. The default VRRP priority for Backup routers is 100.

Because the router that owns the IP addresses associated with the VRID always has the highest priority, when all the routers in the virtual router are operating normally, the negotiation process results in the Owner of the VRID IP addresses becoming the Master router. Thus, the VRRP negotiation results in the normal case, in which the hosts’ path to the default route is to the router that owns the interface for that route.
Hello messages

VRRP routers use Hello messages for negotiation to determine the Master router. VRRP routers send Hello messages to IP Multicast address 224.0.0.18. The frequency with which the Master sends Hello messages is the Hello Interval. Only the Master sends Hello messages. However, a Backup uses the Hello interval you configure for the Backup if it becomes the Master.

The Backup routers wait for a period of time called the Dead Interval for a Hello message from the Master. If a Backup router does not receive a Hello message by the time the dead interval expires, the Backup router assumes that the Master router is dead and negotiates with the other Backups to select a new Master router. The Backup router with the highest priority becomes the new Master.

If the Owner becomes unavailable, but then comes back online, the Owner again becomes the Master router. The Owner becomes the Master router again because it has the highest priority. The Owner always becomes the Master again when the Owner comes back online.

**NOTE**

If you configure a track port on the Owner and the track port is down, the Owner priority is changed to the track priority. In this case, the Owner does not have a higher priority than the Backup that is acting as Master and the Owner therefore does not resume its position as Master. For more information about track ports, refer to “Track ports and track priority” on page 1265.

By default, if a Backup is acting as the Master, and the Master is still unavailable, another Backup can “preempt” the Backup that is acting as the Master. This can occur if the new Backup has a higher priority than the Backup who is acting as Master. You can disable this behavior if you want. When you disable preemption, a Backup router that has a higher priority than the router who is currently acting as Master does not preempt the new Master by initiating a new Master negotiation. Refer to “Backup preempt” on page 1279.

**NOTE**

Regardless of the setting for the preempt parameter, the Owner always becomes the Master again when it comes back online.

Track ports and track priority

The Brocade implementation of VRRP enhances the protocol by giving a VRRP router the capability to monitor the state of the interfaces on the other end of the route path through the router. For example, in Figure 154 on page 1263, interface e1/6 on Switch 1 owns the IP address to which Host1 directs route traffic on its default gateway. The exit path for this traffic is through Router1 e2/4 interface.

Suppose interface e2/4 goes down. Even if interface e1/6 is still up, Host1 is nonetheless cut off from other networks. In conventional VRRP, Switch 1 would continue to be the Master router despite the unavailability of the exit interface for the path the router is supporting. However, if you configure interface e1/6 to track the state of interface e2/4, if e2/4 goes down, interface e1/6 responds by changing Switch 1 VRRP priority to the value of the track priority. In the configuration shown in Figure 154 on page 1263, Switch 1 priority changes from 255 to 20. One of the parameters contained in the Hello messages the Master router sends to its Backups is the Master router priority. If the track port feature results in a change in the Master router priority, the Backup routers quickly become aware of the change and initiate a negotiation for Master router.
In Figure 154 on page 1263, the track priority results in Switch 1 VRRP priority becoming lower than Switch 2 VRRP priority. As a result, when Switch 2 learns that it now has a higher priority than Switch 1, Switch 2 initiates negotiation for Master router and becomes the new Master router, thus providing an open path for Host1 traffic. To take advantage of the track port feature, make sure the track priorities are always lower than the VRRP priorities. The default track priority for the router that owns the VRID IP addresses is 2. The default track priority for Backup routers is 1. If you change the track port priorities, make sure you assign a higher track priority to the Owner of the IP addresses than the track priority you assign on the Backup routers.

**Suppression of RIP advertisements for backed up interfaces**

The Brocade implementation also enhances VRRP by allowing you to configure the protocol to suppress RIP advertisements for the backed up paths from Backup routers. Normally, a VRRP Backup router includes route information for the interface it is backing up in RIP advertisements. As a result, other routers receive multiple paths for the interface and might sometimes unsuccessfully use the path to the Backup rather than the path to the Master. If you enable the Brocade implementation of VRRP to suppress the VRRP Backup routers from advertising the backed up interface in RIP, other routers learn only the path to the Master router for the backed up interface.

**Authentication**

The Brocade implementation of VRRP can use simple passwords to authenticate VRRP packets. The VRRP authentication type is not a parameter specific to the VRID. Instead, VRRP uses the authentication type associated with the interfaces on which you define the VRID. For example, if you configure your router interfaces to use a simple password to authenticate traffic, VRRP uses the same simple password and VRRP packets that do not contain the password are dropped. If your interfaces do not use authentication, neither does VRRP.

---

**NOTE**
The MD5 authentication type is not supported for VRRP.

---

**Independent operation of VRRP alongside RIP, OSPF, and BGP4**

VRRP operation is independent of the RIP, OSPF, and BGP4 protocols. Their operation is unaffected when VRRP is enabled on a RIP, OSPF, or BGP4 interface.

**Dynamic VRRP configuration**

All VRRP global and interface parameters take effect immediately. You do not need to reset the system to place VRRP configuration parameters into effect.
NOTE

VRRPE is not supported in the base Layer 3 code.

VRRPE is similar to VRRP, but differs in the following respects:

- Owners and Backup:
  - VRRP has an Owner and one or more Backups for each VRID. The Owner is the router on which the VRID's IP address is also configured as a real address. All the other routers supporting the VRID are Backups.
  - VRRPE does not use Owners. All routers are Backups for a given VRID. The router with the highest priority becomes Master. If there is a tie for highest priority, the router with the highest IP address becomes Master. The elected Master owns the virtual IP address and answers ping and ARP requests and so on.

- VRID's IP address:
  - VRRP requires that the VRID also be a real IP address configured on the VRID's interface on the Owner.
  - VRRPE requires only that the VRID be in the same subnet as an interface configured on the VRID's interface. In fact, VRRPE does not allow you to specify a real IP address configured on the interface as the VRID IP address.

- VRID's MAC Address:
  - VRRP source MAC is a virtual MAC address defined as 00-00-5E-00-01-<vrid>, where <vrid> is the VRID. The Master owns the Virtual MAC address.
  - VRRPE uses the interface actual MAC address as the source MAC address. The MAC address is 02-E0-52-<hash-value>-<vrid>, where <hash-value> is a two-octet hashed value for the IP address and <vrid> is the VRID.

- Hello packets:
  - VRRP sends Hello messages to IP Multicast address 224.0.0.18.
  - VRRPE uses UDP to send Hello messages in IP multicast messages. The Hello packets use the interface actual MAC address and IP address as the source addresses. The destination MAC address is 01-00-5E-00-00-02, and the destination IP address is 224.0.0.2 (the well-known IP multicast address for “all routers”). Both the source and destination UDP port number is 8888. VRRP messages are encapsulated in the data portion of the packet.

- Track ports and track priority:
  - VRRP changes the priority of the VRID to the track priority, which typically is lower than the VRID priority and lower than the VRID priorities configured on the Backups. For example, if the VRRP interface priority is 100 and a tracked interface with track priority 20 goes down, the software changes the VRRP interface priority to 20.
  - VRRPE reduces the priority of a VRRPE interface by the amount of a tracked interface priority if the tracked interface link goes down. For example, if the VRRPE interface priority is 200 and a tracked interface with track priority 20 goes down, the software changes the VRRPE interface priority to 180. If another tracked interface goes down, the software reduces the VRID priority again, by the amount of the tracked interface track priority.

The most important difference is that all VRRPE routers are Backups. There is no Owner router. VRRP overcomes the limitations in standard VRRP by removing the Owner.

Figure 155 shows an example of a VRRPE configuration.
In this example, Switch 1 and Switch 2 use VRRPE to load share as well as provide redundancy to the hosts. The load sharing is accomplished by creating two VRRPE groups. Each group has its own virtual IP addresses. Half of the clients point to VRID 1’s virtual IP address as their default gateway and the other half point to VRID 2’s virtual IP address as their default gateway. This will enable some of the outbound Internet traffic to go through Switch 1 and the rest to go through Switch 2.

Switch 1 is the master for VRID 1 (backup priority = 110) and Switch 2 is the backup for VRID 1 (backup priority = 100). Switch 1 and Switch 2 both track the uplinks to the Internet. If an uplink failure occurs on Switch 1, its backup priority is decremented by 20 (track priority = 20), so that all traffic destined to the Internet is sent through Switch 2 instead.

Similarly, Switch 2 is the master for VRID 2 (backup priority = 110) and Switch 1 is the backup for VRID 2 (backup priority = 100). Switch 1 and Switch 2 are both tracking the uplinks to the Internet. If an uplink failure occurs on Switch 1, its backup priority is decremented by 20 (track priority = 20), so that all traffic destined to the Internet is sent through Switch 2 instead.

**Configuration note**

VRRP-E is supported in the full Layer 3 code only. It is not supported in the Base Layer 3 code.
Comparison of VRRP and VRRPE

This section compares router redundancy protocols.

VRRP

VRRP is a standards-based protocol, described in RFC 2338. The Brocade implementation of VRRP contains the features in RFC 2338. The Brocade implementation also provides the following additional features:

- **Track ports** – A Brocade feature that enables you to diagnose the health of all the Layer 3 Switch ports used by the backed-up VRID, instead of only the port connected to the client subnet. Refer to “Track ports and track priority” on page 1265.

- **Suppression of RIP advertisements on Backup routes for the backed up interface** – You can enable the Layer 3 Switches to advertise only the path to the Master router for the backed up interface. Normally, a VRRP Backup router includes route information for the interface it is backing up in RIP advertisements.

Brocade Layer 3 Switches configured for VRRP can interoperate with third-party routers using VRRP.

VRRPE

VRRPE is a Brocade protocol that provides the benefits of VRRP without the limitations. VRRPE is unlike VRRP in the following ways:

- There is no “Owner” router. You do not need to use an IP address configured on one of the Layer 3 Switches as the virtual router ID (VRID), which is the address you are backing up for redundancy. The VRID is independent of the IP interfaces configured in the Layer 3 Switches. As a result, the protocol does not have an “Owner” as VRRP does.

- There is no restriction on which router can be the default master router. In VRRP, the “Owner” (the Layer 3 Switch on which the IP interface that is used for the VRID is configured) must be the default Master.

Brocade Layer 3 Switches configured for VRRPE can interoperate only with other Brocade Layer 3 Switches.

Architectural differences

The protocols have the following architectural differences:

**Management protocol**

- **VRRP** – VRRP routers send VRRP Hello and Hello messages to IP Multicast address 224.0.0.18.

- **VRRPE** – VRRPE sends messages to destination MAC address 01-00-5E-00-00-02 and destination IP address 224.0.0.2 (the standard IP multicast address for “all routers”).
**Virtual router IP address (the address you are backing up)**

- **VRRP** – The virtual router IP address is the same as an IP address or virtual interface configured on one of the Layer 3 Switches, which is the “Owner” and becomes the default Master.
- **VRRPE** – The virtual router IP address is the gateway address you want to backup, but does not need to be an IP interface configured on one of the Layer 3 Switch ports or a virtual interface.

**Master and Backups**

- **VRRP** – The “Owner” of the IP address of the VRID is the default Master and has the highest priority (255). The precedence of the Backups is determined by their priorities. The default Master is always the Owner of the IP address of the VRID.
- **VRRPE** – The Master and Backups are selected based on their priority. You can configure any of the Layer 3 Switches to be the Master by giving it the highest priority. There is no Owner.

### VRRP and VRRPE parameters

**Table 216** lists the VRRP and VRRPE parameters. Most of the parameters and default values are the same for both protocols. The exceptions are noted in the table.

#### TABLE 216  VRRP and VRRPE parameters

</table>
| VRID MAC address                | The source MAC address in VRRP or VRRPE packets sent from the VRID interface, and the destination for packets sent to the VRID:  
  - VRRP – A virtual MAC address defined as 00-00-5e-00-01-<vrid>. The Master owns the Virtual MAC address.  
  - VRRPE – A virtual MAC address defined as 02-E0-52-<hash-value>-<vrid>, where <hash-value> is a two-octet hashed value for the IP address and <vrid> is the VRID.  |
|                                 |                                                                                                   | Not configurable               | page 1263   |
| Authentication type             | The type of authentication the VRRP or VRRPE routers use to validate VRRP or VRRPE packets. The authentication type must match the authentication type the VRID port uses with other routing protocols such as OSPF:  
  - No authentication – The interfaces do not use authentication. This is the VRRP default.  
  - Simple – The interface uses a simple text-string as a password in packets sent on the interface. If the interface uses simple password authentication, the VRID configured on the interface must use the same authentication type and the same password. |
|                                 |                                                                                                   | No authentication              | page 1266 page 1275 |
| Router type                     | Whether the router is an Owner or a Backup.                                                        | VRRP – The Owner is always the router that has the real IP address used by the VRID. All other routers for the VRID are Backups.  
  - Owner (VRRP only) – The router on which the real IP address used by the VRID is configured.  
  - Backup – Routers that can provide routing services for the VRID but do not have a real IP address matching the VRID. |
|                                 |                                                                                                   | page 1276                      |             |
| Backup priority                 | A numeric value that determines a Backup preferability for becoming the Master for the VRID. During negotiation, the router with the highest priority becomes the Master.  
  - VRRP – The Owner has the highest priority (255); other routers can have a priority from 3 – 254.  
  - VRRPE – All routers are Backups and have the same priority by default.  
  If two or more Backups are tied with the highest priority, the Backup interface with the highest IP address becomes the Master for the VRID. |
|                                 |                                                                                                   | VRRP – 255 for the Owner; 100 for each Backup VRRPE – 100 for all Backups | page 1276   |
| Suppression of RIP advertisements| A router that is running RIP normally advertises routes to a backed up VRID even when the router is not currently the active router for the VRID. Suppression of these advertisements helps ensure that other routers do not receive invalid route paths for the VRID. |
|                                 |                                                                                                   | Disabled                       | page 1277   |
| Hello interval                  | The number of seconds between Hello messages from the Master to the Backups for a given VRID. The interval can from 1 – 84 seconds. |
|                                 |                                                                                                   | One second                     | page 1265 page 1277 |
### VRRP and VRRPE parameters (Continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>See page...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dead interval</td>
<td>The number of seconds a Backup waits for a Hello message from the Master for the VRID before determining that the Master is no longer active. If the Master does not send a Hello message before the dead interval expires, the Backups negotiate (compare priorities) to select a new Master for the VRID.</td>
<td>Three times the Hello Interval plus one-half second</td>
<td>page 1265 page 1278</td>
</tr>
<tr>
<td>Backup Hello interval</td>
<td>The number of seconds between Hello messages from a Backup to the Master. The message interval can be from 60 – 3600 seconds. You must enable the Backup to send the messages. The messages are disabled by default on Backups. The current Master (whether the VRRP Owner or a Backup) sends Hello messages by default.</td>
<td>Disabled 60 seconds when enabled</td>
<td>page 1265 page 1278</td>

</tbody>
</table>
Configuring basic VRRP parameters

To implement a simple VRRP configuration using all the default values, enter commands such as the following.

Configuring the Owner

Router1(config)# router vrrp
Router1(config)# int e 1/6
Router1(config-if-1/6)# ip address 192.53.5.1
Router1(config-if-1/6)# ip vrrp vrid 1
Router1(config-if-1/6-vrid-1)# owner
Router1(config-if-1/6-vrid-1)# ip-address 192.53.5.1
Router1(config-if-1/6-vrid-1)# activate

Configuring a Backup

Router2(config)# router vrrp
Router2(config)# int e 1/5
Router2(config-if-1/5)# ip address 192.53.5.3
Router2(config-if-1/5)# ip vrrp vrid 1
Router2(config-if-1/5-vrid-1)# backup
Router2(config-if-1/5-vrid-1)# advertise backup
Router2(config-if-1/5-vrid-1)# ip-address 192.53.5.1
Router2(config-if-1/5-vrid-1)# activate

Configuration rules for VRRP

- The interfaces of all routers in a VRID must be in the same IP subnet.
- The IP addresses associated with the VRID must already be configured on the router that will be the Owner router.
- An IP address associated with the VRID must be on only one router.
- The Hello interval must be set to the same value on both the Owner and Backups for the VRID.
- The Dead interval must be set to the same value on both the Owner and Backups for the VRID.
- The track priority on a router must be lower than the router VRRP priority. Also, the track priority on the Owner must be higher than the track priority on the Backups.

Configuring basic VRRPE parameters

To implement a simple VRRPE configuration using all the default values, enter commands such as the following on each Layer 3 Switch.

Router2(config)# router vrrp-extended
Router2(config)# int e 1/5
Router2(config-if-1/5)# ip address 192.53.5.3
Router2(config-if-1/5)# ip vrrp-extended vrid 1
Router2(config-if-1/5-vrid-1)# backup
Router2(config-if-1/5-vrid-1)# advertise backup
Router2(config-if-1/5-vrid-1)# ip-address 192.53.5.254
Router2(config-if-1/5-vrid-1)# activate
Note regarding disabling VRRP or VRRPE

If you disable VRRP or VRRPE, the Layer 3 Switch removes all the configuration information for the disabled protocol from the running-config. Moreover, when you save the configuration to the startup-config file after disabling one of these protocols, all the configuration information for the disabled protocol is removed from the startup-config file.

The CLI displays a warning message such as the following.

Router1(config-vrrp-router)# no router vrrp
router vrrp mode now disabled. All vrrp config data will be lost when writing to flash!

If you have disabled the protocol but have not yet saved the configuration to the startup-config file and reloaded the software, you can restore the configuration information by re-entering the command to enable the protocol (ex: `router vrrp`). If you have already saved the configuration to the startup-config file and reloaded the software, the information is gone.

If you are testing a VRRP or VRRPE configuration and are likely to disable and re-enable the protocol, you might want to make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

Configuring additional VRRP and VRRPE parameters

You can modify the following VRRP and VRRPE parameters on an individual VRID basis. These parameters apply to both protocols:

- Authentication type (if the interfaces on which you configure the VRID use authentication)
- Router type (Owner or Backup)

For VRRP, change the router type only if you have moved the real IP address from one router to another or you accidentally configured the IP address Owner as a Backup.

For VRRPE, the router type is always Backup. You cannot change the type to Owner.
Configuring additional VRRP and VRRPE parameters

- Backup priority
- Suppression of RIP advertisements on Backup routes for the backed up interface
- Hello interval
- Dead interval
- Backup Hello messages and message timer (Backup advertisement)
- Track port
- Track priority
- Backup preempt mode
- Timer scale
- VRRP-E slow start timer

For information about the fields, see the parameter descriptions in the following sections.

Refer to “VRRP and VRRPE parameters” on page 1270 for a summary of the parameters and their defaults.

Authentication type

If the interfaces on which you configure the VRID use authentication, the VRRP or VRRPE packets on those interfaces also must use the same authentication. The Brocade implementation of VRRP and VRRPE supports the following authentication types:

- **No authentication** – The interfaces do not use authentication. This is the default for VRRP and VRRPE.
- **Simple** – The interfaces use a simple text-string as a password in packets sent on the interface. If the interfaces use simple password authentication, the VRID configured on the interfaces must use the same authentication type and the same password.

To configure the VRID interface on Router1 for simple-password authentication using the password “ourpword”, enter the following commands.

**Configuring Router 1**

Router1(config)# inter e 1/6
Router1(config-if-1/6)# ip vrrp auth-type simple-text-auth ourpword

**Configuring Router 2**

Router2(config)# inter e 1/5
Router2(config-if-1/5)# ip vrrp auth-type simple-text-auth ourpword

VRRP syntax

**Syntax:** ip vrrp auth-type no-auth | simple-text-auth <auth-data>

The **auth-type no-auth** parameter indicates that the VRID and the interface it is configured on do not use authentication.

The **auth-type simple-text-auth <auth-data>** parameter indicates that the VRID and the interface it is configured on use a simple text password for authentication. The **<auth-data>** parameter is the password. If you use this parameter, make sure all interfaces on all the routers supporting this VRID are configured for simple password authentication and use the same password.

VRRPE syntax

**Syntax:** ip vrrp-extended auth-type no-auth | simple-text-auth <auth-data>
Configuring additional VRRP and VRRPE parameters

The parameter values are the same as for VRRP.

**Router type**

A VRRP interface is either an Owner or a Backup for a given VRID. By default, the Owner becomes the Master following the negotiation. A Backup becomes the Master only if the Master becomes unavailable.

A VRRPE interface is always a Backup for its VRID. The Backup with the highest VRRP priority becomes the Master.

This section describes how to specify the interface type, how to change the type for VRRP, and how to set or change the interface VRRP or VRRPE priority and track priority for the VRID.

---

**NOTE**

You can force a VRRP master router to abdicate (give away control) of the VRID to a Backup by temporarily changing the Master VRRP priority to a value less than the Backup. Refer to “Forcing a Master router to abdicate to a standby router” on page 1281.

---

**NOTE**

The type Owner is not applicable to VRRPE.

---

**NOTE**

The IP address(es) you associate with the Owner must be a real IP address (or addresses) on the interface on which you configure the VRID.

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

To configure Router1 as a VRRP VRID Owner, enter the following commands.

```
Router1(config)# inter e 1/6
Router1(config-if-1/6)# ip vrrp vrid 1
Router1(config-if-1/6-vrid-1)# owner
```

To configure Router2 as a VRRP Backup for the same VRID, enter the following commands.

```
Router2(config)# inter e 1/5
Router2(config-if-1/5)# ip vrrp vrid 1
Router2(config-if-1/5-vrid-1)# backup
Router2(config-if-1/5-vrid-1)# advertise backup
```

To configure a VRRPE interface as a Backup for a VRID and set its VRRPE priority and track priority, enter commands such as the following.

```
FastIron(config)# inter e 1/1
FastIron(config-if-1/1)# ip vrrp-extended vrid 1
FastIron(config-if-1/1-vrid-1)# backup priority 50 track-priority 10
Router2(config-if-1/1-vrid-1)# advertise backup
```

**VRRP syntax**

**Syntax: owner [track-priority <value>]**

The *track-priority* `<value>` parameter changes the track-port priority for this interface and VRID from the default (2) to a value from 1 – 254.
Syntax: \texttt{backup [priority \textless value\textgreater] [track-priority \textless value\textgreater]}

The \texttt{priority \textless value\textgreater} parameter specifies the VRRP priority for this interface and VRID. You can specify a value from 3 – 254. The default is 100.

The \texttt{track-priority \textless value\textgreater} parameter is the same as above.

\textbf{NOTE}

You cannot set the priority of a VRRP Owner. The Owner priority is always 255.

\textbf{VRRPE syntax}

Syntax: \texttt{backup [priority \textless value\textgreater] [track-priority \textless value\textgreater]}

The software requires you to identify a VRRPE in interface as a Backup for its VRID before you can activate the interface for the VRID. However, after you configure the VRID, you can use this command to change its priority or track priority. The parameter values are the same as for VRRP.

\textbf{Suppression of RIP advertisements on Backup routers for the Backup interface}

Normally, a VRRP or VRRPE Backup includes route information for the virtual IP address (the backed up interface) in RIP advertisements. As a result, other routers receive multiple paths for the backed up interface and might sometimes unsuccessfully use the path to the Backup rather than the path to the Master.

You can prevent the Backups from advertising route information for the backed up interface by enabling suppression of the advertisements.

To suppress RIP advertisements for the backed up interface in Router2, enter the following commands.

\begin{verbatim}
Router2(config)# router rip
Router2(config-rip-router)# use-vrrp-path
\end{verbatim}

Syntax: \texttt{use-vrrp-path}

The syntax is the same for VRRP and VRRPE.

\textbf{Hello interval}

The Master periodically sends Hello messages to the Backups. The Backups use the Hello messages as verification that the Master is still on-line. If the Backup routers stop receiving the Hello messages for the period of time specified by the Dead interval, the Backup routers determine that the Master router is dead. At this point, the Backup router with the highest priority becomes the new Master router. The Hello interval can be from 1 – 84 seconds. The default is 1 second.

\textbf{NOTE}

The default Dead interval is three times the Hello Interval plus one-half second. Generally, if you change the Hello interval, you also should change the Dead interval on the Backup routers.

To change the Hello interval on the Master to 10 seconds, enter the following commands.

\begin{verbatim}
Router1(config)# int e 1/6
Router1(config-if-1/6)# ip vrrp vrid 1
Router1(config-if-1/6-vrid-1)# hello-interval 10
\end{verbatim}

Syntax: \texttt{hello-interval \textless value\textgreater}

The syntax is the same for VRRP and VRRPE.
**Dead interval**

The Dead interval is the number of seconds a Backup waits for a Hello message from the Master before determining that the Master is dead. When Backups determine that the Master is dead, the Backup with the highest priority becomes the new Master. The Dead interval can be from 1 – 84 seconds. The default is 3.5 seconds. This is three times the default Hello interval (1 second) plus one-half second added by the router software. The software automatically adds one-half second to the Dead interval value you enter.

To change the Dead interval on a Backup to 30 seconds, enter the following commands.

```plaintext
Router2(config)# inter e 1/5
Router2(config-if-1/5)# ip vrrp vrid 1
Router2(config-if-1/5-vrid-1)# dead-interval 30
```

**Syntax:** `dead-interval <value>`

The syntax is the same for VRRP and VRRPE.

**Backup Hello message state and interval**

By default, Backup do not send Hello messages to advertise themselves to the Master. You can enable these messages if desired and also change the message interval.

To enable a Backup to send Hello messages to the Master, enter commands such as the following.

```plaintext
FastIron(config)# router vrrp
FastIron(config)# inter e 1/6
FastIron(config-if-1/6)# ip vrrp vrid 1
FastIron(config-if-1/6-vrid-1)# advertise backup
```

**Syntax:** `[no] advertise backup`

When you enable a Backup to send Hello messages, the Backup sends a Hello messages to the Master every 60 seconds by default. You can change the interval to be up to 3600 seconds. To do so, enter commands such as the following.

```plaintext
FastIron(config)# router vrrp
FastIron(config)# inter e 1/6
FastIron(config-if-1/6)# ip vrrp vrid 1
FastIron(config-if-1/6-vrid-1)# backup-hello-interval 180
```

**Syntax:** `[no] backup-hello-interval <num>`

The `<num>` parameter specifies the message interval and can be from 60 – 3600 seconds. The default is 60 seconds.

The syntax is the same for VRRP and VRRPE.

**Track port**

You can configure the VRID on one interface to track the link state of another interface on the Layer 3 Switch. This capability is quite useful for tracking the state of the exit interface for the path for which the VRID is providing redundancy. Refer to “Track ports and track priority” on page 1265.

To configure 1/6 on Router1 to track interface 2/4, enter the following commands.

```plaintext
Router1(config)# inter e 1/6
Router1(config-if-1/6)# ip vrrp vrid 1
Router1(config-if-1/6-vrid-1)# track-port e 2/4
```
Syntax: **track-port ethernet** [<slotnum>/]<portnum> | ve <num>

The syntax is the same for VRRP and VRRPE.

**Track priority**

When you configure a VRID to track the link state of other interfaces, if one of the tracked interface goes down, the software changes the VRRP or VRRPE priority of the VRID interface:

- For VRRP, the software changes the priority of the VRID to the track priority, which typically is lower than the VRID priority and lower than the VRID priorities configured on the Backups. For example, if the VRRPE interface priority is 100 and a tracked interface with track priority 60 goes down, the software changes the VRRPE interface priority to 60.
- For VRRPE, the software reduces the VRID priority by the amount of the priority of the tracked interface that went down. For example, if the VRRPE interface priority is 100 and a tracked interface with track priority 60 goes down, the software changes the VRRPE interface priority to 40. If another tracked interface goes down, the software reduces the VRID priority again, by the amount of the tracked interface track priority.

The default track priority for a VRRP Owner is 2. The default track priority for Backups is 1.

You enter the track priority as a parameter with the **owner** or **backup** command. Refer to “**Track port**” on page 1278.

**Syntax:** **owner** [track-priority <value>]

**Syntax:** **backup** [priority <value>] [track-priority <value>]

The syntax is the same for VRRP and VRRPE.

**Backup preempt**

By default, a Backup that has a higher priority than another Backup that has become the Master can preempt the Master, and take over the role of Master. If you want to prevent this behavior, disable preemption.

Preemption applies only to Backups and takes effect only when the Master has failed and a Backup has assumed ownership of the VRID. The feature prevents a Backup with a higher priority from taking over as Master from another Backup that has a lower priority but has already become the Master of the VRID.

Preemption is especially useful for preventing flapping in situations where there are multiple Backups and a Backup with a lower priority than another Backup has assumed ownership, because the Backup with the higher priority was unavailable when ownership changed.

If you enable the non-preempt mode (thus disabling the preemption feature) on all the Backups, the Backup that becomes the Master following the disappearance of the Master continues to be the Master. The new Master is not preempted.

In the VRRP non-preempt mode, the VRRP router controlling the IP addresses associated with the virtual router becomes the Master. When the Master becomes unavailable, the Backup router with highest priority becomes the Master. If the Master router changes its priority to lower priority (due to track port going down), the Backup router in the non-preempt mode does not take over.

**NOTE**

In VRRP, regardless of the setting for the preempt parameter, the Owner always becomes the Master again when it comes back online.
To disable preemption on a Backup, enter commands such as the following.

Router1(config)# interface e 1/6
Router1(config-if-1/6)# ip vrrp vrid 1
Router1(config-if-1/6-vrid-1)# non-preempt-mode

**Syntax: non-preempt-mode**

The syntax is the same for VRRP and VRRPE.

### Changing the timer scale

To achieve sub-second failover times, you can shorten the duration of all scale timers for VSRP, VRRP, and VRRP-E by adjusting the timer scale. The **timer scale** is a value used by the software to calculate the timers. By default, the scale value is 1. If you increase the timer scale, each timer's value is divided by the scale value. Using the timer scale to adjust timer values enables you to easily change all the timers while preserving the ratios among their values. Here is an example.

<table>
<thead>
<tr>
<th>Timer</th>
<th>Timer scale</th>
<th>Timer value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hello interval</td>
<td>1</td>
<td>1 second</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>0.5 seconds</td>
</tr>
<tr>
<td>Dead interval</td>
<td>1</td>
<td>3 seconds</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>1.5 seconds</td>
</tr>
<tr>
<td>Backup Hello interval</td>
<td>1</td>
<td>60 seconds</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>30 seconds</td>
</tr>
<tr>
<td>Hold-down interval</td>
<td>1</td>
<td>2 seconds</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>1 second</td>
</tr>
</tbody>
</table>

If you configure the device to receive its timer values from the Master, the Backup also receives the timer scale value from the Master.

**NOTE**

The Backups always use the value of the timer scale received from the Master, regardless of whether the timer values that are saved in the configuration are the values configured on the Backup or the values received from the Master.

To change the timer scale, enter a command such as the following at the global CONFIG level of the CLI.

FastIron(config)# scale-timer 2

This command changes the scale to 2. All VSRP, VRRP, and VRRP-E timer values will be divided by 2.

**Syntax:** `[no] scale-timer <num>`

The `<num>` parameter specifies the multiplier. You can specify a timer scale from 1 – 10.
VRRP-E slow start timer

In a VRRP-E configuration, if a Master router goes down, the Backup router with the highest priority takes over. When the Master comes back up again, it takes over from the Backup. By default, this transition from Backup back to Master takes place immediately. However, you can configure the VRRP-E slow start timer feature, which causes a specified amount of time to elapse between the time the Master is restored and when it takes over from the Backup. This interval allows time for OSPF convergence when the Master is restored.

**NOTE**
This feature is not supported on FGS, FWS, or FLS devices.

To set the VRRP-E slow start timer to 30 seconds, enter the following commands.

```
FastIron(config)# router vrrp-e
FastIron(config-vrrpe-router)# slow-start 30
```

**Syntax:**
```
[no] slow-start <seconds>
```
For `<seconds>`, enter a value from 1 – 255.

When the VRRP-E slow start timer is enabled, if the Master goes down, the Backup takes over immediately. If the Master subsequently comes back up again, the amount of time specified by the VRRP-E slow start timer elapses (in this example, 30 seconds) before the Master takes over from the Backup.

The VRRP-E slow start timer is effective only if another VRRP-E Master (Standby) is detected. It is not effective during the initial boot up.

**NOTE**
The VRRP-E slow start timer applies only to VRRP-E configurations. It does not apply to VRRP configurations.

Forcing a Master router to abdicate to a standby router

You can force a VRRP Master to abdicate (give away control) of a VRID to a Backup by temporarily changing the Master priority to a value less than the Backup.

The VRRP Owner always has priority 255. You can even use this feature to temporarily change the Owner priority to a value from 1 – 254.

**NOTE**
When you change a VRRP Owner priority, the change takes effect only for the current power cycle. The change is not saved to the startup-config file when you save the configuration and is not retained across a reload or reboot. Following a reload or reboot, the VRRP Owner again has priority 255.

To temporarily change the Master priority, use the following CLI method.

```
To change the Master priority, enter commands such as the following.
```

```
FastIron(config)# ip int eth 1/6
FastIron(config-if-1/6)# ip vrrp vrid 1
FastIron(config-if-1/6-vrid-1)# owner priority 99
```

**Syntax:**
```
[no] owner priority | track-priority <num>
```
The `<num>` parameter specifies the new priority and can be a number from 1 – 254.

When you press Enter, the software changes the priority of the Master to the specified priority. If the new priority is lower than at least one Backup priority for the same VRID, the Backup takes over and becomes the new Master until the next software reload or system reset.

To verify the change, enter the following command from any level of the CLI.

```
FastIron# show ip vrrp
Total number of VRRP routers defined: 1
Interface ethernet 1/6
auth-type no authentication
VRID 1
  state backup
  administrative-status enabled
  mode owner
  priority 99
  current priority 99
  hello-interval 1 sec
  ip-address 192.53.5.1
  backup routers 192.53.5.2
```

This example shows that even though this Layer 3 Switch is the Owner of the VRID (“mode owner”), the Layer 3 Switch priority for the VRID is only 99 and the state is now “backup” instead of “active”. In addition, the administrative status is “enabled”.

To change the Master priority back to the default Owner priority 255, enter “no” followed by the command you entered to change the priority. For example, to change the priority of a VRRP Owner back to 255 from 99, enter the following command.

```
FastIron(config-if-1/6-vrid-1)# no owner priority 99
```

You cannot set the priority to 255 using the `owner priority` command.

### Displaying VRRP and VRRPE information

You can display the following information for VRRP or VRRPE:

- Summary configuration and status information
- Detailed configuration and status information
- VRRP and VRRPE Statistics
- CPU utilization statistics

#### Displaying summary information

To display summary information for a Layer 3 Switch, enter the following command at any level of the CLI.

```
FastIron# show ip vrrp brief
Total number of VRRP routers defined: 1
Interface VRID CurPri P State Master addr Backup addr VIP
1/6 1 255 P Init 192.53.5.1 192.53.5.3 192.53.5.1
```

The above example is for VRRP. Here is an example for VRRPE.
Displaying VRRP and VRRPE information

FastIron# show ip vrrp-extended brief

Total number of VRRP-Extended routers defined: 1
Interface VRID CurPri P State  Master addr  Backup addr  VIP
1/6  1   255  P  Init  192.53.5.2  192.53.5.3  192.53.5.254

Syntax:  show ip vrrp brief | ethernet [<slotnum>/]<portnum> | ve <num> | stat

Syntax:  show ip vrrp-extended brief | ethernet [<slotnum>/]<portnum> | ve <num> | stat

The brief parameter displays the summary information. If you do not use this parameter, detailed information is displayed instead. Refer to “Displaying detailed information” on page 1284.

The <slotnum> parameter is required on chassis devices if you specify a port number.

The <portnum> parameter specifies an Ethernet port. If you use this parameter, the command displays VRRP or VRRPE information only for the specified port.

The ve <num> parameter specifies a virtual interface. If you use this parameter, the command displays VRRP or VRRPE information only for the specified virtual interface.

The stat parameter displays statistics. Refer to “Displaying statistics” on page 1289.

This display shows the following information.

**TABLE 217  CLI display of VRRP or VRRPE summary information**

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total number of VRRP (or VRRP-Extended) routers defined</td>
<td>The total number of VRIDs configured on this Layer 3 Switch. <strong>NOTE:</strong> The total applies only to the protocol the Layer 3 Switch is running. For example, if the Layer 3 Switch is running VRRPE, the total applies only to VRRPE routers.</td>
</tr>
<tr>
<td>Interface</td>
<td>The interface on which VRRP or VRRPE is configured. If VRRP or VRRPE is configured on multiple interfaces, information for each interface is listed separately.</td>
</tr>
<tr>
<td>VRID</td>
<td>The VRID configured on this interface. If multiple VRIDs are configured on the interface, information for each VRID is listed in a separate row.</td>
</tr>
<tr>
<td>CurPri</td>
<td>The current VRRP or VRRPE priority of this Layer 3 Switch for the VRID.</td>
</tr>
<tr>
<td>P</td>
<td>Whether the backup preempt mode is enabled. If the backup preempt mode is enabled, this field contains a “P”. If the mode is disabled, this field is blank.</td>
</tr>
</tbody>
</table>
| State | This Layer 3 Switch VRRP or VRRPE state for the VRID. The state can be one of the following:

  - **Init** – The VRID is not enabled (activated). If the state remains Init after you activate the VRID, make sure that the VRID is also configured on the other routers and that the routers can communicate with each other.

  **NOTE:** If the state is Init and the mode is incomplete, make sure you have specified the IP address for the VRID.

  - **Backup** – This Layer 3 Switch is a Backup for the VRID.

  - **Master** – This Layer 3 Switch is the Master for the VRID. |
| Master addr | IP address of the router interface that is currently Master for the VRID. |
| Backup addr | IP addresses of router interfaces that are currently Backups for the VRID. |
| VIP | The virtual IP address that is being backed up by the VRID. |
Displaying detailed information

To display detailed VRRP or VRRPE information, enter the following command at any level of the CLI.

FastIron# show ip vrrp

Total number of VRRP routers defined: 1
Interface ethernet 1/6
  auth-type no authentication
VRID 1
    state master
    administrative-status enabled
    mode owner
    priority 255
    current priority 255
    hello-interval 10000 msec
    advertise backup: disabled
    track-port 2/4

This example is for a VRRP Owner. Here is an example for a VRRP Backup.

FastIron# show ip vrrp

Total number of VRRP routers defined: 1
Interface ethernet 1/5
  auth-type no authentication
VRID 1
    state backup
    administrative-status enabled
    mode non-owner(backup)
    priority 100
    current priority 100
    hello-interval 10000 msec
    dead-interval 30000 msec
    current dead-interval 10000 msec
    preempt-mode true
    advertise backup: enabled
    backup router 192.53.5.3 expires in 00:00:03.0
    next hello sent in 00:00:02.0
    track-port 3/2

Here is an example for a VRRPE Backup.
Displaying VRRP and VRRPE information

FastIron# show ip vrrp-extended

Total number of VRRP-Extended routers defined: 1
Interface ethernet 1/6
  auth-type no authentication
  VRID 1
    state master
    administrative-status enabled
    priority 200
    current priority 200
    hello-interval 10000 msec
    dead-interval 30000 msec
    current dead-interval 30000 msec
    preempt-mode true
    virtual ip address 192.53.5.254
    advertise backup: enabled
    master router 192.53.5.2 expires in 00:00:03.0
    track-port 2/4

Syntax: show ip vrrp brief | ethernet [<slotnum>/]<portnum> | ve <num> | stat
Syntax: show ip vrrp-extended brief | ethernet [<slotnum>/]<portnum> | ve <num> | stat

The brief parameter displays summary information. Refer to “Displaying summary information” on page 1282.

The <portnum> parameter specifies an Ethernet port. If you use this parameter, the command displays VRRP or VRRPE information only for the specified port. Also, you must specify the <slotnum> on chassis devices.

The ve <num> parameter specifies a virtual interface. If you use this parameter, the command displays VRRP or VRRPE information only for the specified virtual interface.

The stat parameter displays statistics. Refer to “Displaying statistics” on page 1289.

This display shows the following information.

**TABLE 218  CLI display of VRRP or VRRPE detailed information**

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total number of VRRP (or VRRP-Extended) routers defined</td>
<td>The total number of VRIDs configured on this Layer 3 Switch. NOTE: The total applies only to the protocol the Layer 3 Switch is running. For example, if the Layer 3 Switch is running VRRPE, the total applies only to VRRPE routers.</td>
</tr>
</tbody>
</table>

**Interface parameters**

| Interface | The interface on which VRRP or VRRPE is configured. If VRRP or VRRPE is configured on multiple interfaces, information for each interface is listed separately. |
| auth-type | The authentication type enabled on the interface. |

**VRID parameters**

| VRID | The VRID configured on this interface. If multiple VRIDs are configured on the interface, information for each VRID is listed separately. |
TABLE 218  CLI display of VRRP or VRRPE detailed information (Continued)

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
</table>
| state        | This Layer 3 Switch VRRP or VRRPE state for the VRID. The state can be one of the following:  
• initialize – The VRID is not enabled (activated). If the state remains “initialize” after you activate the VRID, make sure that the VRID is also configured on the other routers and that the routers can communicate with each other.  
**NOTE:** If the state is “initialize” and the mode is incomplete, make sure you have specified the IP address for the VRID.  
• backup – This Layer 3 Switch is a Backup for the VRID.  
• master – This Layer 3 Switch is the Master for the VRID. |
| administrative-status | The administrative status of the VRID. The administrative status can be one of the following:  
• disabled – The VRID is configured on the interface but VRRP or VRRPE has not been activated on the interface.  
• enabled – VRRP or VRRPE has been activated on the interface. |
| mode | Indicates whether the Layer 3 Switch is the Owner or a Backup for the VRID.  
**NOTE:** If “incomplete” appears after the mode, configuration for this VRID is incomplete. For example, you might not have configured the virtual IP address that is being backed up by the VRID.  
**NOTE:** This field applies only to VRRP. All Layer 3 Switches configured for VRRPE are Backups. |
| priority | The device preferability for becoming the Master for the VRID. During negotiation, the router with the highest priority becomes the Master. If two or more devices are tied with the highest priority, the Backup interface with the highest IP address becomes the active router for the VRID. |
| current priority | The current VRRP or VRRPE priority of this Layer 3 Switch for the VRID. The current priority can differ from the configured priority (see the row above) for the following reasons:  
• The VRID is still in the initialization stage and has not become a Master or Backup yet. In this case, the current priority is 0.  
• The VRID is configured with track ports and the link on a tracked interface has gone down. Refer to “Track ports and track priority” on page 1265. |
| hello-interval | The configured value for the hello interval. This is the amount of time between Hello messages from the Master to the Backups for a given VRID:  
• Software releases prior to 03.0.00 show the dead interval in number of seconds.  
• Software releases 03.0.00 and later show the dead interval in number of milliseconds. |
| dead-interval | The configured value for the dead interval. This is the amount of time a Backup waits for a Hello message from the Master for the VRID before determining that the Master is no longer active:  
• Software releases prior to 03.0.00 show the dead interval in number of seconds.  
• Software releases 03.0.00 and later show the dead interval in number of milliseconds.  
If the Master does not send a Hello message before the dead interval expires, the Backups negotiate (compare priorities) to select a new Master for the VRID.  
**NOTE:** If the value is 0, then you have not configured this parameter.  
**NOTE:** This field does not apply to VRRP Owners. |
Displaying VRRP and VRRPE information

<table>
<thead>
<tr>
<th>This field...</th>

</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> This field is displayed only if track interfaces are configured for this VRID.</td>
</tr>
</tbody>
</table>

**TABLE 218** CLI display of VRRP or VRRPE detailed information (Continued)

Displaying detailed information for an individual VRID

You can display information about the settings configured for a specified VRRP Virtual Router ID (VRID). For example, to display information about VRID 1.
Syntax: `show ip vrrp vrid <num> [ethernet <num> | ve <num>]`

The `<num>` parameter specifies the VRID.

The `ethernet <num> | ve <num>` specifies an interface on which the VRID is configured. If you specify an interface, VRID information is displayed for that interface only. Otherwise, information is displayed for all the interfaces on which the specified VRID is configured.

This display shows the following information.

**TABLE 219** Output from the `show ip vrrp vrid` command

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>VRID</td>
<td>The specified VRID.</td>
</tr>
<tr>
<td>Interface</td>
<td>The interface on which VRRP is configured.</td>
</tr>
<tr>
<td>State</td>
<td>This Layer 3 Switch VRRP state for the VRID. The state can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Init – The VRID is not enabled (activated). If the state remains Init after you activate the VRID, make sure that the VRID is also configured on the other routers and that the routers can communicate with each other.</td>
</tr>
<tr>
<td></td>
<td>NOTE: If the state is Init and the mode is incomplete, make sure you have specified the IP address for the VRID:</td>
</tr>
<tr>
<td></td>
<td>• Backup – This Layer 3 Switch is a Backup for the VRID.</td>
</tr>
<tr>
<td></td>
<td>• Master – This Layer 3 Switch is the Master for the VRID.</td>
</tr>
<tr>
<td>priority</td>
<td>The configured VRRP priority of this Layer 3 Switch for the VRID.</td>
</tr>
<tr>
<td>current priority</td>
<td>The current VRRP priority of this Layer 3 Switch for the VRID.</td>
</tr>
<tr>
<td>track-priority</td>
<td>The new VRRP priority that the router receives for this VRID if the interface goes down</td>
</tr>
<tr>
<td>hello-interval</td>
<td>How often the Master router sends Hello messages to the Backups.</td>
</tr>
<tr>
<td>dead-interval</td>
<td>The amount of time a Backup waits for a Hello message from the Master before determining that the Master is dead.</td>
</tr>
<tr>
<td>current dead-interval</td>
<td>The current Dead interval. The software automatically adds one-half second to the Dead interval value you enter.</td>
</tr>
<tr>
<td>preempt-mode</td>
<td>Whether the backup preempt mode is enabled. If the backup preempt mode is enabled, this field contains “true”. If the mode is disabled, this field contains “false”.</td>
</tr>
<tr>
<td>advertise backup</td>
<td>Whether Backup routers send Hello messages to the Master.</td>
</tr>
</tbody>
</table>
Displaying statistics

To display statistics on most Brocade devices, enter a command such as the following at any level of the CLI.

```
FastIron# show ip vrrp statistic
```

```
Interface ethernet 1/5
  rxed vrrp header error count = 0
  rxed vrrp auth error count = 0
  rxed vrrp auth passwd mismatch error count = 0
  rxed vrrp vrid not found error count = 0
  VRID 1
    rxed arp packet drop count = 0
    rxed ip packet drop count = 0
    rxed vrrp port mismatch count = 0
    rxed vrrp ip address mismatch count = 0
    rxed vrrp hello interval mismatch count = 0
    rxed vrrp priority zero from master count = 0
    transitioned to master state count = 1
    transitioned to backup state count = 1
```

The same statistics are listed for VRRP and VRRPE.

Syntax:  show ip vrrp brief | ethernet [<slotnum>/]<portnum> | ve <num> | statistic

Syntax:  show ip vrrp-extended brief | ethernet [<slotnum>/]<portnum> | ve <num> | stat

The `brief` parameter displays summary information. Refer to “Displaying summary information” on page 1282.

If you specify a port, the `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter specifies an Ethernet port. If you use this parameter, the command displays detailed VRRP or VRRPE information only for the specified port. Refer to “Displaying detailed information” on page 1284.

The `ve <num>` parameter specifies a virtual interface. If you use this parameter, the command displays detailed VRRP or VRRPE information only for the specified virtual interface. Refer to “Displaying detailed information” on page 1284.

The `statistic` parameter displays statistics. This parameter is required for displaying the statistics.

This display shows the following information.

**TABLE 220**  CLI display of VRRP or VRRPE statistics

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface statistics</td>
<td></td>
</tr>
<tr>
<td>Interface</td>
<td>The interface on which VRRP or VRRPE is configured. If VRRP or VRRPE is configured on more than one interface, the display lists the statistics separately for each interface.</td>
</tr>
<tr>
<td>rxed vrrp header error count</td>
<td>The number of VRRP or VRRPE packets received by the interface that had a header error.</td>
</tr>
<tr>
<td>rxed vrrp auth error count</td>
<td>The number of VRRP or VRRPE packets received by the interface that had an authentication error.</td>
</tr>
</tbody>
</table>
Clearing VRRP or VRRPE statistics

Use the following methods to clear VRRP or VRRPE statistics.

To clear VRRP or VRRPE statistics, enter the following command at the Privileged EXEC level or any configuration level of the CLI.

Router1# clear ip vrrp-stat

Syntax: clear ip vrrp-stat

Displaying CPU utilization statistics

You can display CPU utilization statistics for VRRP and other IP protocols.

To display CPU utilization statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI.

TABLE 220  CLI display of VRRP or VRRPE statistics (Continued)

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>rxed vrrp auth passwd mismatch error count</td>
<td>The number of VRRP or VRRPE packets received by the interface that had a password value that does not match the password used by the interface for authentication.</td>
</tr>
<tr>
<td>rxed vrrp vrid not found error count</td>
<td>The number of VRRP or VRRPE packets received by the interface that contained a VRID that is not configured on this interface.</td>
</tr>
<tr>
<td>VRID statistics</td>
<td></td>
</tr>
<tr>
<td>rxed arp packet drop count</td>
<td>The number of ARP packets addressed to the VRID that were dropped.</td>
</tr>
<tr>
<td>rxed ip packet drop count</td>
<td>The number of IP packets addressed to the VRID that were dropped.</td>
</tr>
<tr>
<td>rxed vrrp port mismatch count</td>
<td>The number of packets received that did not match the configuration for the receiving interface.</td>
</tr>
<tr>
<td>rxed vrrp ip address mismatch count</td>
<td>The number of packets received that did not match the configured IP addresses.</td>
</tr>
<tr>
<td>rxed vrrp hello interval mismatch count</td>
<td>The number of packets received that did not match the configured Hello interval.</td>
</tr>
<tr>
<td>rxed vrrp priority zero from master count</td>
<td>The current Master has resigned.</td>
</tr>
<tr>
<td>rxed vrrp higher priority count</td>
<td>The number of VRRP or VRRPE packets received by the interface that had a higher backup priority for the V RID than this Layer 3 Switch backup priority for the V RID.</td>
</tr>
<tr>
<td>transitioned to master state count</td>
<td>The number of times this Layer 3 Switch has changed from the backup state to the master state for the V RID.</td>
</tr>
<tr>
<td>transitioned to backup state count</td>
<td>The number of times this Layer 3 Switch has changed from the master state to the backup state for the V RID.</td>
</tr>
</tbody>
</table>
If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.

```
FastIron# show process cpu
```

</tbody>
</table>

When you specify how many seconds’ worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

**Syntax:** `show process cpu [<num>]`

The `<num>` parameter specifies the number of seconds and can be from 1 – 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.
Configuration examples

The following sections contain the CLI commands for implementing the VRRP and VRRPE configurations shown in Figure 154 on page 1263 and Figure 155 on page 1268.

VRRP example

To implement the VRRP configuration shown in Figure 154 on page 1263, use the following method.

**Configuring Router1**

To configure VRRP Router1, enter the following commands.

```
Router1(config)# router vrrp
Router1(config)# int e 1/6
Router1(config-if-1/6)# ip address 192.53.5.1
Router1(config-if-1/6)# ip vrrp vrid 1
Router1(config-if-1/6-vrid-1)# owner track-priority 20
Router1(config-if-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-1/6-vrid-1)# ip-address 192.53.5.1
Router1(config-if-1/6-vrid-1)# activate
```

**NOTE**

When you configure the Master (Owner), the address you enter with the `ip-address` command must already be configured on the interface.

The `ip vrrp owner` command specifies that this router owns the IP address you are associating with the VRID. Because this router owns the IP address, this router is the default Master router and its VRRP priority is thus 255.

**Configuring Router2**

To configure Router2 in Figure 154 on page 1263 after enabling VRRP, enter the following commands.

```
Router2(config)# router vrrp
Router2(config)# int e 1/5
Router2(config-if-1/5)# ip address 192.53.5.3
Router2(config-if-1/5)# ip vrrp vrid 1
Router2(config-if-1/5-vrid-1)# backup priority 100 track-priority 19
Router2(config-if-1/5-vrid-1)# track-port ethernet 3/2
Router2(config-if-1/5-vrid-1)# ip-address 192.53.5.1
Router2(config-if-1/5-vrid-1)# activate
```

The `backup` command specifies that this router is a VRRP Backup for virtual router VRID1. The IP address entered with the `ip-address` command is the same IP address as the one entered when configuring Router1. In this case, the IP address cannot also exist on Router2, but the interface on which you are configuring the VRID Backup must have an IP address in the same subnet. By entering the same IP address as the one associated with this VRID on the Owner, you are configuring the Backup to back up the address, but you are not duplicating the address.
NOTE
When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

The priority parameter establishes the router VRRP priority in relation to the other VRRP routers in this virtual router. The track-priority parameter specifies the new VRRP priority that the router receives for this VRID if the interface goes down. Refer to “Track ports and track priority” on page 1265.

The activate command activates the VRID configuration on this interface. The interface does not provide backup service for the virtual IP address until you activate the VRRP configuration.

Syntax: router vrrp
Syntax: ip vrrp vrid <vrid>
Syntax: owner [track-priority <value>]
Syntax: backup [priority <value>] [track-priority <value>]
Syntax: track-port ethernet [<slotnum>/<portnum> | ve <num>]
Syntax: ip-address <ip-addr>
Syntax: activate

VRRPE example
To implement the VRRPE configuration shown in Figure 155 on page 1268, use the following CLI method.

Configuring Router1
To configure VRRP Router1 in Figure 155 on page 1268, enter the following commands.

Router1(config)# router vrrp-extended
Router1(config)# interface ethernet 1/6
Router1(config-if-1/6)# ip address 192.53.5.2/24
Router1(config-if-1/6)# ip vrrp-extended vrid 1
Router1(config-if-1/6-vrid-1)# backup priority 110 track-priority 20
Router1(config-if-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-1/6-vrid-1)# ip-address 192.53.5.254
Router1(config-if-1/6-vrid-1)# activate
VRRP router 1 for this interface is activating
Router1(config-if-1/6-vrid-1)# exit
Router1(config)# interface ethernet 1/6
Router1(config-if-1/6)# ip vrrp-extended vrid 2
Router1(config-if-1/6-vrid-1)# backup priority 100 track-priority 20
Router1(config-if-1/6-vrid-1)# track-port ethernet 2/4
Router1(config-if-1/6-vrid-1)# ip-address 192.53.5.253
Router1(config-if-1/6-vrid-1)# activate
VRRP router 2 for this interface is activating

NOTE
The address you enter with the ip-address command cannot be the same as a real IP address configured on the interface.
Configuring Router2

To configure Router2, enter the following commands.

Router1(config)# router vrrp-extended
Router1(config)# interface ethernet 5/1
Router1(config-if-5/1)# ip address 192.53.5.3/24
Router1(config-if-5/1)# ip vrrp-extended vrid 1
Router1(config-if-5/1-vrid-1)# backup priority 100 track-priority 20
Router1(config-if-5/1-vrid-1)# track-port ethernet 3/2
Router1(config-if-5/1-vrid-1)# ip-address 192.53.5.254
Router1(config-if-5/1-vrid-1)# activate

VRRP router 1 for this interface is activating

Router1(config-if-5/1-vrid-1)# exit
Router1(config)# interface ethernet 5/1
Router1(config-if-5/1)# ip vrrp-extended vrid 2
Router1(config-if-5/1-vrid-1)# backup priority 110 track-priority 20
Router1(config-if-5/1-vrid-1)# track-port ethernet 2/4
Router1(config-if-5/1-vrid-1)# ip-address 192.53.5.253
Router1(config-if-5/1-vrid-1)# activate

VRRP router 2 for this interface is activating

The **backup** command specifies that this router is a VRRPE Backup for virtual router VRID1. The IP address entered with the **ip-address** command is the same IP address as the one entered when configuring Router1. In this case, the IP address cannot also exist on Router2, but the interface on which you are configuring the VRID Backup must have an IP address in the same subnet. By entering the same IP address as the one associated with this VRID on the Owner, you are configuring the Backup to back up the address, but you are not duplicating the address.

**NOTE**

When you configure a Backup router, the router interface on which you are configuring the VRID must have a real IP address that is in the same subnet as the address associated with the VRID by the Owner. However, the address cannot be the same.

The **priority** parameter establishes the router VRRPE priority in relation to the other VRRPE routers in this virtual router. The **track-priority** parameter specifies the new VRRPE priority that the router receives for this VRID if the interface goes down. Refer to “Track ports and track priority” on page 1265.

The **activate** command activates the VRID configuration on this interface. The interface does not provide backup service for the virtual IP address until you activate the VRRPE configuration. Alternatively, you can use the **enable** command. The **activate** and **enable** commands do the same thing.

**Syntax:**  
router vrrp-extended  
**Syntax:**  
ip vrrp-extended vrid \(<vrid>\)  
**Syntax:**  
backup [priority \(<value>\)] [track-priority \(<value>\)]  
**Syntax:**  
track-port ethernet [\(<slotnum>\)/]<portnum> | ve \(<num>\)  
**Syntax:**  
ip-address <\<ip-addr>  
**Syntax:**  
activate
This chapter provides details on how to configure Border Gateway Protocol version 4 (BGP4) on Brocade products using the CLI.

BGP4 is described in RFC 1771. The Brocade implementation fully complies with RFC 1771. The Brocade BGP4 implementation also supports the following RFCs:

- RFC 1745 (OSPF Interactions)
- RFC 1997 (BGP Communities Attributes)
- RFC 2385 (TCP MD5 Signature Option)
- RFC 2439 (Route Flap Dampening)
- RFC 2796 (Route Reflection)
- RFC 2842 (Capability Advertisement)
- RFC 3065 (BGP4 Confederations)

To display BGP4 configuration information and statistics, refer to “Displaying BGP4 information” on page 1372.

This chapter shows the commands you need in order to configure the Brocade Layer 3 Switch for BGP4.

**NOTE**
Your Layer 3 Switch management module must have 32MB or higher to run BGP4.

### Overview of BGP4

BGP4 is the standard Exterior Gateway Protocol (EGP) used on the Internet to route traffic between Autonomous Systems (AS) and to maintain loop-free routing. An autonomous system is a collection of networks that share the same routing and administration characteristics. For example, a corporate intranet consisting of several networks under common administrative control might be considered an AS. The networks in an AS can but do not need to run the same routing protocol to be in the same AS, nor do they need to be geographically close.

Routers within an AS can use different Interior Gateway Protocols (IGPs) such as RIP and OSPF to communicate with one another. However, for routers in different ASs to communicate, they need to use an EGP. BGP4 is the standard EGP used by Internet routers and therefore is the EGP implemented on Brocade Layer 3 Switches.
Figure 156 on page 1296 shows a simple example of two BGP4 ASs. Each AS contains three BGP4 switches. All of the BGP4 switches within an AS communicate using IBGP. BGP4 switches communicate with other ASs using EBGP. Notice that each of the switches also is running an Interior Gateway Protocol (IGP). The switches in AS1 are running OSPF and the switches in AS2 are running RIP. Brocade Layer 3 Switches can be configured to redistribute routes among BGP4, RIP, and OSPF. They also can redistribute static routes.

FIGURE 156  Example BGP4 ASs

![Diagram of BGP4 ASs]

**Relationship between the BGP4 route table and the IP route table**

The Brocade Layer 3 Switch BGP4 route table can have multiple routes to the same destination, which are learned from different BGP4 neighbors. A BGP4 neighbor is another switch that also is running BGP4. BGP4 neighbors communicate using Transmission Control Protocol (TCP) port 179 for BGP communication. When you configure the Brocade Layer 3 Switch for BGP4, one of the configuration tasks you perform is to identify the Layer 3 Switch BGP4 neighbors.

Although a Layer 3 Switch BGP4 route table can have multiple routes to the same destination, the BGP4 protocol evaluates the routes and chooses only one of the routes to send to the IP route table. The route that BGP4 chooses and sends to the IP route table is the preferred route and will be used by the Brocade Layer 3 Switch. If the preferred route goes down, BGP4 updates the route information in the IP route table with a new BGP4 preferred route.

**NOTE**

If IP load sharing is enabled and you enable multiple equal-cost paths for BGP4, BGP4 can select more than one equal-cost path to a destination.

A BGP4 route consists of the following information:

- **Network number (prefix)** – A value comprised of the network mask bits and an IP address (\(<IP address>/ <mask bits>\)); for example, 192.215.129.0/18 indicates a network mask of 18 bits applied to the IP address 192.215.129.0. When a BGP4 Layer 3 Switch advertises a route to one of its neighbors, the route is expressed in this format.
• **AS-path** – A list of the other ASs through which a route passes. BGP4 routers can use the AS-path to detect and eliminate routing loops. For example, if a route received by a BGP4 router contains the AS that the router is in, the router does not add the route to its own BGP4 table. (The BGP4 RFCs refer to the AS-path as “AS_PATH”.)

• **Additional path attributes** – A list of additional parameters that describe the route. The route origin and next hop are examples of these additional path attributes.

**NOTE**
The Layer 3 Switch re-advertises a learned best BGP4 route to the Layer 3 Switch neighbors even when the software does not select that route for installation in the IP route table. The best BGP4 route is the route that the software selects based on comparison of the BGP4 route path attributes.

After a Brocade Layer 3 Switch successfully negotiates a BGP4 session with a neighbor (a BGP4 peer), the Brocade Layer 3 Switch exchanges complete BGP4 route tables with the neighbor. After this initial exchange, the Brocade Layer 3 Switch and all other RFC 1771-compliant BGP4 routers send UPDATE messages to inform neighbors of new, changed, or no longer feasible routes. BGP4 routers do not send regular updates. However, if configured to do so, a BGP4 router does regularly send KEEPALIVE messages to its peers to maintain BGP4 sessions with them if the router does not have any route information to send in an UPDATE message. Refer to “BGP4 message types” on page 1298 for information about BGP4 messages.

**How BGP4 selects a path for a route**

When multiple paths for the same route are known to a BGP4 router, the router uses the following algorithm to weigh the paths and determine the optimal path for the route. The optimal path depends on various parameters, which can be modified. (Refer to “Optional configuration tasks” on page 1317.)

1. If the next hop is not accessible though an Interior Gateway Protocol (IGP) route, ignore the route.

**NOTE**
The device does not use the default route to resolve BGP4 next hop. Also refer to “Enabling next-hop recursion” on page 1324.

2. Use the path with the largest weight.

3. If the weights are the same, prefer the route with the largest local preference.

4. If the routes have the same local preference, prefer the route that was originated locally (by this BGP4 Layer 3 Switch).

5. If the local preferences are the same, prefer the route with the shortest AS-path. An AS-SET counts as 1. A confederation path length, if present, is not counted as part of the path length.

6. If the AS-path lengths are the same, prefer the route with the lowest origin type. From low to high, route origin types are valued as follows:
   - IGP is lowest
   - EGP is higher than IGP but lower than INCOMPLETE
   - INCOMPLETE is highest
7. If the routes have the same origin type, prefer the route with the lowest MED. For a definition of MED, refer to “Configuring the Layer 3 Switch to always compare Multi-Exit Discriminators (MEDs)” on page 1329.

BGP4 compares the MEDs of two otherwise equivalent paths if and only if the routes were learned from the same neighboring AS. This behavior is called deterministic MED. Deterministic MED is always enabled and cannot be disabled. In addition, you can enable the Layer 3 Switch to always compare the MEDs, regardless of the AS information in the paths. To enable this comparison, enter the `always-compare-med` command at the BGP4 configuration level of the CLI. This option is disabled by default.

**NOTE**
By default, value 0 (most favorable) is used in MED comparison when the MED attribute is not present. The default MED comparison results in the Layer 3 Switch favoring the route paths that are missing their MEDs. You can use the `med-missing-as-worst` command to make the Layer 3 Switch regard a BGP route with a missing MED attribute as the least favorable route, when comparing the MEDs of the routes.

**NOTE**
MED comparison is not performed for internal routes originated within the local AS or confederation.

8. Prefer routes in the following order:
   - Routes received through EBGP from a BGP4 neighbor outside of the confederation
   - Routes received through EBGP from a BGP4 router within the confederation
   - Routes received through IBGP

9. If all the comparisons above are equal, prefer the route with the lowest IGP metric to the BGP4 next hop. This is the closest internal path inside the AS to reach the destination.

10. If the internal paths also are the same and BGP4 load sharing is enabled, load share among the paths. Otherwise, prefer the route that comes from the BGP4 router with the lowest router ID.

**NOTE**
Brocade Layer 3 Switches support BGP4 load sharing among multiple equal-cost paths. BGP4 load sharing enables the Layer 3 Switch to balance the traffic across the multiple paths instead of choosing just one path based on router ID. For EBGP routes, load sharing applies only when the paths are from neighbors within the same remote AS. EBGP paths from neighbors in different ASs are not compared.

**BGP4 message types**

BGP4 routers communicate with their neighbors (other BGP4 routers) using the following types of messages:

- OPEN
- UPDATE
- KEEPALIVE
- NOTIFICATION
OPEN message

After a BGP4 router establishes a TCP connection with a neighboring BGP4 router, the routers exchange OPEN messages. An OPEN message indicates the following:

- **BGP version** – Indicates the version of the protocol that is in use on the router. BGP version 4 supports Classless Interdomain Routing (CIDR) and is the version most widely used in the Internet. Version 4 also is the only version supported on Brocade Layer 3 Switches.

- **AS number** – A two-byte number that identifies the AS to which the BGP4 router belongs.

- **Hold Time** – The number of seconds a BGP4 router will wait for an UPDATE or KEEPALIVE message (described below) from a BGP4 neighbor before assuming that the neighbor is dead. BGP4 routers exchange UPDATE and KEEPALIVE messages to update route information and maintain communication. If BGP4 neighbors are using different Hold Times, the lowest Hold Time is used by the neighbors. If the Hold Time expires, the BGP4 router closes its TCP connection to the neighbor and clears any information it has learned from the neighbor and cached.

You can configure the Hold Time to be 0, in which case a BGP4 router will consider its neighbors to always be up. For directly-attached neighbors, you can configure the Brocade Layer 3 Switch to immediately close the TCP connection to the neighbor and clear entries learned from an EBGP neighbor if the interface to that neighbor goes down. This capability is provided by the fast external fallover feature, which is disabled by default.

- **BGP Identifier** – The router ID. The BGP Identifier (router ID) identifies the BGP4 router to other BGP4 routers. Brocade Layer 3 Switches use the same router ID for OSPF and BGP4. If you do not set a router ID, the software uses the IP address on the lowest numbered loopback interface configured on the router. If the Layer 3 Switch does not have a loopback interface, the default router ID is the lowest numbered IP address configured on the device. For more information or to change the router ID, refer to “Changing the router ID” on page 1002.

- **Parameter list** – An optional list of additional parameters used in peer negotiation with BGP4 neighbors.

UPDATE message

After BGP4 neighbors establish a BGP4 connection over TCP and exchange their BGP4 routing tables, they do not send periodic routing updates. Instead, a BGP4 neighbor sends an update to its neighbor when it has a new route to advertise or routes have changed or become unfeasible. An UPDATE message can contain the following information:

- **Network Layer Reachability Information (NLRI)** – The mechanism by which BGP4 supports Classless Interdomain Routing (CIDR). An NLRI entry consists of an IP prefix that indicates a network being advertised by the UPDATE message. The prefix consists of an IP network number and the length of the network portion of the number. For example, an UPDATE message with the NLRI entry 192.215.129.0/18 indicates a route to IP network 192.215.129.0 with network mask 255.255.192.0. The binary equivalent of this mask is 18 consecutive one bits, thus “18” in the NLRI entry.

- **Path attributes** – Parameters that indicate route-specific information such as path information, route preference, next hop values, and aggregation information. BGP4 uses the path attributes to make filtering and routing decisions.
Basic configuration and activation for BGP4

BGP4 is disabled by default. Follow the steps given below to enable BGP4 and place your Brocade Layer 3 Switch into service as a BGP4 router.

1. Enable the BGP4 protocol.
2. Set the local AS number.
   
   **NOTE**
   You must specify the local AS number for BGP4 to become functional.

3. Add each BGP4 neighbor (peer BGP4 router) and identify the AS the neighbor is in.
4. Save the BGP4 configuration information to the system configuration file.

---

**Unreachable routes** – A list of routes that have been in the sending router BGP4 table but are no longer feasible. The UPDATE message lists unreachable routes in the same format as new routes.

\(<\text{IP address}\>/\langle\text{CIDR prefix}\rangle>.

**KEEPALIVE message**

BGP4 routers do not regularly exchange UPDATE messages to maintain the BGP4 sessions. For example, if a Layer 3 Switch configured to perform BGP4 routing has already sent the latest route information to its peers in UPDATE messages, the router does not send more UPDATE messages. Instead, BGP4 routers send KEEPALIVE messages to maintain the BGP4 sessions. KEEPALIVE messages are 19 bytes long and consist only of a message header; they contain no routing data.

BGP4 routers send KEEPALIVE messages at a regular interval, the Keep Alive Time. The default Keep Alive Time on Brocade Layer 3 Switches is 60 seconds.

A parameter related to the Keep Alive Time is the Hold Time. A BGP4 router Hold Time determines how many seconds the router will wait for a KEEPALIVE or UPDATE message from a BGP4 neighbor before deciding that the neighbor is dead. The Hold Time is negotiated when BGP4 routers exchange OPEN messages; the lower Hold Time is then used by both neighbors. For example, if BGP4 Router A sends a Hold Time of 5 seconds and BGP4 Router B sends a Hold Time of 4 seconds, both routers use 4 seconds as the Hold Time for their BGP4 session. The default Hold Time is 180 seconds. Generally, the Hold Time is configured to three times the value of the Keep Alive Time.

If the Hold Time is 0, a BGP4 router assumes that its neighbor is alive regardless of how many seconds pass between receipt of UPDATE or KEEPALIVE messages.

**NOTIFICATION message**

When you close the router BGP4 session with a neighbor, or the router detects an error in a message received from the neighbor, or an error occurs on the router, the router sends a NOTIFICATION message to the neighbor. No further communication takes place between the BGP4 router that sent the NOTIFICATION and the neighbors that received the NOTIFICATION.
NOTE
By default, the Brocade router ID is the IP address configured on the lowest numbered loopback interface. If the Layer 3 Switch does not have a loopback interface, the default router ID is the lowest numbered IP interface address configured on the device. For more information or to change the router ID, refer to “Changing the router ID” on page 1002. If you change the router ID, all current BGP4 sessions are cleared.

FastIron># enable
FastIron# configure terminal
FastIron(config)# router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
FastIron(config-bgp-router)# local-as 10
FastIron(config-bgp-router)# neighbor 209.157.23.99 remote-as 100
FastIron(config-bgp-router)# write memory

NOTE
When BGP4 is enabled on a Brocade Layer 3 Switch, you do not need to reset the system. The protocol is activated as soon as you enable it. Moreover, the router begins a BGP4 session with a BGP4 neighbor as soon as you add the neighbor.

Note regarding disabling BGP4
If you disable BGP4, the Layer 3 Switch removes all the running configuration information for the disabled protocol from the running-config. To restore the BGP4 configuration, you must reload the software to load the configuration from the startup-config. Moreover, when you save the configuration to the startup-config file after disabling the protocol, all the configuration information for the disabled protocol is removed from the startup-config file.

The CLI displays a warning message such as the following.

FastIron(config-bgp-router)# no router bgp
router bgp mode now disabled. All bgp config data will be lost when writing to flash!

If you are testing a BGP4 configuration and are likely to disable and re-enable the protocol, you might want to make a backup copy of the startup-config file containing the protocol configuration information. This way, if you remove the configuration information by saving the configuration after disabling the protocol, you can restore the configuration by copying the backup copy of the startup-config file onto the flash memory.

NOTE
To disable BGP4 without losing the BGP4 configuration information, remove the local AS (for example, by entering the no local-as <num> command). In this case, BGP4 retains the other configuration information but is not operational until you set the local AS again.

BGP4 parameters
You can modify or set the following BGP4 parameters:

- Optional – Define the router ID. (The same router ID also is used by OSPF.)
- Required – Specify the local AS number.
- Optional – Add a loopback interface for use with neighbors.
- Required – Identify BGP4 neighbors.
- Optional – Change the Keep Alive Time and Hold Time.
- Optional – Change the update timer for route changes.
- Optional – Enable fast external fallover.
- Optional – Specify a list of individual networks in the local AS to be advertised to remote ASs using BGP4.
- Optional – Change the default local preference for routes.
- Optional – Enable the default route (default-information-originate).
- Optional – Enable use of a default route to resolve a BGP4 next-hop route.
- Optional – Change the default MED (metric).
- Optional – Enable next-hop recursion.
- Optional – Change the default administrative distances for EBGP, IBGP, and locally originated routes.
- Optional – Require the first AS in an Update from an EBGP neighbor to be the neighbor AS.
- Optional – Change MED comparison parameters.
- Optional – Disable comparison of the AS-Path length.
- Optional – Enable comparison of the router ID.
- Optional – Enable auto summary to summarize routes at an IP class boundary (A, B, or C).
- Optional – Aggregate routes in the BGP4 route table into CIDR blocks.
- Optional – Configure the router as a BGP4 router reflector.
- Optional – Configure the Layer 3 Switch as a member of a BGP4 confederation.
- Optional – Change the default metric for routes that BGP4 redistributes into RIP or OSPF.
- Optional – Change the parameters for RIP, OSPF, or static routes redistributed into BGP4.
- Optional – Change the number of paths for BGP4 load sharing.
- Optional – Change other load-sharing parameters
- Optional – Define BGP4 address filters.
- Optional – Define BGP4 AS-path filters.
- Optional – Define BGP4 community filters.
- Optional – Define IP prefix lists.
- Optional – Define neighbor distribute lists.
- Optional – Define BGP4 route maps for filtering routes redistributed into RIP and OSPF.
- Optional – Define route flap dampening parameters.

**NOTE**
When using CLI, you set global level parameters at the BGP CONFIG Level of the CLI. You can reach the BGP CONFIG level by entering `router bgp`... at the global CONFIG level.

**When parameter changes take effect**

Some parameter changes take effect immediately while others do not take full effect until the router sessions with its neighbors are reset. Some parameters do not take effect until the router is rebooted.
Immediately

The following parameter changes take effect immediately:

- Enable or disable BGP.
- Set or change the local AS.
- Add neighbors.
- Change the update timer for route changes.
- Disable or enable fast external fallover.
- Specify individual networks that can be advertised.
- Change the default local preference, default information originate setting, or administrative distance.
- Enable or disable use of a default route to resolve a BGP4 next-hop route.
- Enable or disable MED (metric) comparison.
- Require the first AS in an Update from an EBGP neighbor to be the neighbor AS.
- Change MED comparison parameters.
- Disable comparison of the AS-Path length.
- Enable comparison of the router ID.
- Enable next-hop recursion.
- Enable or disable auto summary.
- Change the default metric.
- Disable or re-enable route reflection.
- Configure confederation parameters.
- Disable or re-enable load sharing.
- Change the maximum number of load-sharing paths.
- Change other load-sharing parameters.
- Define route flap dampening parameters.
- Add, change, or negate redistribution parameters (except changing the default MED; see below).
- Add, change, or negate route maps (when used by the network command or a redistribution command).

After resetting neighbor sessions

The following parameter changes take effect only after the router BGP4 sessions are cleared, or reset using the “soft” clear option. (Refer to “Closing or resetting a neighbor session” on page 1407.)

The parameter are as follows:

- Change the Hold Time or Keep Alive Time.
- Aggregate routes.
- Add, change, or negate filter tables.
After disabling and re-enabling redistribution

The following parameter change takes effect only after you disable and then re-enable redistribution:

- Change the default MED (metric).

Memory considerations

BGP4 handles a very large number of routes and therefore requires a lot of memory. For example, in a typical configuration with just a single BGP4 neighbor, a BGP4 router may need to be able to hold up to 80,000 routes. Many configurations, especially those involving more than one neighbor, can require the router to hold even more routes. Brocade Layer 3 Switches provide dynamic memory allocation for BGP4 data. These devices automatically allocate memory when needed to support BGP4 neighbors, routes, and route attribute entries. Dynamic memory allocation is performed automatically by the software and does not require a reload.

Table 221 lists the maximum total amount of system memory (DRAM) BGP4 can use. The maximum depends on the total amount of system memory on the device.

TABLE 221  Maximum memory usage

<table>
<thead>
<tr>

</tbody>
</table>

The memory amounts listed in the table are for all BGP4 data, including routes received from neighbors, BGP route advertisements (routes sent to neighbors), and BGP route attribute entries. The routes sent to and received from neighbors use the most BGP4 memory. Generally, the actual limit to the number of neighbors, routes, or route attribute entries the device can accommodate depends on how many routes the Layer 3 Switch sends to and receives from the neighbors.

In some cases, where most of the neighbors do not send or receive a full BGP route table (about 80,000 routes), the memory can support a larger number of BGP4 neighbors. However, if most of the BGP4 neighbors send or receive full BGP route tables, the number of BGP neighbors the memory can support is less than in configurations where the neighbors send smaller route tables.

As a guideline, Layer 3 Switches with a 512 MB Management 4 module can accommodate 150 – 200 neighbors, with the assumption that the Layer 3 Switch receives about one million routes total from all neighbors and sends about eight million routes total to neighbors. For each additional one million incoming routes, the capacity for outgoing routes decreases by around two million.

Memory configuration options obsoleted by dynamic memory

Devices that support dynamic BGP4 memory allocation do not require or even support static configuration of memory for BGP4 neighbors, routes, or route attributes. Consequently, the following CLI commands and equivalent Web management options are not supported on these devices:

- max-neighbors <num>
Basic configuration tasks

The following sections describe how to perform the configuration tasks that are required to use BGP4 on the Brocade Layer 3 Switch. You can modify many parameters in addition to the ones described in this section. Refer to “Optional configuration tasks” on page 1317.

Enabling BGP4 on the router

When you enable BGP4 on the router, BGP4 is automatically activated. To enable BGP4 on the router, enter the following commands.

```plaintext
FastIron> enable
FastIron# configure terminal
FastIron(config)# router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
FastIron(config-bgp-router)# local-as 10
FastIron(config-bgp-router)# neighbor 209.157.23.99 remote-as 100
FastIron(config-bgp-router)# write memory
```

Changing the router ID

The OSPF and BGP4 protocols use router IDs to identify the routers that are running the protocols. A router ID is a valid, unique IP address and sometimes is an IP address configured on the router. The router ID cannot be an IP address in use by another device.

By default, the router ID on a Brocade Layer 3 Switch is one of the following:

- If the router has loopback interfaces, the default router ID is the IP address configured on the lowest numbered loopback interface configured on the Layer 3 Switch. For example, if you configure loopback interfaces 1, 2, and 3 as follows, the default router ID is 9.9.9.9/24:
  - Loopback interface 1, 9.9.9.9/24
  - Loopback interface 2, 4.4.4.4/24
  - Loopback interface 3, 1.1.1.1/24
- If the device does not have any loopback interfaces, the default router ID is the lowest numbered IP interface address configured on the device.

**NOTE**
Brocade Layer 3 Switches use the same router ID for both OSPF and BGP4. If the router is already configured for OSPF, you may want to use the router ID that is already in use on the router rather than set a new one. To display the router ID, enter the `show ip` CLI command at any CLI level.

To change the router ID, enter a command such as the following.

```plaintext
FastIron(config)# ip router-id 209.157.22.26
```
Syntax:  \texttt{ip router-id <ip-addr>}

The \texttt{<ip-addr>} can be any valid, unique IP address.

\textbf{NOTE}

You can specify an IP address used for an interface on the Brocade Layer 3 Switch, but do not specify an IP address in use by another device.

\section*{Setting the local AS number}

The local AS number identifies the AS the Brocade BGP4 router is in. The AS number can be from 1 – 65535. There is no default. AS numbers 64512 – 65535 are the well-known private BGP4 AS numbers and are not advertised to the Internet community.

To set the local AS number, enter commands such as the following.

\begin{verbatim}
FastIron(config)# router bgp
BGP4: Please configure 'local-as' parameter in order to enable BGP4.
FastIron(config-bgp-router)# local-as 10
FastIron(config-bgp-router)# write memory
\end{verbatim}

Syntax:  \texttt{[no] local-as <num>}

The \texttt{<num>} parameter specifies the local AS number.

\section*{Adding a loopback interface}

You can configure the router to use a loopback interface instead of a specific port or virtual routing interface to communicate with a BGP4 neighbor. A loopback interface adds stability to the network by working around route flap problems that can occur due to unstable links between the router and its neighbors.

Loopback interfaces are always up, regardless of the states of physical interfaces. Loopback interfaces are especially useful for IBGP neighbors (neighbors in the same AS) that are multiple hops away from the router. When you configure a BGP4 neighbor on the router, you can specify whether the router uses the loopback interface to communicate with the neighbor. As long as a path exists between the router and its neighbor, BGP4 information can be exchanged. The BGP4 session is not associated with a specific link but instead is associated with the virtual interfaces.

You can add up to 24 IP addresses to each loopback interface.

\textbf{NOTE}

If you configure the Brocade Layer 3 Switch to use a loopback interface to communicate with a BGP4 neighbor, the peer IP address on the remote router pointing to your loopback address must be configured.

To add a loopback interface, enter commands such as those shown in the following example.

\begin{verbatim}
FastIron(config-bgp-router)# exit
FastIron(config)# int loopback 1
FastIron(config-lbif-1)# ip address 10.0.0.1/24
\end{verbatim}

Syntax:  \texttt{interface loopback <num>}

The \texttt{<num>} value can be from 1 – 8 on Chassis Layer 3 Switches. The value can be from 1 – 4 on the Compact Layer 3 Switch.
Adding BGP4 neighbors

The BGP4 protocol does not contain a peer discovery process. Therefore, for each of the router BGP4 neighbors (peers), you must indicate the neighbor IP address and the AS each neighbor is in. Neighbors that are in different ASs communicate using EBGP. Neighbors within the same AS communicate using IBGP.

**NOTE**
If the Layer 3 Switch has multiple neighbors with similar attributes, you can simplify configuration by configuring a peer group, then adding individual neighbors to it. The configuration steps are similar, except you specify a peer group name instead of a neighbor IP address when configuring the neighbor parameters, then add individual neighbors to the peer group. Refer to “Adding a BGP4 peer group” on page 1313.

**NOTE**
The Layer 3 Switch attempts to establish a BGP4 session with a neighbor as soon as you enter a command specifying the neighbor IP address. If you want to completely configure the neighbor parameters before the Layer 3 Switch establishes a session with the neighbor, you can administratively shut down the neighbor. Refer to “Administratively shutting down a session with a BGP4 neighbor” on page 1316.

To add a BGP4 neighbor with IP address 209.157.22.26, enter the following command.

```
FastIron(config-bgp-router)# neighbor 209.157.22.26
```

The neighbor `<ip-addr>` must be a valid IP address.

The `neighbor` command has some additional parameters, as shown in the following syntax:

**Syntax:**
```
[no] neighbor <ip-addr> | <peer-group-name>
  [advertisement-interval <num>]
  [capability orf prefix [send | receive]]
  [default-originate [route-map <map-name>]]
  [description <string>]
  [distribute-list in | out <num,num,...> | <ACL-num> in | out]
  [ebgp-multihop <num>]
  [filter-list in | out <num,num,...> | <ACL-num> in | out | weight]
  [maximum-prefix <num> [threshold] [teardown]]
  [next-hop-self]
  [nlri multicast | unicast | multicast unicast]
  [password [0 | 1] <string>]
  [prefix-list <string> in | out]
  [remote-as <as-number>]
  [remove-private-as]
  [route-map in | out <map-name>]
  [route-reflector-client]
  [send-community]
  [soft-reconfiguration inbound]
  [shutdown]
  [timers keep-alive <num> hold-time <num>]
  [unsuppress-map <map-name>]
  [update-source <ip-addr> | ethernet [slotnum/]<portnum> | loopback <num> | ve <num>]
  [weight <num>]
```
The `<ip-addr> | <peer-group-name>` parameter indicates whether you are configuring an individual neighbor or a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. If you specify a peer group name, you are configuring a peer group. Refer to “Adding a BGP4 peer group” on page 1313.

`advertisement-interval <num>` specifies the minimum delay (in seconds) between messages to the specified neighbor. The default is 30 for EBGP neighbors (neighbors in other ASs). The default is 5 for IBGP neighbors (neighbors in the same AS). The range is 0 – 600.

**NOTE**
The Layer 3 Switch applies the advertisement interval only under certain conditions. The Layer 3 Switch does not apply the advertisement interval when sending initial updates to a BGP4 neighbor. As a result, the Layer 3 Switch sends the updates one immediately after another, without waiting for the advertisement interval.

`capability orf prefixlist [send | receive]` configures cooperative router filtering. The `send | receive` parameter specifies the support you are enabling:
- **send** – The Layer 3 Switch sends the IP prefix lists as Outbound Route Filters (ORFs) to the neighbor.
- **receive** – The Layer 3 Switch accepts filters as Outbound Route Filters (ORFs) from the neighbor.

If you do not specify the capability, both capabilities are enabled. The `prefixlist` parameter specifies the type of filter you want to send to the neighbor.

For more information, refer to “Configuring cooperative BGP4 route filtering” on page 1362.

**NOTE**
The current release supports cooperative filtering only for filters configured using IP prefix lists.

`default-originate [route-map <map-name>]` configures the Layer 3 Switch to send the default route 0.0.0.0 to the neighbor. If you use the route-map `<map-name>` parameter, the route map injects the default route conditionally, based on the match conditions in the route map.

`description <string>` specifies a name for the neighbor. You can enter an alphanumeric text string up to 80 characters long.

`distribute-list in | out <num,num,...>` specifies a distribute list to be applied to updates to or from the specified neighbor. The `in | out` keyword specifies whether the list is applied on updates received from the neighbor or sent to the neighbor. The `<num,num,...>` parameter specifies the list of address-list filters. The router applies the filters in the order in which you list them and stops applying the filters in the distribute list when a match is found.

Alternatively, you can specify `distribute-list <ACL-num> in | out` to use an IP ACL instead of a distribute list. In this case, `<ACL-num>` is an IP ACL.

**NOTE**
By default, if a route does not match any of the filters, the Layer 3 Switch denies the route. To change the default behavior, configure the last filter as “permit any any”.

**NOTE**
The address filter must already be configured. Refer to “Filtering specific IP addresses” on page 1345.
ebgp-multihop [<num>] specifies that the neighbor is more than one hop away and that the session type with the neighbor is thus EBGP-multihop. This option is disabled by default. The <num> parameter specifies the TTL you are adding for the neighbor. You can specify a number from 0 – 255. The default is 0. If you leave the EBGP TTL value set to 0, the software uses the IP TTL value.

filter-list in | out <num,num,...> specifies an AS-path filter list or a list of AS-path ACLs. The in | out keyword specifies whether the list is applied on updates received from the neighbor or sent to the neighbor. If you specify in or out, The <num,num,...> parameter specifies the list of AS-path filters. The router applies the filters in the order in which you list them and stops applying the filters in the AS-path filter list when a match is found. The weight <num> parameter specifies a weight that the Layer 3 Switch applies to routes received from the neighbor that match the AS-path filter or ACL. You can specify a number from 0 – 65535.

Alternatively, you can specify filter-list <ACL-num> in | out | weight to use an AS-path ACL instead of an AS-path filter list. In this case, <ACL-num> is an AS-path ACL.

NOTE
By default, if an AS-path does not match any of the filters or ACLs, the Layer 3 Switch denies the route. To change the default behavior, configure the last filter or ACL as “permit any any”.

NOTE
The AS-path filter or ACL must already be configured. Refer to “Filtering AS-paths” on page 1346.

maximum-prefix <num> specifies the maximum number of IP network prefixes (routes) that can be learned from the specified neighbor or peer group. You can specify a value from 0 – 4294967295. The default is 0 (unlimited):

- The <num> parameter specifies the maximum number. You can specify a value from 0 – 4294967295. The default is 0 (unlimited).
- The <threshold> parameter specifies the percentage of the value you specified for the maximum-prefix <num>, at which you want the software to generate a Syslog message. You can specify a value from 1 (one percent) to 100 (100 percent). The default is 100.
- The teardown parameter tears down the neighbor session if the maximum-prefix limit is exceeded. The session remains shutdown until you clear the prefixes using the clear ip bgp neighbor all or clear ip bgp neighbor <ip-addr> command, or change the neighbor maximum-prefix configuration. The software also generates a Syslog message.

next-hop-self specifies that the router should list itself as the next hop in updates sent to the specified neighbor. This option is disabled by default.

The nlri multicast | unicast | multicast unicast parameter specifies whether the neighbor is a multicast neighbor or a unicast neighbor. Optionally, you also can specify unicast if you want the Layer 3 Switch to exchange unicast (BGP4) routes as well as multicast routes with the neighbor. The default is unicast only.

password [0 | 1] <string> specifies an MD5 password for securing sessions between the Layer 3 Switch and the neighbor. You can enter a string up to 80 characters long. The string can contain any alphanumeric characters, but the first character cannot be a number. If the password contains a number, do not enter a space following the number.

The 0 | 1 parameter is the encryption option, which you can omit (the default) or which can be one of the following:
Basic configuration tasks

- **0** – Disables encryption for the authentication string you specify with the command. The password or string is shown as clear text in the output of commands that display neighbor or peer group configuration information.
- **1** – Assumes that the authentication string you enter is the encrypted form, and decrypts the value before using it.

For more information, refer to “Encryption of BGP MD5 authentication keys” on page 1311.

**NOTE**

If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter 0 or 1. Instead, omit the encryption option and allow the software to use the default behavior.

If you specify encryption option 1, the software assumes that you are entering the encrypted form of the password or authentication string. In this case, the software decrypts the password or string you enter before using the value for authentication. If you accidentally enter option 1 followed by the clear-text version of the password or string, authentication will fail because the value used by the software will not match the value you intended to use.

**prefix-list <string> in | out** specifies an IP prefix list. You can use IP prefix lists to control routes to and from the neighbor. IP prefix lists are an alternative method to AS-path filters. The **in | out** keyword specifies whether the list is applied on updates received from the neighbor or sent to the neighbor. You can configure up to 1000 prefix list filters. The filters can use the same prefix list or different prefix lists. To configure an IP prefix list, refer to “Defining IP prefix lists” on page 1352.

**remote-as <as-number>** specifies the AS the remote neighbor is in. The **<as-number>** can be a number from 1 – 65535. There is no default.

**remove-private-as** configures the router to remove private AS numbers from UPDATE messages the router sends to this neighbor. The router will remove AS numbers 64512 – 65535 (the well-known BGP4 private AS numbers) from the AS-path attribute in UPDATE messages the Layer 3 Switch sends to the neighbor. This option is disabled by default.

**route-map in | out <map-name>** specifies a route map the Layer 3 Switch will apply to updates sent to or received from the specified neighbor. The **in | out** keyword specifies whether the list is applied on updates received from the neighbor or sent to the neighbor.

**NOTE**

The route map must already be configured. Refer to “Defining route maps” on page 1353.

**route-reflector-client** specifies that this neighbor is a route-reflector client of the router. Use the parameter only if this router is going to be a route reflector. For information, refer to “Configuring route reflection parameters” on page 1330. This option is disabled by default.

**send-community** enables sending the community attribute in updates to the specified neighbor. By default, the router does not send the community attribute.

**shutdown** administratively shuts down the session with this neighbor. Shutting down the session allows you to completely configure the neighbor and save the configuration without actually establishing a session with the neighbor. This option is disabled by default.

**soft-reconfiguration inbound** enables the soft reconfiguration feature, which stores all the route updates received from the neighbor. If you request a soft reset of inbound routes, the software performs the reset by comparing the policies against the stored route updates, instead of requesting the neighbor BGP4 route table or resetting the session with the neighbor. Refer to “Using soft reconfiguration” on page 1401.
Basic configuration tasks

**timers keep-alive** `<num>`  **hold-time** `<num>` overrides the global settings for the Keep Alive Time and Hold Time. For the Keep Alive Time, you can specify from 0 – 65535 seconds. For the Hold Time, you can specify 0 or 3 – 65535 (1 and 2 are not allowed). If you set the Hold Time to 0, the router waits indefinitely for messages from a neighbor without concluding that the neighbor is dead. The defaults for these parameters are the currently configured global Keep Alive Time and Hold Time. For more information about these parameters, refer to “Changing the Keep Alive Time and Hold Time” on page 1317.

**unsuppress-map** `<map-name>` removes route dampening from a neighbor routes when those routes have been dampened due to aggregation. Refer to “Removing route dampening from a neighbor routes suppressed due to aggregation” on page 1369.

**update-source** `<ip-addr>` | **ethernet** `<slotnum>/`<portnum>` | **loopback** `<num>` | **ve** `<num>` configures the router to communicate with the neighbor through the specified interface. There is no default.

**weight** `<num>` specifies a weight the Layer 3 Switch will add to routes received from the specified neighbor. BGP4 prefers larger weights over smaller weights. The default weight is 0.

**Encryption of BGP4 MD5 authentication keys**

When you configure a BGP4 neighbor or neighbor peer group, you can specify an MD5 authentication string for authenticating packets exchanged with the neighbor or peer group of neighbors.

For added security, the software encrypts display of the authentication string by default. The software also provides an optional parameter to disable encryption of the authentication string, on an individual neighbor or peer group basis. By default, the MD5 authentication strings are displayed in encrypted format in the output of the following commands:

- show running-config (or write terminal)
- show configuration
- show ip bgp config

When encryption of the authentication string is enabled, the string is encrypted in the CLI regardless of the access level you are using.

If you display the running-config after reloading, the BGP4 commands that specify an authentication string show the string in encrypted form.

In addition, when you save the configuration to the startup-config file, the file contains the new BGP4 command syntax and encrypted passwords or strings.

**NOTE**

Brocade recommends that you save a copy of the startup-config file for each switch you plan to upgrade.

**Encryption example**

The following commands configure a BGP4 neighbor and a peer group, and specify MD5 authentication strings (passwords) for authenticating packets exchanged with the neighbor or peer group.
Here is how the commands appear when you display the BGP4 configuration commands.

```
FastIron(config-bgp-router)# local-as 2
FastIron(config-bgp-router)# neighbor xyz peer-group
FastIron(config-bgp-router)# neighbor xyz password abc
FastIron(config-bgp-router)# neighbor 10.10.200.102 peer-group xyz
FastIron(config-bgp-router)# neighbor 10.10.200.102 password test
```

Notice that the software has converted the commands that specify an authentication string into the new syntax (described below), and has encrypted display of the authentication strings.

**Command syntax**

Since the default behavior does not affect the BGP4 configuration itself but does encrypt display of the authentication string, the CLI does not list the encryption options.

**Syntax:** `[no] neighbor <ip-addr> | <peer-group-name> password [0 | 1] <string>

The `<ip-addr> | <peer-group-name>` parameter indicates whether you are configuring an individual neighbor or a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. If you specify a peer group name, you are configuring a peer group.

The `password <string>` parameter specifies an MD5 authentication string for securing sessions between the Layer 3 Switch and the neighbor. You can enter a string up to 80 characters long. The string can contain any alphanumeric characters, but the first character cannot be a number. If the password contains a number, do not enter a space following the number.

The `0 | 1` parameter is the encryption option, which you can omit (the default) or which can be one of the following:

- **0** – Disables encryption for the authentication string you specify with the command. The password or string is shown as clear text in the output of commands that display neighbor or peer group configuration information.
- **1** – Assumes that the authentication string you enter is the encrypted form, and decrypts the value before using it.

**NOTE**

If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter 0 or 1. Instead, omit the encryption option and allow the software to use the default behavior.

If you specify encryption option 1, the software assumes that you are entering the encrypted form of the password or authentication string. In this case, the software decrypts the password or string you enter before using the value for authentication. If you accidentally enter option 1 followed by the clear-text version of the password or string, authentication will fail because the value used by the software will not match the value you intended to use.
Displaying the Authentication String
If you want to display the authentication string, enter the following commands.

```
FastIron(config)# enable password-display
FastIron# show ip bgp neighbors
```

The `enable password-display` command enables display of the authentication string, but only in the output of the `show ip bgp neighbors` command. Display of the string is still encrypted in the startup-config file and running-config. Enter the command at the global CONFIG level of the CLI.

**NOTE**
The command also displays SNMP community strings in clear text, in the output of the `show snmp server` command.

Adding a BGP4 peer group
A peer group is a set of BGP4 neighbors that share common parameters. Peer groups provide the following benefits:

- **Simplified neighbor configuration** – You can configure a set of neighbor parameters and then apply them to multiple neighbors. You do not need to individually configure the common parameters individually on each neighbor.
- **Flash memory conservation** – Using peer groups instead of individually configuring all the parameters for each neighbor requires fewer configuration commands in the startup-config file.

You can perform the following tasks on a peer-group basis:

- Reset neighbor sessions
- Perform soft-outbound resets (the Layer 3 Switch updates outgoing route information to neighbors but does not entirely reset the sessions with those neighbors)
- Clear BGP message statistics
- Clear error buffers

**Peer group parameters**
You can set all neighbor parameters in a peer group. When you add a neighbor to the peer group, the neighbor receives all the parameter settings you set in the group, except parameter values you have explicitly configured for the neighbor. If you do not set a neighbor parameter in the peer group and the parameter also is not set for the individual neighbor, the neighbor uses the default value.

**Configuration rules**
The following rules apply to peer group configuration:

- You must configure a peer group before you can add neighbors to the peer group.
- If you remove a parameter from a peer group, the value for that parameter is reset to the default for all the neighbors within the peer group, unless you have explicitly set that parameter on individual neighbors. In this case, the value you set on the individual neighbors applies to those neighbors, while the default value applies to neighbors for which you have not explicitly set the value.
NOTE
If you enter a command to remove the remote AS parameter from a peer group, the software checks to ensure that the peer group does not contain any neighbors. If the peer group does contain neighbors, the software does not allow you to remove the remote AS. The software prevents removing the remote AS in this case so that the neighbors in the peer group that are using the remote AS do not lose connectivity to the Layer 3 Switch.

• Once you add a neighbor to a peer group, you cannot configure the following outbound parameters (the parameters governing outbound traffic) for the neighbor:
  • Default-information-originate
  • Next-hop-self
  • Outbound route map
  • Outbound filter list
  • Outbound distribute list
  • Outbound prefix list
  • Remote AS, if configured for the peer group
  • Remove private AS
  • Route reflector client
  • Send community
  • Timers
  • Update source

If you want to change an outbound parameter for an individual neighbor, you must first remove the neighbor from the peer group. In this case, you cannot re-add the neighbor to the same peer group, but you can add the neighbor to a different peer group. All the neighbors within a peer group must have the same values for the outbound parameters. To change an outbound parameter to the same value for all neighbors within a peer group, you can change the parameter on a peer-group basis. In this case, you do not need to remove the neighbors and change the parameter individually for each neighbor.

• If you add an outbound parameter to a peer group, that parameter is automatically applied to all neighbors within the peer group.

• When you add a neighbor to a peer group, the software removes any outbound parameters for that neighbor from the running configuration (running-config). As a result, when you save the configuration to the startup-config file, the file does not contain any outbound parameters for the individual neighbors you have placed in a peer group. The only outbound parameters the startup-config file contains for neighbors within a peer group are the parameters associated with the peer group itself. However, the running-config and the startup-config file can contain individual parameters listed in the previous section as well as the settings for those parameters within a peer group.

You can override neighbor parameters that do not affect outbound policy on an individual neighbor basis.

• If you do not specify a parameter for an individual neighbor, the neighbor uses the value in the peer group.
• If you set the parameter for the individual neighbor, that value overrides the value you set in the peer group.
Basic configuration tasks

- If you add a parameter to a peer group that already contains neighbors, the parameter value is applied to neighbors that do not already have the parameter explicitly set. If a neighbor has the parameter explicitly set, the explicitly set value overrides the value you set for the peer group.
- If you remove the setting for a parameter from a peer group, the value for that parameter changes to the default value for all the neighbors in the peer group that do not have that parameter individually set.

**Configuring a peer group**

To configure a BGP4 peer group, enter commands such as the following at the BGP configuration level.

```
FastIron(config-bgp-router)# neighbor PeerGroup1 peer-group
FastIron(config-bgp-router)# neighbor PeerGroup1 description "EastCoast Neighbors"
FastIron(config-bgp-router)# neighbor PeerGroup1 remote-as 100
FastIron(config-bgp-router)# neighbor PeerGroup1 distribute-list out 1
```

The commands in this example configure a peer group called “PeerGroup1” and set the following parameters for the peer group:

- A description, “EastCoast Neighbors”
- A remote AS number, 100
- A distribute list for outbound traffic

The software applies these parameters to each neighbor you add to the peer group. You can override the description parameter for individual neighbors. If you set the description parameter for an individual neighbor, the description overrides the description configured for the peer group. However, you cannot override the remote AS and distribute list parameters for individual neighbors. Since these parameters control outbound traffic, the parameters must have the same values for all neighbors within the peer group.

**Syntax:** `neighbor <peer-group-name> peer-group`

The `<peer-group-name>` parameter specifies the name of the group and can be up to 80 characters long. The name can contain special characters and internal blanks. If you use internal blanks, you must use quotation marks around the name. For example, the command `neighbor "My Three Peers" peer-group` is valid, but the command `neighbor My Three Peers peer-group` is not valid.

**Syntax:**

```
[no] neighbor <ip-addr> | <peer-group-name>
 [advertisement-interval <num>]
 [default-originate [route-map <map-name>]]
 [description <string>]
 [distribute-list in | out <num,num,...> | <ACL-num> in | out]
 [ebgp-multihop [ <num>]]
 [filter-list in | out <num,num,...> | <ACL-num> in | out | weight]
 [maximum-prefix <num> [<threshold>] [teardown]]
 [next-hop-self]
 [password [0 | 1] <string>]
 [prefix-list <string> in | out]
 [remote-as <as-number>]
 [remove-private-as]
 [route-map in | out <map-name>]
 [route-reflector-client]
```
Basic configuration tasks

Basic configuration tasks

• [send-community]
• [soft-reconfiguration inbound]
• [shutdown]
• [timers keep-alive <num> hold-time <num>]
• [update-source loopback <num>]
• [weight <num>]

The <ip-addr> | <peer-group-name> parameter indicates whether you are configuring a peer group or an individual neighbor. You can specify a peer group name or IP address with the neighbor command. If you specify a peer group name, you are configuring a peer group. If you specify a neighbor IP address, you are configuring that individual neighbor. Use the <ip-addr> parameter if you are configuring an individual neighbor instead of a peer group. Refer to “Adding BGP4 neighbors” on page 1307.

The remaining parameters are the same ones supported for individual neighbors. Refer to “Adding BGP4 neighbors” on page 1307.

Applying a peer group to a neighbor

After you configure a peer group, you can add neighbors to the group. When you add a neighbor to a peer group, you are applying all the neighbor attributes specified in the peer group to the neighbor.

To add neighbors to a peer group, enter commands such as the following.

FastIron(config-bgp-router)# neighbor 192.168.1.12 peer-group PeerGroup1
FastIron(config-bgp-router)# neighbor 192.168.2.45 peer-group PeerGroup1
FastIron(config-bgp-router)# neighbor 192.168.3.69 peer-group PeerGroup1

The commands in this example add three neighbors to the peer group “PeerGroup1”. As members of the peer group, the neighbors automatically receive the neighbor parameter values configured for the peer group. You also can override the parameters (except parameters that govern outbound traffic) on an individual neighbor basis. For neighbor parameters not specified for the peer group, the neighbors use the default values.

Syntax: neighbor <ip-addr> peer-group <peer-group-name>

The <ip-addr> parameter specifies the IP address of the neighbor.

The <peer-group-name> parameter specifies the peer group name.

NOTE
You must add the peer group before you can add neighbors to it.

Administratively shutting down a session with a BGP4 neighbor

You can prevent the Layer 3 Switch from starting a BGP4 session with a neighbor by administratively shutting down the neighbor. This option is very useful for situations in which you want to configure parameters for a neighbor but are not ready to use the neighbor. You can shut the neighbor down as soon as you have added it the Layer 3 Switch, configure the neighbor parameters, then allow the Layer 3 Switch to re-establish a session with the neighbor by removing the shutdown option from the neighbor.

When you apply the new option to shut down a neighbor, the option takes place immediately and remains in effect until you remove the option. If you save the configuration to the startup-config file, the shutdown option remains in effect even after a software reload.
NOTE
The software also contains an option to end the session with a BGP4 neighbor and thus clear the routes learned from the neighbor. Unlike this clear option, the option for shutting down the neighbor can be saved in the startup-config file and thus can prevent the Layer 3 Switch from establishing a BGP4 session with the neighbor even after reloading the software.

NOTE
If you notice that a particular BGP4 neighbor never establishes a session with the Brocade Layer 3 Switch, check the Layer 3 Switch running-config and startup-config files to see whether the configuration contains a command that is shutting down the neighbor. The neighbor may have been shut down previously by an administrator.

To shut down a BGP4 neighbor, enter commands such as the following.

FastIron(config)# router bgp
FastIron(config-bgp-router)# neighbor 209.157.22.26 shutdown
FastIron(config-bgp-router)# write memory

Syntax: [no] neighbor <ip-addr> shutdown

The <ip-addr> parameter specifies the IP address of the neighbor.

Optional configuration tasks

The following sections describe how to perform optional BGP4 configuration tasks.

Changing the Keep Alive Time and Hold Time

The Keep Alive Time specifies how frequently the router will send KEEPALIVE messages to its BGP4 neighbors. The Hold Time specifies how long the router will wait for a KEEPALIVE or UPDATE message from a neighbor before concluding that the neighbor is dead. When the router concludes that a BGP4 neighbor is dead, the router ends the BGP4 session and closes the TCP connection to the neighbor.

The default Keep Alive time is 60 seconds. The default Hold Time is 180 seconds. To change the timers, use either of the following methods.

NOTE
Generally, you should set the Hold Time to three times the value of the Keep Alive Time.

NOTE
You can override the global Keep Alive Time and Hold Time on individual neighbors. Refer to “Adding BGP4 neighbors” on page 1307.

To change the Keep Alive Time to 30 and Hold Time to 90, enter the following command.

FastIron(config-bgp-router)# timers keep-alive 30 hold-time 90

Syntax: timers keep-alive <num> hold-time <num>
Optional configuration tasks

For each keyword, <num> indicates the number of seconds. The Keep Alive Time can be 0 – 65535. The Hold Time can be 0 or 3 – 65535 (1 and 2 are not allowed). If you set the Hold Time to 0, the router waits indefinitely for messages from a neighbor without concluding that the neighbor is dead.

Changing the BGP4 next-hop update timer

By default, the Layer 3 Switch updates its BGP4 next-hop tables and affected BGP4 routes five seconds after IGP route changes. You can change the update timer to a value from 1 – 30 seconds.

To change the BGP4 update timer value, enter a command such as the following at the BGP configuration level of the CLI.

FastIron(config-bgp-router)# update-time 15

This command changes the update timer to 15 seconds.

Syntax: [no] update-time <secs>

The <secs> parameter specifies the number of seconds and can be from 1 – 30. The default is 5.

Enabling fast external fallover

BGP4 routers rely on KEEPALIVE and UPDATE messages from neighbors to signify that the neighbors are alive. For BGP4 neighbors that are two or more hops away, such messages are the only indication that the BGP4 protocol has concerning the alive state of the neighbors. As a result, if a neighbor dies, the router will wait until the Hold Time expires before concluding that the neighbor is dead and closing its BGP4 session and TCP connection with the neighbor.

The router waits for the Hold Time to expire before ending the connection to a directly-attached BGP4 neighbor that dies.

For directly attached neighbors, the router immediately senses loss of a connection to the neighbor from a change of state of the port or interface that connects the router to its neighbor. For directly attached EBGP neighbors, the router can use this information to immediately close the BGP4 session and TCP connection to locally attached neighbors that die.

NOTE

The fast external fallover feature applies only to directly attached EBGP neighbors. The feature does not apply to IBGP neighbors.

If you want to enable the router to immediately close the BGP4 session and TCP connection to locally attached neighbors that die, use either of the following methods.

To enable fast external fallover, enter the following command.

FastIron(config-bgp-router)# fast-external-fallover

To disable fast external fallover again, enter the following command.

FastIron(config-bgp-router)# no fast-external-fallover

Syntax: [no] fast-external-fallover
Changing the maximum number of paths for BGP4 load sharing

Load sharing enables the Layer 3 Switch to balance traffic to a route across multiple equal-cost paths of the same type (EBGP or IBGP) for the route.

To configure the Layer 3 Switch to perform BGP4 load sharing:

- Enable IP load sharing if it is disabled.
- Set the maximum number of paths. The default maximum number of BGP4 load sharing paths is 1, which means no BGP4 load sharing takes place by default.

NOTE
The maximum number of BGP4 load sharing paths cannot be greater than the maximum number of IP load sharing paths.

How load sharing affects route selection

During evaluation of multiple paths to select the best path to a given destination for installment in the IP route table, the last comparison the Layer 3 Switch performs is a comparison of the internal paths:

- When IP load sharing is disabled, the Layer 3 Switch prefers the path to the router with the lower router ID.
- When IP load sharing and BGP4 load sharing are enabled, the Layer 3 Switch balances the traffic across the multiple paths instead of choosing just one path based on router ID.

Refer to “How BGP4 selects a path for a route” on page 1297 for a description of the BGP4 algorithm.

When you enable IP load sharing, the Layer 3 Switch can load balance BGP4 or OSPF routes across up to four equal paths by default. You can change the number of IP load sharing paths to a value from 2 – 6.

How load sharing works

Load sharing is performed in round-robin fashion and is based on the destination IP address only. The first time the router receives a packet destined for a specific IP address, the router uses a round-robin algorithm to select the path that was not used for the last newly learned destination IP address. Once the router associates a path with a particular destination IP address, the router will always use that path as long as the router contains the destination IP address in its cache.

NOTE
The Layer 3 Switch does not perform source routing. The router is concerned only with the paths to the next-hop routers, not the entire paths to the destination hosts.

A BGP4 destination can be learned from multiple BGP4 neighbors, leading to multiple BGP4 paths to reach the same destination. Each of the paths may be reachable through multiple IGP paths (multiple OSPF or RIP paths). In this case, the software installs all the multiple equal-cost paths in the BGP4 route table, up to the maximum number of BGP4 equal-cost paths allowed. The IP load sharing feature then distributes traffic across the equal-cost paths to the destination.
If an IGP path used by a BGP4 next-hop route path installed in the IP route table changes, then the BGP4 paths and IP paths are adjusted accordingly. For example, if one of the OSPF paths to reach the BGP4 next hop goes down, the software removes this path from the BGP4 route table and the IP route table. Similarly, if an additional OSPF path becomes available to reach the BGP4 next-hop router for a particular destination, the software adds the additional path to the BGP4 route table and the IP route table.

**Changing the maximum number of shared BGP4 paths**

When IP load sharing is enabled, BGP4 can balance traffic to a specific destination across up to four equal paths. You can set the maximum number of paths to a value from 1 – 4. The default is 1.

**NOTE**

The maximum number of BGP4 load sharing paths cannot be greater than the maximum number of IP load sharing paths. To increase the maximum number of IP load sharing paths, use the `ip load-sharing <num>` command at the global CONFIG level of the CLI.

To change the maximum number of shared paths, enter commands such as the following.

```
FastIron(config)# router bgp
FastIron(config-bgp-router)# maximum-paths 4
FastIron(config-bgp-router)# write memory
```

**Syntax:** `[no] maximum-paths <num>`

The `<num>` parameter specifies the maximum number of paths across which the Layer 3 Switch can balance traffic to a given BGP4 destination. You can change the maximum number of paths to a value from 2 – 4. The default is 1.

**Customizing BGP4 load sharing**

By default, when BGP4 load sharing is enabled, both IBGP and EBGP paths are eligible for load sharing, while paths from different neighboring ASs are not eligible. You can change load sharing to apply only to IBGP or EBGP paths, or to support load sharing among paths from different neighboring ASs.

To enable load sharing of IBGP paths only, enter the following command at the BGP configuration level of the CLI.

```
FastIron(config-bgp-router)# multipath ibgp
```

To enable load sharing of EBGP paths only, enter the following command at the BGP configuration level of the CLI.

```
FastIron(config-bgp-router)# multipath ebgp
```

To enable load sharing of paths from different neighboring ASs, enter the following command at the BGP configuration level of the CLI.

```
FastIron(config-bgp-router)# multipath multi-as
```

**Syntax:** `[no] multipath ebgp | ibgp | multi-as`

The `ebgp | ibgp | multi-as` parameter specifies the change you are making to load sharing:

- **ebgp** – Load sharing applies only to EBGP paths. Load sharing is disabled for IBGP paths.
- **ibgp** – Load sharing applies only to IBGP paths. Load sharing is disabled for EBGP paths.
• **multi-as** – Load sharing is enabled for paths from different ASs.

By default, load sharing applies to EBGP and IBGP paths, and does not apply to paths from different neighboring ASs.

### Specifying a list of networks to advertise

By default, the router sends BGP4 routes only for the networks you identify using the `network` command or that are redistributed into BGP4 from RIP or OSPF. You can specify up to 600 networks.

To specify a network to be advertised, use either of the following methods.

**NOTE**
The exact route must exist in the IP route table before the Layer 3 Switch can create a local BGP route.

To configure the Layer 3 Switch to advertise network 209.157.22.0/24, enter the following command.

```
FastIron(config-bgp-router)# network 209.157.22.0 255.255.255.0
```

**Syntax:** `network <ip-addr> <ip-mask> [nri multicast | unicast | multicast unicast] [route-map <map-name>] | [weight <num>] | [backdoor]`

The `<ip-addr>` is the network number and the `<ip-mask>` specifies the network mask.

The `nri multicast | unicast | multicast unicast` parameter specifies whether the neighbor is a multicast neighbor or a unicast neighbor. Optionally, you also can specify `unicast` if you want the Layer 3 Switch to exchange unicast (BGP4) routes as well as multicast routes with the neighbor. The default is `unicast` only.

The `route-map <map-name>` parameter specifies the name of the route map you want to use to set or change BGP4 attributes for the network you are advertising. The route map must already be configured.

The `weight <num>` parameter specifies a weight to be added to routes to this network.

The `backdoor` parameter changes the administrative distance of the route to this network from the EBGP administrative distance (20 by default) to the Local BGP weight (200 by default), thus tagging the route as a backdoor route. Use this parameter when you want the router to prefer IGP routes such as RIP or OSPF routes over the EBGP route for the network.

### Specifying a route map name when configuring BGP4 network information

You can specify a route map as one of the parameters when you configure a BGP4 network to be advertised. The Layer 3 Switch can use the route map to set or change BGP4 attributes when creating a local BGP4 route.

To configure network information and use a route map to set or change BGP4 attributes, use the following CLI method.

**NOTE**
You must configure the route map before you can specify the route map name in a BGP4 network configuration.
To configure a route map, and use it to set or change route attributes for a network you define for BGP4 to advertise, enter commands such as the following.

FastIron(config)# route-map set_net permit 1
FastIron(config-route-map set_net)# set community no-export
FastIron(config-route-map set_net)# exit
FastIron(config)# router bgp
FastIron(config-bgp-router)# network 100.100.1.0/24 route-map set_net

The first two commands in this example create a route map named “set_net” that sets the community attribute for routes that use the route map to “NO_EXPORT”. The next two commands change the CLI to the BGP4 configuration level. The last command configures a network for advertising from BGP4, and associates the “set_net” route map with the network. When BGP4 originates the 100.100.1.0/24 network, BGP4 also sets the community attribute for the network to “NO_EXPORT”.

**Syntax:** network <ip-addr> <ip-mask> [route-map <map-name>] | [weight <num>] | [backdoor]

The `route-map <map-name>` parameter specifies the name of the route map you want to use to set or change BGP4 attributes for the network you are advertising. The route map must already be configured.

For information about the other parameters, refer to “Defining route maps” on page 1353.

### Changing the default local preference

When the router uses the BGP4 algorithm to select a route to send to the IP route table, one of the parameters the algorithm uses is the local preference. Local preference is an attribute that indicates a degree of preference for a route relative to other routes. BGP4 neighbors can send the local preference value as an attribute of a route in an UPDATE message.

Local preference applies only to routes within the local AS. BGP4 routers can exchange local preference information with neighbors who also are in the local AS, but BGP4 routers do not exchange local preference information with neighbors in remote ASs.

The default local preference is 100. For routes learned from EBGP neighbors, the default local preference is assigned to learned routes. For routes learned from IBGP neighbors, the local preference value is not changed for the route.

When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen.

**NOTE**

To set the local preference for individual routes, use route maps. Refer to “Defining route maps” on page 1353. Refer to “How BGP4 selects a path for a route” on page 1297 for information about the BGP4 algorithm.

To change the default local preference to 200, enter the following command.

FastIron(config-bgp-router)# default-local-preference 200

**Syntax:** default-local-preference <num>

The `<num>` parameter indicates the preference and can be a value from 0 – 4294967295.
Using the IP default route as a valid next hop for a BGP4 route

By default, the Layer 3 Switch does not use a default route to resolve a BGP4 next-hop route. If the IP route lookup for the BGP4 next hop does not result in a valid IGP route (including static or direct routes), the BGP4 next hop is considered to be unreachable and the BGP4 route is not used.

In some cases, such as when the Layer 3 Switch is acting as an edge router, you might want to allow the device to use the default route as a valid next hop. To do so, enter the following command at the BGP4 configuration level of the CLI.

`FastIron(config-bgp-router)# next-hop-enable-default`

**Syntax:** `[no] next-hop-enable-default`

Advertising the default route

By default, the Layer 3 Switch does not originate and advertise a default route using BGP4. A BGP4 default route is the IP address 0.0.0.0 and the route prefix 0 or network mask 0.0.0.0. For example, 0.0.0.0/0 is a default route. You can enable the router to advertise a default BGP4 route using either of the following methods.

**NOTE**
The Brocade Layer 3 Switch checks for the existence of an IGP route for 0.0.0.0/0 in the IP route table before creating a local BGP route for 0.0.0.0/0.

To enable the router to originate and advertise a default BGP4 route, enter the following command.

`FastIron(config-bgp-router)# default-information-originate`

**Syntax:** `[no] default-information-originate`

Changing the default MED (Metric) used for route redistribution

The Brocade Layer 3 Switch can redistribute directly connected routes, static IP routes, RIP routes, and OSPF routes into BGP4. The MED (metric) is a global parameter that specifies the cost that will be applied to all routes by default when they are redistributed into BGP4. When routes are selected, lower metric values are preferred over higher metric values. The default BGP4 MED value is 0 and can be assigned a value from 0 – 4294967295.

**NOTE**
RIP and OSPF also have default metric parameters. The parameters are set independently for each protocol and have different ranges.

To change the default metric to 40, enter the following command.

`FastIron(config-bgp-router)# default-metric 40`

**Syntax:** `default-metric <num>`

The `<num>` indicates the metric and can be a value from 0 – 4294967295.
Enabling next-hop recursion

For each BGP4 route a Layer 3 Switch learns, the Layer 3 Switch performs a route lookup to obtain the IP address of the route next hop. A BGP4 route becomes eligible for installation into the IP route table only if the following conditions are true:

- The lookup succeeds in obtaining a valid next-hop IP address for the route.
- The path to the next-hop IP address is an Interior Gateway Protocol (IGP) path or a static route path.

By default, the software performs only one lookup for a BGP route next-hop IP address. If the next-hop lookup does not result in a valid next-hop IP address or the path to the next-hop IP address is a BGP path, the software considers the BGP route destination to be unreachable. The route is not eligible to be installed in the IP route table.

It is possible for the BGP route table to contain a route whose next-hop IP address is not reachable through an IGP route, even though a hop farther away can be reached by the Layer 3 Switch through an IGP route. This can occur when the IGPs do not learn a complete set of IGP routes, resulting in the Layer 3 Switch learning about an internal route through IBGP instead of through an IGP. In this case, the IP route table does not contain a route that can be used to reach the BGP route destination.

To enable the Layer 3 Switch to find the IGP route to a BGP route next-hop gateway, enable recursive next-hop lookups. When you enable recursive next-hop lookup, if the first lookup for a BGP route results in an IBGP path originated within the same Autonomous System (AS), rather than an IGP path or static route path, the Layer 3 Switch performs a lookup on the next-hop gateway next-hop IP address. If this second lookup results in an IGP path, the software considers the BGP route to be valid and thus eligible for installation in the IP route table. Otherwise, the Layer 3 Switch performs a lookup on the next-hop IP address of the next-hop gateway next hop, and so on, until one of the lookups results in an IGP route.

**NOTE**
The software does not support using the default route to resolve a BGP4 route’s next hop. Instead, you must configure a static route or use an IGP to learn the route to the EBGP multihop peer.

Previous software releases support use of the default route to resolve routes learned from EBGP multihop neighbors. However, even in this case Brocade recommends that you use a static route for the EBGP multihop neighbor instead. In general, we recommend that you do not use the default route as the next hop for BGP4 routes, especially when there are two or more BGP4 neighbors. Using the default route can cause loops.

**Example when recursive route lookups are disabled**

Here is an example of the results of an unsuccessful next-hop lookup for a BGP route. In this case, next-hop recursive lookups are disabled. The example is for the BGP route to network 240.0.0.0/24.
In this example, the Layer 3 Switch cannot reach 240.0.0.0/24, because the next-hop IP address for the route is an IBGP route instead of an IGP route, and thus is considered unreachable by the Layer 3 Switch. Here is the IP route table entry for the BGP route next-hop gateway (102.0.0.1/24).

```
FastIron# show ip bgp route
Total number of BGP Routes: 5
Prefix      Next Hop     Metric  LocPrf  Weight  Status
 1 0.0.0.0/0        10.1.0.2   0    100   0    BI
 2 102.0.0.0/24     10.0.0.1   1    100   0    BI
 3 104.0.0.0/24     10.1.0.2   0    100   0    BI
 4 240.0.0.0/24     102.0.0.1  1    100   0    I
 5 250.0.0.0/24     209.157.24.1 1    100   0    I

FastIron# show ip route 102.0.0.1
Total number of IP routes: 37
Network Address NetMask      Gateway     Port  Cost  Type
102.0.0.0    255.255.255.0   10.0.0.1   1/1   1    B

FastIron# show ip route 240.0.0.0/24
Total number of IP routes: 37
Network Address NetMask      Gateway     Port  Cost  Type
 0.0.0.0      0.0.0.0        10.0.0.202 1/1   1    S
```

In this example, the Layer 3 Switch cannot reach 240.0.0.0/24, because the next-hop IP address for the route is an IBGP route instead of an IGP route, and thus is considered unreachable by the Layer 3 Switch. Here is the IP route table entry for the BGP route next-hop gateway (102.0.0.1/24).

```
FastIron# show ip bgp route
Total number of BGP Routes: 5
Prefix      Next Hop     Metric  LocPrf  Weight  Status
 1 0.0.0.0/0        10.1.0.2   0    100   0    BI
 2 102.0.0.0/24     10.0.0.1   1    100   0    BI
 3 104.0.0.0/24     10.1.0.2   0    100   0    BI
 4 240.0.0.0/24     102.0.0.1  1    100   0    I
 5 250.0.0.0/24     209.157.24.1 1    100   0    I

FastIron# show ip route 102.0.0.1
Total number of IP routes: 37
Network Address NetMask      Gateway     Port  Cost  Type
102.0.0.0    255.255.255.0   10.0.0.1   1/1   1    B

FastIron# show ip route 240.0.0.0/24
Total number of IP routes: 37
Network Address NetMask      Gateway     Port  Cost  Type
 0.0.0.0      0.0.0.0        10.0.0.202 1/1   1    S
```

Example when recursive route lookups are enabled

When recursive next-hop lookups are enabled, the Layer 3 Switch recursively looks up the next-hop gateways along the route until the Layer 3 Switch finds an IGP route to the BGP route destination. Here is an example.
The first lookup results in an IBGP route, to network 102.0.0.0/24.

FastIron# show ip route 102.0.0.1
Total number of IP routes: 38
Network Address     NetMask         Gateway           Port    Cost   Type
102.0.0.0           255.255.255.0  10.0.0.1         1/1     1      B
AS_PATH: 65001 4355 1

Since the route to 102.0.0.1/24 is not an IGP route, the Layer 3 Switch cannot reach the next hop through IP, and thus cannot use the BGP route. In this case, since recursive next-hop lookups are enabled, the Layer 3 Switch next performs a lookup on 102.0.0.1 next-hop gateway, 10.0.0.1.

FastIron# show ip bgp route 102.0.0.0
Number of BGP Routes matching display condition : 1
Prefix           Next Hop        Metric     LocPrf      Weight Status
102.0.0.0/24     10.0.0.1        1          100        0      BI
AS_PATH: 65001 4355 1

The next-hop IP address for 102.0.0.1 is not an IGP route, which means the BGP route destination still cannot be reached through IP. The recursive next-hop lookup feature performs a lookup on 102.0.0.1 next-hop gateway.

FastIron# show ip route 10.0.0.1
Total number of IP routes: 38
Network Address     NetMask         Gateway           Port    Cost   Type
10.0.0.0            255.255.255.0  0.0.0.0          1/1     1      D
AS_PATH: 65001 4355 1

This lookup results in an IGP route. In fact, this route is a directly-connected route. As a result, the BGP route destination is now reachable through IGP, which means the BGP route is eligible for installation in the IP route table. Here is the BGP route in the IP route table.

FastIron# show ip bgp route 240.0.0.0/24
Number of BGP Routes matching display condition : 1
Prefix           Next Hop        Metric     LocPrf      Weight Status
240.0.0.0/24     10.0.0.1        1          100        0      B
AS_PATH: 65001 4355 1

FastIron# show ip bgp route
Total number of BGP Routes: 5
Prefix          Next Hop        Metric     LocPrf      Weight Status
0.0.0.0/0       10.1.0.2        0          100         0      BI
AS_PATH: 65001 4355 701 80
102.0.0.0/24    10.0.0.1        1          100         0      BI
AS_PATH: 65001 4355 1
104.0.0.0/24    10.1.0.2        0          100         0      BI
AS_PATH: 65001 4355 701 1 189
240.0.0.0/24    10.0.0.1        1          100         0      BI
AS_PATH: 65001 4355 3356 3356 7170 1455
250.0.0.0/24    209.157.24.1    1          100         0      I
AS_PATH: 65001 4355 701
This Layer 3 Switch can use this route because the Layer 3 Switch has an IP route to the next-hop gateway. Without recursive next-hop lookups, this route would not be in the IP route table.

**Enabling recursive next-hop lookups**

The recursive next-hop lookups feature is disabled by default. To enable recursive next-hop lookups, enter the following command at the BGP configuration level of the CLI.

```
FastIron(config-bgp-router)# next-hop-recursion
```

**Syntax:** `[no] next-hop-recursion`

**Changing administrative distances**

BGP4 routers can learn about networks from various protocols, including the EBGP portion of BGP4 and IGP s such as OSPF and RIP. Consequently, the routes to a network may differ depending on the protocol from which the routes were learned.

To select one route over another based on the source of the route information, the Layer 3 Switch can use the administrative distances assigned to the sources. The administrative distance is a protocol-independent metric that IP routers use to compare routes from different sources.

The Layer 3 Switch re-advertises a learned best BGP4 route to the Layer 3 Switch neighbors even when the software does not also select that route for installation in the IP route table. The best BGP4 routes is the BGP4 path that the software selects based on comparison of the paths’ BGP4 route parameters. Refer to “How BGP4 selects a path for a route” on page 1297.

When selecting a route from among different sources (BGP4, OSPF, RIP, static routes, and so on), the software compares the routes on the basis of each route administrative distance. If the administrative distance of the paths is lower than the administrative distance of paths from other sources (such as static IP routes, RIP, or OSPF), the BGP4 paths are installed in the IP route table.

**NOTE**

The software will replace a statically configured default route with a learned default route if the learned route administrative distance is lower than the statically configured default route distance. However, the default administrative distance for static routes is changed to 1, so only directly-connected routes are preferred over static routes when the default administrative distances for the routes are used.

The following default administrative distances are found on the Brocade Layer 3 Switch:

- Directly connected – 0 (this value is not configurable)
- Static – 1 (applies to all static routes, including default routes)
- EBGP – 20
- OSPF – 110
- RIP – 120
- IBGP – 200
- Local BGP – 200
- Unknown – 255 (the router will not use this route)
Lower administrative distances are preferred over higher distances. For example, if the router receives routes for the same network from OSPF and from RIP, the router will prefer the OSPF route by default. The administrative distances are configured in different places in the software. The Layer 3 Switch re-advertises a learned best BGP4 route to neighbors by default, regardless of whether the route administrative distance is lower than other routes from different route sources to the same destination.

- To change the EBGP, IBGP, and Local BGP default administrative distances, see the instructions in this section.
- To change the default administrative distance for OSPF, refer to “Modify administrative distance” on page 1204.
- To change the default administrative distance for RIP, refer to “Changing the administrative distance” on page 1147.
- To change the default administrative distance for static routes, refer to “Configuring static routes” on page 1015.

You can change the default EBGP, IBGP, and Local BGP administrative distances using either of the following methods.

To change the default administrative distances for EBGP, IBGP, and Local BGP, enter a command such as the following.

```
FastIron(config-bgp-router)# distance 180 160 40
```

**Syntax:** `distance <external-distance> <internal-distance> <local-distance>`

The `<external-distance>` sets the EBGP distance and can be a value from 1 – 255.

The `<internal-distance>` sets the IBGP distance and can be a value from 1 – 255.

The `<local-distance>` sets the Local BGP distance and can be a value from 1 – 255.

### Requiring the first AS to be the neighbor AS

By default, the Brocade device does not require the first AS listed in the AS_SEQUENCE field of an AS path Update from an EBGP neighbor to be the AS that the neighbor who sent the Update is in. You can enable the Brocade device for this requirement.

When you enable the Brocade device to require the AS that an EBGP neighbor is in to be the same as the first AS in the AS_SEQUENCE field of an Update from the neighbor, the Brocade device accepts the Update only if the ASs match. If the ASs do not match, the Brocade device sends a Notification message to the neighbor and closes the session. The requirement applies to all Updates received from EBGP neighbors.

To enable this feature, enter the following command at the BGP configuration level of the CLI.

```
FastIron(config-bgp-router)# enforce-first-as
```

**Syntax:** `[no] enforce-first-as`

### Disabling or re-enabling comparison of the AS-Path length

AS-Path comparison is Step 5 in the algorithm BGP4 uses to select the next path for a route. Comparison of the AS-Path length is enabled by default. To disable it, enter the following command at the BGP configuration level of the CLI.

```
FastIron(config-bgp-router)# as-path-ignore
```

**Syntax:** `as-path-ignore`
This command disables comparison of the AS-Path lengths of otherwise equal paths. When you disable AS-Path length comparison, the BGP4 algorithm shown in “How BGP4 selects a path for a route” on page 1297 skips from Step 4 to Step 6.

**Syntax:** `[no] as-path-ignore`

### Enabling or disabling comparison of the router IDs

Router ID comparison is Step 10 in the algorithm BGP4 uses to select the next path for a route.

**NOTE**

Comparison of router IDs is applicable only when BGP4 load sharing is disabled.

When router ID comparison is enabled, the path comparison algorithm compares the router IDs of the neighbors that sent the otherwise equal paths:

- If BGP4 load sharing is disabled (maximum-paths 1), the Layer 3 Switch selects the path that came from the neighbor with the lower router ID.
- If BGP4 load sharing is enabled, the Layer 3 Switch load shares among the remaining paths. In this case, the router ID is not used to select a path.

**NOTE**

Router ID comparison is disabled by default. In previous releases, router ID comparison is enabled by default and cannot be disabled.

To enable router ID comparison, enter the following command at the BGP configuration level of the CLI.

```
FastIron(config-bgp-router)# compare-routerid
```

**Syntax:** `[no] compare-routerid`

For more information, refer to “How BGP4 selects a path for a route” on page 1297.

### Configuring the Layer 3 Switch to always compare Multi-Exit Discriminators (MEDs)

A Multi-Exit Discriminator (MED) is a value that the BGP4 algorithm uses when comparing multiple paths received from different BGP4 neighbors in the same AS for the same route. In BGP4, a route MED is equivalent to its “metric”:

- BGP4 compares the MEDs of two otherwise equivalent paths if and only if the routes were learned from the same neighboring AS. This behavior is called deterministic MED. Deterministic MED is always enabled and cannot be disabled.

In addition, you can enable the Layer 3 Switch to always compare the MEDs, regardless of the AS information in the paths. To enable this comparison, enter the `always-compare-med` command at the BGP4 configuration level of the CLI. This option is disabled by default.

- The Layer 3 Switch compares the MEDs based on one or more of the following conditions. By default, the Layer 3 Switch compares the MEDs of paths only if the first AS in the paths is the same. (The Layer 3 Switch skips over the AS-CONFED-SEQUENCE if present.)
You can enable the Layer 3 Switch to always compare the MEDs, regardless of the AS information in the paths. For example, if the router receives UPDATES for the same route from neighbors in three ASs, the router would compare the MEDs of all the paths together, rather than comparing the MEDs for the paths in each AS individually.

**NOTE**
By default, value 0 (most favorable) is used in MED comparison when the MED attribute is not present. The default MED comparison results in the Layer 3 Switch favoring the route paths that are missing their MEDs. You can use the `med-missing-as-worst` command to make the Layer 3 Switch regard a BGP route with a missing MED attribute as the least favorable route, when comparing the MEDs of the routes.

**NOTE**
MED comparison is not performed for internal routes originated within the local AS or confederation.

To configure the router to always compare MEDs, enter the following command.

```
FastIron(config-bgp-router)# always-compare-med
```

**Syntax:** `[no] always-compare-med`

### Treating missing MEDs as the worst MEDs

By default, the Layer 3 Switch favors a lower MED over a higher MED during MED comparison. Since the Layer 3 Switch assigns the value 0 to a route path MED if the MED value is missing, the default MED comparison results in the Layer 3 Switch favoring the route paths that are missing their MEDs.

To change this behavior so that the Layer 3 Switch favors a route that has a MED over a route that is missing its MED, enter the following command at the BGP4 configuration level of the CLI.

```
FastIron(config-bgp-router)# med-missing-as-worst
```

**Syntax:** `[no] med-missing-as-worst`

**NOTE**
This command affects route selection only when route paths are selected based on MED comparison. It is still possible for a route path that is missing its MED to be selected based on other criteria. For example, a route path with no MED can be selected if its weight is larger than the weights of the other route paths.

### Configuring route reflection parameters

Normally, all the BGP routers within an AS are fully meshed. Each of the routers has an IBGP session with each of the other BGP routers in the AS. Each IBGP router thus has a route for each of its IBGP neighbors. For large ASs containing many IBGP routers, the IBGP route information in each of the fully-meshed IBGP routers can introduce too much administrative overhead.

To avoid this problem, you can hierarchically organize your IGP routers into clusters:
A cluster is a group of IGP routers organized into route reflectors and route reflector clients. You configure the cluster by assigning a cluster ID on the route reflector and identifying the IGP neighbors that are members of that cluster. All the configuration for route reflection takes place on the route reflectors. The clients are unaware that they are members of a route reflection cluster. All members of the cluster must be in the same AS. The cluster ID can be any number from 0 – 4294967295. The default is the router ID, expressed as a 32-bit number.

NOTE
If the cluster contains more than one route reflector, you need to configure the same cluster ID on all the route reflectors in the cluster. The cluster ID helps route reflectors avoid loops within the cluster.

A route reflector is an IGP router configured to send BGP route information to all the clients (other BGP4 routers) within the cluster. Route reflection is enabled on all Brocade BGP4 routers by default but does not take effect unless you add route reflector clients to the router.

A route reflector client is an IGP router identified as a member of a cluster. You identify a router as a route reflector client on the router that is the route reflector, not on the client. The client itself requires no additional configuration. In fact, the client does not know that it is a route reflector client. The client just knows that it receives updates from its neighbors and does not know whether one or more of those neighbors are route reflectors.

NOTE
Route reflection applies only among IBGP routers within the same AS. You cannot configure a cluster that spans multiple ASs.

Figure 157 shows an example of a route reflector configuration. In this example, two Layer 3 Switches are configured as route reflectors for the same cluster. The route reflectors provide redundancy in case one of the reflectors becomes unavailable. Without redundancy, if a route reflector becomes unavailable, its clients are cut off from BGP4 updates.

AS1 contains a cluster with two route reflectors and two clients. The route reflectors are fully meshed with other BGP4 routers, but the clients are not fully meshed. They rely on the route reflectors to propagate BGP4 route updates.
Support for RFC 2796

Route reflection on Brocade devices is based on RFC 2796. This updated RFC helps eliminate routing loops that are possible in some implementations of the older specification, RFC 1966.

NOTE
The configuration procedure for route reflection is the same regardless of whether your software release is using RFC 1966 or RFC 2796. However, the operation of the feature is different as explained below.

RFC 2796 provides more details than RFC 1966 regarding the use of the route reflection attributes, ORIGINATOR_ID and CLUSTER_LIST, to help prevent loops:

- **ORIGINATOR_ID** – Specifies the router ID of the BGP4 switch that originated the route. The route reflector inserts this attribute when reflecting a route to an IBGP neighbor. If a BGP4 switch receives an advertisement that contains its own router ID as the ORIGINATOR_ID, the switch discards the advertisement and does not forward it.

- **CLUSTER_LIST** – A list of the route reflection clusters through which the advertisement has passed. A cluster contains a route reflector and its clients. When a route reflector reflects a route, the route reflector adds its cluster ID to the front of the CLUSTER_LIST. If a route reflector receives a route that has its own cluster ID, the switch discards the advertisement and does not forward it.

The Brocade device handles the attributes as follows:

- The Layer 3 Switch adds the attributes only if it is a route reflector, and only when advertising IBGP route information to other IBGP neighbors. The attributes are not used when communicating with EBGP neighbors.
• A Layer 3 Switch configured as a route reflector sets the ORIGINATOR_ID attribute to the router ID of the router that originated the route. Moreover, the route reflector sets the attribute only if this is the first time the route is being reflected (sent by a route reflector). In previous software releases, the route reflector set the attribute to the router ID of the route reflector itself. When a Layer 3 Switch receives a route that already has the ORIGINATOR_ID attribute set, the Layer 3 Switch does not change the value of the attribute.

• If a Layer 3 Switch receives a route whose ORIGINATOR_ID attribute has the value of the Layer 3 Switch own router ID, the Layer 3 Switch discards the route and does not advertise it. By discarding the route, the Layer 3 Switch prevents a routing loop. The Layer 3 Switch did not discard the route in previous software releases.

• The first time a route is reflected by a Layer 3 Switch configured as a route reflector, the route reflector adds the CLUSTER_LIST attribute to the route. Other route reflectors who receive the route from an IBGP neighbor add their cluster IDs to the front of the route CLUSTER_LIST. If the route reflector does not have a cluster ID configured, the Layer 3 Switch adds its router ID to the front of the CLUSTER_LIST.

• If Layer 3 Switch configured as a route reflector receives a route whose CLUSTER_LIST contains the route reflector own cluster ID, the route reflector discards the route and does not forward it.

Configuration procedures

To configure a Brocade Layer 3 Switch to be a BGP4 route reflector, use either of the following methods.

**NOTE**
All configuration for route reflection takes place on the route reflectors, not on the clients.

Enter the following commands to configure a Brocade Layer 3 Switch as route reflector 1 in Figure 157 on page 1332. To configure route reflector 2, enter the same commands on the Layer 3 Switch that will be route reflector 2. The clients require no configuration for route reflection.

```
FastIron(config-bgp-router)# cluster-id 1
FastIron(config-bgp-router)# neighbor 10.0.1.0 route-reflector-client
FastIron(config-bgp-router)# neighbor 10.0.2.0 route-reflector-client
```

**Syntax:** `[no] cluster-id <num> | <ip-addr>

The `<num>` | `<ip-addr>` parameter specifies the cluster ID and can be a number from 0 – 4294967295 or an IP address. The default is the router ID. You can configure one cluster ID on the router. All route-reflector clients for the router are members of the cluster.

**NOTE**
If the cluster contains more than one route reflector, you need to configure the same cluster ID on all the route reflectors in the cluster. The cluster ID helps route reflectors avoid loops within the cluster.

To add an IBGP neighbor to the cluster, enter the following command.

**Syntax:** `neighbor <ip-addr> route-reflector-client`

For more information about the `neighbor` command, refer to "Adding BGP4 neighbors" on page 1307.
By default, the clients of a route reflector are not required to be fully meshed; the routes from a client are reflected to other clients. However, if the clients are fully meshed, route reflection is not required between clients.

If you need to disable route reflection between clients, enter the following command. When the feature is disabled, route reflection does not occur between clients but reflection does still occur between clients and non-clients.

```bash
FastIron(config-bgp-router)# no client-to-client-reflection
```

Enter the following command to re-enable the feature.

```bash
FastIron(config-bgp-router)# client-to-client-reflection
```

**Syntax:** `[no] client-to-client-reflection`

---

**Configuration notes**

A **confederation** is a BGP4 Autonomous System (AS) that has been subdivided into multiple, smaller ASs. Subdividing an AS into smaller ASs simplifies administration and reduces BGP-related traffic, thus reducing the complexity of the Interior Border Gateway Protocol (IBGP) mesh among the BGP routers in the AS.

The Brocade implementation of this feature is based on RFC 3065.

Normally, all BGP routers within an AS must be fully meshed, so that each BGP router has interfaces to all the other BGP routers within the AS. This is feasible in smaller ASs but becomes unmanageable in ASs containing many BGP routers.

When you configure BGP routers into a confederation, all the routers within a sub-AS (a subdivision of the AS) use IBGP and must be fully meshed. However, routers use EBGP to communicate between different sub-ASs.

**NOTE**

Another method for reducing the complexity of an IBGP mesh is to use route reflection. However, if you want to run different Interior Gateway Protocols (IGPs) within an AS, configure a confederation. You can run a separate IGP within each sub-AS.

To configure a confederation, configure groups of BGP routers into sub-ASs. A sub-AS is simply an AS. The term "sub-AS" distinguishes ASs within a confederation from ASs that are not in a confederation. For the viewpoint of remote ASs, the confederation ID is the AS ID. Remote ASs do not know that the AS represents multiple sub-ASs with unique AS IDs.

**NOTE**

You can use any valid AS numbers for the sub-ASs. If your AS is connected to the Internet, Brocade recommends that you use numbers from within the private AS range (64512 – 65535). These are private ASs numbers and BGP4 routers do not propagate these AS numbers to the Internet.

Figure 158 shows an example of a BGP4 confederation.
In this example, four switches are configured into two sub-ASs, each containing two of the switches. The sub-ASs are members of confederation 10. Switches within a sub-AS must be fully meshed and communicate using IBGP. In this example, Switches A and B use IBGP to communicate. Switches C and D also use IBGP. However, the sub-ASs communicate with one another using EBGP. For example, Switch A communicates with Switch C using EBGP. The switches in the confederation communicate with other ASs using EBGP.

Switches in other ASs are unaware that Switches A – D are configured in a confederation. In fact, when switches in confederation 10 send traffic to switches in other ASs, the confederation ID is the same as the AS number for the switches in the confederation. Thus, switches in other ASs see traffic from AS 10 and are unaware that the switches in AS 10 are subdivided into sub-ASs within a confederation.

**Configuring a BGP confederation**

Perform the following configuration tasks on each BGP router within the confederation:

- Configure the local AS number. The local AS number indicates membership in a sub-AS. All BGP switches with the same local AS number are members of the same sub-AS. BGP switches use the local AS number when communicating with other BGP switches within the confederation.

- Configure the confederation ID. The confederation ID is the AS number by which BGP switches outside the confederation know the confederation. Thus, a BGP switch outside the confederation is not aware and does not care that your BGP switches are in multiple sub-ASs. BGP switches use the confederation ID when communicating with switches outside the confederation. The confederation ID must be different from the sub-AS numbers.
Optional configuration tasks

- Configure the list of the sub-AS numbers that are members of the confederation. All the switches within the same sub-AS use IBGP to exchange switch information. Switches in different sub-ASs within the confederation use EBGP to exchange switch information.

To configure four Layer 3 Switches to be a member of confederation 10 (as shown in Figure 158), consisting of two sub-ASs (64512 and 64513), enter commands such as the following.

Commands for router A

- FastIronA(config)# router bgp
- FastIronA(config-bgp-router)# local-as 64512
- FastIronA(config-bgp-router)# confederation identifier 10
- FastIronA(config-bgp-router)# confederation peers 64512 64513
- FastIronA(config-bgp-router)# write memory

Syntax: local-as <num>

The <num> parameter with the local-as command indicates the AS number for the BGP switches within the sub-AS. You can specify a number from 1 – 65535. Brocade recommends that you use a number within the range of well-known private ASs, 64512 – 65535.

Syntax: confederation identifier <num>

The <num> parameter with the confederation identifier command indicates the confederation number. The confederation ID is the AS number by which BGP switches outside the confederation know the confederation. Thus, a BGP switch outside the confederation is not aware and does not care that your BGP switches are in multiple sub-ASs. BGP switches use the confederation ID when communicating with switches outside the confederation. The confederation ID must be different from the sub-AS numbers. You can specify a number from 1 – 65535.

Syntax: confederation peers <num> [ <num> ...

The <num> parameter with the confederation peers command indicates the sub-AS numbers for the sub-ASs in the confederation. You must specify all the sub-ASs contained in the confederation. All the switches within the same sub-AS use IBGP to exchange switch information. Switches in different sub-ASs within the confederation use EBGP to exchange switch information. You can specify a number from 1 – 65535.

Commands for router B

- FastIronB(config)# router bgp
- FastIronB(config-bgp-router)# local-as 64512
- FastIronB(config-bgp-router)# confederation identifier 10
- FastIronB(config-bgp-router)# confederation peers 64512 64513
- FastIronB(config-bgp-router)# write memory

Commands for router C

- FastIronC(config)# router bgp
- FastIronC(config-bgp-router)# local-as 64513
- FastIronC(config-bgp-router)# confederation identifier 10
- FastIronC(config-bgp-router)# confederation peers 64512 64513
- FastIronC(config-bgp-router)# write memory

Commands for router D

- FastIronD(config)# router bgp
- FastIronD(config-bgp-router)# local-as 64513
- FastIronD(config-bgp-router)# confederation identifier 10
- FastIronD(config-bgp-router)# confederation peers 64512 64513
- FastIronD(config-bgp-router)# write memory
Aggregating routes advertised to BGP4 neighbors

By default, the Layer 3 Switch advertises individual routes for all the networks. The aggregation feature allows you to configure the Layer 3 Switch to aggregate routes in a range of networks into a single CIDR number. For example, without aggregation, the Layer 3 Switch will individually advertise routes for networks 207.95.1.0, 207.95.2.0, and 207.95.3.0. You can configure the Layer 3 Switch to instead send a single, aggregate route for the networks. The aggregate route would be advertised as 207.95.0.0.

**NOTE**
To summarize CIDR networks, you must use the aggregation feature. The auto summary feature does not summarize networks that use CIDR numbers instead of class A, B, or C numbers.

To aggregate routes for 209.157.22.0, 209.157.23.0, and 209.157.24.0, enter the following command.

```
FastIron(config-bgp-router)# aggregate-address 209.157.0.0 255.255.0.0
```

**Syntax:** aggregate-address \<ip-addr> \<ip-mask> [as-set] [nlri multicast | unicast | multicast unicast]
[summary-only] [suppress-map \<map-name>] [advertise-map \<map-name>]
[attribute-map \<map-name>]

The \<ip-addr> and \<ip-mask> parameters specify the aggregate value for the networks. Specify 0 for the host portion and for the network portion that differs among the networks in the aggregate. For example, to aggregate 10.0.1.0, 10.0.2.0, and 10.0.3.0, enter the IP address 10.0.0.0 and the network mask 255.255.0.0.

The as-set parameter causes the router to aggregate AS-path information for all the routes in the aggregate address into a single AS-path.

The nlri multicast | unicast | multicast unicast parameter specifies whether the neighbor is a multicast neighbor or a unicast neighbor. Optionally, you also can specify unicast if you want the Layer 3 Switch to exchange unicast (BGP4) routes as well as multicast routes with the neighbor. The default is unicast only.

The summary-only parameter prevents the router from advertising more specific routes contained within the aggregate route.

The suppress-map \<map-name> parameter prevents the more specific routes contained in the specified route map from being advertised.

The advertise-map \<map-name> parameter configures the router to advertise the more specific routes in the specified route map.

The attribute-map \<map-name> parameter configures the router to set attributes for the aggregate routes based on the specified route map.

**NOTE**
For the suppress-map, advertise-map, and attribute-map parameters, the route map must already be defined. Refer to “Defining route maps” on page 1353 for information on defining a route map.
BGP null0 routing

Platform Support:
- FastIron X Series devices running software release 03.0.00 and later

The null0 routes were previously treated as invalid routes for BGP next hop resolution. BGP now uses the null0 route to resolve its next hop. Thus, null0 route in the routing table (for example, static route) is considered as a valid route by BGP. If the next hop for BGP resolves into a null0 route, the BGP route is also installed as a null0 route in the routing table.

The null0 routing feature allows network administrators to block certain network prefixes, by using null0 routes and route-maps. The combined use of null0 routes and route maps blocks traffic from a particular network prefix, telling a remote router to drop all traffic for this network prefix by redistributing a null0 route into BGP.

Figure 159 shows a topology for a null0 routing application example.

**FIGURE 159** Example of a null0 routing application

The following steps configure a null0 routing application for stopping denial of service attacks from remote hosts on the internet.

**Configuration steps**

1. Select one switch, S6, to distribute null0 routes throughout the BGP network.
2. Configure a route-map to match a particular tag (50) and set the next-hop address to an unused network address (199.199.1.1).
3. Set the local-preference to a value higher than any possible internal or external local-preference (50).

4. Complete the route map by setting origin to IGP.

5. On S6, redistribute the static routes into BGP, using route-map `<route-map-name>` (redistribute static route-map block user).

6. On S1, the router facing the internet, configure a null0 route matching the next-hop address in the route-map (ip route 199.199.1.1/32 null0).

7. Repeat step 3 for all switches interfacing with the internet (edge corporate routers). In this case, S2 has the same null0 route as S1.

8. On S6, configure the network prefixes associated with the traffic you want to drop. The static route IP address references a destination address. You are required to point the static route to the egress port, for example, Ethernet 3/7, and specify the tag 50, matching the route-map configuration.

**Configuration examples**

**S6**

The following configuration defines specific prefixes to filter.

```
FastIron(config)# ip route 110.0.0.40/29 ethernet 3/7 tag 50
FastIron(config)# ip route 115.0.0.192/27 ethernet 3/7 tag 50
FastIron(config)# ip route 120.014.0/23 ethernet 3/7 tag 50
```

The following configuration redistributes routes into BGP.

```
FastIron(config)# router bgp
FastIron(config-bgp-router)# local-as 100
FastIron(config-bgp-router)# neighbor <router1_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router2_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router3_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router4_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router5_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router7_int_ip address> remote-as 100
FastIron(config-bgp-router)# redistribute static route-map blockuser
FastIron(config-bgp-router)# exit
```

The following configuration defines the specific next hop address and sets the local preference to preferred.

```
FastIron(config)# route-map blockuser permit 10
FastIron(config-route-map blockuser)# match tag 50
FastIron(config-route-map blockuser)# set ip next-hop 199.199.1.1
FastIron(config-route-map blockuser)# set local-preference 1000000
FastIron(config-route-map blockuser)# set origin igp
FastIron(config-route-map blockuser)# exit
```

**S1**

The following configuration defines the null0 route to the specific next hop address. The next hop address 199.199.1.1 points to the null0 route.

```
FastIron(config)# ip route 199.199.1.1/32 null0
FastIron(config)# router bgp
FastIron(config-bgp-router)# local-as 100
FastIron(config-bgp-router)# neighbor <router2_int_ip address> remote-as 100
```
BGP null0 routing

FastIron(config-bgp-router)# neighbor <router3_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router4_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router5_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router6_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router7_int_ip address> remote-as 100

S2

The following configuration defines a null0 route to the specific next hop address. The next hop address 199.199.1.1 points to the null0 route, which gets blocked.

FastIron(config)# ip route 199.199.1.1/32 null0
FastIron(config)# router bgp
FastIron(config-bgp-router)# local-as 100
FastIron(config-bgp-router)# neighbor <router1_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router3_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router4_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router5_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router6_int_ip address> remote-as 100
FastIron(config-bgp-router)# neighbor <router7_int_ip address> remote-as 100

Show commands

After configuring the null0 application, you can display the output.

S6

The following is the Show ip route static output for S6.

Modifying redistribution parameters

By default, the Layer 3 Switch does not redistribute route information between BGP4 and the IP IGPs (RIP and OSPF). You can configure the switch to redistribute OSPF routes, RIP routes, directly connected routes, or static routes into BGP4 by using the following methods.

To enable redistribution of all OSPF routes and directly attached routes into BGP4, enter the following commands.

```
FastIron(config)# router bgp
FastIron(config-bgp-router)# redistribute ospf
FastIron(config-bgp-router)# redistribute connected
FastIron(config-bgp-router)# write memory
```

Syntax: `[no] redistribute connected | ospf | rip | static`

The `connected` parameter indicates that you are redistributing routes to directly attached devices into BGP.

The `ospf` parameter indicates that you are redistributing OSPF routes into BGP4.

```
NOTE
Entering `redistribute ospf` simply redistributes internal OSPF routes. If you want to redistribute external OSPF routes also, you must use the `redistribute ospf match external...` command. Refer to “Redistributing OSPF external routes” on page 1343.
```

The `rip` parameter indicates that you are redistributing RIP routes into BGP4.

The `static` parameter indicates that you are redistributing static routes into BGP.

Refer to the following sections for details on redistributing specific routes using the CLI:

- “Redistributing connected routes” on page 1342
- “Redistributing RIP routes” on page 1343
- “Redistributing OSPF external routes” on page 1343
- “Redistributing static routes” on page 1344

Redistributing connected routes

To configure BGP4 to redistribute directly connected routes, enter the following command.

```
FastIron(config-bgp-router)# redistribute connected
```

Syntax: `redistribute connected [metric <num>] [route-map <map-name>]`

The `connected` parameter indicates that you are redistributing routes to directly attached devices into BGP4.

The `metric <num>` parameter changes the metric. You can specify a value from 0 – 4294967295. The default is 0.

The `route-map <map-name>` parameter specifies a route map to be consulted before adding the RIP route to the BGP4 route table.

```
NOTE
The route map you specify must already be configured on the switch. Refer to “Defining route maps” on page 1353 for information about defining route maps.
```
Redistributing RIP routes

To configure BGP4 to redistribute RIP routes and add a metric of 10 to the redistributed routes, enter the following command.

FastIron(config-bgp-router)# redistribute rip metric 10

Syntax: redistribute rip [metric <num>] [route-map <map-name>]

The rip parameter indicates that you are redistributing RIP routes into BGP4.

The metric <num> parameter changes the metric. Specify a value from 0 – 4294967295. The default is 0.

The route-map <map-name> parameter specifies a route map to be consulted before adding the RIP route to the BGP4 route table.

**NOTE**

The route map you specify must already be configured on the switch. Refer to “Defining route maps” on page 1353 for information about defining route maps.

Redistributing OSPF external routes

To configure the Layer 3 Switch to redistribute OSPF external type 1 routes, enter the following command.

FastIron(config-bgp-router)# redistribute ospf match external1

Syntax: redistribute ospf [match internal | external1 | external2] [metric <num>] [route-map <map-name>]

The ospf parameter indicates that you are redistributing OSPF routes into BGP4.

The match internal | external1 | external2 parameter applies only to OSPF. This parameter specifies the types of OSPF routes to be redistributed into BGP4. The default is internal.

**NOTE**

If you do not enter a value for the match parameter, (for example, you enter redistribute ospf only) then only internal OSPF routes will be redistributed.

The metric <num> parameter changes the metric. Specify a value from 0 – 4294967295. The default is 0.

The route-map <map-name> parameter specifies a route map to be consulted before adding the OSPF route to the BGP4 route table.

**NOTE**

The route map you specify must already be configured on the switch. Refer to “Defining route maps” on page 1353 for information about defining route maps.

**NOTE**

If you use both the redistribute ospf route-map <map-name> command and the redistribute ospf match internal | external1 | external2 command, the software uses only the route map for filtering.
Modifying redistribution parameters

Redistributing static routes

To configure the Layer 3 Switch to redistribute static routes, enter the following command.

```
FastIron(config-bgp-router)# redistribute static
```

Syntax: `redistribute static [metric <num>] [route-map <map-name>]`

The `static` parameter indicates that you are redistributing static routes into BGP4.

The `metric <num>` parameter changes the metric. Specify a value from 0 – 4294967295. The default is 0.

The `route-map <map-name>` parameter specifies a route map to be consulted before adding the static route to the BGP4 route table.

**NOTE**
The route map you specify must already be configured on the switch. Refer to “Defining route maps” on page 1353 for information about defining route maps.

Disabling or re-enabling re-advertisement of all learned BGP4 routes to all BGP4 neighbors

By default, the Layer 3 Switch re-advertises all learned best BGP4 routes to BGP4 neighbors, unless the routes are discarded or blocked by route maps or other filters.

If you want to prevent the Layer 3 Switch from re-advertising a learned best BGP4 route unless that route also is installed in the IP route table, use the following CLI method.

To disable re-advertisement of BGP4 routes to BGP4 neighbors except for routes that the software also installs in the route table, enter the following command.

```
FastIron(config-bgp-router)# no readvertise
```

Syntax: `[no] readvertise`

To re-enable re-advertisement, enter the following command.

```
FastIron(config-bgp-router)# readvertise
```

Redistributing IBGP routes into RIP and OSPF

By default, the Layer 3 Switch does not redistribute IBGP routes from BGP4 into RIP or OSPF. This behavior helps eliminate routing loops. However, if your network can benefit from redistributing the IBGP routes from BGP4 into OSPF or RIP, you can enable the Layer 3 Switch to redistribute the routes. To do so, use the following CLI method.

To enable the Layer 3 Switch to redistribute BGP4 routes into OSPF and RIP, enter the following command.

```
FastIron(config-bgp-router)# bgp-redistribute-internal
```

Syntax: `[no] bgp-redistribute-internal`

To disable redistribution of IBGP routes into RIP and OSPF, enter the following command.

```
FastIron(config-bgp-router)# no bgp-redistribute-internal
```
Filtering

This section describes the following:

- “Filtering specific IP addresses” on page 1345
- “Filtering AS-paths” on page 1346
- “Filtering communities” on page 1349
- “Defining IP prefix lists” on page 1352
- “Defining neighbor distribute lists” on page 1353
- “Defining route maps” on page 1353
- “Using a table map to set the rag value” on page 1361
- “Configuring cooperative BGP4 route filtering” on page 1362

Filtering specific IP addresses

You can configure the router to explicitly permit or deny specific IP addresses received in updates from BGP4 neighbors by defining IP address filters. The router permits all IP addresses by default. You can define up to 100 IP address filters for BGP4.

- If you want **permit** to remain the default behavior, define individual filters to deny specific IP addresses.
- If you want to change the default behavior to **deny**, define individual filters to permit specific IP addresses.

**NOTE**

Once you define a filter, the default action for addresses that do not match a filter is “deny”. To change the default action to “permit”, configure the last filter as “permit any any”.

Address filters can be referred to by a BGP neighbor's distribute list number as well as by match statements in a route map.

**NOTE**

If the filter is referred to by a route map match statement, the filter is applied in the order in which the filter is listed in the match statement.

**NOTE**

You also can filter on IP addresses by using IP ACLs.

To define an IP address filter to deny routes to 209.157.0.0, enter the following command.

```
FastIron(config-bgp-router)# address-filter 1 deny 209.157.0.0 255.255.0.0
```

**Syntax:** `address-filter <num> permit | deny <ip-addr> <wildcard> <mask> <wildcard>`

The `<num>` parameter is the filter number.

The `permit | deny` parameter indicates the action the Layer 3 Switch takes if the filter match is true.

- If you specify **permit**, the Layer 3 Switch permits the route into the BGP4 table if the filter match is true.
- If you specify **deny**, the Layer 3 Switch denies the route from entering the BGP4 table if the filter match is true.
NOTE
Once you define a filter, the default action for addresses that do not match a filter is “deny”. To change the default action to “permit”, configure the last filter as “permit any any”.

The <ip-addr> parameter specifies the IP address. If you want the filter to match on all addresses, enter any.

The <wildcard> parameter specifies the portion of the IP address to match against. The <wildcard> is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the <source-ip>. Ones mean any value matches. For example, the <ip-addr> and < wildcard > values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C subnet 209.157.22.x match the policy.

If you prefer to specify the wildcard (mask value) in Classless Interdomain Routing (CIDR) format, you can enter a forward slash after the IP address, then enter the number of significant bits in the mask. For example, you can enter the CIDR equivalent of “209.157.22.26 0.0.0.255” as “209.157.22.26/24”. The CLI automatically converts the CIDR number into the appropriate mask (where zeros instead of ones are the significant bits) and changes the non-significant portion of the IP address into zeros. For example, if you specify 209.157.22.26/24 or 209.157.22.26 0.0.0.255, then save the changes to the startup-config file, the value appears as 209.157.22.0/24 (if you have enabled display of subnet lengths) or 209.157.22.0 0.0.0.255 in the startup-config file.

If you enable the software to display IP subnet masks in CIDR format, the mask is saved in the file in “/ <mask-bits>” format. To enable the software to display the CIDR masks, enter the ip show-subnet-length command at the global CONFIG level of the CLI. You can use the CIDR format to configure the filter regardless of whether the software is configured to display the masks in CIDR format.

The <mask> parameter specifies the network mask. If you want the filter to match on all destination addresses, enter any. The wildcard works the same as described above.

Filtering AS-paths

You can filter updates received from BGP4 neighbors based on the contents of the AS-path list accompanying the updates. For example, if you want to deny routes that have the AS 4.3.2.1 in the AS-path from entering the BGP4 route table, you can define a filter to deny such routes.

The Layer 3 Switch provides the following methods for filtering on AS-path information:

- AS-path filters
- AS-path ACLs

NOTE
The Layer 3 Switch cannot actively support AS-path filters and AS-path ACLs at the same time. Use one method or the other but do not mix methods.

NOTE
Once you define a filter or ACL, the default action for updates that do not match a filter is “deny”. To change the default action to “permit”, configure the last filter or ACL as “permit any any”.

AS-path filters or AS-path ACLs can be referred to by a BGP neighbor’s filter list number as well as by match statements in a route map.
Defining an AS-path filter

To define AS-path filter 4 to permit AS 2500, enter the following command.

FastIron(config-bgp-router)# as-path-filter 4 permit 2500

Syntax: as-path-filter <num> permit | deny <as-path>

The <num> parameter identifies the filter position in the AS-path filter list and can be from 1 – 100. Thus, the AS-path filter list can contain up to 100 filters. The Brocade Layer 3 Switch applies the filters in numerical order, beginning with the lowest-numbered filter. When a filter match is true, the Layer 3 Switch stops and does not continue applying filters from the list.

NOTE
If the filter is referred to by a route map match statement, the filter is applied in the order in which the filter is listed in the match statement.

The permit | deny parameter indicates the action the router takes if the filter match is true.

• If you specify permit, the router permits the route into the BGP4 table if the filter match is true.
• If you specify deny, the router denies the route from entering the BGP4 table if the filter match is true.

The <as-path> parameter indicates the AS-path information. You can enter an exact AS-path string if you want to filter for a specific value. You also can use regular expressions in the filter string.

Defining an AS-path ACL

To configure an AS-path list that uses ACL 1, enter a command such as the following.

FastIron(config)# ip as-path access-list 1 permit 100
FastIron(config)# router bgp
FastIron(config-bgp-router)# neighbor 10.10.10.1 filter-list 1 in

The ip as-path command configures an AS-path ACL that permits routes containing AS number 100 in their AS paths. The neighbor command then applies the AS-path ACL to advertisements and updates received from neighbor 10.10.10.1. In this example, the only routes the Layer 3 Switch permits from neighbor 10.10.10.1 are those whose AS-paths contain AS-path number 100.

Syntax: ip as-path access-list <string> [seq <seq-value>] deny | permit <regular-expression>

The <string> parameter specifies the ACL name. (If you enter a number, the CLI interprets the number as a text string.)

The seq <seq-value> parameter is optional and specifies the AS-path list sequence number. You can configure up to 199 entries in an AS-path list. If you do not specify a sequence number, the software numbers them in increments of 5, beginning with number 5. The software interprets the entries in an AS-path list in numerical order, beginning with the lowest sequence number.

The deny | permit parameter specifies the action the software takes if a route AS-path list matches a match statement in this ACL. To configure the AS-path match statements in a route map, use the match as-path command. Refer to “Matching based on AS-path ACL” on page 1356.

The <regular-expression> parameter specifies the AS path information you want to permit or deny to routes that match any of the match statements within the ACL. You can enter a specific AS number or use a regular expression. For the regular expression syntax, refer to “Using regular expressions” on page 1348.
The `neighbor` command uses the `filter-list` parameter to apply the AS-path ACL to the neighbor. Refer to “Adding BGP4 neighbors” on page 1307.

**Using regular expressions**

You use a regular expression for the `<as-path>` parameter to specify a single character or multiple characters as a filter pattern. If the AS-path matches the pattern specified in the regular expression, the filter evaluation is true; otherwise, the evaluation is false.

In addition, you can include special characters that influence the way the software matches the AS-path against the filter value.

To filter on a specific single-character value, enter the character for the `<as-path>` parameter. For example, to filter on AS-paths that contain the letter “z”, enter the following command.

```
FastIron(config-bgp-router)# as-path-filter 1 permit z
```

To filter on a string of multiple characters, enter the characters in brackets. For example, to filter on AS-paths that contain “x”, “y”, or “z”, enter the following command.

```
FastIron(config-bgp-router)# as-path-filter 1 permit [xyz]
```

**Special characters**

When you enter as single-character expression or a list of characters, you also can use the following special characters. Table 222 on page 1348 lists the special characters. The description for each special character includes an example. Notice that you place some special characters in front of the characters they control but you place other special characters after the characters they control. In each case, the examples show where to place the special character.

**TABLE 222** BGP4 special characters for regular expressions

<table>
<thead>
<tr>
<th>Character</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>The period matches any single character, including a blank space. For example, the following regular expression matches for “aa”, “ab”, “ac”, and so on, but not just “a”.</td>
</tr>
<tr>
<td>a</td>
<td>a.</td>
</tr>
<tr>
<td>*</td>
<td>The asterisk matches on zero or more sequences of a pattern. For example, the following regular expression matches on an AS-path that contains the string “1111” followed by any value: 1111*</td>
</tr>
<tr>
<td>+</td>
<td>The plus sign matches on one or more sequences of a pattern. For example, the following regular expression matches on an AS-path that contains a sequence of “g”s, such as “deg”, “degg”, “deggg”, and so on: deg+</td>
</tr>
<tr>
<td>?</td>
<td>The question mark matches on zero occurrences or one occurrence of a pattern. For example, the following regular expression matches on an AS-path that contains “dg” or “deg”: de?g</td>
</tr>
<tr>
<td>^</td>
<td>A caret (when not used within brackets) matches on the beginning of an input string. For example, the following regular expression matches on an AS-path that begins with “3”: ^3</td>
</tr>
<tr>
<td>$</td>
<td>A dollar sign matches on the end of an input string. For example, the following regular expression matches on an AS-path that ends with “deg”: deg$</td>
</tr>
</tbody>
</table>
Filtering

If you want to filter for a special character instead of using the special character as described in Table 221 on page 1304, enter \"\" (backslash) in front of the character. For example, to filter on AS-path strings containing an asterisk, enter the asterisk portion of the regular expression as \"\*\".

FastIron(config-bgp-router)# as-path-filter 2 deny \*  

To use the backslash as a string character, enter two slashes. For example, to filter on AS-path strings containing a backslash, enter the backslash portion of the regular expression as \"\\".

FastIron(config-bgp-router)# as-path-filter 2 deny \\  

Filtering communities

You can filter routes received from BGP4 neighbors based on community names. Use either of the following methods to do so.
A community is an optional attribute that identifies the route as a member of a user-defined class of routes. Community names are arbitrary values made of two five-digit integers joined by a colon. You determine what the name means when you create the community name as one of a route attributes. Each string in the community name can be a number from 0 – 65535.

This format allows you to easily classify community names. For example, a common convention used in community naming is to configure the first string as the local AS and the second string as the unique community within that AS. Using this convention, communities 1:10, 1:20, and 1:30 can be easily identified as member communities of AS 1.

The Layer 3 Switch provides the following methods for filtering on community information:

- Community filters
- Community list ACLs

**NOTE**
The Layer 3 Switch cannot actively support community filters and community list ACLs at the same time. Use one method or the other but do not mix methods.

**NOTE**
Once you define a filter or ACL, the default action for communities that do not match a filter or ACL is “deny”. To change the default action to “permit”, configure the last filter or ACL entry as “permit any any”.

Community filters or ACLs can be referred to by match statements in a route map.

**Defining a community filter**

To define filter 3 to permit routes that have the NO_ADVERTISE community, enter the following command.

```
FastIron(config-bgp-router)# community-filter 3 permit no-advertise
```

**Syntax:**

```
community-filter <num> permit | deny <num>:<num> | internet | local-as | no-advertise | no-export
```

The `<num>` parameter identifies the filter position in the community filter list and can be from 1 – 100. Thus, the community filter list can contain up to 100 filters. The router applies the filters in numerical order, beginning with the lowest-numbered filter. When a filter match is true, the router stops and does not continue applying filters from the list.

**NOTE**
If the filter is referred to by a route map match statement, the filter is applied in the order in which the filter is listed in the match statement.

The `permit` | `deny` parameter indicates the action the router takes if the filter match is true.

- If you specify `permit`, the router permits the route into the BGP4 table if the filter match is true.
- If you specify `deny`, the router denies the route from entering the BGP4 table if the filter match is true.

The `<num>:<num>` parameter indicates a specific community number to filter. Use this parameter to filter for a private (administrator-defined) community. You can enter up to 20 community numbers with the same command.
If you want to filter for the well-known communities “LOCAL_AS”, “NO_EXPORT” or “NO_ADVERTISE”, use the corresponding keyword (described below).

The **internet** keyword checks for routes that do not have the community attribute. Routes without a specific community are considered by default to be members of the largest community, the Internet.

The **local-as** keyword checks for routes with the well-known community “LOCAL_AS”. This community applies only to confederations. The Layer 3 Switch advertises the route only within the sub-AS. For information about confederations, refer to “Configuration notes” on page 1334.

The **no-advertise** keyword filters for routes with the well-known community “NO_ADVERTISE”. A route in this community should not be advertised to any BGP4 neighbors.

The **no-export** keyword filters for routes with the well-known community “NO_EXPORT”. A route in this community should not be advertised to any BGP4 neighbors outside the local AS. If the router is a member of a confederation, the Layer 3 Switch advertises the route only within the confederation. For information about confederations, refer to “Configuration notes” on page 1334.

### Defining a community ACL

To configure community ACL 1, enter a command such as the following.

```
FastIron(config)# ip community-list 1 permit 123:2
```

This command configures a community ACL that permits routes that contain community 123:2.

---

**NOTE**

Refer to “Matching based on community ACL” on page 1357 for information about how to use a community list as a match condition in a route map.

---

**Syntax:**

- For **standard** IP community lists:
  
  ```
  ip community-list standard <string> [seq <seq-value>] deny | permit <community-num>
  ```

- For **extended** IP community lists:
  
  ```
  ip community-list extended <string> [seq <seq-value>] deny | permit <community-num> | <regular-expression>
  ```

The `<string>` parameter specifies the ACL name. (If you enter a number, the CLI interprets the number as a text string.)

The **standard** or **extended** parameter specifies whether you are configuring a standard community ACL or an extended one. A standard community ACL does not support regular expressions whereas an extended one does. This is the only difference between standard and extended IP community lists.

The **seq** parameter is optional and specifies the community list sequence number. You can configure up to 199 entries in a community list. If you do not specify a sequence number, the software numbers them in increments of 5, beginning with number 5. The software interprets the entries in a community list in numerical order, beginning with the lowest sequence number.

The **deny** | **permit** parameter specifies the action the software takes if a route community list matches a match statement in this ACL. To configure the community-list match statements in a route map, use the **match community** command. Refer to “Matching based on community ACL” on page 1357.

The `<community-num>` parameter specifies the community type or community number. This parameter can have the following values:

- `<num>;<num>` – A specific community number
Filtering

- **internet** – The Internet community
- **no-export** – The community of sub-ASs within a confederation. Routes with this community can be exported to other sub-ASs within the same confederation but cannot be exported outside the confederation to other ASs or otherwise sent to EBGP neighbors.
- **local-as** – The local sub-AS within the confederation. Routes with this community can be advertised only within the local subAS.
- **no-advertise** – Routes with this community cannot be advertised to any other BGP4 routers at all.

The `<regular-expression>` parameter specifies a regular expression for matching on community names. For information about regular expression syntax, refer to “Using regular expressions” on page 1348. You can specify a regular expression only in an extended community ACL.

Defining IP prefix lists

An IP prefix list specifies a list of networks. When you apply an IP prefix list to a neighbor, the Layer 3 Switch sends or receives only a route whose destination is in the IP prefix list. You can configure up to 100 prefix lists. The software interprets the prefix lists in order, beginning with the lowest sequence number.

To configure an IP prefix list and apply it to a neighbor, enter commands such as the following.

```
FastIron(config)# ip prefix-list Routesfor20 permit 20.20.0.0/24
FastIron(config)# router bgp
FastIron(config-bgp-router)# neighbor 10.10.10.1 prefix-list Routesfor20 out
```

These commands configure an IP prefix list named Routesfor20, which permits routes to network 20.20.0.0/24. The `neighbor` command configures the Layer 3 Switch to use IP prefix list Routesfor20 to determine which routes to send to neighbor 10.10.10.1. The Layer 3 Switch sends routes that go to 20.20.x.x to neighbor 10.10.10.1 because the IP prefix list explicitly permits these routes to be sent to the neighbor.

**Syntax:** `ip prefix-list <name> [seq <seq-value>] [description <string>] deny | permit <network-addr>/ <mask-bits> [ge <ge-value>] [le <le-value>]`

The `<name>` parameter specifies the prefix list name. You use this name when applying the prefix list to a neighbor.

The `description <string>` parameter is a text string describing the prefix list.

The `seq <seq-value>` parameter is optional and specifies the IP prefix list sequence number. You can configure up to 100 prefix list entries. If you do not specify a sequence number, the software numbers them in increments of 5, beginning with prefix list entry 5. The software interprets the prefix list entries in numerical order, beginning with the lowest sequence number.

The `deny | permit` parameter specifies the action the software takes if a neighbor route is in this prefix list.

The prefix-list matches only on this network unless you use the `ge <ge-value>` or `le <le-value>` parameters. (See below.)

The `<network-addr>/ <mask-bits>` parameter specifies the network number and the number of bits in the network mask.

You can specify a range of prefix length for prefixes that are more specific than `<network-addr>/ <mask-bits>`.

- If you specify only `ge <ge-value>`, then the mask-length range is from `<ge-value>` to 32.
• If you specify only le <le-value>, then the mask-length range is from length to <le-value>. The <ge-value> or <le-value> you specify must meet the following condition.

\[
\text{length} < \text{ge-value} \leq \text{le-value} \leq 32
\]

If you do not specify ge <ge-value> or le <le-value>, the prefix list matches only on the exact network prefix you specify with the <network-addr>/<mask-bits> parameter.

For the syntax of the neighbor command shown in the example above, refer to “Adding BGP4 neighbors” on page 1307.

**Defining neighbor distribute lists**

A neighbor distribute list is a list of BGP4 address filters or ACLs that filter the traffic to or from a neighbor. To configure a neighbor distribute list, use either of the following methods.

To configure a distribute list that uses ACL 1, enter a command such as the following.

```plaintext
FastIron(config-bgp-router)# neighbor 10.10.10.1 distribute-list 1 in
```

This command configures the Layer 3 Switch to use ACL 1 to select the routes that the Layer 3 Switch will accept from neighbor 10.10.10.1.

**Syntax:** `neighbor <ip-addr> distribute-list <name-or-num> in | out`

The `<ip-addr>` parameter specifies the neighbor.

The `<name-or-num>` parameter specifies the name or number of a standard, extended, or named ACL.

The **in** | **out** parameter specifies whether the distribute list applies to inbound or outbound routes:

- **in** – controls the routes the Layer 3 Switch will accept from the neighbor.
- **out** – controls the routes sent to the neighbor.

**NOTE**

The command syntax shown above is new. However, the `neighbor <ip-addr> distribute-list in | out <num>` command (where the direction is specified before the filter number) is the same as in earlier software releases. Use the new syntax when you are using an IP ACL with the distribute list. Use the old syntax when you are using a BGP4 address filter with the distribute list.

**Defining route maps**

A **route map** is a named set of match conditions and parameter settings that the router can use to modify route attributes and to control redistribution of the routes into other protocols. A route map consists of a sequence of up to 50 **instances**. If you think of a route map as a table, an instance is a row in that table. The router evaluates a route according to a route map instances in ascending numerical order. The route is first compared against instance 1, then against instance 2, and so on. As soon as a match is found, the router stops evaluating the route against the route map instances.

Route maps can contain **match** statements and **set** statements. Each route map contains a “permit” or “deny” action for routes that match the match statements:

- If the route map contains a permit action, a route that matches a match statement is permitted; otherwise, the route is denied.
• If the route map contains a deny action, a route that matches a match statement is denied.
• If a route does not match any match statements in the route map, the route is denied. This is the default action. To change the default action, configure the last match statement in the last instance of the route map to “permit any any”.
• If there is no match statement, the software considers the route to be a match.
• For route maps that contain address filters, AS-path filters, or community filters, if the action specified by a filter conflicts with the action specified by the route map, the route map action takes precedence over the individual filter action.

If the route map contains set statements, routes that are permitted by the route map match statements are modified according to the set statements.

Match statements compare the route against one or more of the following:
• The route BGP4 MED (metric)
• A sequence of AS-path filters
• A sequence of community filters
• A sequence of address filters
• The IP address of the next hop router
• The route tag
• For OSPF routes only, the route type (internal, external type-1, or external type-2)
• An AS-path ACL
• A community ACL
• An IP prefix list
• An IP ACL

For routes that match all of the match statements, the route map set statements can perform one or more of the following modifications to the route attributes:
• Prepend AS numbers to the front of the route AS-path. By adding AS numbers to the AS-path, you can cause the route to be less preferred when compared to other routes on the basis of the length of the AS-path.
• Add a user-defined tag to the route or add an automatically calculated tag to the route.
• Set the community value.
• Set the local preference.
• Set the MED (metric).
• Set the IP address of the next hop router.
• Set the origin to IGP or INCOMPLETE.
• Set the weight.

For example, when you configure parameters for redistributing routes into RIP, one of the optional parameters is a route map. If you specify a route map as one of the redistribution parameters, the router will match the route against the match statements in the route map. If a match is found and if the route map contains set statements, the router will set attributes in the route according to the set statements.

To create a route map, you define instances of the map. Each instance is identified by a sequence number. A route map can contain up to 50 instances.

To define a route map, use the procedures in the following sections.
**Entering the route map into the software**

To add instance 1 of a route map named "GET_ONE" with a permit action, enter the following command.

```
FastIron(config)# route-map GET_ONE permit 1
FastIron(config-routemap GET_ONE)#
```

**Syntax:** `[no] route-map <map-name> permit | deny <num>

As shown in this example, the command prompt changes to the Route Map level. You can enter the match and set statements at this level. Refer to "Specifying the match conditions" on page 1355 and "Setting parameters in the routes" on page 1359.

The `<map-name>` is a string of characters that names the map. Map names can be up to 32 characters in length.

The `permit` | `deny` parameter specifies the action the router will take if a route matches a match statement.

- If you specify `deny`, the Layer 3 Switch does not advertise or learn the route.
- If you specify `permit`, the Layer 3 Switch applies the match and set statements associated with this route map instance.

The `<num>` parameter specifies the instance of the route map you are defining. Each route map can have up to 50 instances.

To delete a route map, enter a command such as the following. When you delete a route map, all the permit and deny entries in the route map are deleted.

```
FastIron(config)# no route-map Map1
```

This command deletes a route map named "Map1". All entries in the route map are deleted.

To delete a specific instance of a route map without deleting the rest of the route map, enter a command such as the following.

```
FastIron(config)# no route-map Map1 permit 10
```

This command deletes the specified instance from the route map but leaves the other instances of the route map intact.

**Specifying the match conditions**

Use the following command to define the match conditions for instance 1 of the route map GET_ONE. This instance compares the route updates against BGP4 address filter 11.

```
FastIron(config-routemap GET_ONE)# match address-filters 11
```

**Syntax:** `match [as-path <num>] | [address-filters | as-path-filters | community-filters <num,num,...>] | [community <num>] | [community <ACL> | exact-match] | [ip address <ACL> | prefix-list <string>] | [ip route-source <ACL> | prefix <name>] | [metric <num>] | [next-hop <address-filter-list>] | [nri multicast | unicast | multicast unicast] | [route-type internal | external-type1 | external-type2] | [tag <tag-value>]`

The `as-path <num>` parameter specifies an AS-path ACL. You can specify up to five AS-path ACLs. To configure an AS-path ACL, use the `ip as-path access-list` command. Refer to "Defining an AS-path ACL" on page 1347.
The **address-filters | as-path-filters | community-filters <num,num,...>** parameter specifies a filter or list of filters to be matched for each route. The router treats the first match as the best match. If a route does not match any filter in the list, then the router considers the match condition to have failed. To configure these types of filters, use commands at the BGP configuration level:

- To configure an address filter, refer to “Filtering specific IP addresses” on page 1345.
- To configure an AS-path filter or AS-path ACL, refer to “Filtering AS-paths” on page 1346.
- To configure a community filter or community ACL, refer to “Filtering communities” on page 1349.

You can enter up to six community names on the same command line.

**NOTE**
The filters must already be configured.

The **community <num>** parameter specifies a community ACL.

**NOTE**
The ACL must already be configured.

The **community <ACL> exact-match** parameter matches a route if (and only if) the route’s community attributes field contains the same community numbers specified in the match statement.

The **ip address | next-hop <ACL-num> | prefix-list <string>** parameter specifies an ACL or IP prefix list. Use this parameter to match based on the destination network or next-hop gateway. To configure an IP ACL for use with this command, use the **ip access-list** command. Refer to “ACL overview” on page 629. To configure an IP prefix list, use the **ip prefix-list** command. Refer to “Defining IP prefix lists” on page 1352.

The **ip route-source <ACL> | prefix <name>** parameter matches based on the source of a route (the IP address of the neighbor from which the Brocade device learned the route).

The **metric <num>** parameter compares the route MED (metric) to the specified value.

The **next-hop <address-filter-list>** parameter compares the IP address of the route next hop to the specified IP address filters. The filters must already be configured.

The **nlri multicast | unicast | multicast unicast** parameter specifies whether you want the route map to match on multicast routes, unicast routes, or both route types.

**NOTE**
By default, route maps apply to both unicast and multicast traffic.

The **route-type internal | external-type1 | external-type2** parameter applies only to OSPF routes. This parameter compares the route type to the specified value.

The **tag <tag-value>** parameter compares the route tag to the specified value.

### Match examples using ACLs

The following sections show some detailed examples of how to configure route maps that include match statements that match on ACLs.

### Matching based on AS-path ACL

To construct a route map that matches based on AS-path ACL 1, enter the following commands.
FastIron(config)# route-map PathMap permit 1
FastIron(config-routemap PathMap)# match as-path 1

Syntax: match as-path <num>

The <num> parameter specifies an AS-path ACL and can be a number from 1 – 199. You can specify up to five AS-path ACLs. To configure an AS-path ACL, use the ip as-path access-list command. Refer to “Defining an AS-path ACL” on page 1347.

Matching based on community ACL

To construct a route map that matches based on community ACL 1, enter the following commands.

FastIron(config)# ip community-list 1 permit 123:2
FastIron(config)# route-map CommMap permit 1
FastIron(config-routemap CommMap)# match community 1

Syntax: match community <string>

The <string> parameter specifies a community list ACL. To configure a community list ACL, use the ip community-list command. Refer to “Defining a community ACL” on page 1351.

Matching based on destination network

To construct match statements for a route map that match based on destination network, use the following method. You can use the results of an IP ACL or an IP prefix list as the match condition.

FastIron(config)# route-map NetMap permit 1
FastIron(config-routemap NetMap)# match ip address 1

Syntax: match ip address <name-or-num>

Syntax: match ip address prefix-list <name>

The <name-or-num> parameter with the first command specifies an IP ACL and can be a number from 1 – 199 or the ACL name if it is a named ACL. To configure an IP ACL, use the ip access-list or access-list command. Refer to Chapter 17, “Configuring Rule-Based IP Access Control Lists (ACLs)”.

The <name> parameter with the second command specifies an IP prefix list name. To configure an IP prefix list, refer to “Defining IP prefix lists” on page 1352.

Matching based on next-hop router

To construct match statements for a route map that match based on the IP address of the next-hop router, use either of the following methods. You can use the results of an IP ACL or an IP prefix list as the match condition.

To construct a route map that matches based on the next-hop router, enter commands such as the following.

FastIron(config)# route-map HopMap permit 1
FastIron(config-routemap HopMap)# match ip next-hop 2

Syntax: match ip next-hop <num>

Syntax: match ip next-hop prefix-list <name>

The <num> parameter with the first command specifies an IP ACL and can be a number from 1 – 199 or the ACL name if it is a named ACL. To configure an IP ACL, use the ip access-list or access-list command. Refer to Chapter 17, “Configuring Rule-Based IP Access Control Lists (ACLs)”.

The <name> parameter with the second command specifies an IP prefix list name. To configure an IP prefix list, refer to “Defining IP prefix lists” on page 1352.
Matching based on the route source
To match a BGP4 route based on its source, use the `match ip route-source` statement. Here is an example.

```
FastIron(config)# access-list 10 permit 192.168.6.0 0.0.0.255
FastIron(config)# route-map bgp1 permit 1
FastIron(config-route-map bgp1)# match ip route-source 10
```

The first command configures an IP ACL that matches on routes received from 192.168.6.0/24. The remaining commands configure a route map that matches on all BGP4 routes advertised by the BGP4 neighbors whose addresses match addresses in the IP prefix list. You can add a set statement to change a route attribute in the routes that match. You also can use the route map as input for other commands, such as the `neighbor` and `network` commands and some `show` commands.

**Syntax:** `match ip route-source <ACL> | prefix <name>

The `<ACL> | prefix <name>` parameter specifies the name or ID of an IP ACL, or an IP prefix list.

Matching on routes containing a specific set of communities
Brocade software enables you to match routes based on the presence of a community name or number in a route, and to match when a route contains exactly the set of communities you specify. To match based on a set of communities, configure a community ACL that lists the communities, then compare routes against the ACL.

Here is an example.

```
FastIron(config)# ip community-list standard std_1 permit 12:34 no-export
FastIron(config)# route-map bgp2 permit 1
FastIron(config-route-map bgp2)# match community std_1 exact-match
```

The first command configures a community ACL that contains community number 12:34 and community name no-export. The remaining commands configure a route map that matches the community attributes field in BGP4 routes against the set of communities in the ACL. A route matches the route map only if the route contains all the communities in the ACL and no other communities.

**Syntax:** `match community <ACL> exact-match`

The `<ACL>` parameter specifies the name of a community list ACL. You can specify up to five ACLs. Separate the ACL names or IDs with spaces.

Here is another example.

```
FastIron(config)# ip community-list standard std_2 permit 23:45 56:78
FastIron(config)# route-map bgp3 permit 1
FastIron(config-route-map bgp3)# match community std_1 std_2 exact-match
```

These commands configure an additional community ACL, std_2, that contains community numbers 23:45 and 57:68. Route map bgp3 compares each BGP4 route against the sets of communities in ACLs std_1 and std_2. A BGP4 route that contains either but not both sets of communities matches the route map. For example, a route containing communities 23:45 and 57:68 matches. However, a route containing communities 23:45, 57:68 and 12:34, or communities 23:45, 57:68, 12:34, and no-export does not match. To match, the route communities must be the same as those in exactly one of the community ACLs used by the match community statement.
Setting parameters in the routes

Use the following command to define a set statement that prepends an AS number to the AS path on each route that matches the corresponding match statement.

FastIron(config-routemap GET_ONE)# set as-path prepend 65535

Syntax: set [as-path [prepend <as-num,as-num,...>]] | [automatic-tag] | [comm-list <ACL> delete] | [community <num>:<num> | <num> | internet | local-as | no-advertise | no-export] | [dampening [half-life] | <reuse> | <suppress> | <max-suppress-time>] | [(default) interface null0 | [ip [default] next hop <ip-addr> | [ip next-hop peer-address] | [local-preference <num>] | [metric [+ | -]<num> | none] | [metric-type type-1 | type-2] | [metric-type internal] | [next-hop <ip-addr>] | [nhrp multicast | unicast | multicast unicast] | [origin igp | incomplete] | [tag <tag-value>] | [weight <num>]

The as-path prepend <num,num,...> parameter adds the specified AS numbers to the front of the AS-path list for the route.

The automatic-tag parameter calculates and sets an automatic tag value for the route.

NOTE
This parameter applies only to routes redistributed into OSPF.

The comm-list parameter deletes a community from a BGP4 route community attributes field.

The community parameter sets the community attribute for the route to the number or well-known type you specify.

The dampening [half-life] | <reuse> | <suppress> | <max-suppress-time>] parameter sets route dampening parameters for the route. The half-life parameter specifies the number of minutes after which the route penalty becomes half its value. The reuse parameter specifies how low a route penalty must become before the route becomes eligible for use again after being suppressed. The suppress parameter specifies how high a route penalty can become before the Layer 3 Switch suppresses the route. The max-suppress-time parameter specifies the maximum number of minutes that a route can be suppressed regardless of how unstable it is. For information and examples, refer to “Configuring route flap dampening” on page 1365.

The [default] interface null0 parameter redirects the traffic to the specified interface. You can send the traffic to the null0 interface, which is the same as dropping the traffic. You can specify more than one interface, in which case the Layer 3 Switch uses the first available port. If the first port is unavailable, the Layer 3 Switch sends the traffic to the next port in the list. If you specify default, the route map redirects the traffic to the specified interface only if the Layer 3 Switch does not already have explicit routing information for the traffic. This option is used in Policy-Based Routing (PBR).

The ip [default] next hop <ip-addr> parameter sets the next-hop IP address for traffic that matches a match statement in the route map. If you specify default, the route map sets the next-hop gateway only if the Layer 3 Switch does not already have explicit routing information for the traffic. This option is used in Policy-Based Routing (PBR).

The ip next-hop peer-address parameter sets the BGP4 next hop for a route to the specified neighbor address.

The local-preference <num> parameter sets the local preference for the route. You can set the preference to a value from 0 – 4294967295.

The metric [+ | -]<num> | none parameter sets the MED (metric) value for the route. The default MED value is 0. You can set the preference to a value from 0 – 4294967295.
- set metric <num> – Sets the route metric to the number you specify.
- set metric +<num> – Increases route metric by the number you specify.
- set metric -<num> – Decreases route metric by the number you specify.
- set metric none – Removes the metric from the route (removes the MED attribute from the BGP4 route).

The metric-type type-1 | type-2 parameter changes the metric type of a route redistributed into OSPF.

The metric-type internal parameter sets the route's MED to the same value as the IGP metric of the BGP4 next-hop route. The parameter does this when advertising a BGP4 route to an EBGP neighbor.

The next-hop <ip-addr> parameter sets the IP address of the route next hop router.

The nlri multicast | unicast | multicast unicast parameter redistributes routes into the multicast Routing Information Base (RIB) instead of the unicast RIB.

**NOTE**
Setting the NLRI type to multicast applies only when you are using the route map to redistribute directly-connected routes. Otherwise, the set option is ignored.

The origin igp | incomplete parameter sets the route origin to IGP or INCOMPLETE.

The tag <tag-value> parameter sets the route tag. You can specify a tag value from 0 – 4294967295.

**NOTE**
This parameter applies only to routes redistributed into OSPF.

**NOTE**
You also can set the tag value using a table map. The table map changes the value only when the Layer 3 Switch places the route in the IP route table instead of changing the value in the BGP route table. Refer to “Using a table map to set the tag value” on page 1361.

The weight <num> parameter sets the weight for the route. You can specify a weight value from 0 – 4294967295.

**Setting a BP4 route MED to the same value as the IGP metric of the next-hop route**
To set a route's MED to the same value as the IGP metric of the BGP4 next-hop route, when advertising the route to a neighbor, enter commands such as the following.

FastIron(config)# access-list 1 permit 192.168.9.0 0.0.0.255
FastIron(config)# route-map bgp4 permit 1
FastIron(config-route-map bgp4)# match ip address 1
FastIron(config-route-map bgp4)# set metric-type internal

The first command configures an ACL that matches on routes with destination network 192.168.9.0. The remaining commands configure a route map that matches on the destination network in ACL 1, then sets the metric type for those routes to the same value as the IGP metric of the BGP4 next-hop route.

**Syntax:** set metric-type internal
Setting the next hop of a BGP4 route
To set the next hop address of a BGP4 route to a neighbor address, enter commands such as the following.

```
FastIron(config)# route-map bgp5 permit 1
FastIron(config-route-map bgp5)# match ip address 1
FastIron(config-route-map bgp5)# set ip next-hop peer-address
```

These commands configure a route map that matches on routes whose destination network is specified in ACL 1, and sets the next hop in the routes to the neighbor address (inbound filtering) or the local IP address of the BGP4 session (outbound filtering).

**Syntax:** `set ip next-hop peer-address`

The value that the software substitutes for `peer-address` depends on whether the route map is used for inbound filtering or outbound filtering:

- When you use the `set ip next-hop peer-address` command in an inbound route map filter, `peer-address` substitutes for the neighbor IP address.
- When you use the `set ip next-hop peer-address` command in an outbound route map filter, `peer-address` substitutes for the local IP address of the BGP4 session.

**NOTE**
You can use this command for a peer group configuration.

Deleting a community from a BGP4 route
To delete a community from a BGP4 route community attributes field, enter commands such as the following.

```
FastIron(config)# ip community-list standard std_3 permit 12:99 12:86
FastIron(config)# route-map bgp6 permit 1
FastIron(config-route-map bgp6)# match ip address 1
FastIron(config-route-map bgp6)# set comm-list std_3 delete
```

The first command configures a community ACL containing community numbers 12:99 and 12:86. The remaining commands configure a route map that matches on routes whose destination network is specified in ACL 1, and deletes communities 12:99 and 12:86 from those routes. The route does not need to contain all the specified communities in order for them to be deleted. For example, if a route contains communities 12:86, 33:44, and 66:77, community 12:86 is deleted.

**Syntax:** `set comm-list <ACL> delete`

The `<ACL>` parameter specifies the name of a community list ACL.

Using a table map to set the tag value
Route maps that contain set statements change values in routes when the routes are accepted by the route map. For inbound route maps (route maps that filter routes received from neighbors), this means that the routes are changed before they enter the BGP4 route table.

For tag values, if you do not want the value to change until a route enters the IP route table, you can use a table map to change the value. A table map is a route map that you have associated with the IP routing table. The Layer 3 Switch applies the set statements for tag values in the table map to routes before adding them to the route table.
To configure a table map, you configure the route map, then identify it as a table map. The table map does not require separate configuration. You create it simply by calling an existing route map a table map. You can have one table map.

**NOTE**
Use table maps only for setting the tag value. Do not use table maps to set other attributes. To set other route attributes, use route maps or filters.

To create a route map and identify it as a table map, enter commands such as following. These commands create a route map that uses an address filter. For routes that match the address filter, the route map changes the tag value to 100. This route map is then identified as a table map. As a result, the route map is applied only to routes that the Layer 3 Switch places in the IP route table. The route map is not applied to all routes. This example assumes that address filter 11 has already been configured.

```
FastIron(config)# route-map TAG_IP permit 1
FastIron(config-route-map TAG_IP)# match address-filters 11
FastIron(config-route-map TAG_IP)# set tag 100
FastIron(config-route-map TAG_IP)# router bgp
FastIron(config-bgp-router)# table-map TAG_IP
```

### Configuring cooperative BGP4 route filtering

By default, the Layer 3 Switch performs all filtering of incoming routes locally, on the Layer 3 Switch itself. You can use cooperative BGP4 route filtering to cause the filtering to be performed by a neighbor before it sends the routes to the Layer 3 Switch. Cooperative filtering conserves resources by eliminating unnecessary route updates and filter processing. For example, the Layer 3 Switch can send a deny filter to its neighbor, which the neighbor uses to filter out updates before sending them to the Layer 3 Switch. The neighbor saves the resources it would otherwise use to generate the route updates, and the Layer 3 Switch saves the resources it would use to filter out the routes.

When you enable cooperative filtering, the Layer 3 Switch advertises this capability in its Open message to the neighbor when initiating the neighbor session. The Open message also indicates whether the Layer 3 Switch is configured to send filters, receive filters or both, and the types of filters it can send or receive. The Layer 3 Switch sends the filters as Outbound Route Filters (ORFs) in Route Refresh messages.

To configure cooperative filtering, perform the following tasks on the Layer 3 Switch and on its BGP4 neighbor:

- Configure the filter.

**NOTE**
The current release supports cooperative filtering only for filters configured using IP prefix lists.

- Apply the filter as in **inbound** filter to the neighbor.
- Enable the cooperative route filtering feature on the Layer 3 Switch. You can enable the Layer 3 Switch to send ORFs to the neighbor, to receive ORFs from the neighbor, or both. The neighbor uses the ORFs you send as outbound filters when it sends routes to the Layer 3 Switch. Likewise, the Layer 3 Switch uses the ORFs it receives from the neighbor as outbound filters when sending routes to the neighbor.
- Reset the BGP4 neighbor session to send and receive ORFs.
- Perform these steps on the other device.
NOTE
If the Layer 3 Switch has inbound filters, the filters are still processed even if equivalent filters have been sent as ORFs to the neighbor.

Enabling cooperative filtering

To configure cooperative filtering, enter commands such as the following.

FastIron(config)# ip prefix-list Routesfrom1234 deny 20.20.0.0/24
FastIron(config)# ip prefix-list Routesfrom1234 permit 0.0.0.0/0 le 32
FastIron(config)# router bgp
FastIron(config-bgp-router)# neighbor 1.2.3.4 prefix-list Routesfrom1234 in
FastIron(config-bgp-router)# neighbor 1.2.3.4 capability orf prefixlist send

The first two commands configure statements for the IP prefix list Routesfrom1234. The first command configures a statement that denies routes to 20.20.0.0/24. The second command configures a statement that permits all other routes. (Once you configure an IP prefix list statement, all routes not explicitly permitted by statements in the prefix list are denied.)

The next two commands change the CLI to the BGP4 configuration level, then apply the IP prefix list to neighbor 1.2.3.4. The last command enables the Layer 3 Switch to send the IP prefix list as an ORF to neighbor 1.2.3.4. When the Layer 3 Switch sends the IP prefix list to the neighbor, the neighbor filters out the 20.20.0.x routes from its updates to the Layer 3 Switch. (This assumes that the neighbor also is configured for cooperative filtering.)

The \(<ip-addr> | <peer-group-name>\) parameter specifies the IP address of a neighbor or the name of a peer group of neighbors.

The \(send | receive\) parameter specifies the support you are enabling:

- \(send\) – The Layer 3 Switch sends the IP prefix lists to the neighbor.
- \(receive\) – The Layer 3 Switch accepts filters from the neighbor.

If you do not specify the capability, both capabilities are enabled.

The \(prefixlist\) parameter specifies the type of filter you want to send to the neighbor.

NOTE
The current release supports cooperative filtering only for filters configured using IP prefix lists.

Sending and receiving ORFs

Cooperative filtering affects neighbor sessions that start after the filtering is enabled, but do not affect sessions that are already established.

To activate cooperative filtering, reset the session with the neighbor. This is required because the cooperative filtering information is exchanged in Open messages during the start of a session.

To place a prefix-list change into effect after activating cooperative filtering, perform a soft reset of the neighbor session. A soft reset does not end the current session, but sends the prefix list to the neighbor in the next route refresh message.

NOTE
Make sure cooperative filtering is enabled on the Layer 3 Switch and on the neighbor before you send the filters.
To reset a neighbor session and send ORFs to the neighbor, enter a command such as the following.

```bash
FastIron# clear ip bgp neighbor 1.2.3.4
```

This command resets the BGP4 session with neighbor 1.2.3.4 and sends the ORFs to the neighbor. If the neighbor sends ORFs to the Layer 3 Switch, the Layer 3 Switch accepts them if the send capability is enabled.

To perform a soft reset of a neighbor session and send ORFs to the neighbor, enter a command such as the following.

```bash
FastIron# clear ip bgp neighbor 1.2.3.4 soft in prefix-list
```

**Syntax:** `clear ip bgp neighbor <ip-addr> [soft in prefix-filter]`

If you use the `soft in prefix-filter` parameter, the Layer 3 Switch sends the updated IP prefix list to the neighbor as part of its route refresh message to the neighbor.

---

**NOTE**

If the Layer 3 Switch or the neighbor is not configured for cooperative filtering, the command sends a normal route refresh message.

---

**Displaying cooperative filtering information**

You can display the following cooperative filtering information:

- The cooperative filtering configuration on the Layer 3 Switch.
- The ORFs received from neighbors.

To display the cooperative filtering configuration on the Layer 3 Switch, enter a command such as the following. The line shown in bold type shows the cooperative filtering status.

```bash
FastIron# show ip bgp neighbor 10.10.10.1
```

```
1   IP Address: 10.10.10.1, AS: 65200 (IBGP), RouterID: 10.10.10.1

```

**Syntax:** `show ip bgp neighbor <ip-addr>`

To display the ORFs received from a neighbor, enter a command such as the following.
Configuring route flap dampening

A “route flap” is the change in a route state, from up to down or down to up. When a route state changes, the state change causes changes in the route tables of the routers that support the route. Frequent changes in a route state can cause Internet instability and add processing overhead to the routers that support the route.

Route flap dampening is a mechanism that reduces the impact of route flap by changing a BGP4 router response to route state changes. When route flap dampening is configured, the Layer 3 Switch suppresses unstable routes until the route state changes reduce enough to meet an acceptable degree of stability. The Brocade implementation of route flap dampening is based on RFC 2439.

Route flap dampening is disabled by default. You can enable the feature globally or on an individual route basis using route maps.

**NOTE**
The Layer 3 Switch applies route flap dampening only to routes learned from EBGP neighbors.

The route flap dampening mechanism is based on penalties. When a route exceeds a configured penalty value, the Layer 3 Switch stops using that route and also stops advertising it to other routers. The mechanism also allows a route penalties to reduce over time if the route stability improves. The route flap dampening mechanism uses the following parameters:

- **Suppression threshold** – Specifies the penalty value at which the Layer 3 Switch stops using the route. Each time a route becomes unreachable or is withdrawn by a BGP4 UPDATE from a neighbor, the route receives a penalty of 1000. By default, when a route has a penalty value greater than 2000, the Layer 3 Switch stops using the route. Thus, by default, if a route goes down more than twice, the Layer 3 Switch stops using the route. You can set the suppression threshold to a value from 1 – 20000. The default is 2000.

- **Half-life** – Once a route has been assigned a penalty, the penalty decreases exponentially and decreases by half after the half-life period. The default half-life period is 15 minutes. The software reduces route penalties every five seconds. For example, if a route has a penalty of 2000 and does not receive any more penalties (it does not go down again) during the half-life, the penalty is reduced to 1000 after the half-life expires. You can configure the half-life to be from 1 – 45 minutes. The default is 15 minutes.

- **Reuse threshold** – Specifies the minimum penalty a route can have and still be suppressed by the Layer 3 Switch. If the route's penalty falls below this value, the Layer 3 Switch un-suppresses the route and can use it again. The software evaluates the dampened routes every ten seconds and un-suppresses the routes that have penalties below the reuse threshold. You can set the reuse threshold to a value from 1 – 20000. The default is 750.

```shell
FastIron# show ip bgp neighbor 10.10.10.1 received prefix-filter
ip prefix-list 10.10.10.1: 4 entries
  seq 5 permit 10.10.0.0/16 ge 18 le 28
  seq 10 permit 20.20.10.0/24
  seq 15 permit 30.0.0.0/8 le 32
  seq 20 permit 40.10.0.0/16 ge 18
```
• **Maximum suppression time** – Specifies the maximum number of minutes a route can be suppressed regardless of how unstable the route has been before this time. You can set the parameter to a value from 1 – 20000 minutes. The default is four times the half-life. When the half-life value is set to its default (15 minutes), the maximum suppression time defaults to 60 minutes.

You can configure route flap dampening globally or for individual routes using route maps. If you configure route flap dampening parameters globally and also use route maps, the settings in the route maps override the global values.

### Globally configuring route flap dampening

To enable route flap dampening using the default values, enter the following command.

```
FastIron(config-bgp-router)# dampening
```

**Syntax:** `dampening [<half-life> <reuse> <suppress> <max-suppress-time>]`

The `<half-life>` parameter specifies the number of minutes after which the route penalty becomes half its value. The route penalty allows routes that have remained stable for a while despite earlier instability to eventually become eligible for use again. The decay rate of the penalty is proportional to the value of the penalty. After the half-life expires, the penalty decays to half its value. Thus, a dampened route that is no longer unstable can eventually become eligible for use again. You can configure the half-life to be from 1 - 45 minutes. The default is 15 minutes.

The `<reuse>` parameter specifies how low a route penalty must become before the route becomes eligible for use again after being suppressed. You can set the reuse threshold to a value from 1 – 20000. The default is 750 (0.75, or three-fourths, of the penalty assessed for a one “flap”).

The `<suppress>` parameter specifies how high a route penalty can become before the Layer 3 Switch suppresses the route. You can set the suppression threshold to a value from 1 – 20000. The default is 2000 (two “flaps”).

The `<max-suppress-time>` parameter specifies the maximum number of minutes that a route can be suppressed regardless of how unstable it is. You can set the maximum suppression time to a value from 1 – 20000 minutes. The default is four times the half-life setting. Thus, if you use the default half-life of 15 minutes, the maximum suppression time is 60 minutes.

The following example shows how to change the dampening parameters.

```
FastIron(config-bgp-router)# dampening 20 200 2500 40
```

This command changes the half-life to 20 minutes, the reuse threshold to 200, the suppression threshold to 2500, and the maximum number of minutes a route can be dampened to 40.

**NOTE**

To change any of the parameters, you must specify all the parameters with the command. If you want to leave some parameters unchanged, enter their default values.
Using a route map to configure route flap dampening for specific routes

Route maps enable you to fine tune route flap dampening parameters for individual routes. To configure route flap dampening parameters using route maps, configure BGP4 address filters for each route you want to set the dampening parameters for, then configure route map entries that set the dampening parameters for those routes. The following sections show examples.

To configure address filters and a route map for dampening specific routes, enter commands such as the following.

```
FastIron(config)# router bgp
FastIron(config-bgp-router)# address-filter 9 permit 209.157.22.0 255.255.255.0
255.255.255.0 255.255.255.0
FastIron(config-bgp-router)# address-filter 10 permit 209.157.23.0 255.255.255.0
255.255.255.0 255.255.255.0
FastIron(config-bgp-router)# exit
FastIron(config)# route-map DAMPENING_MAP permit 9
FastIron(config-routemap DAMPENING_MAP)# match address-filters 9
FastIron(config-routemap DAMPENING_MAP)# set dampening 10 200 2500 40
FastIron(config-routemap DAMPENING_MAP)# exit
FastIron(config)# route-map DAMPENING_MAP permit 10
FastIron(config-routemap DAMPENING_MAP)# match address-filters 10
FastIron(config-routemap DAMPENING_MAP)# set dampening 20 200 2500 60
FastIron(config-routemap DAMPENING_MAP)# router bgp
FastIron(config-bgp-router)# dampening route-map DAMPENING_MAP
```

The address-filter commands in this example configure two BGP4 address filters, for networks 209.157.22.0 and 209.157.23.0. The first route-map command creates an entry in a route map called "DAMPENING_MAP". Within this entry of the route map, the match command matches based on address filter 9, and the set command sets the dampening parameters for the route that matches. Thus, for BGP4 routes to 209.157.22.0, the Layer 3 Switch uses the route map to set the dampening parameters. These parameters override the globally configured dampening parameters.

The commands for the second entry in the route map (instance 10 in this example) perform the same functions for route 209.157.23.0. Notice that the dampening parameters are different for each route.

Using a route map to configure route flap dampening for a specific neighbor

You can use a route map to configure route flap dampening for a specific neighbor by performing the following tasks:

- Configure an empty route map with no match or set statements. This route map does not specify particular routes for dampening but does allow you to enable dampening globally when you refer to this route map from within the BGP configuration level.
- Configure another route map that explicitly enables dampening. Use a set statement within the route map to enable dampening. When you associate this route map with a specific neighbor, the route map enables dampening for all routes associated with the neighbor. You also can use match statements within the route map to selectively perform dampening on some routes from the neighbor.
Configuring route flap dampening

NOTE
You still need to configure the first route map to enable dampening globally. The second route map does not enable dampening by itself; it just applies dampening to a neighbor.

- Apply the route map to the neighbor.

To enable route flap dampening for a specific BGP4 neighbor, enter commands such as the following.

```plaintext
FastIron(config)# route-map DAMPENING_MAP_ENABLE permit 1
FastIron(config)# route-map DAMPENING_MAP_NEIGHBOR_A permit 1
FastIron(config)# set dampening
FastIron(config)# router bgp
FastIron(config-router)# dampening route-map DAMPENING_MAP_ENABLE
FastIron(config-router)# neighbor 10.10.10.1 route-map in DAMPENING_MAP_NEIGHBOR_A
```

In this example, the first command globally enables route flap dampening. This route map does not contain any match or set statements. At the BGP configuration level, the `dampening route-map` command refers to the DAMPENING_MAP_ENABLE route map created by the first command, thus enabling dampening globally.

The third and fourth commands configure a second route map that explicitly enables dampening. Notice that the route map does not contain a match statement. The route map implicitly applies to all routes. Since the route map will be applied to a neighbor at the BGP configuration level, the route map will apply to all routes associated with the neighbor.

Although the second route map enables dampening, the first route map is still required. The second route map enables dampening for the neighbors to which the route map is applied. However, unless dampening is already enabled globally by the first route map, the second route map has no effect.

The last two commands apply the route maps. The `dampening route-map` command applies the first route map, which enables dampening globally. The `neighbor` command applies the second route map to neighbor 10.10.10.1. Since the second route map does not contain match statements for specific routes, the route map enables dampening for all routes received from the neighbor.

Removing route dampening from a route

You can un-suppress routes by removing route flap dampening from the routes. The Layer 3 Switch allows you to un-suppress all routes at once or un-suppress individual routes.

To un-suppress all the suppressed routes, enter the following command at the Privileged EXEC level of the CLI.

```plaintext
FastIron(config)# clear ip bgp damping
```

**Syntax:** `clear ip bgp damping <ip-addr> <ip-mask>`

The `<ip-addr>` parameter specifies a particular network.

The `<ip-mask>` parameter specifies the network mask.

To un-suppress a specific route, enter a command such as the following.

```plaintext
FastIron(config)# clear ip bgp damping 209.157.22.0 255.255.255.0
```

This command un-suppresses only the routes for network 209.157.22.0/24.
Removing route dampening from a neighbor routes suppressed due to aggregation

You can selectively unsuppress more-specific routes that have been suppressed due to aggregation, and allow the routes to be advertised to a specific neighbor or peer group.

Here is an example.

```
FastIron(config-bgp-router)# aggregate-address 209.1.0.0 255.255.0.0
summary-only
FastIron(config-bgp-router)# show ip bgp route 209.1.0.0/16 longer
Number of BGP Routes matching display condition : 2
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
Prefix Next Hop Metric LocPrf Weight Status
1 209.1.0.0/16 0.0.0.0 101 32768 BAL
AS_PATH:
2 209.1.44.0/24 10.2.0.1 1 101 32768 BLS
AS_PATH:

The `aggregate-address` command configures an aggregate address. The `summary-only` parameter prevents the Layer 3 Switch from advertising more specific routes contained within the aggregate route. The `show ip bgp route` command shows that the more specific routes aggregated into 209.1.0.0/16 have been suppressed. In this case, the route to 209.1.44.0/24 has been suppressed. The following command indicates that the route is not being advertised to the Layer 3 Switch BGP4 neighbors.

```
FastIron(config)# show ip bgp route 209.1.44.0/24
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST C:CONFED_EBGP D:DAMPED
Prefix Next Hop Metric LocPrf Weight Status
1 209.1.44.0/24 10.2.0.1 1 101 32768 BLS
AS_PATH:
Route is not advertised to any peers
```

If you want to override the `summary-only` parameter and allow a specific route to be advertised to a neighbor, enter commands such as the following.

```
FastIron(config)# ip prefix-list Unsuppress1 permit 209.1.44.0/24
FastIron(config)# route-map RouteMap1 permit 1
FastIron(config-routeemap RouteMap1)# match prefix-list Unsuppress1
FastIron(config-routeemap RouteMap1)# exit
FastIron(config)# router bgp
FastIron(config-bgp-router)# neighbor 10.1.0.2 unsuppress-map RouteMap1
FastIron(config-bgp-router)# clear ip bgp neighbor 10.1.0.2 soft-out
```

The `ip prefix-list` command configures an IP prefix list for network 209.1.44.0/24, which is the route you want to unsuppress. The next two commands configure a route map that uses the prefix list as input. The `neighbor` command enables the Layer 3 Switch to advertise the routes specified in the route map to neighbor 10.1.0.2. The `clear` command performs a soft reset of the session with the neighbor so that the Layer 3 Switch can advertise the unsuppressed route.

**Syntax:** `[no] neighbor <ip-addr> | <peer-group-name> unsuppress-map <map-name>
```
The following command verifies that the route has been unsuppressed.
Configuring route flap dampening

Displaying and clearing route flap dampening statistics

The software provides many options for displaying and clearing route flap statistics. To display the statistics, use either of the following methods.

Displaying route flap dampening statistics

To display route dampening statistics or all the dampened routes, enter the following command at any level of the CLI.

FastIron# show ip bgp route 209.1.44.0/24
Number of BGP Routes matching display condition : 1
Status A:AGGREGATE B:BEST b:NOT-INSTALLED BEST C:CONFED_EBGP D:DAMPED
Prefix Next Hop Metric LocPrf Weight Status
1 209.1.44.0/24 10.2.0.1 1 101 32768 BLS AS_PATH:
Route is advertised to 1 peers: 10.1.0.2(4)

FastIron# show ip bgp flap-statistics
Total number of flapping routes: 414
Status Code >:best d:damped h:history *:valid

<table>

</tbody>
</table>

Syntax: show ip bgp flap-statistics [regular-expression <regular-expression> | <address> <mask> [longer-prefixes] | neighbor <ip-addr>]

The regular-expression <regular-expression> parameter is a regular expression. The regular expressions are the same ones supported for BGP4 AS-path filters. Refer to “Using regular expressions” on page 1348.

The <address> <mask> parameter specifies a particular route. If you also use the optional longer-prefixes parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify 209.157.0.0 longer, then all routes with the prefix 209.157. or that have a longer prefix (such as 209.157.22.) are displayed.

The neighbor <ip-addr> parameter displays route flap dampening statistics only for routes learned from the specified neighbor. You also can display route flap statistics for routes learned from a neighbor by entering the following command: show ip bgp neighbor <ip-addr> flap-statistics.

This display shows the following information.
Generating traps for BGP

You also can display all the dampened routes by entering the following command.

```
show ip bgp dampened-paths
```

### Clearing route flap dampening statistics

To clear route flap dampening statistics, use the following CLI method.

**NOTE**

Clearing the dampening statistics for a route does not change the dampening status of the route.

To clear all the route dampening statistics, enter the following command at any level of the CLI.

```
FastIron# clear ip bgp flap-statistics
```

**Syntax:** `clear ip bgp flap-statistics [regular-expression <regular-expression> | <address> <mask> | neighbor <ip-addr>]`

The parameters are the same as those for the `show ip bgp flap-statistics` command (except the `longer-prefixes` option is not supported). Refer to “Displaying route flap dampening statistics” on page 1370.

**NOTE**

The `clear ip bgp damping` command not only clears statistics but also un-suppresses the routes. Refer to “Displaying route flap dampening statistics” on page 1370.

### Generating traps for BGP

You can enable and disable SNMP traps for BGP. BGP traps are enabled by default.

To enable BGP traps after they have been disabled, enter the following command.

```
FastIron(config)# snmp-server enable traps bgp
```
Displaying BGP4 information

You can display the following configuration information and statistics for the BGP4 protocol on the router:

- Summary BGP4 configuration information for the router
- Active BGP4 configuration information (the BGP4 information in the running-config)
- CPU utilization statistics
- Neighbor information
- Peer-group information
- Information about the paths from which BGP4 selects routes
- Summary BGP4 route information
- The router BGP4 route table
- Route flap dampening statistics
- Active route maps (the route map configuration information in the running-config)

Displaying summary BGP4 information

You can display the local AS number, the maximum number of routes and neighbors supported, and some BGP4 statistics.

To view summary BGP4 information for the router, enter the following command at any CLI prompt.

```
FastIron# show ip bgp summary
```

BGP4 Summary

Router ID: 101.0.0.1   Local AS Number : 4
Confederation Identifier : not configured
Confederation Peers: 4 5
Maximum Number of Paths Supported for Load Sharing : 1
Number of Neighbors Configured : 11
Number of Routes Installed : 2
Number of Routes Advertising to All Neighbors : 8
Number of Attribute Entries Installed : 6

Displaying BGP4 information

Table 224  BGP4 summary information (Continued)

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>State</td>
<td>The state of this router neighbor session with each neighbor. The states are from this router perspective of the session, not the neighbor perspective. The state values are based on the BGP4 state machine values described in RFC 1771 and can be one of the following for each router:</td>
</tr>
<tr>
<td></td>
<td>• IDLE – The BGP4 process is waiting to be started. Usually, enabling BGP4 or establishing a neighbor session starts the BGP4 process. A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes.</td>
</tr>
<tr>
<td></td>
<td>• ADMND – The neighbor has been administratively shut down. Refer to “Administratively shutting down a session with a BGP4 neighbor” on page 1316. A minus sign (-) indicates that the session has gone down and the software is clearing or removing routes.</td>
</tr>
<tr>
<td></td>
<td>• CONNECT – BGP4 is waiting for the connection process for the TCP neighbor session to be completed.</td>
</tr>
<tr>
<td></td>
<td>• ACTIVE – BGP4 is waiting for a TCP connection from the neighbor.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> If the state frequently changes between CONNECT and ACTIVE, there may be a problem with the TCP connection.</td>
</tr>
<tr>
<td></td>
<td>• OPEN SENT – BGP4 is waiting for an Open message from the neighbor.</td>
</tr>
<tr>
<td></td>
<td>• OPEN CONFIRM – BGP4 has received an OPEN message from the neighbor and is now waiting for either a KEEPALIVE or NOTIFICATION message. If the router receives a KEEPALIVE message from the neighbor, the state changes to Established. If the message is a NOTIFICATION, the state changes to Idle.</td>
</tr>
<tr>
<td></td>
<td>• ESTABLISHED – BGP4 is ready to exchange UPDATE packets with the neighbor. If there is more BGP data in the TCP receiver queue, a plus sign (+) is also displayed.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> If you display information for the neighbor using the show ip bgp neighbor &lt;ip-addr&gt; command, the TCP receiver queue value will be greater than 0.</td>
</tr>
<tr>
<td>Time</td>
<td>The time that has passed since the state last changed.</td>
</tr>
<tr>
<td>Accepted</td>
<td>The number of routes received from the neighbor that this router installed in the BGP4 route table. Usually, this number is lower than the RoutesRcvd number. The difference indicates that this router filtered out some of the routes received in the UPDATE messages.</td>
</tr>
<tr>
<td>Filtered</td>
<td>The routes or prefixes that have been filtered out:</td>
</tr>
<tr>
<td></td>
<td>• If soft reconfiguration is enabled, this field shows how many routes were filtered out (not placed in the BGP4 route table) but retained in memory.</td>
</tr>
<tr>
<td></td>
<td>• If soft reconfiguration is not enabled, this field shows the number of BGP4 routes that have been filtered out.</td>
</tr>
<tr>
<td>Sent</td>
<td>The number of BGP4 routes that the Layer 3 Switch has sent to the neighbor.</td>
</tr>
<tr>
<td>ToSend</td>
<td>The number of routes the Layer 3 Switch has queued to send to this neighbor.</td>
</tr>
</tbody>
</table>

Displaying the active BGP4 configuration

To view the active BGP4 configuration information contained in the running-config without displaying the entire running-config, use the following CLI method.

To display the device active BGP4 configuration, enter the following command at any level of the CLI.
FastIron# show ip bgp config
Current BGP configuration:
  router bgp
  address-filter 1 deny any any
  as-path-filter 1 permit ^65001$
  local-as 65002
  maximum-paths 4
  neighbor pg1 peer-group
  neighbor pg1 remote-as 65001
  neighbor pg1 description "FastIron group 1"
  neighbor pg1 distribute-list out 1
  neighbor 192.169.100.1 peer-group pg1
  neighbor 192.169.101.1 peer-group pg1
  neighbor 192.169.102.1 peer-group pg1
  neighbor 192.169.201.1 remote-as 65101
  neighbor 192.169.201.1 shutdown
  neighbor 192.169.220.3 remote-as 65432
  network 1.1.1.0 255.255.255.0
  network 2.2.2.0 255.255.255.0
  redistribute connected

Syntax:  show ip bgp config

Displaying CPU utilization statistics

You can display CPU utilization statistics for BGP4 and other IP protocols.

To display CPU utilization statistics for BGP4 for the previous one-second, one-minute, five-minute, and fifteen-minute intervals, enter the following command at any level of the CLI.

FastIron# show process cpu

<table>
<thead>
<tr>
<th>Process Name</th>
<th>5Sec(%)</th>
<th>1Min(%)</th>
<th>5Min(%)</th>
<th>15Min(%)</th>
<th>Runtime (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARP</td>
<td>0.01</td>
<td>0.03</td>
<td>0.09</td>
<td>0.22</td>
<td>9</td>
</tr>
<tr>
<td>BGP</td>
<td>0.04</td>
<td>0.06</td>
<td>0.08</td>
<td>0.14</td>
<td>13</td>
</tr>
<tr>
<td>GVRP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>ICMP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>IP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>OSPF</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>RIP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>STP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>VRRP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
</tbody>
</table>

If the software has been running less than 15 minutes (the maximum interval for utilization statistics), the command indicates how long the software has been running. Here is an example.
Displaying BGP4 information

```
FastIron# show process cpu
The system has only been up for 6 seconds.

<table>
<thead>
<tr>
<th>Process Name</th>
<th>5Sec(%)</th>
<th>1Min(%)</th>
<th>5Min(%)</th>
<th>15Min(%)</th>
<th>Runtime(ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARP</td>
<td>0.01</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>BGP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>GVRP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>ICMP</td>
<td>0.01</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>1</td>
</tr>
<tr>
<td>IP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>OSPF</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>RIP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>STP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>VRRP</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0.00</td>
<td>0</td>
</tr>
</tbody>
</table>

To display utilization statistics for a specific number of seconds, enter a command such as the following.

```
FastIron# show process cpu 2
Statistics for last 1 sec and 80 ms

<table>
<thead>
<tr>
<th>Process Name</th>
<th>Sec(%)</th>
<th>Time(ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>BGP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>GVRP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>ICMP</td>
<td>0.01</td>
<td>1</td>
</tr>
<tr>
<td>IP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>OSPF</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>RIP</td>
<td>0.00</td>
<td>0</td>
</tr>
<tr>
<td>STP</td>
<td>0.01</td>
<td>0</td>
</tr>
<tr>
<td>VRRP</td>
<td>0.00</td>
<td>0</td>
</tr>
</tbody>
</table>

When you specify how many seconds’ worth of statistics you want to display, the software selects the sample that most closely matches the number of seconds you specified. In this example, statistics are requested for the previous two seconds. The closest sample available is actually for the previous 1 second plus 80 milliseconds.

**Syntax:** `show process cpu [<num>]`

The `<num>` parameter specifies the number of seconds and can be from 1 – 900. If you use this parameter, the command lists the usage statistics only for the specified number of seconds. If you do not use this parameter, the command lists the usage statistics for the previous one-second, one-minute, five-minute, and fifteen-minute intervals.

### Displaying summary neighbor information

To display summary neighbor information, enter a command such as the following at any level of the CLI.
Syntax: show ip bgp neighbor <ip-addr> [route-summary]

This display shows the following information.

**TABLE 225**  BGP4 route summary information for a neighbor

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Address</td>
<td>The IP address of the neighbor</td>
</tr>
<tr>
<td>Routes Received</td>
<td>How many routes the Layer 3 Switch has received from the neighbor during the current BGP4 session:</td>
</tr>
<tr>
<td></td>
<td>• Accepted/Installed – Indicates how many of the received routes the Layer 3 Switch accepted and installed in the BGP4 route table.</td>
</tr>
<tr>
<td></td>
<td>• Filtered/Kept – Indicates how many routes were filtered out, but were nonetheless retained in memory for use by the soft reconfiguration feature.</td>
</tr>
<tr>
<td></td>
<td>• Filtered – Indicates how many of the received routes were filtered out.</td>
</tr>
<tr>
<td>Routes Selected as BEST Routes</td>
<td>The number of routes that the Layer 3 Switch selected as the best routes to their destinations.</td>
</tr>
<tr>
<td>BEST Routes not Installed in IP</td>
<td>The number of routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 Switch received better routes from other sources (such as OSPF, RIP, or static IP routes).</td>
</tr>
<tr>
<td>Forwarding Table</td>
<td></td>
</tr>
<tr>
<td>Unreachable Routes</td>
<td>The number of routes received from the neighbor that are unreachable because the Layer 3 Switch does not have a valid RIP, OSPF, or static route to the next hop.</td>
</tr>
<tr>
<td>History Routes</td>
<td>The number of routes that are down but are being retained for route flap dampening purposes.</td>
</tr>
<tr>
<td>NLRIs Received in Update Message</td>
<td>The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages:</td>
</tr>
<tr>
<td></td>
<td>• Withdraws – The number of withdrawn routes the Layer 3 Switch has received.</td>
</tr>
<tr>
<td></td>
<td>• Replacements – The number of replacement routes the Layer 3 Switch has received.</td>
</tr>
</tbody>
</table>
Displaying BGP4 information

To view BGP4 neighbor information including the values for all the configured parameters, enter the following command.

**NOTE**
The display shows all the configured parameters for the neighbor. Only the parameters that have values different from their defaults are shown.
Displaying BGP4 information

This example shows how to display information for a specific neighbor, by specifying the neighbor IP address with the command. None of the other display options are used; thus, all of the information is displayed for the neighbor. The number in the far left column indicates the neighbor for which information is displayed. When you list information for multiple neighbors, this number makes the display easier to read.

The TCP statistics at the end of the display show status for the TCP session with the neighbor. Most of the fields show information stored in the Layer 3 Switch Transmission Control Block (TCB) for the TCP session between the Layer 3 Switch and its neighbor. These fields are described in detail in section 3.2 of RFC 793, “Transmission Control Protocol Functional Specification”.

The <ip-addr> option lets you narrow the scope of the command to a specific neighbor.

The advertised-routes option displays only the routes that the Layer 3 Switch has advertised to the neighbor during the current BGP4 neighbor session.
The **attribute-entries** option shows the attribute-entries associated with routes received from the neighbor.

The **flap-statistics** option shows the route flap statistics for routes received from or sent to the neighbor.

The **last-packet-with-error** option displays the last packet from the neighbor that contained an error. The packet's contents are displayed in decoded (human-readable) format.

The **received prefix-filter** option shows the Outbound Route Filters (ORFs) received from the neighbor. This option applies to cooperative route filtering.

The **received-routes option** lists all the route information received in route updates from the neighbor since the soft reconfiguration feature was enabled. Refer to “Using soft reconfiguration” on page 1401.

The **routes** option lists the routes received in UPDATE messages from the neighbor. You can specify the following additional options:

- **best** – Displays the routes received from the neighbor that the Layer 3 Switch selected as the best routes to their destinations.
- **not-installed-best** – Displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 Switch received better routes from other sources (such as OSPF, RIP, or static IP routes).
- **unreachable** – Displays the routes that are unreachable because the Layer 3 Switch does not have a valid RIP, OSPF, or static route to the next hop.
- **detail** – Displays detailed information for the specified routes. You can refine your information request by also specifying one of the options above (best, not-installed-best, or unreachable).

The **rib-out-routes** option lists the route information base (RIB) for outbound routes. You can display all the routes or specify a network address.

The **routes-summary option** displays a summary of the following information:

- Number of routes received from the neighbor
- Number of routes accepted by this Layer 3 Switch from the neighbor
- Number of routes this Layer 3 Switch filtered out of the UPDATES received from the neighbor and did not accept
- Number of routes advertised to the neighbor
- Number of attribute entries associated with routes received from or advertised to the neighbor.

This display shows the following information.

**TABLE 226**  BGP4 neighbor information

<table>
<thead>
<tr>
<th>This field…</th>

If the router receives a NOTIFICATION message from the neighbor, the message contains an error code corresponding to one of the following errors. Some errors have subcodes that clarify the reason for the error. Where applicable, the subcode messages are listed underneath the error code messages.

**Message Header Error:**
- Connection Not Synchronized
- Bad Message Length
- Bad Message Type
- Unspecified

**Open Message Error:**
- Unsupported Version
- Bad Peer As
- Bad BGP Identifier
- Unsupported Optional Parameter
- Authentication Failure
- Unacceptable Hold Time
- Unspecified

**Update Message Error:**
- Malformed Attribute List
- Unrecognized Attribute
- Missing Attribute
- Attribute Flag Error
- Attribute Length Error
- Invalid Origin Attribute
- Invalid NextHop Attribute
- Optional Attribute Error
- Invalid Network Field
- Malformed AS Path
- Unspecified

**Hold Timer Expired**

**Finite State Machine Error**
- Cease
- Unsatisfied

</table>
TCP Connection state | The state of the connection with the neighbor. The connection can have one of the following states:
| | • LISTEN – Waiting for a connection request.
| | • SYN-SENT – Waiting for a matching connection request after having sent a connection request.
| | • SYN-RECEIVED – Waiting for a confirming connection request acknowledgment after having both received and sent a connection request.
| | • ESTABLISHED – Data can be sent and received over the connection. This is the normal operational state of the connection.
| | • FIN-WAIT-1 – Waiting for a connection termination request from the remote TCP, or an acknowledgment of the connection termination request previously sent.
| | • FIN-WAIT-2 – Waiting for a connection termination request from the remote TCP.
| | • CLOSE-WAIT – Waiting for a connection termination request from the local user.
| | • CLOSING – Waiting for a connection termination request acknowledgment from the remote TCP.
| | • LAST-ACK – Waiting for an acknowledgment of the connection termination request previously sent to the remote TCP (which includes an acknowledgment of its connection termination request).
| | • TIME-WAIT – Waiting for enough time to pass to be sure the remote TCP received the acknowledgment of its connection termination request.
| | • CLOSED – There is no connection state.

| Byte Sent | The number of bytes sent. |
| Byte Received | The number of bytes received. |
| Local host | The IP address of the Layer 3 Switch. |
| Local port | The TCP port the Layer 3 Switch is using for the BGP4 TCP session with the neighbor. |
| Remote host | The IP address of the neighbor. |
| Remote port | The TCP port the neighbor is using for the BGP4 TCP session with the Layer 3 Switch. |
| ISentSeq | The initial send sequence number for the session. |
| SendNext | The next sequence number to be sent. |
| TotUnAck | The number of sequence numbers sent by the Layer 3 Switch that have not been acknowledged by the neighbor. |
| TotSent | The number of sequence numbers sent to the neighbor. |
| ReTrans | The number of sequence numbers that the Layer 3 Switch retransmitted because they were not acknowledged. |
| UnAckSeq | The current acknowledged sequence number. |
| IRcvSeq | The initial receive sequence number for the session. |
| RcvNext | The next sequence number expected from the neighbor. |
| SendWnd | The size of the send window. |
| TotalRcv | The number of sequence numbers received from the neighbor. |
| DuplRcv | The number of duplicate sequence numbers received from the neighbor. |
Displaying BGP4 information

Displaying route information for a neighbor

You can display routes based on the following criteria:

- A summary of the routes for a specific neighbor.
- The routes received from the neighbor that the Layer 3 Switch selected as the best routes to their destinations.
- The routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 Switch received better routes from other sources (such as OSPF, RIP, or static IP routes).
- The routes that are unreachable because the Layer 3 Switch does not have a valid RIP, OSPF, or static route to the next hop.
- Routes for a specific network advertised by the Layer 3 Switch to the neighbor.
- The Routing Information Base (RIB) for a specific network advertised to the neighbor. You can display the RIB regardless of whether the Layer 3 Switch has already sent it to the neighbor.

To display route information for a neighbor, use the following CLI methods.

Displaying summary route information

To display summary route information, enter a command such as the following at any level of the CLI.

FastIron# show ip bgp neighbor 10.1.0.2 routes-summary
1   IP Address: 10.1.0.2
Routes Accepted/Installed:1, Filtered/Kept:11, Filtered:11
Routes Selected as BEST Routes:1
   BEST Routes not Installed in IP Forwarding Table:0
Unreachable Routes (no IGP Route for NEXTHOP):0
History Routes:0
NLRIs Received in Update Message:24, Withdraws:0 (0), Replacements:1
NLRIs Discarded due to
   Maximum Prefix Limit:0, AS Loop:0
   Invalid Nexthop:0, Invalid Nexthop Address:0.0.0.0
   Duplicated Originator_ID:0, Cluster_ID:0
Routes Advertised:0, To be Sent:0, To be Withdrawn:0
NLRIs Sent in Update Message:0, Withdraws:0, Replacements:0
Peer Out of Memory Count for:
   Receiving Update Messages:0, Accepting Routes(NLRI):0
   Attributes:0, Outbound Routes(RIB-out):0

This display shows the following information.

<table>
<thead>
<tr>

<td>The number of routes that are down but are being retained for route flap dampening purposes.</td>
</tr>
<tr>
<td>NLRIs Received in Update Message</td>
<td>The number of routes received in Network Layer Reachability (NLRI) format in UPDATE messages:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Withdraws</strong> – The number of withdrawn routes the Layer 3 Switch has received.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Replacements</strong> – The number of replacement routes the Layer 3 Switch has received.</td>
</tr>
<tr>
<td>NLRIs Discarded due to</td>
<td>Indicates the number of times the Layer 3 Switch discarded an NLRI for the neighbor due to the following reasons:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Maximum Prefix Limit</strong> – The Layer 3 Switch configured maximum prefix amount had been reached.</td>
</tr>
<tr>
<td></td>
<td>• <strong>AS Loop</strong> – An AS loop occurred. An AS loop occurs when the BGP4 AS-path attribute contains the local AS number.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Invalid Nexthop</strong> – The next hop value was not acceptable.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Duplicated Originator_ID</strong> – The originator ID was the same as the local router ID.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Cluster_ID</strong> – The cluster list contained the local cluster ID, or contained the local router ID (see above) if the cluster ID is not configured.</td>
</tr>
<tr>
<td>Routes Advertised</td>
<td>The number of routes the Layer 3 Switch has advertised to this neighbor:</td>
</tr>
<tr>
<td></td>
<td>• <strong>To be Sent</strong> – The number of routes the Layer 3 Switch has queued to send to this neighbor.</td>
</tr>
</tbody>
</table>
|                                      | • **To be Withdrawn** – The number of NLRIs for withdrawing routes the Layer 3 Switch has queued up to send to this neighbor in UPDATE messages.
Displaying BGP4 information

Displaying advertised routes
To display the routes the Layer 3 Switch has advertised to a specific neighbor for a specific network, enter a command such as the following at any level of the CLI.

FastIron# show ip bgp neighbors 192.168.4.211 advertised-routes
There are 2 routes advertised to neighbor 192.168.4.211
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL

<table>
<thead>
<tr>
<th>Network</th>
<th>Next Hop</th>
<th>Metric</th>
<th>LocPrf</th>
<th>Weight</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0.0.0.0/24</td>
<td>192.168.2.102</td>
<td>12</td>
<td>32768</td>
<td>BL</td>
<td></td>
</tr>
<tr>
<td>2 0.1.1.0/24</td>
<td>192.168.2.102</td>
<td>0</td>
<td>32768</td>
<td>BL</td>
<td></td>
</tr>
</tbody>
</table>

You also can enter a specific route, as in the following example.

FastIron# show ip bgp neighbors 192.168.4.211 advertised 200.1.1.0/24
Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL

<table>
<thead>
<tr>
<th>Network</th>
<th>Next Hop</th>
<th>Metric</th>
<th>LocPrf</th>
<th>Weight</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 200.1.1.0/24</td>
<td>192.168.2.102</td>
<td>0</td>
<td>32768</td>
<td>BL</td>
<td></td>
</tr>
</tbody>
</table>

Syntax: show ip bgp neighbor <ip-addr> advertised-routes [<ip-addr> / <prefix>]

For information about the fields in this display, refer to Table 229 on page 1394. The fields in this display also appear in the show ip bgp display.

Displaying the best routes
To display the routes received from a specific neighbor that are the “best” routes to their destinations, enter a command such as the following at any level of the CLI.

FastIron# show ip bgp neighbor 192.168.4.211 routes best

Syntax: show ip bgp neighbor <ip-addr> routes best

For information about the fields in this display, refer to Table 229 on page 1394. The fields in this display also appear in the show ip bgp display.
Displaying the best routes that were nonetheless not installed in the IP route table
To display the BGP4 routes received from a specific neighbor that are the “best” routes to their destinations but are not installed in the Layer 3 Switch IP route table, enter a command such as the following at any level of the CLI.

FastIron# show ip bgp neighbor 192.168.4.211 routes not-installed-best

Each of the displayed routes is a valid path to its destination, but the Layer 3 Switch received another path from a different source (such as OSPF, RIP, or a static route) that has a lower administrative distance. The Layer 3 Switch always selects the path with the lowest administrative distance to install in the IP route table.

Syntax:  show ip bgp neighbor <ip-addr> routes not-installed-best

For information about the fields in this display, refer to Table 229 on page 1394. The fields in this display also appear in the show ip bgp display.

Displaying the routes whose destinations are unreachable
To display BGP4 routes whose destinations are unreachable using any of the BGP4 paths in the BGP4 route table, enter a command such as the following at any level of the CLI.

FastIron# show ip bgp neighbor 192.168.4.211 routes unreachable

Syntax:  show ip bgp neighbor <ip-addr> routes unreachable

For information about the fields in this display, refer to Table 229 on page 1394. The fields in this display also appear in the show ip bgp display.

Displaying the Adj-RIB-Out for a neighbor
To display the Layer 3 Switch current BGP4 Routing Information Base (Adj-RIB-Out) for a specific neighbor and a specific destination network, enter a command such as the following at any level of the CLI.

FastIron# show ip bgp neighbor 192.168.4.211 rib-out-routes 192.168.1.0/24

Status A:AGGREGATE B:BEST b:NOT-INSTALLED-BEST I:IBGP L:LOCAL

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Next Hop</th>
<th>Metric</th>
<th>LocPrf</th>
<th>Weight</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 200.1.1.0/24</td>
<td>0.0.0.0</td>
<td>0</td>
<td>101</td>
<td>32768</td>
<td>BL</td>
</tr>
</tbody>
</table>

The Adj-RIB-Out contains the routes that the Layer 3 Switch either has most recently sent to the neighbor or is about to send to the neighbor.

Syntax:  show ip bgp neighbor <ip-addr> rib-out-routes [<ip-addr>/<prefix>]

For information about the fields in this display, refer to Table 229 on page 1394. The fields in this display also appear in the show ip bgp display.

Displaying peer group information
You can display configuration information for peer groups.

To display peer-group information, enter a command such as the following at the Privileged EXEC level of the CLI.
Displaying BGP4 information

Displaying BGP4 information

Syntax: show ip bgp peer-group [<peer-group-name>]

Only the parameters that have values different from their defaults are listed.

Displaying summary route information

To display summary statistics for all the routes in the Layer 3 Switch BGP4 route table, enter a command such as the following at any level of the CLI.

FastIron# show ip bgp routes summary
  Total number of BGP routes (NLRIs) Installed : 20
  Distinct BGP destination networks : 20
  Filtered BGP routes for soft reconfig : 100178
  Routes originated by this router : 2
  Routes selected as BEST routes : 19
  BEST routes not installed in IP forwarding table : 1
  Unreachable routes (no IGP route for NEXTHOP) : 1
  IBGP routes selected as best routes : 0
  EBGP routes selected as best routes : 17

Syntax: show ip bgp routes summary

This display shows the following information.

TABLE 228  BGP4 summary route information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total number of BGP routes (NLRIs) Installed</td>
<td>The number of BGP4 routes the Layer 3 Switch has installed in the BGP4 route table.</td>
</tr>
<tr>
<td>Distinct BGP destination networks</td>
<td>The number of destination networks the installed routes represent. The BGP4 route table can have multiple routes to the same network.</td>
</tr>
<tr>
<td>Filtered BGP routes for soft reconfig</td>
<td>The number of route updates received from soft-reconfigured neighbors or peer groups that have been filtered out but retained. For information about soft reconfiguration, refer to “Using soft reconfiguration” on page 1401.</td>
</tr>
<tr>
<td>Routes originated by this router</td>
<td>The number of routes in the BGP4 route table that this Layer 3 Switch originated.</td>
</tr>
<tr>
<td>Routes selected as BEST routes</td>
<td>The number of routes in the BGP4 route table that this Layer 3 Switch has selected as the best routes to the destinations.</td>
</tr>
<tr>
<td>BEST routes not installed in IP forwarding table</td>
<td>The number of BGP4 routes that are the best BGP4 routes to their destinations but were not installed in the IP route table because the Layer 3 Switch received better routes from other sources (such as OSPF, RIP, or static IP routes).</td>
</tr>
<tr>
<td>Unreachable routes (no IGP route for NEXTHOP)</td>
<td>The number of routes in the BGP4 route table whose destinations are unreachable because the next hop is unreachable.</td>
</tr>
</tbody>
</table>
Displaying BGP4 information

BGP4 uses filters you define as well as the algorithm described in “How BGP4 selects a path for a route” on page 1297 to determine the preferred route to a destination. BGP4 sends only the preferred route to the router IP table. However, if you want to view all the routes BGP4 knows about, you can display the BGP4 table using either of the following methods.

To view the BGP4 route table, enter the following command.

FastIron# show ip bgp routes
Total number of BGP Routes: 97371
Prefix Next Hop Metric LocPrf Weight Status
1 3.0.0.0/8 192.168.4.106 100 0 BE
   AS_PATH: 65001 4355 701 80
2 4.0.0.0/8 192.168.4.106 100 0 BE
   AS_PATH: 65001 4355 1
3 4.60.212.0/22 192.168.4.106 100 0 BE
   AS_PATH: 65001 4355 701 1 189
4 6.0.0.0/8 192.168.4.106 100 0 BE
   AS_PATH: 65001 4355 3356 7170 1455
5 8.8.1.0/24 192.168.4.106 0 100 0 BE
   AS_PATH: 65001

Syntax:  show ip bgp routes [[network] <ip-addr> | [num] | [age <secs>] | [as-path-access-list <num>] | [best] | [cidr-only] | [community <num>] | [no-export] | [no-advertise] | [internet | [local-as] | [community-access-list <num>] | [community-list <num>] | [detail <option>] | [filter-list <num, num,...> | [next-hop <ip-addr>] | [not-best] | [not-installed-best] | [prefix-list <string> | [regular-expression <regular-expression>] | [route-map <map-name> | [summary] | [unreachable]

The <ip-addr> option displays routes for a specific network. The network keyword is optional. You can enter the network address without entering “network” in front of it.

The <num> option specifies the table entry with which you want the display to start. For example, if you want to list entries beginning with table entry 100, specify 100.

The age <secs> parameter displays only the routes that have been received or updated more recently than the number of seconds you specify.

The as-path-access-list <num> parameter filters the display using the specified AS-path ACL.

The best parameter displays the routes received from the neighbor that the Layer 3 Switch selected as the best routes to their destinations.

The cidr-only option lists only the routes whose network masks do not match their class network length.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBGP routes selected as best routes</td>
<td>The number of “best” routes in the BGP4 route table that are IBGP routes.</td>
</tr>
<tr>
<td>EBGP routes selected as best routes</td>
<td>The number of “best” routes in the BGP4 route table that are EBGP routes.</td>
</tr>
</tbody>
</table>
The **community** option lets you display routes for a specific community. You can specify **local-as**, **no-export**, **no-advertise**, **internet**, or a private community number. You can specify the community number as either two five-digit integer values of up to 1–65535, separated by a colon (for example, 12345:6789) or a single long integer value.

The **community-access-list <num>** parameter filters the display using the specified community ACL.

The **community-list** option lets you display routes that match a specific community filter.

The **detail** option lets you display more details about the routes. You can refine your request by also specifying one of the other display options after the detail keyword.

The **filter-list** option displays routes that match a specific address filter list.

The **next-hop <ip-addr>** option displays the routes for a given next-hop IP address.

The **no-best** option displays the routes for which none of the routes to a given prefix were selected as the best route. The IP route table does not contain a BGP4 route for any of the routes listed by the command.

The **not-installed-best** option displays the routes received from the neighbor that are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 Switch received better routes from other sources (such as OSPF, RIP, or static IP routes).

The **prefix-list <string>** parameter filters the display using the specified IP prefix list.

The **regular-expression <regular-expression>** option filters the display based on a regular expression. Refer to “Using regular expressions” on page 1348.

The **route-map <map-name>** parameter filters the display using the specified route map. The software displays only the routes that match the match statements in the route map. The software disregards the route map set statements.

The **summary** option displays summary information for the routes.

The **unreachable** option displays the routes that are unreachable because the Layer 3 Switch does not have a valid RIP, OSPF, or static route to the next hop.

### Displaying the best BGP4 routes

To display all the BGP4 routes in the Layer 3 Switch BGP4 route table that are the best routes to their destinations, enter a command such as the following at any level of the CLI.

```
FastIron# show ip bgp routes best
Searching for matching routes, use ^C to quit...
Prefix             Next Hop        Metric     LocPrf     Weight Status
1      3.0.0.0/8          192.168.4.106               100        0      BE
   AS_PATH: 65001 4355 701 80
2      4.0.0.0/8          192.168.4.106               100        0      BE
   AS_PATH: 65001 4355 1
3      4.60.212.0/22      192.168.4.106               100        0      BE
   AS_PATH: 65001 4355 701 1 189
4      6.0.0.0/8          192.168.4.106               100        0      BE
   AS_PATH: 65001 4355 701 1 189
5      9.2.0.0/16         192.168.4.106               100        0      BE
   AS_PATH: 65001 4355 701

Syntax: show ip bgp routes best
Displaying BGP4 information

For information about the fields in this display, refer to Table 229 on page 1394. The fields in this display also appear in the `show ip bgp` display.

**Displaying those best BGP4 routes that are nonetheless not in the IP route table**

When the Layer 3 Switch has multiple routes to a destination from different sources (such as BGP4, OSPF, RIP, or static routes), the Layer 3 Switch selects the route with the lowest administrative distance as the best route, and installs that route in the IP route table.

To display the BGP4 routes that are the “best” routes to their destinations but are not installed in the Layer 3 Switch IP route table, enter a command such as the following at any level of the CLI.

```
FastIron# show ip bgp routes not-installed-best
```

For information about the fields in this display, refer to Table 229 on page 1394. The fields in this display also appear in the `show ip bgp` display.

**NOTE**

To display the routes that the Layer 3 Switch has selected as the best routes and installed in the IP route table, display the IP route table using the `show ip route` command.

**Displaying BGP4 routes whose destinations are unreachable**

To display BGP4 routes whose destinations are unreachable using any of the BGP4 paths in the BGP4 route table, enter a command such as the following at any level of the CLI.

```
FastIron# show ip bgp routes unreachable
```

For information about the fields in this display, refer to Table 229 on page 1394. The fields in this display also appear in the `show ip bgp` display.
Displaying information for a specific route

To display BGP4 network information by specifying an IP address within the network, enter a command such as the following at any level of the CLI.

```
FastIron# show ip bgp 9.3.4.0
Number of BGP Routes matching display condition : 1
Status codes: s suppressed, d damped, h history, * valid, > best, i internal
Origin codes: i - IGP, e - EGP, ? - incomplete
```

```
Network         Next Hop    Metric LocPrf Weight Path
9.3.4.0/24     192.168.4.106 100   0       65001 4355 1 1221 ?
```

Last update to IP routing table: 0h11m38s, 1 path(s) installed:
```
Gateway           Port
192.168.2.1       2/1
```

Route is advertised to 1 peers:
```
20.20.20.2(65300)
```

If you use the `route` option, the display for the information is different, as shown in the following example.

```
FastIron# show ip bgp route 9.3.4.0
Number of BGP Routes matching display condition : 1
```

```
Prefix         Next Hop    Metric LocPrf  Status
9.3.4.0/24     192.168.4.106              100        0     BE
```

AS_PATH: 65001 4355 1 1221

Last update to IP routing table: 0h12m1s, 1 path(s) installed:
```
Gateway           Port
192.168.2.1       2/1
```

Route is advertised to 1 peers:
```
20.20.20.2(65300)
```

These displays show the following information.

**TABLE 229**  BGP4 network information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of BGP Routes matching display condition</td>
<td>The number of routes that matched the display parameters you entered. This is the number of routes displayed by the command.</td>
</tr>
<tr>
<td>Status codes</td>
<td>A list of the characters the display uses to indicate the route status. The status code appears in the left column of the display, to the left of each route. The status codes are described in the command output. <strong>NOTE:</strong> This field appears only if you do not enter the <code>route</code> option.</td>
</tr>
<tr>
<td>Prefix</td>
<td>The network address and prefix.</td>
</tr>
<tr>
<td>Next Hop</td>
<td>The next-hop router for reaching the network from the Layer 3 Switch.</td>
</tr>
<tr>
<td>Metric</td>
<td>The value of the route MED attribute. If the route does not have a metric, this field is blank.</td>
</tr>
<tr>
<td>LocPrf</td>
<td>The degree of preference for this route relative to other routes in the local AS. When the BGP4 algorithm compares routes on the basis of local preferences, the route with the higher local preference is chosen. The preference can have a value from 0 – 4294967295.</td>
</tr>
</tbody>
</table>
Displaying BGP4 information

Here is an example of the information displayed when you use the `detail` option. In this example, the information for one route is shown.

```
FastIron# show ip bgp routes detail
Total number of BGP Routes: 2
Status A: AGGREGATE B: BEST b: NOT-INSTALLED-BEST C: CONFED_EBGP D: DAMPED
1 Prefix: 10.5.0.0/24, Status: BME, Age: 0h28m28s
   NEXT_HOP: 201.1.1.2, Learned from Peer: 10.1.0.2 (5)
   LOCAL_PREF: 101, MED: 0, ORIGIN: igp, Weight: 10
   AS_PATH: 5
   Adj_RIB_out count: 4, Admin distance 20
```
These displays show the following information.

**TABLE 230**  BGP4 route information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total number of BGP Routes</td>
<td>The number of BGP4 routes.</td>
</tr>
<tr>

<td>A list of the characters the display uses to indicate the route status. The status code is appears in the left column of the display, to the left of each route. The status codes are described in the command output.</td>
</tr>
<tr>
<td>Prefix</td>
<td>The network prefix and mask length.</td>
</tr>
<tr>
<td>Status</td>
<td>The route status, which can be one or more of the following:</td>
</tr>
<tr>
<td></td>
<td>• A – AGGREGATE. The route is an aggregate route for multiple networks.</td>
</tr>
<tr>
<td></td>
<td>• B – BEST. BGP4 has determined that this is the optimal route to the destination.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> If the “b” is shown in lowercase, the software was not able to install the route in the IP route table.</td>
</tr>
<tr>
<td></td>
<td>• b – NOT-INSTALLED-BEST. The routes received from the neighbor are the best BGP4 routes to their destinations, but were nonetheless not installed in the IP route table because the Layer 3 Switch received better routes from other sources (such as OSPF, RIP, or static IP routes).</td>
</tr>
<tr>
<td></td>
<td>• C – CONFED_EBGP. The route was learned from a neighbor in the same confederation and AS, but in a different sub-AS within the confederation.</td>
</tr>
<tr>
<td></td>
<td>• D – DAMPED. This route has been dampened (by the route dampening feature), and is currently unusable.</td>
</tr>
<tr>
<td></td>
<td>• H – HISTORY. Route dampening is configured for this route, and the route has a history of flapping and is unreachable now.</td>
</tr>
<tr>
<td></td>
<td>• I – INTERNAL. The route was learned through BGP4.</td>
</tr>
<tr>
<td></td>
<td>• L – LOCAL. The route originated on this Layer 3 Switch.</td>
</tr>
<tr>
<td></td>
<td>• M – MULTIPATH. BGP4 load sharing is enabled and this route was selected as one of the best ones to the destination. The best route among the multiple paths also is marked with “B”.</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> If the “m” is shown in lowercase, the software was not able to install the route in the IP route table.</td>
</tr>
<tr>
<td></td>
<td>• S – SUPPRESSED. This route was suppressed during aggregation and thus is not advertised to neighbors.</td>
</tr>

</tr>
<tr>
<td></td>
<td>• IGP – The routes with this set of attributes came to BGP through IGP.</td>
</tr>
<tr>
<td></td>
<td>• INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP. When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE.</td>
</tr>
</tbody>
</table>
Displaying BGP4 route-attribute entries

The route-attribute entries table lists the sets of BGP4 attributes stored in the router memory. Each set of attributes is unique and can be associated with one or more routes. In fact, the router typically has fewer route attribute entries than routes. To display the route-attribute entries table, use one of the following methods.

To display the IP route table, enter the following command.

FastIron# show ip bgp attribute-entries

Syntax: show ip bgp attribute-entries

Here is an example of the information displayed by this command. A zero value indicates that the attribute is not set.

<table>
<thead>
<tr>
<th>FastIron# show ip bgp attribute-entries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total number of BGP Attribute Entries: 7753</td>
</tr>
<tr>
<td>1  Next Hop :192.168.11.1  Metric :0  Origin:IGP</td>
</tr>
<tr>

</tr>
<tr>
<td>Aggregator:AS Number :0  Router-ID:0.0.0.0  Atomic:FALSE</td>
</tr>
<tr>
<td>Local Pref:100  Communities:Internet</td>
</tr>
<tr>
<td>AS Path  :(65002) 65001 4355 2548</td>
</tr>
</tbody>
</table>

This display shows the following information.
TABLE 231  BGP4 route-attribut entries information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total number of BGP Attribute Entries</td>
<td>The number of routes contained in this router BGP4 route table.</td>
</tr>
<tr>
<td>Next Hop</td>
<td>The IP address of the next hop router for routes that have this set of attributes.</td>
</tr>
<tr>
<td>Metric</td>
<td>The cost of the routes that have this set of attributes.</td>
</tr>
</tbody>
</table>
| Origin | The source of the route information. The origin can be one of the following:  
  • EGP – The routes with this set of attributes came to BGP through EGP.  
  • IGP – The routes with this set of attributes came to BGP through IGP.  
  • INCOMPLETE – The routes came from an origin other than one of the above. For example, they may have been redistributed from OSPF or RIP.  When BGP4 compares multiple routes to a destination to select the best route, IGP is preferred over EGP and both are preferred over INCOMPLETE. |
| Originator | The originator of the route in a route reflector environment. |
| Cluster List | The route-reflector clusters through which this set of attributes has passed. |
| Aggregator | Aggregator information:  
  • AS Number shows the AS in which the network information in the attribute set was aggregated. This value applies only to aggregated routes and is otherwise 0.  
  • Router-ID shows the router that originated this aggregator. |
| Atomic | Whether the network information in this set of attributes has been aggregated and this aggregation has resulted in information loss:  
  • TRUE – Indicates information loss has occurred  
  • FALSE – Indicates no information loss has occurred  
  NOTE: Information loss under these circumstances is a normal part of BGP4 and does not indicate an error. |
| Local Pref | The degree of preference for routes that use this set of attributes relative to other routes in the local AS. |
| Communities | The communities that routes with this set of attributes are in. |
| AS Path | The ASs through which routes with this set of attributes have passed. The local AS is shown in parentheses. |

Displaying the routes BGP4 has placed in the IP route table

The IP route table indicates the routes it has received from BGP4 by listing “BGP” as the route type.

To display the IP route table, enter the following command.

FastIron# show ip route

Syntax: show ip route [<ip-addr> | <num> | bgp | ospf | rip]

Here is an example of the information displayed by this command. Notice that most of the routes in this example have type “B”, indicating that their source is BGP4.
Displaying BGP4 information

FastIron# show ip route
Total number of IP routes: 50834
B:BGP D:Directly-Connected O:OSPF R:RIP S:Static
Network Address   NetMask          Gateway          Port      Cost   Type

<td>0:1:4:0:0:65001:4355:701:62</td>
</tr>
</tbody>
</table>

Syntax: show ip bgp flap-statistics [regular-expression <regular-expression> | <address> <mask> [longer-prefixes] | neighbor <ip-addr> | filter-list <num>...]

The regular-expression <regular-expression> parameter is a regular expression. The regular expressions are the same ones supported for BGP4 AS-path filters. Refer to “Using regular expressions” on page 1348.

The <address> <mask> parameter specifies a particular route. If you also use the optional longer-prefixes parameter, then all statistics for routes that match the specified route or have a longer prefix than the specified route are displayed. For example, if you specify 209.157.0.0 longer, then all routes with the prefix 209.157 or that have a longer prefix (such as 209.157.22) are displayed.

The neighbor <ip-addr> parameter displays route flap dampening statistics only for routes learned from the specified neighbor. You also can display route flap statistics for routes learned from a neighbor by entering the following command: show ip bgp neighbor <ip-addr> flap-statistics.

The filter-list <num> parameter specifies one or more filters. Only the routes that have been dampened and that match the specified filters are displayed.

This display shows the following information.
You also can display all the dampened routes by entering the following command.

`show ip bgp dampened-paths`

### Displaying the active route map configuration

To view the device active route map configuration (contained in the running-config) without displaying the entire running-config, enter the following command at any level of the CLI.

```
FastIron# show route-map
route-map permitnet4 permit 10
    match ip address prefix-list plist1
route-map permitnet1 permit 1
    match ip address prefix-list plist2
route-map setcomm permit 1
    set community 1234:2345 no-export
route-map test111 permit 111
    match address-filters 11
    set community 11:12 no-export
route-map permit1122 permit 12
    match ip address 11
route-map permit1122 permit 13
    match ip address std_22
```

This example shows that the running-config contains six route maps. Notice that the match and set statements within each route map are listed beneath the command for the route map itself. In this simplified example, each route map contains only one match or set statement.

To display the active configuration for a specific route map, enter a command such as the following, which specifies a route map name.

```
FastIron# show route-map setcomm
route-map setcomm permit 1
    set community 1234:2345 no-export
```
This example shows the active configuration for a route map called “setcomm”.

Syntax: show route-map [<map-name>]

Updating route information and resetting a neighbor session

The following sections describe ways to update route information with a neighbor, reset the session with a neighbor, and close a session with a neighbor.

Whenever you change a policy (ACL, route map, and so on) that affects the routes that the Layer 3 Switch learns from a BGP4 neighbor or peer group of neighbors, you must enter a command to place the changes into effect. The changes take place automatically, but only affect new route updates. To make changes retroactive for routes received or sent before the changes were made, you need to enter a clear command.

You can update the learned routes using either of the following methods:

- Request the complete BGP4 route table from the neighbor or peer group. You can use this method if the neighbor supports the refresh capability (RFCs 2842 and 2858).
- Clear (reset) the session with the neighbor or peer group. This is the only method you can use if the neighbor does not support the refresh capability.

Each of these methods is effective, but can be disruptive to the network. The first method adds overhead while the Layer 3 Switch learns and filters the neighbor or group entire route table, while the second method adds more overhead while the devices re-establish their BGP4 sessions.

You also can clear and reset the BGP4 routes that have been installed in the IP route table. Refer to “Clearing and resetting BGP4 routes in the IP route table” on page 1407.

Using soft reconfiguration

The soft reconfiguration feature places policy changes into effect without resetting the BGP4 session. Soft reconfiguration does not request the neighbor or group to send its entire BGP4 table, nor does the feature reset the session with the neighbor or group. Instead, the soft reconfiguration feature stores all the route updates received from the neighbor or group. When you request a soft reset of inbound routes, the software performs route selection by comparing the policies against the stored route updates, instead of requesting the neighbor BGP4 route table or resetting the session with the neighbor.

When you enable the soft reconfiguration feature, it sends a refresh message to the neighbor or group if the neighbor or group supports dynamic refresh. Otherwise, the feature resets the neighbor session. This step is required to ensure that the soft reconfiguration feature has a complete set of updates to use, and occurs only once, when you enable the feature. The feature accumulates all the route updates from the neighbor, eliminating the need for additional refreshes or resets when you change policies in the future.

To use soft reconfiguration:

- Enable the feature.
- Make the policy changes.
- Apply the changes by requesting a soft reset of the inbound updates from the neighbor or group.
Use the following CLI methods to configure soft configuration, apply policy changes, and display information for the updates that are filtered out by the policies.

**Enabling soft reconfiguration**

To configure a neighbor for soft reconfiguration, enter a command such as the following.

```
FastIron(config-bgp-router)# neighbor 10.10.200.102 soft-reconfiguration inbound
```

This command enables soft reconfiguration for updates received from 10.10.200.102. The software dynamically refreshes or resets the session with the neighbor, then retains all route updates from the neighbor following the reset.

**Syntax:** `[no] neighbor <ip-addr> | <peer-group-name> soft-reconfiguration inbound

**NOTE**
The syntax related to soft reconfiguration is shown. For complete command syntax, refer to “Adding BGP4 neighbors” on page 1307.

**Placing a policy change into effect**

To place policy changes into effect, enter a command such as the following.

```
FastIron(config-bgp-router)# clear ip bgp neighbor 10.10.200.102 soft in
```

This command updates the routes by comparing the route policies against the route updates that the Layer 3 Switch has stored. The command does not request additional updates from the neighbor or otherwise affect the session with the neighbor.

**Syntax:** `clear ip bgp neighbor <ip-addr> | <peer-group-name> soft in

**NOTE**
If you do not specify “in”, the command applies to both inbound and outbound updates.

**NOTE**
The syntax related to soft reconfiguration is shown. For complete command syntax, refer to “Dynamically refreshing routes” on page 1404.

**Displaying the filtered routes received from the neighbor or peer group**

When you enable soft reconfiguration, the Layer 3 Switch saves all updates received from the specified neighbor or peer group. This includes updates that contain routes that are filtered out by the BGP4 route policies in effect on the Layer 3 Switch. To display the routes that have been filtered out, enter the following command at any level of the CLI.
Updating route information and resetting a neighbor session

The routes displayed by the command are the routes that the Layer 3 Switch BGP4 policies filtered out. The Layer 3 Switch did not place the routes in the BGP4 route table, but did keep the updates. If a policy change causes these routes to be permitted, the Layer 3 Switch does not need to request the route information from the neighbor, but instead uses the information in the updates.

Syntax: `show ip bgp filtered-routes [<ip-addr>] [as-path-access-list <num>] [detail] [prefix-list <string>]`

The `<ip-addr>` parameter specifies the IP address of the destination network.

The `as-path-access-list <num>` parameter specifies an AS-path ACL. Only the routes permitted by the AS-path ACL are displayed.

The `detail` parameter displays detailed information for the routes. (The example above shows summary information.) You can specify any of the other options after `detail` to further refine the display request.

The `prefix-list <string>` parameter specifies an IP prefix list. Only the routes permitted by the prefix list are displayed.

**NOTE**
The syntax for displaying filtered routes is shown. For complete command syntax, refer to “Displaying the BGP4 route table” on page 1391.

**Displaying all the routes received from the neighbor**

To display all the route information received in route updates from a neighbor since you enabled soft reconfiguration, enter a command such as the following at any level of the CLI.

Syntax: `show ip bgp neighbors <ip-addr> received-routes [detail]`
The **detail** parameter displays detailed information for the routes. The example above shows summary information.

---

**NOTE**
The syntax for displaying received routes is shown. For complete command syntax, refer to “Displaying BGP4 neighbor information” on page 1378.

---

**NOTE**
The **show ip bgp neighbor** `<ip-addr>` received-routes syntax supported in previous software releases is changed to the following syntax: **show ip bgp neighbor `<ip-addr>` routes**.

---

**Dynamically requesting a route refresh from a BGP4 neighbor**

You can easily apply changes to filters that control BGP4 routes received from or advertised to a neighbor, without resetting the BGP4 session between the Layer 3 Switch and the neighbor. For example, if you add, change, or remove a BGP4 address filter that denies specific routes received from a neighbor, you can apply the filter change by requesting a route refresh from the neighbor. If the neighbor also supports dynamic route refreshes, the neighbor resends its Adj-RIB-Out, its table of BGP4 routes. Using the route refresh feature, you do not need to reset the session with the neighbor.

The route refresh feature is based on the following specifications:

- RFC 2842. This RFC specifies the Capability Advertisement, which a BGP4 router uses to dynamically negotiate a capability with a neighbor.
- RFC 2858 for Multi-protocol Extension.

**NOTE**
The Brocade implementation of dynamic route refresh supports negotiation of IP version 4 unicast only.

- RFC 2918, which describes the dynamic route refresh capability

The dynamic route refresh capability is enabled by default and cannot be disabled. When the Layer 3 Switch sends a BGP4 OPEN message to a neighbor, the Layer 3 Switch includes a Capability Advertisement to inform the neighbor that the Layer 3 Switch supports dynamic route refresh.

**NOTE**
The option for dynamically refreshing routes received from a neighbor requires the neighbor to support dynamic route refresh. If the neighbor does not support this feature, the option does not take effect and the software displays an error message. The option for dynamically re-advertising routes to a neighbor does not require the neighbor to support dynamic route refresh.

To use the dynamic refresh feature, use either of the following methods.

**Dynamically refreshing routes**

The following sections describe how to dynamically refresh BGP4 routes to place new or changed filters into effect.

To request a dynamic refresh of all routes from a neighbor, enter a command such as the following.
Updating route information and resetting a neighbor session

FastIron(config-bgp-router)# clear ip bgp neighbor 192.168.1.170 soft in

This command asks the neighbor to send its BGP4 table (Adj-RIB-Out) again. The Layer 3 Switch applies its filters to the incoming routes and adds, modifies, or removes BGP4 routes as necessary.

**Syntax:**
```
clear ip bgp neighbor all | <ip-addr> | <peer-group-name> | <as-num> [soft-outbound | soft [in | out]]
```

The `all | <ip-addr> | <peer-group-name> | <as-num>` specifies the neighbor. The `<ip-addr>` parameter specifies a neighbor by its IP interface with the Layer 3 Switch. The `<peer-group-name>` specifies all neighbors in a specific peer group. The `<as-num>` parameter specifies all neighbors within the specified AS. The `all` parameter specifies all neighbors.

The `soft-outbound` parameter updates all outbound routes by applying the new or changed filters, but sends only the existing routes affected by the new or changed filters to the neighbor.

The `soft [in | out]` parameter specifies whether you want to refresh the routes received from the neighbor or sent to the neighbor:

- **soft in** does one of the following:
  - If you enabled soft reconfiguration for the neighbor or peer group, `soft in` updates the routes by comparing the route policies against the route updates that the Layer 3 Switch has stored. Soft reconfiguration does not request additional updates from the neighbor or otherwise affect the session with the neighbor. Refer to “Using soft reconfiguration” on page 1401.
  - If you did not enable soft reconfiguration, `soft in` requests the neighbor entire BGP4 route table (Adj-RIB-Out), then applies the filters to add, change, or exclude routes.
  - If a neighbor does not support dynamic refresh, `soft in` resets the neighbor session.

- **soft out** updates all outbound routes, then sends the Layer 3 Switch entire BGP4 route table (Adj-RIB-Out) to the neighbor, after changing or excluding the routes affected by the filters.

If you do not specify `in` or `out`, the Layer 3 Switch performs both options.

**NOTE**
The `soft-outbound` parameter updates all outbound routes by applying the new or changed filters, but sends only the existing routes affected by the new or changed filters to the neighbor. The `soft out` parameter updates all outbound routes, then sends the Layer 3 Switch entire BGP4 route table (Adj-RIB-Out) to the neighbor, after changing or excluding the routes affected by the filters. Use `soft-outbound` if only the outbound policy is changed.

To dynamically resend all the Layer 3 Switch BGP4 routes to a neighbor, enter a command such as the following.

FastIron(config-bgp-router)# clear ip bgp neighbor 192.168.1.170 soft out

This command applies its filters for outgoing routes to the Layer 3 Switch BGP4 route table (Adj-RIB-Out), changes or excludes routes accordingly, then sends the resulting Adj-RIB-Out to the neighbor.

**NOTE**
The Brocade Layer 3 Switch does not automatically update outbound routes using a new or changed outbound policy or filter when a session with the neighbor goes up or down. Instead, the Layer 3 Switch applies a new or changed policy or filter when a route is placed in the outbound queue (Adj-RIB-Out).
To place a new or changed outbound policy or filter into effect, you must enter a `clear ip bgp neighbor` command regardless of whether the neighbor session is up or down. You can enter the command without optional parameters or with the `soft out` or `soft-outbound` option. Either way, you must specify a parameter for the neighbor (`<ip-addr>`, `<as-num>`, `<peer-group-name>`, or `all`).

**Displaying dynamic refresh information**

You can use the `show ip bgp neighbors` command to display information for dynamic refresh requests. For each neighbor, the display lists the number of dynamic refresh requests the Layer 3 Switch has sent to or received from the neighbor and indicates whether the Layer 3 Switch received confirmation from the neighbor that the neighbor supports dynamic route refresh.

The RefreshCapability field indicates whether this Layer 3 Switch has received confirmation from the neighbor that the neighbor supports the dynamic refresh capability. The statistics in the Message Sent and Message Received rows under Refresh-Req indicate how many dynamic refreshes have been sent to and received from the neighbor. The statistic is cumulative across sessions.

```
FastIron# show ip bgp neighbor 10.4.0.2
1   IP Address: 10.4.0.2, AS: 5 (EBGP), RouterID: 100.0.0.1
    Description: neighbor 10.4.0.2

```
Closing or resetting a neighbor session

You can close a neighbor session or resend route updates to a neighbor.

If you make changes to filters or route maps and the neighbor does not support dynamic route refresh, use the following methods to ensure that neighbors contain only the routes you want them to contain:

- If you close a neighbor session, the Layer 3 Switch and the neighbor clear all the routes they learned from each other. When the Layer 3 Switch and neighbor establish a new BGP4 session, they exchange route tables again. Use this method if you want the Layer 3 Switch to relearn routes from the neighbor and resend its own route table to the neighbor.

- If you use the soft-outbound option, the Layer 3 Switch compiles a list of all the routes it would normally send to the neighbor at the beginning of a session. However, before sending the updates, the Brocade Layer 3 Switch also applies the filters and route maps you have configured to the list of routes. If the filters or route maps result in changes to the list of routes, the Layer 3 Switch sends updates to advertise, change, or even withdraw routes on the neighbor as needed. This ensures that the neighbor receives only the routes you want it to contain. Even if the neighbor already contains a route learned from the Layer 3 Switch that you later decided to filter out, using the soft-outbound option removes that route from the neighbor.

You can specify a single neighbor or a peer group.

To close a neighbor session and thus flush all the routes exchanged by the Layer 3 Switch and the neighbor, enter the following command.

```plaintext
FastIron# clear ip bgp neighbor all
```

**Syntax:** clear ip bgp neighbor all | <ip-addr> | <peer-group-name> | <as-num> [soft-outbound | soft [in | out]]

The `all` | `<ip-addr>` | `<peer-group-name>` | `<as-num>` specifies the neighbor. The `<ip-addr>` parameter specifies a neighbor by its IP interface with the Layer 3 Switch. The `<peer-group-name>` specifies all neighbors in a specific peer group. The `<as-num>` parameter specifies all neighbors within the specified AS. The `all` parameter specifies all neighbors.

To resend routes to a neighbor without closing the neighbor session, enter a command such as the following.

```plaintext
FastIron# clear ip bgp neighbor 10.0.0.1 soft out
```

Clearing and resetting BGP4 routes in the IP route table

To clear BGP4 routes from the IP route table and reset the routes, enter a command such as the following.

```plaintext
FastIron# clear ip bgp routes
```

**Syntax:** clear ip bgp routes [\(<ip-addr>>\/<prefix-length>\)]

**NOTE**
The `clear ip bgp routes` command has the same effect as the `clear ip route` command, but applies only to routes that come from BGP4.
Clearing traffic counters

You can clear the counters (reset them to 0) for BGP4 messages. To do so, use one of the following methods.

To clear the BGP4 message counter for all neighbors, enter the following command.

`FastIron# clear ip bgp traffic`

**Syntax:** clear ip bgp traffic

To clear the BGP4 message counter for a specific neighbor, enter a command such as the following.

`FastIron# clear ip bgp neighbor 10.0.0.1 traffic`

To clear the BGP4 message counter for all neighbors within a peer group, enter a command such as the following.

`FastIron# clear ip bgp neighbor PeerGroup1 traffic`

**Syntax:** clear ip bgp neighbor all | <ip-addr> | <peer-group-name> | <as-num> traffic

The `all` | `<ip-addr>` | `<peer-group-name>` | `<as-num>` specifies the neighbor. The `<ip-addr>` parameter specifies a neighbor by its IP interface with the Layer 3 Switch. The `<peer-group-name>` specifies all neighbors in a specific peer group. The `<as-num>` parameter specifies all neighbors within the specified AS. The `all` parameter specifies all neighbors.

Clearing route flap dampening statistics

To clear route flap dampening statistics, use the following CLI method.

**NOTE**  
Clearing the dampening statistics for a route does not change the dampening status of the route.

To clear all the route dampening statistics, enter the following command at any level of the CLI.

`FastIron# clear ip bgp flap-statistics`

**Syntax:** clear ip bgp flap-statistics [regular-expression | <address> <mask> | neighbor <ip-addr>]

The parameters are the same as those for the `show ip bgp flap-statistics` command (except the `longer-prefixes` option is not supported). Refer to “Displaying route flap dampening statistics” on page 1370.

**NOTE**  
The `clear ip bgp damping` command not only clears statistics but also un-suppresses the routes. Refer to “Displaying route flap dampening statistics” on page 1370.

Removing route flap dampening

You can un-suppress routes by removing route flap dampening from the routes. The Layer 3 Switch allows you to un-suppress all routes at once or un-suppress individual routes.
To un-suppress all the suppressed routes, enter the following command at the Privileged EXEC level of the CLI.

```
FastIron# clear ip bgp damping
```

**Syntax:** `clear ip bgp damping [ <ip-addr> <ip-mask> ]`

The `<ip-addr>` parameter specifies a particular network.

The `<ip-mask>` parameter specifies the network mask.

To un-suppress a specific route, enter a command such as the following.

```
FastIron# clear ip bgp damping 209.157.22.0 255.255.255.0
```

This command un-suppresses only the routes for network 209.157.22.0/24.

### Clearing diagnostic buffers

The Layer 3 Switch stores the following BGP4 diagnostic information in buffers:

- The first 400 bytes of the last packet that contained an error
- The last NOTIFICATION message either sent or received by the Layer 3 Switch

To display these buffers, use options with the `show ip bgp neighbors` command. Refer to “Displaying BGP4 neighbor information” on page 1378.

This information can be useful if you are working with Brocade Technical Support to resolve a problem. The buffers do not identify the system time when the data was written to the buffer. If you want to ensure that diagnostic data in a buffer is recent, you can clear the buffers. You can clear the buffers for a specific neighbor or for all neighbors.

If you clear the buffer containing the first 400 bytes of the last packet that contained errors, all the bytes are changed to zeros. The Last Connection Reset Reason field of the BGP neighbor table also is cleared.

If you clear the buffer containing the last NOTIFICATION message sent or received, the buffer contains no data.

You can clear the buffers for all neighbors, for an individual neighbor, or for all the neighbors within a specific peer group.

To clear these buffers for neighbor 10.0.0.1, enter the following commands.

```
FastIron# clear ip bgp neighbor 10.0.0.1 last-packet-with-error
FastIron# clear ip bgp neighbor 10.0.0.1 notification-errors
```

**Syntax:**
```
clear ip bgp neighbor all | <ip-addr> | <peer-group-name> | <as-num> last-packet-with-error | notification-errors
```

The `all` | `<ip-addr>` | `<peer-group-name>` | `<as-num>` specifies the neighbor. The `<ip-addr>` parameter specifies a neighbor by its IP interface with the Layer 3 Switch. The `<peer-group-name>` specifies all neighbors in a specific peer group. The `<as-num>` parameter specifies all neighbors within the specified AS. The `all` parameter specifies all neighbors.
This chapter explains how to secure access to management functions on a Brocade device.

**NOTE**
For all Brocade devices, RADIUS Challenge is supported for 802.1x authentication but not for login authentication. Also, multiple challenges are supported for TACACS+ login authentication.

### Securing access methods

The following table lists the management access methods available on a Brocade device, how they are secured by default, and the ways in which they can be secured.

**TABLE 233** Ways to secure management access to Brocade devices

### Restricting remote access to management functions

You can restrict access to management functions from remote sources, including Telnet, the Web Management Interface, and SNMP. The following methods for restricting remote access are supported:

**TABLE 233  Ways to secure management access to Brocade devices (Continued)**

<table>
<thead>
<tr>
<th>Access method</th>
<th>How the access method is secured by default</th>

</tbody>
</table>

**NOTE:** SNMP read or read-write community strings are always required for SNMP access to the device.
Using ACLs to restrict remote access

You can use standard ACLs to control the following access methods to management functions on a Brocade device:

- Telnet
- SSH
- Web management
- SNMP

Consider the following to configure access control for these management access methods.

1. Configure an ACL with the IP addresses you want to allow to access the device.
2. Configure a Telnet access group, SSH access group, Web access group, and SNMP community strings. Each of these configuration items accepts an ACL as a parameter. The ACL contains entries that identify the IP addresses that can use the access method.

The following sections present examples of how to secure management access using ACLs. Refer to Chapter 17, “Configuring Rule-Based IP Access Control Lists (ACLs)” for more information on configuring ACLs.

Using an ACL to restrict Telnet access

To configure an ACL that restricts Telnet access to the device, enter commands such as the following.

```
FastIron(config)# access-list 10 deny host 209.157.22.32 log
FastIron(config)# access-list 10 deny 209.157.23.0 0.0.0.255 log
FastIron(config)# access-list 10 deny 209.157.24.0 0.0.0.255 log
FastIron(config)# access-list 10 deny 209.157.25.0/24 log
FastIron(config)# access-list 10 permit any
FastIron(config)# telnet access-group 10
FastIron(config)# write memory
```

Syntax: `telnet access-group <num>`

The `<num>` parameter specifies the number of a standard ACL and must be from 1 – 99.

The commands above configure ACL 10, then apply the ACL as the access list for Telnet access. The device allows Telnet access to all IP addresses except those listed in ACL 10.
Restricting remote access to management functions

To configure a more restrictive ACL, create permit entries and omit the `permit any` entry at the end of the ACL.

**Example**

```
FastIron(config)# access-list 10 permit host 209.157.22.32
FastIron(config)# access-list 10 permit 209.157.23.0 0.0.0.255
FastIron(config)# access-list 10 permit 209.157.24.0 0.0.0.255
FastIron(config)# access-list 10 permit 209.157.25.0/24
FastIron(config)# telnet access-group 10
FastIron(config)# write memory
```

The ACL in this example permits Telnet access only to the IP addresses in the `permit` entries and denies Telnet access from all other IP addresses.

**Using an ACL to restrict SSH access**

To configure an ACL that restricts SSH access to the device, enter commands such as the following.

```
FastIron(config)# access-list 12 deny host 209.157.22.98 log
FastIron(config)# access-list 12 deny 209.157.23.0 0.0.0.255 log
FastIron(config)# access-list 12 deny 209.157.24.0/24 log
FastIron(config)# access-list 12 permit any
FastIron(config)# ssh access-group 12
FastIron(config)# write memory
```

**Syntax: ssh access-group <num>**

The `<num>` parameter specifies the number of a standard ACL and must be from 1 – 99.

These commands configure ACL 12, then apply the ACL as the access list for SSH access. The device denies SSH access from the IP addresses listed in ACL 12 and permits SSH access from all other IP addresses. Without the last ACL entry for permitting all packets, this ACL would deny SSH access from all IP addresses.

**NOTE**

In this example, the command `ssh access-group 10` could have been used to apply the ACL configured in the example for Telnet access. You can use the same ACL multiple times.

**Using an ACL to restrict Web management access**

To configure an ACL that restricts Web management access to the device, enter commands such as the following.

```
FastIron(config)# access-list 12 deny host 209.157.22.98 log
FastIron(config)# access-list 12 deny 209.157.23.0 0.0.0.255 log
FastIron(config)# access-list 12 deny 209.157.24.0/24 log
FastIron(config)# access-list 12 permit any
FastIron(config)# web access-group 12
FastIron(config)# write memory
```

**Syntax: web access-group <num>**

The `<num>` parameter specifies the number of a standard ACL and must be from 1 – 99.
These commands configure ACL 12, then apply the ACL as the access list for Web management access. The device denies Web management access from the IP addresses listed in ACL 12 and permits Web management access from all other IP addresses. Without the last ACL entry for permitting all packets, this ACL would deny Web management access from all IP addresses.

**Using ACLs to restrict SNMP access**

To restrict SNMP access to the device using ACLs, enter commands such as the following.

**NOTE**
The syntax for using ACLs for SNMP access is different from the syntax for controlling Telnet, SSH, and Web management access using ACLs.

```
FastIron(config)# access-list 25 deny host 209.157.22.98 log
FastIron(config)# access-list 25 deny 209.157.23.0 0.0.0.255 log
FastIron(config)# access-list 25 deny 209.157.24.0 0.0.0.255 log
FastIron(config)# access-list 25 permit any
FastIron(config)# access-list 30 deny 209.157.25.0 0.0.0.255 log
FastIron(config)# access-list 30 deny 209.157.26.0/24 log
FastIron(config)# access-list 30 permit any
FastIron(config)# snmp-server community public ro 25
FastIron(config)# snmp-server community private rw 30
FastIron(config)# write memory
```

**Syntax:** `snmp-server community <string> ro | rw <num>`

The `<string>` parameter specifies the SNMP community string the user must enter to gain SNMP access.

The `ro` parameter indicates that the community string is for read-only (“get”) access. The `rw` parameter indicates the community string is for read-write (“set”) access.

The `<num>` parameter specifies the number of a standard ACL and must be from 1 – 99.

These commands configure ACLs 25 and 30, then apply the ACLs to community strings.

ACL 25 is used to control read-only access using the “public” community string. ACL 30 is used to control read-write access using the “private” community string.

**NOTE**
When `snmp-server community` is configured, all incoming SNMP packets are validated first by their community strings and then by their bound ACLs.

**Defining the console idle time**

By default, a Brocade device does not time out serial console sessions. A serial session remains open indefinitely until you close it. You can however define how many minutes a serial management session can remain idle before it is timed out.

**NOTE**
You must enable AAA support for console commands, AAA authentication, and Exec authorization in order to set the console idle time.

To configure the idle time for a serial console session, use the following command.

```
FastIron(config)# console timeout 120
```
Restricting remote access to management functions

Syntax: [no] console timeout <0 – 240>
Possible values: 0 – 240 minutes
Default value: 0 minutes (no timeout)

**NOTE**
In RADIUS, the standard attribute Idle-Timeout is used to define the console session timeout value. The attribute Idle-Timeout value is specified in seconds. Within the switch, it is truncated to the nearest minute, because the switch configuration is defined in minutes.

Restricting remote access to the device to specific IP addresses

By default, a Brocade device does not control remote management access based on the IP address of the managing device. You can restrict remote management access to a single IP address for the following access methods:

- Telnet access
- SSH access
- Web management access
- SNMP access

In addition, you can restrict all access methods to the same IP address using a single command.

The following examples show the CLI commands for restricting remote access. You can specify only one IP address with each command. However, you can enter each command ten times to specify up to ten IP addresses.

**NOTE**
You cannot restrict remote management access using the Web Management Interface.

**Restricting Telnet access to a specific IP address**

To allow Telnet access to the Brocade device only to the host with IP address 209.157.22.39, enter the following command.

```
FastIron(config)# telnet-client 209.157.22.39
```

**Syntax:** [no] telnet-client <ip-addr> | <ipv6-addr>

**Restricting SSH access to a specific IP address**

To allow SSH access to the Brocade device only to the host with IP address 209.157.22.39, enter the following command.

```
FastIron(config)# ip ssh client 209.157.22.39
```

**Syntax:** [no] ip ssh client <ip-addr> | <ipv6-addr>
Restricting remote access to management functions

**Restricting Web management access to a specific IP address**

To allow Web management access to the Brocade device only to the host with IP address 209.157.22.26, enter the following command.

FastIron(config)# web-client 209.157.22.26

Syntax: [no] web-client <ip-addr> | <ipv6-addr>

**Restricting SNMP access to a specific IP address**

To allow SNMP access (which includes IronView Network Manager) to the Brocade device only to the host with IP address 209.157.22.14, enter the following command.

FastIron(config)# snmp-client 209.157.22.14

Syntax: [no] snmp-client <ip-addr> | <ipv6-addr>

**Restricting all remote management access to a specific IP address**

To allow Telnet, Web, and SNMP management access to the Brocade device only to the host with IP address 209.157.22.69, enter three separate commands (one for each access type) or enter the following command.

FastIron(config)# all-client 209.157.22.69

Syntax: [no] all-client <ip-addr> | <ipv6-addr>

**Restricting access to the device based on IP or MAC address**

Platform Support:
- FastIron X Series devices running software release 03.0.00 and later
- FGS devices running software release 02.5.00 and later
- FLS devices running software release 03.0.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later (IPv4 only)

You can restrict remote management access to the Brocade device, using Telnet, SSH, HTTP, and HTTPS, based on the connecting client IP or MAC address.

**Restricting Telnet connection**

You can restrict Telnet connection to a device based on the client IP address or MAC address.

To allow Telnet access to the Brocade device only to the host with IP address 209.157.22.39 and MAC address 0007.e90f.e9a0, enter the following command.

FastIron(config)# telnet client 209.157.22.39 0007.e90f.e9a0

Syntax: [no] telnet client <ip-addr> | <ipv6-addr> <mac-addr>
NOTE
For FastIron CX devices, this feature applies only to IPv4 clients.

The following command allows Telnet access to the Brocade device to a host with any IP address and MAC address 0007.e90f.e9a0.

```
FastIron(config)# telnet client any 0007.e90f.e9a0
```

Syntax: `[no] telnet client any <mac-addr>`

Restricting SSH connection

Platform Support:
- FastIron X Series devices running software release 03.0.00 and later
- FGS and FLS devices running software release 02.5.00 and later
- FLS devices running software release 03.0.00 and later
- FWS devices running software release 04.3.00 or later
- Turbolron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

You can restrict SSH connection to a device based on the client IP address or MAC address.

To allow SSH access to the Brocade device only to the host with IP address 209.157.22.39 and MAC address 0007.e90f.e9a0, enter the following command.

```
FastIron(config)# ip ssh client 209.157.22.39 0007.e90f.e9a0
```

Syntax: `[no] ip ssh client <ip-addr> | <ipv6-addr> <mac-addr>`

To allow SSH access to the Brocade device to a host with any IP address and MAC address 0007.e90f.e9a0, enter the following command.

```
FastIron(config)# ip ssh client any 0007.e90f.e9a0
```

Syntax: `[no] ip ssh client any <mac-addr>`

Restricting HTTP and HTTPS connection

Platform Support:
- FGS and FLS devices running software release 02.6.00 and later
- FWS devices running software release 04.3.00 or later
- FastIron X Series devices running software release 03.3.00 and later
- Turbolron X Series devices running software release 04.1.00 and later
- FCX-S devices running software release 06.0.00 and later

You can restrict an HTTP or HTTPS connection to a device based on the client IP address or MAC address.

To allow HTTP and HTTPS access to the Brocade device only to the host with IP address 209.157.22.40 and MAC address 0007.e90f.ab1c, enter the following command.

```
FastIron(config)# web client 209.157.22.40 0007.e90f.ab1c
```

Syntax: `[no] web client <ip-addr> | <ipv6-addr> <mac-addr>`
The following command allows HTTP and HTTPS access to the Brocade device to a host with any IP address and MAC address 0007.e90f.10ba.

```
FastIron(config)# web client any 0007.e90f.10ba
```

**Syntax:**  
```
[no] web client any <mac-addr>
```

**Specifying the maximum number of login attempts for Telnet access**

If you are connecting to the Brocade device using Telnet, the device prompts you for a username and password. By default, you have up to 4 chances to enter a correct username and password. If you do not enter a correct username or password after 4 attempts, the Brocade device disconnects the Telnet session.

You can specify the number of attempts a Telnet user has to enter a correct username and password before the device disconnects the Telnet session. For example, to allow a Telnet user up to 5 chances to enter a correct username and password, enter the following command.

```
FastIron(config)# telnet login-retries 5
```

**Syntax:**  
```
[no] telnet login-retries <number>
```

You can specify from 0 – 5 attempts. The default is 4 attempts.

**Restricting remote access to the device to specific VLAN IDs**

You can restrict management access to a Brocade device to ports within a specific port-based VLAN. VLAN-based access control applies to the following access methods:

- Telnet access
- Web management access
- SNMP access
- TFTP access

By default, access is allowed for all the methods listed above on all ports. Once you configure security for a given access method based on VLAN ID, access to the device using that method is restricted to only the ports within the specified VLAN.

VLAN-based access control works in conjunction with other access control methods. For example, suppose you configure an ACL to permit Telnet access only to specific client IP addresses, and you also configure VLAN-based access control for Telnet access. In this case, the only Telnet clients that can access the device are clients that have one of the IP addresses permitted by the ACL and are connected to a port that is in a permitted VLAN. Clients who have a permitted IP address but are connected to a port in a VLAN that is not permitted still cannot access the device through Telnet.

**Restricting Telnet access to a specific VLAN**

To allow Telnet access only to clients in a specific VLAN, enter a command such as the following.

```
FastIron(config)# telnet server enable vlan 10
```
Restricting remote access to management functions

The command in this example configures the device to allow Telnet management access only to clients connected to ports within port-based VLAN 10. Clients connected to ports that are not in VLAN 10 are denied management access.

Syntax: [no] telnet server enable vlan <vlan-id>

Restricting Web management access to a specific VLAN

To allow Web management access only to clients in a specific VLAN, enter a command such as the following.

```
FastIron(config)# web-management enable vlan 10
```

The command in this example configures the device to allow Web management access only to clients connected to ports within port-based VLAN 10. Clients connected to ports that are not in VLAN 10 are denied management access.

Syntax: [no] web-management enable vlan <vlan-id>

Restricting SNMP access to a specific VLAN

To allow SNMP access only to clients in a specific VLAN, enter a command such as the following.

```
FastIron(config)# snmp-server enable vlan 40
```

The command in this example configures the device to allow SNMP access only to clients connected to ports within port-based VLAN 40. Clients connected to ports that are not in VLAN 40 are denied access.

Syntax: [no] snmp-server enable vlan <vlan-id>

Restricting TFTP access to a specific VLAN

To allow TFTP access only to clients in a specific VLAN, enter a command such as the following.

```
FastIron(config)# tftp client enable vlan 40
```

The command in this example configures the device to allow TFTP access only to clients connected to ports within port-based VLAN 40. Clients connected to ports that are not in VLAN 40 are denied access.

Syntax: [no] tftp client enable vlan <vlan-id>

Designated VLAN for Telnet management sessions to a Layer 2 Switch

All Brocade FastIron devices support the creation of management VLANs. By default, the management IP address you configure on a Layer 2 Switch applies globally to all the ports on the device. This is true even if you divide the device ports into multiple port-based VLANs.

If you want to restrict the IP management address to a specific port-based VLAN, you can make that VLAN the designated management VLAN for the device. When you configure a VLAN to be the designated management VLAN, the management IP address you configure on the device is associated only with the ports in the designated VLAN. To establish a Telnet management session with the device, a user must access the device through one of the ports in the designated VLAN.
You also can configure up to five default gateways for the designated VLAN, and associate a metric with each one. The software uses the gateway with the lowest metric. The other gateways reside in the configuration but are not used. To use one of the other gateways, modify the configuration so that the gateway you want to use has the lowest metric.

If more than one gateway has the lowest metric, the gateway that appears first in the running-config is used.

**NOTE**

If you have already configured a default gateway globally and you do not configure a gateway in the VLAN, the software uses the globally configured gateway and gives the gateway a metric value of 1.

To configure a designated management VLAN, enter commands such as the following.

```plaintext
FastIron(config)# vlan 10 by port
FastIron(config-vlan-10)# untag ethernet 1/1 to 1/4
FastIron(config-vlan-10)# management-vlan
FastIron(config-vlan-10)# default-gateway 10.10.10.1 1
FastIron(config-vlan-10)# default-gateway 20.20.20.1 2
```

These commands configure port-based VLAN 10 to consist of ports 1/1 – 1/4 and to be the designated management VLAN. The last two commands configure default gateways for the VLAN. Since the 10.10.10.1 gateway has a lower metric, the software uses this gateway. The other gateway remains in the configuration but is not used. You can use the other one by changing the metrics so that the 20.20.20.1 gateway has the lower metric.

**Syntax:**

```
[no] default-gateway <ip-addr> <metric>
```

The `<ip-addr>` parameters specify the IP address of the gateway router.

The `<metric>` parameter specifies the metric (cost) of the gateway. You can specify a value from 1 – 5. There is no default. The software uses the gateway with the lowest metric.

**Device management security**

By default, all management access is disabled. Each of the following management access methods must be specifically enabled as required in your installation:

- SSHv2
- SNMP
- Web management through HTTP
- Web management through HTTPS

The commands for granting access to each of these management interfaces is described in the following.

**SSHv2**

To allow SSHv2 access to the Brocade device, you must generate a Crypto Key as shown in the following command.

```plaintext
FastIron(config)# crypto key generate
```

**Syntax:** `crypto key [generate | zeroize]`

The `generate` parameter generates a dsa key pair.
The **zeroize** parameter deletes the currently operative dsa key pair.

In addition, you must use AAA authentication to create a password to allow SSHv2 access. For example, the following command configures AAA authentication to use TACACS+ for authentication as the default or local if TACACS+ is not available.

```
FastIron(config)# aaa authentication login default tacacs+ local
```

### SNMP

To allow SNMP access to the Brocade device, enter the following command.

```
FastIron(config)# snmp-server
```

**Syntax:** `[no] snmp-server`

### Web management through HTTP

To allow web management through HTTP for the Brocade device, you enable web management as shown in the following command.

```
FastIron(config)# web-management
```

**Syntax:** `[no] web-management [http | https]`

Using the web-management command without the `http` or `https` option makes web management available for both.

The `http` option specifies that web management is enabled for HTTP access.

The `https` option specifies that web management is enabled for HTTPS access.

### Web management through HTTPS

To allow web management through HTTPS, you must enable web management as shown in “Web management through HTTP”. Additionally, you must generate a crypto SSL certificate or import digital certificates issued by a third-party Certificate Authority (CA).

To generate a crypto SSL certificate use the following command.

```
FastIron(config)# crypto-ssl certificate generate
```

**Syntax:** `crypto-ssl certificate [generate | zeroize]`

Using the web-management command without the `http` or `https` option makes web management available for both.

The `generate` parameter generates an ssl certificate.

The `zeroize` parameter deletes the currently operative ssl certificate.

To import a digital certificate issued by a third-party Certificate Authority (CA) and save it in the flash memory, use the following command.

```
FastIron(config)# ip ssl certificate-data-file tftp 10.10.10.1 cacert.pem
```

**Syntax:** `ip ssl certificate-data-file tftp <ip-addr> <file-name>`

The `<ip-addr>` variable is the IP address of the TFTP server from which the digital certificate file is being downloaded.
Restricting remote access to management functions

The `<file-name>` variable is the file name of the digital certificate that you are importing to the router.

**Disabling specific access methods**

You can specifically disable the following access methods:

- Telnet access
- Web management access
- SNMP access
- TFTP

**NOTE**

If you disable Telnet access, you will not be able to access the CLI except through a serial connection to the management module. If you disable SNMP access, you will not be able to use IronView Network Manager or third-party SNMP management applications.

**Disabling Telnet access**

You can use a Telnet client to access the CLI on the device over the network. If you do not plan to use the CLI over the network and want to disable Telnet access to prevent others from establishing CLI sessions with the device, enter the following command.

```
FastIron(config)# no telnet server
```

To re-enable Telnet operation, enter the following command.

```
FastIron(config)# telnet server
```

**Syntax:** `[no] telnet server`

**NOTE**

The Telnet server is enabled by default.

**Disabling Web management access**

If you want to prevent access to the device through the Web Management Interface, you can disable the Web Management Interface.

**NOTE**

As soon as you make this change, the device stops responding to Web management sessions. If you make this change using your Web browser, your browser can contact the device, but the device will not reply once the change takes place.

To disable the Web Management Interface, enter the following command.

```
FastIron(config)# no web-management
```

To re-enable the Web Management Interface, enter the following command.

```
FastIron(config)# web-management
```

**Syntax:** `[no] web-management`
Disabling Web management access by HP ProCurve Manager

By default, TCP ports 80 and 280 are enabled on the Brocade device. TCP port 80 (HTTP) allows access to the device Web Management Interface. TCP port 280 allows access to the device by HP ProCurve Manager.

The `no web-management` command disables both TCP ports. However, if you want to disable only port 280 and leave port 80 enabled, use the `hp-top-tools` option with the command. Here is an example.

```
FastIron(config)# no web-management hp-top-tools
```

**Syntax:** `[no] web-management [allow-no-password | enable [vlan <vlan-id>] | front-panel | hp-top-tools | list-menu]`

The `hp-top-tools` parameter disables TCP port 280.

Disabling SNMP access

SNMP is required if you want to manage a Brocade device using IronView Network Manager.

To disable SNMP management of the device.

```
FastIron(config)# no snmp-server
```

To later re-enable SNMP management of the device.

```
FastIron(config)# snmp-server
```

**Syntax:** `no snmp-server`

Disabling TFTP access

On FastIron X Series and TurboIron X Series devices, you can globally disable TFTP to block TFTP client access. By default, TFTP client access is enabled.

To disable TFTP client access, enter the following command at the Global CONFIG level of the CLI.

```
FastIron(config)# tftp disable
```

When TFTP is disabled, users are prohibited from using the `copy tftp` command to copy files to the system flash. If users enter this command while TFTP is disabled, the system will reject the command and display an error message.

To re-enable TFTP client access once it is disabled, enter the following command.

```
FastIron(config)# no tftp disable
```

**Syntax:** `[no] tftp disable`

Setting passwords

Passwords can be used to secure the following access methods:

- Telnet access can be secured by setting a Telnet password. Refer to “Setting a Telnet password” on page 1426.
Setting passwords

- Access to the Privileged EXEC and CONFIG levels of the CLI can be secured by setting passwords for management privilege levels. Refer to “Setting passwords for management privilege levels” on page 1426.

This section also provides procedures for enhancing management privilege levels, recovering from a lost password, and disabling password encryption.

**NOTE**
You also can configure up to 16 user accounts consisting of a user name and password, and assign each user account a management privilege level. Refer to “Setting up local user accounts” on page 1430.

### Setting a Telnet password

By default, the device does not require a user name or password when you log in to the CLI using Telnet. You can assign a password for Telnet access using one of the following methods.

Set the password “letmein” for Telnet access to the CLI using the following command at the global CONFIG level.

```
FastIron(config)# enable telnet password letmein
```

**Syntax:** `[no] enable telnet password <string>`

**Suppressing Telnet connection rejection messages**

By default, if a Brocade device denies Telnet management access to the device, the software sends a message to the denied Telnet client. You can optionally suppress the rejection message. When you enable the option, a denied Telnet client does not receive a message from the Brocade device. Instead, the denied client simply does not gain access.

To suppress the connection rejection message, use the following CLI method.

To suppress the connection rejection message sent by the device to a denied Telnet client, enter the following command at the global CONFIG level of the CLI.

```
FastIron(config)# telnet server suppress-reject-message
```

**Syntax:** `[no] telnet server suppress-reject-message`

### Setting passwords for management privilege levels

You can set one password for each of the following management privilege levels:

- **Super User level** – Allows complete read-and-write access to the system. This is generally for system administrators and is the only management privilege level that allows you to configure passwords.

- **Port Configuration level** – Allows read-and-write access for specific ports but not for global (system-wide) parameters.

- **Read Only level** – Allows access to the Privileged EXEC mode and CONFIG mode of the CLI but only with read access.

You can assign a password to each management privilege level. You also can configure up to 16 user accounts consisting of a user name and password, and assign each user account to one of the three privilege levels. Refer to “Setting up local user accounts” on page 1430.
NOTE
You must use the CLI to assign a password for management privilege levels. You cannot assign a password using the Web Management Interface.

If you configure user accounts in addition to privilege level passwords, the device will validate a user access attempt using one or both methods (local user account or privilege level password), depending on the order you specify in the authentication-method lists. Refer to “Configuring authentication-method lists” on page 1477.

Follow the steps given below to set passwords for management privilege levels.

1. At the opening CLI prompt, enter the following command to change to the Privileged level of the EXEC mode.
   
   FastIron> enable
   FastIron#

2. Access the CONFIG level of the CLI by entering the following command.
   
   FastIron# configure terminal
   FastIron(config)#

3. Enter the following command to set the Super User level password.
   
   FastIron(config)# enable super-user-password <text>

   NOTE
   You must set the Super User level password before you can set other types of passwords. The Super User level password can be an alphanumeric string, but cannot begin with a number.

4. Enter the following commands to set the Port Configuration level and Read Only level passwords.
   
   FastIron(config)# enable port-config-password <text>
   FastIron(config)# enable read-only-password <text>

   Syntax: enable super-user-password <text>
   Syntax: enable port-config-password <text>
   Syntax: enable read-only-password <text>

   NOTE
   If you forget your Super User level password, refer to “Recovering from a lost password” on page 1429.

Augmenting management privilege levels

Each management privilege level provides access to specific areas of the CLI by default:

- Super User level provides access to all commands and displays.
- Port Configuration level gives access to:
  - The User EXEC and Privileged EXEC levels
  - The port-specific parts of the CONFIG level
  - All interface configuration levels
- Read Only level gives access to:
  - The User EXEC and Privileged EXEC levels
You can grant additional access to a privilege level on an individual command basis. To grant the additional access, you specify the privilege level you are enhancing, the CLI level that contains the command, and the individual command.

**NOTE**
This feature applies only to management privilege levels on the CLI. You cannot augment management access levels for the Web Management Interface.

Enhance the Port Configuration privilege level so users also can enter IP commands at the global CONFIG level.

`FastIron(config)# privilege configure level 4 ip`

In this command, `configure` specifies that the enhanced access is for a command at the global CONFIG level of the CLI. The `level 4` parameter indicates that the enhanced access is for management privilege level 4 (Port Configuration). All users with Port Configuration privileges will have the enhanced access. The `ip` parameter indicates that the enhanced access is for the IP commands. Users who log in with valid Port Configuration level user names and passwords can enter commands that begin with “ip” at the global CONFIG level.

**Syntax:** `[no] privilege <cli-level> level <privilege-level> <command-string>`

The `<cli-level>` parameter specifies the CLI level and can be one of the following values:

- `exec` – EXEC level; for example, FastIron> or FastIron#
- `configure` – CONFIG level; for example, FastIron(config)#
- `interface` – Interface level; for example, FastIron(config-if-6)#
- `loopback-interface` – loopback interface level
- `virtual-interface` – Virtual-interface level; for example, FastIron(config-vif-6)#
- `dot1x` – 802.1X configuration level
- `ipv6-access-list` – IPv6 access list configuration level
- `rip-router` – RIP router level; for example, FastIron(config-rip-router)#
- `ospf-router` – OSPF router level; for example, FastIron(config-ospf-router)#
- `dvmrp-router` – DVMRP router level; for example, FastIron(config-dvmrp-router)#
- `pim-router` – PIM router level; for example, FastIron(config-pim-router)#
- `bgp-router` – BGP4 router level; for example, FastIron(config-bgp-router)#
- `vrrp-router` – VRRP configuration level
- `gvrp` – GVRP configuration level
- `trunk` – trunk configuration level
- `port-vlan` – Port-based VLAN level; for example, FastIron(config-vlan)#
- `protocol-vlan` – Protocol-based VLAN level

The `<privilege-level>` indicates the number of the management privilege level you are augmenting. You can specify one of the following:

- `0` – Super User level (full read-write access)
- `4` – Port Configuration level
- `5` – Read Only level
The `<command-string>` parameter specifies the command you are allowing users with the specified privilege level to enter. To display a list of the commands at a CLI level, enter “?” at that level's command prompt.

**Recovering from a lost password**

Recovery from a lost password requires direct access to the serial port and a system reset.

**NOTE**  
You can perform this procedure only from the CLI.

Follow the steps given below to recover from a lost password.

1. Start a CLI session over the serial interface to the device.
2. Reboot the device.
3. At the initial boot prompt at system startup, enter `b` to enter the boot monitor mode.
4. Enter `no password` at the prompt. (You cannot abbreviate this command.) This command will cause the device to bypass the system password check.
5. Enter `boot system flash primary` at the prompt.
6. After the console prompt reappears, assign a new password.

**Displaying the SNMP community string**

If you want to display the SNMP community string, enter the following commands.

```
FastIron(config)# enable password-display
FastIron# show snmp server
```

The `enable password-display` command enables display of the community string, but only in the output of the `show snmp server` command. Display of the string is still encrypted in the startup-config file and running-config. Enter the command at the global CONFIG level of the CLI.

**Disabling password encryption**

When you configure a password, then save the configuration to the flash memory on the Brocade device, the password is also saved to flash as part of the configuration file. By default, the passwords are encrypted so that the passwords cannot be observed by another user who displays the configuration file. Even if someone observes the file while it is being transmitted over TFTP, the password is encrypted.

**NOTE**  
You cannot disable password encryption using the Web Management Interface.

If you want to remove the password encryption, you can disable encryption by entering the following command.

```
FastIron(config)# no service password-encryption
```

**Syntax:** `[no] service password-encryption`
Specifying a minimum password length

By default, the Brocade device imposes no minimum length on the Line (Telnet), Enable, or Local passwords. You can configure the device to require that Line, Enable, and Local passwords be at least a specified length.

For example, to specify that the Line, Enable, and Local passwords be at least 8 characters, enter the following command.

```
FastIron(config)# enable password-min-length 8
```

**Syntax:** `enable password-min-length <number-of-characters>`

The `<number-of-characters>` can be from 1 – 48.

**NOTE**

On TurboIron X Series devices, you can set local password on devices running software release 04.2.00 and later.

Setting up local user accounts

You can define up to 16 local user accounts on a Brocade device. User accounts regulate who can access the management functions in the CLI using the following methods:

- Telnet access
- Web management access
- SNMP access

Local user accounts provide greater flexibility for controlling management access to Brocade devices than do management privilege level passwords and SNMP community strings of SNMP versions 1 and 2. You can continue to use the privilege level passwords and the SNMP community strings as additional means of access authentication. Alternatively, you can choose not to use local user accounts and instead continue to use only the privilege level passwords and SNMP community strings. Local user accounts are backward-compatible with configuration files that contain privilege level passwords. Refer to “Setting passwords for management privilege levels” on page 1426.

If you configure local user accounts, you also need to configure an authentication-method list for Telnet access, Web management access, and SNMP access. Refer to “Configuring authentication-method lists” on page 1477.

For each local user account, you specify a user name. You also can specify the following parameters:

- A password
- A management privilege level, which can be one of the following:
  - **Super User level (default)** – Allows complete read-and-write access to the system. This is generally for system administrators and is the only privilege level that allows you to configure passwords.
  - **Port Configuration level** – Allows read-and-write access for specific ports but not for global parameters.
  - **Read Only level** – Allows access to the Privileged EXEC mode and CONFIG mode with read access only.
• Starting in release 03.0.00 for the FastIron X Series devices, you can set additional username and password rules. Refer to “Enhancements to username and password”.

Enhancements to username and password

Platform Support:
• FastIron X Series devices running software release 03.0.00 or later
• FGS and FLS devices running software release 03.2.00 and later
• FWS devices running software release 04.3.00 or later
• Turbolon X Series devices running software release 04.1.00 and later
• FCX-S devices running software release 06.0.00 and later

This section describes the enhancements to the username and password features introduced in the releases listed above.

The following rules are enabled by default:
• Users are required to accept the message of the day.
• Users are locked out (disabled) if they fail to login after three attempts. This feature is automatically enabled in release 03.0.00 for FastIron X Series devices, and release 03.2.00 for FastIron GS devices. Use the `disable-on-login-failure` command to change the number of login attempts (up to 10) before users are locked out.

The following rules are disabled by default:
• Enhanced user password combination requirements
• User password masking
• Quarterly updates of user passwords
• You can configure the system to store up to 15 previously configured passwords for each user.
• You can use the `disable-on-login-failure` command to change the number of login attempts (up to 10) before users are locked out.
• A password can now be set to expire.

Enabling enhanced user password combination requirements

Platform Support:
• FastIron X Series devices running software release 03.0.00 and later
• FGS and FLS devices running software release 03.2.00 and later
• FWS devices running software release 04.3.00 or later
• Turbolon X Series devices running software release 04.1.00 and later

When strict password enforcement is enabled on the Brocade device, you must enter a minimum of eight characters containing the following combinations when you create an enable and a user password:
• At least two upper case characters
• At least two lower case characters
• At least two numeric characters
• At least two special characters
NOTE
Password minimum and combination requirements are strictly enforced.

Use the `enable strict-password-enforcement` command to enable the password security feature.

```
FastIron(config)# enable strict-password-enforcement
```

**Syntax:** `[no] enable strict-password-enforcement`

This feature is disabled by default.

NOTE
When you upgrade to release FSX 03.0.00 or later or to FGS 03.2.00 or later, the old passwords are still valid; however, users must change their passwords to follow the new format to take advantage of this password enhancement.

The following security upgrades apply to the `enable strict-password-enforcement` command:

- Passwords must not share four or more concurrent characters with any other password configured on the router. If the user tries to create a password with four or more concurrent characters, the following error message will be returned.

  Error - The substring `<str>` within the password has been used earlier, please choose a different password.

For example, the previous password was `Ma!i4aYa&`, the user cannot use any of the following as his or her new password:

- `Ma!imai$D` because “Mail” were used consecutively in the previous password
- `&3B9aYa&` because “aYa&” were used consecutively in the previous password
- `i4aYEv#8` because “i4aY” were used consecutively in the previous password
- If the user tries to configure a password that was previously used, the Local User Account configuration will not be allowed and the following message will be displayed.

  This password was used earlier for same or different user, please choose a different password.

**Enabling user password masking**

By default, when you use the CLI to create a user password, the password displays on the console as you type it. For enhanced security, you can configure the Brocade device to mask the password characters entered at the CLI. When password masking is enabled, the CLI displays asterisks (*) on the console instead of the actual password characters entered.

The following shows the default CLI behavior when configuring a username and password.

```
FastIron(config)# username kelly password summertime
```

The following shows the CLI behavior when configuring a username and password when `password-masking` is enabled.

```
FastIron(config)# username kelly password
Enter Password: ********
```

**NOTE**
When password masking is enabled, press the [Enter] key before entering the password.

**Syntax:** `username <name> password [Enter]`
For [Enter], press the Enter key. Enter the password when prompted.

If **strict-password-enforcement** is enabled, enter a password which contains the required character combination. Refer to "Enabling enhanced user password combination requirements" on page 1431.

To enable password masking, enter the following command.

```
FastIron(config)# enable user password-masking
```

**Syntax:** [no] enable user password-masking

### Enabling user password aging

For enhanced security, password aging enforces quarterly updates of all user passwords. After 180 days, the CLI will automatically prompt users to change their passwords when they attempt to sign on.

When password aging is enabled, the software records the system time that each user password was configured or last changed. The time displays in the output of the `show running configuration` command, indicated by set-time `<time>`.

**Example**

```
FastIron# show run
Current configuration:
...
username waldo password ....
username raveen set-time 2086038248
...
```

The password aging feature uses the SNTP server clock to record the set-time. If the network does not have an SNTP server, then set-time will appear as `set-time 0` in the output of the `show running configuration` command.

A username set-time configuration is removed when:

- The username and password is deleted from the configuration
- The username password expires

When a username set-time configuration is removed, it no longer appears in the `show running configuration` output.

Note that if a username does not have an assigned password, the username will not have a set-time configuration.

Password aging is disabled by default. To enable it, enter the following command at the global CONFIG level of the CLI.

```
FastIron(config)# enable user password-aging
```

**Syntax:** [no] enable user password-aging

### Configuring password history

**Platform Support:**

- FastIron X Series devices running software release 03.0.00 and later
- FGS and FLS devices running software release 03.2.00 and later

FastIron# show run
Current configuration:
....
username waldo password ....
username raveen set-time 2086038248
....

The password aging feature uses the SNTP server clock to record the set-time. If the network does not have an SNTP server, then set-time will appear as `set-time 0` in the output of the `show running configuration` command.

A username set-time configuration is removed when:

- The username and password is deleted from the configuration
- The username password expires

When a username set-time configuration is removed, it no longer appears in the `show running configuration` output.

Note that if a username does not have an assigned password, the username will not have a set-time configuration.

Password aging is disabled by default. To enable it, enter the following command at the global CONFIG level of the CLI.

```
FastIron(config)# enable user password-aging
```

**Syntax:** [no] enable user password-aging

### Configuring password history

**Platform Support:**

- FastIron X Series devices running software release 03.0.00 and later
- FGS and FLS devices running software release 03.2.00 and later
• FWS devices running software release 04.3.00 or later

NOTE
This feature is not supported on TurboIron X Series devices, which store the last five user passwords for each user. When changing a user password, the five previously configured passwords cannot be used.

By default, the Brocade device stores the last five user passwords for each user. When changing a user password, the user cannot use any of the five previously configured passwords.

For security purposes, you can configure the Brocade device to store up to 15 passwords for each user, so that users do not use the same password multiple times. If a user attempts to use a password that is stored, the system will prompt the user to choose a different password.

To configure enhanced password history, enter a command such as the following at the global CONFIG level of the CLI.

FastIron(config)# enable user password-history 15

Syntax: [no] enable user password-history <1 – 15>

Password history in pre-release 03.0.00 software
The Brocade device stores not only the current password configured for a local user, but the previous two passwords configured for the user as well. The local user’s password cannot be changed to one of the stored passwords.

Consequently, if you change the password for a local user, you must select a password that is different from the current password, as well as different from the previous two passwords that had been configured for that user.

For example, say local user waldo originally had a password of "whereis", and the password was subsequently changed to "whois", then later changed to "whyis". If you change waldo's password again, you cannot change it to "whereis", "whois", or "whyis".

The current and previous passwords are stored in the device running-config file in encrypted form.

Example
FastIron# show run
...
username waldo password 8 $1$Ro2..Ox0$udBu7pQT5XyuaxMUiUHy9. history $1$eq...T62$IfpIXcXnDXX7CSVQK'1odu. $1$QD3..2Q0$DYxgCI642OSsYmA28/
...

In the running-config file, the user previous two passwords are displayed in encrypted form following the history parameter.

Enhanced login lockout

Platform Support:
• FastIron X Series devices running software release 03.0.00 and later
• FGS and FLS devices running software release 03.2.00 and later
• FWS devices running software release 04.3.00 or later
• TurboIron X Series devices running software release 04.1.00 and later
The CLI provides up to three login attempts. If a user fails to login after three attempts, that user is locked out (disabled). If desired, you can increase or decrease the number of login attempts before the user is disabled. To do so, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)# enable user disable-on-login-failure 7
```

**Syntax:** `enable user disable-on-login-failure <1 – 10>`

To re-enable a user that has been locked out, do one of the following:

- Reboot the Brocade device to re-enable all disabled users.
- Enable the user by entering the following command.
  ```
  FastIron(config)# username sandy enable
  ```

**Example**

```
FastIron(config)# user sandy enable
FastIron# show user
Username  Password                           Encrypt   Priv Status   Expire Time
------------------------------------------------------------------------------------------------
---
sandy     $1$Gz...uX/$wQ44fVGtsqbKWkQknzAZ6. enabled   0   enabled  90 days
```

**Syntax:** `username <name> enable`

### Setting passwords to expire

You can set a user password to expire. Once a password expires, the administrator must assign a new password to the user. To configure a user password to expire, enter the following.

```
FastIron(config)# username sandy expires 20
```

**Syntax:** `username <name> expires <days>`

Enter 1 – 365 for number of days. The default is 90 days.

**Example**

```
FastIron(config)# username sandy expires 20
FastIron# show user
Username  Password                              Encrypt   Priv  Status   Expire
Time
------------------------------------------------------------------------------------------------
---
sandy     $1$Gz...uX/$wQ44fVGtsqbKWkQknzAZ6. enabled    0    enabled  20 days
```

### Requirement to accept the message of the day

**Platform Support:**

- FastIron X Series devices running software release 03.1.01a and later
- FGS/FLS devices running software release 03.2.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later
If a message of the day (MOTD) is configured, a user will be required to press the Enter key before he or she can login. MOTD is configured using the `banner motd` command.

There are no new CLI commands for this feature.

**NOTE**
Beginning with release 03.0.01a, this requirement is disabled by default, unless configured. Users are not required to press Enter after the MOTD banner is displayed. Refer to “Requiring users to press the Enter key after the message of the day banner” on page 54.

## Configuring a local user account

You can create accounts for local users with or without passwords. Accounts with passwords can have encrypted or unencrypted passwords.

You can assign privilege levels to local user accounts, but on a new device, you must create a local user account that has a Super User privilege before you can create accounts with other privilege levels.

**NOTE**
You must grant Super User level privilege to at least one account before you add accounts with other privilege levels. You need the Super User account to make further administrative changes.

### Local user accounts with no passwords

To create a user account without a password, enter the following command at the global CONFIG level of the CLI.

```
FastIron(config)# username wonka nopassword
```

**Syntax:** 
\[
\text{[no]} \ username \ <\text{user-string}> \ privilege \ <\text{privilege-level}> \ nopassword
\]

### Local user accounts with unencrypted passwords

If you want to use unencrypted passwords for local user accounts, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)# username wonka password willy
```

If password masking is enabled, press the [Enter] key before entering the password.

```
FastIron(config)# username wonka
Enter Password: willy
```

The above commands add a local user account with the user name “wonka” and the password “willy”. This account has the Super User privilege level; this user has full access to all configuration and display features.

```
FastIron(config)# username waldo privilege 5 password whereis
```

This command adds a user account for user name “waldo”, password “whereis”, with the Read Only privilege level. Waldo can look for information but cannot make configuration changes.

**Syntax:** 
\[
\text{[no]} \ username \ <\text{user-string}> \ privilege \ <\text{privilege-level}> \ password \ | \ nopassword
\]

You can enter up to 255 characters for `<user-string>`.
The **privilege** `<privilege-level>` parameter specifies the privilege level for the account. You can specify one of the following:

- **0** – Super User level (full read-write access)
- **4** – Port Configuration level
- **5** – Read Only level

The default privilege level is **0**. If you want to assign Super User level access to the account, you can enter the command without **privilege 0**, as shown in the command example above.

The **password | nopassword** parameter indicates whether the user must enter a password. If you specify **password**, enter the string for the user's password. You can enter up to 255 characters for `<password-string>`. If **strict password enforcement** is enabled on the device, you must enter a minimum of eight characters containing the following combinations:

- At least two upper case characters
- At least two lower case characters
- At least two numeric characters
- At least two special characters

**NOTE**
You must be logged on with Super User access (privilege level 0) to add user accounts or configure other access parameters.

To display user account information, enter the following command.

```
FastIron# show users
```

**Syntax:** show users

### Local accounts with encrypted passwords

You can create local user accounts with MD5 encrypted passwords using one of the following methods:

- Issuing the **service password-encryption** command after creating the local user account with a `username <user-string> [privilege <privilege-level>] password 0` command
- Using the `username <user-string> create-password` command (on FastIron X Series devices running software release 03.1.00 and later)

**NOTE**
To create an encrypted all-numeric password, use the `username <user-string> create-password` command.

If you create a local user account using the commands discussed in “Local user accounts with unencrypted passwords” on page 1436, you can issue the **service password-encryption** command to encrypt all passwords that have been previously entered.

**Example**

```
FastIron(config)# username wonka privilege 5 password willy
FastIron(config)# service password-encryption
```

If password masking is enabled, enter the commands this way.
Setting up local user accounts

FastIron(config)# username wonka privilege 5 password
Enter Password: willy
FastIron(config)# service password-encryption

Syntax: [no] service password-encryption

Create password option

Platform Support:
- FastIron X Series devices running software release 03.1.00 and later
- TurboIron X Series devices running software release 04.1.00 and later

As an alternative to the commands above, the create-password option allows you to create an encrypted password in one line of command. Also, this new option allows you to create an all-numeric, encrypted password.

You can enter.

FastIron(config)# username wonka privilege 5 create-password willy

Syntax: [no] username <user-string> [privilege <privilege-level>] create-password <password-string>

You can enter up to 255 characters for <user-string>. This string can be alphanumeric or all-numeric.

The privilege parameter specifies the privilege level for the account. You can specify one of the following:
- 0 – Super User level (full read-write access)
- 4 – Port Configuration level
- 5 – Read Only level

Enter up to 255 alphanumeric characters for <password-string>.

Changing a local user password

To change a local user password for an existing local user account, enter a command such as the following at the global CONFIG level of the CLI.

NOTE
You must be logged on with Super User access (privilege level 0) to change user passwords.

FastIron(config)# username wonka password willy

If password masking is enabled, enter the username, press the [Enter] key, then enter the password.

FastIron(config)# username wonka password
Enter Password:  willy

The above commands change wonka's user name password to “willy”.

Syntax: [no] username <user-string> password <password-string>

Enter up to 255 characters for <user-string>. 
The `<password-string>` parameter is the user password. The password can be up to 255 characters and must differ from the current password and two previously configured passwords.

When a password is changed, a message such as the following is sent to the Syslog.

SYSLOG: <14>Jan 1 00:00:00 10.44.9.11 Security: Password has been changed for user tester from console session.

The message includes the name of the user whose password was changed and during which session type, such as Console, Telnet, SSH, Web, SNMP, or others, the password was changed.

### Configuring SSL security for the Web Management Interface

The Brocade device supports Secure Sockets Layer / Transport Level Security (SSL 3.0 / TLS 1.0) for configuring the device using the Web Management Interface.

When enabled, the SSL protocol uses digital certificates and public-private key pairs to establish a secure connection to the Brocade device. Digital certificates serve to prove the identity of a connecting client, and public-private key pairs provide a means to encrypt data sent between the device and the client.

Configuring SSL for the Web Management Interface consists of the following tasks:

- Optionally enabling the SSL server on the Brocade device
- Importing an RSA certificate and private key file from a client (optional)
- Generating a certificate

#### Enabling the SSL server on the Brocade device

To enable the SSL server on the Brocade device, enter the following command.

FastIron(config)# web-management https

**Syntax:**

```plaintext
[no] web-management http | https
```

You can enable either the HTTP or HTTPS servers with this command. You can disable both the HTTP and HTTPS servers by entering the following command.

FastIron(config)# no web-management

**Syntax:**

```plaintext
no web-management
```

#### Specifying a port for SSL communication

By default, SSL protocol exchanges occur on TCP port 443. You can optionally change the port number used for SSL communication.

For example, the following command causes the device to use TCP port 334 for SSL communication.

FastIron(config)# ip ssl port 334

**Syntax:**

```plaintext
[no] ip ssl port <port-number>
```
The default port for SSL communication is 443.

**Changing the SSL server certificate key size**

The default key size for Brocade-issued and imported digital certificates is 1024 bits. If desired, you can change the default key size to a value between 512 and 4096 bits. To do so, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)# ip ssl cert-key-size 3000
```

**Syntax:** `ip ssl cert-key-size <512 – 4096>

**NOTE**
The SSL server certificate key size applies to digital certificates issued by Brocade, as well as imported certificates.

**Support for SSL digital certificates larger than 2048 bits**

**Platform Support:**
- FastIron X Series devices running software release 04.0.00 and later

Devices running software release 04.0.00 and later have the ability to store and retrieve SSL digital certificates that are up to 4000 bits in size. Earlier releases support SSL certificates not larger than 2048 bits.

To accommodate support for the larger SSL certificate file size, the SSL certificate is stored in flash memory, instead of in the configuration file. For backward compatibility, the Brocade device provides support as follows:

- If the SSL certificate size is less than 2048 bits, the certificate will be written to the configuration file and to the flash file. This way, releases prior to FSX 04.0.00 can still store and retrieve the certificate.
- If the SSL certificate is larger than 2048 bits, it will be written to the flash file only. Consequently, software versions prior to FSX 04.0.00 will not be able to store or retrieve an SSL certificate that is larger than 2048 bits. In releases prior to FSX 04.0.00, if the certificate is larger than 2048 bits, the following warning message will display on the console:

```
Certificate is too big to store in the configuration file, this certificate works only with the released version later than 3.2.
```

Support for SSL certificates larger than 2048 bits is automatically enabled in software release FSX 04.0.00 and later. You do not need to perform any configuration procedures to enable it.

**Importing digital certificates and RSA private key files**

To allow a client to communicate with other Brocade device using an SSL connection, you configure a set of digital certificates and RSA public-private key pairs on the device. A digital certificate is used for identifying the connecting client to the server. It contains information about the issuing Certificate Authority, as well as a public key. You can either import digital certificates and private keys from a server, or you can allow the Brocade device to create them.

If you want to allow the Brocade device to create the digital certificates, refer to the next section, “Generating an SSL certificate”. If you choose to import an RSA certificate and private key file from a client, you can use TFTP to transfer the files.
For example, to import a digital certificate using TFTP, enter a command such as the following.

```
FastIron(config)# ip ssl certificate-data-file tftp 192.168.9.210 certfile
```

**Syntax:**

```
[no] ip ssl certificate-data-file tftp <ip-addr> <certificate-filename>
```

**NOTE**

If you are running a software version prior to 04.0.00 and you are importing a digital certificate from a client, it must be no larger than 2048 bits. If you are running software release 04.0.00 or later, the digital certificate can be up to 4096 bits. Refer to “Support for SSL digital certificates larger than 2048 bits” on page 1440.

To import an RSA private key from a client using TFTP, enter a command such as the following.

```
FastIron(config)# ip ssl private-key-file tftp 192.168.9.210 keyfile
```

**Syntax:**

```
[no] ip ssl private-key-file tftp <ip-addr> <key-filename>
```

The `<ip-addr>` is the IP address of a TFTP server that contains the digital certificate or private key.

### Generating an SSL certificate

After you have imported the digital certificate, it should automatically generate.

If the certificate does not automatically generate, enter the following command to generate it.

```
FastIron(config)# crypto-ssl certificate generate
```

**Syntax:**

```
[no] crypto-ssl certificate generate
```

If you did not already import a digital certificate from a client, the device can create a default certificate. To do this, enter the following command.

```
FastIron(config)# crypto-ssl certificate generate default_cert
```

**Syntax:**

```
[no] crypto-ssl certificate generate default_cert
```

### Deleting the SSL certificate

To delete the SSL certificate, enter the following command.

```
FastIron(config)# crypto-ssl certificate zeroize
```

**Syntax:**

```
[no] crypto-ssl certificate zeroize
```

### Configuring TACACS/TACACS+ security

You can use the security protocol Terminal Access Controller Access Control System (TACACS) or TACACS+ to authenticate the following kinds of access to the Brocade device:

- Telnet access
- SSH access
- Console access
- Web management access
- Access to the Privileged EXEC level and CONFIG levels of the CLI
The TACACS and TACACS+ protocols define how authentication, authorization, and accounting information is sent between a Brocade device and an authentication database on a TACACS/TACACS+ server. TACACS/TACACS+ services are maintained in a database, typically on a UNIX workstation or PC with a TACACS/TACACS+ server running.

**NOTE**
On TurboIron X Series devices, the TACACS+ security feature is supported on devices running software release 04.2.00 and later.

### How TACACS+ differs from TACACS

TACACS is a simple UDP-based access control protocol originally developed by BBN for MILNET. TACACS+ is an enhancement to TACACS and uses TCP to ensure reliable delivery.

TACACS+ is an enhancement to the TACACS security protocol. TACACS+ improves on TACACS by separating the functions of authentication, authorization, and accounting (AAA) and by encrypting all traffic between the Brocade device and the TACACS+ server. TACACS+ allows for arbitrary length and content authentication exchanges, which allow any authentication mechanism to be utilized with the Brocade device. TACACS+ is extensible to provide for site customization and future development features. The protocol allows the Brocade device to request very precise access control and allows the TACACS+ server to respond to each component of that request.

**NOTE**
TACACS+ provides for authentication, authorization, and accounting, but an implementation or configuration is not required to employ all three.

### TACACS/TACACS+ authentication, authorization, and accounting

When you configure a Brocade device to use a TACACS/TACACS+ server for **authentication**, the device prompts users who are trying to access the CLI for a user name and password, then verifies the password with the TACACS/TACACS+ server.

If you are using TACACS+, Brocade recommends that you also configure **authorization**, in which the Brocade device consults a TACACS+ server to determine which management privilege level (and which associated set of commands) an authenticated user is allowed to use. You can also optionally configure **accounting**, which causes the Brocade device to log information on the TACACS+ server when specified events occur on the device.

**NOTE**
By default, a user logging into the device from Telnet or SSH would first enter the User EXEC level. The user can enter the `enable` command to get to the Privileged EXEC level.

A user that is successfully authenticated can be automatically placed at the Privileged EXEC level after login. Refer to “Entering privileged EXEC mode after a Telnet or SSH login” on page 1453.

### Configuring TACACS/TACACS+ for devices in a Brocade IronStack

Because devices operating in a Brocade IronStack topology present multiple console ports, you must take additional steps to secure these ports when configuring TACACS/TACACS+. 
The following is a sample AAA console configuration using TACACS+.

```
aaa authentication login default tacacs+ enable
aaa authentication login privilege-mode
aaa authorization commands 0 default tacacs+
aaa authorization exec default tacacs+
aaa accounting commands 0 default start-stop tacacs+
aaa accounting exec default start-stop tacacs+
aaa accounting system default start-stop tacacs+
enable aaa console
hostname Fred
ip address 144.10.6.56/255
tacacs-server host 255.253.255
tacacs-server key 1 $Gsig8U$
```

**kill console**

**Syntax:** `kill console [all | unit]`

- **all** - logs out all console port on stack units that are not the Active Controller
- **unit** - logs out the console port on a specified unit

Once AAA console is enabled, you should log out any open console ports on your IronStack using the `kill console` command:

```
FGS624 Switch(config)# kill console all
```

In case a user forgets to log out or a console is left unattended, you can also configure the console timeout (in minutes) on all stack units (including the Active Controller).

```
FGS624 Switch(config)# stack unit 3
FGS624 Switch(config-unit-3)# console timeout 5
FGS624 Switch(config-unit-3)# exit
FGS624 Switch(config)# stack unit 4
FGS624 Switch(config-unit-4)# console timeout 5
```

Use the `show who` and the `show telnet` commands to confirm the status of console sessions.

```
stack9# show who
Console connections (by unit number):
   1  established
      you are connecting to this session
      4 seconds in idle
   2  established
      1 hours 3 minutes 12 seconds in idle
   3  established
      1 hours 3 minutes 9 seconds in idle
   4  established
      1 hours 3 minutes 3 seconds in idle
Telnet connections (inbound):
   1  closed
   2  closed
   3  closed
   4  closed
   5  closed
Telnet connection (outbound):
   6  closed
SSH connections:
   1  closed
   2  closed
   3  closed
   4  closed
```
TACACS authentication

NOTE
Also, multiple challenges are supported for TACACS+ login authentication.

When TACACS authentication takes place, the following events occur.

1. A user attempts to gain access to the Brocade device by doing one of the following:
   - Logging into the device using Telnet, SSH, or the Web Management Interface
   - Entering the Privileged EXEC level or CONFIG level of the CLI

2. The user is prompted for a username and password.

3. The user enters a username and password.

4. The Brocade device sends a request containing the username and password to the TACACS server.

5. The username and password are validated in the TACACS server database.

6. If the password is valid, the user is authenticated.

TACACS+ authentication

When TACACS+ authentication takes place, the following events occur.
1. A user attempts to gain access to the Brocade device by doing one of the following:
   • Logging into the device using Telnet, SSH, or the Web Management Interface
   • Entering the Privileged EXEC level or CONFIG level of the CLI
2. The user is prompted for a username.
3. The user enters a username.
4. The Brocade device obtains a password prompt from a TACACS+ server.
5. The user is prompted for a password.
6. The user enters a password.
7. The Brocade device sends the password to the TACACS+ server.
8. The password is validated in the TACACS+ server database.
9. If the password is valid, the user is authenticated.

**TACACS+ authorization**

Brocade devices support two kinds of TACACS+ authorization:

- Exec authorization determines a user privilege level when they are authenticated
- Command authorization consults a TACACS+ server to get authorization for commands entered by the user

When TACACS+ exec authorization takes place, the following events occur.
1. A user logs into the Brocade device using Telnet, SSH, or the Web Management Interface
2. The user is authenticated.
3. The Brocade device consults the TACACS+ server to determine the privilege level of the user.
4. The TACACS+ server sends back a response containing an A-V (Attribute-Value) pair with the privilege level of the user.
5. The user is granted the specified privilege level.

When TACACS+ command authorization takes place, the following events occur.
1. A Telnet, SSH, or Web Management Interface user previously authenticated by a TACACS+ server enters a command on the Brocade device.
2. The Brocade device looks at its configuration to see if the command is at a privilege level that requires TACACS+ command authorization.
3. If the command belongs to a privilege level that requires authorization, the Brocade device consults the TACACS+ server to see if the user is authorized to use the command.
4. If the user is authorized to use the command, the command is executed.

**TACACS+ accounting**

TACACS+ accounting works as follows.
1. One of the following events occur on the Brocade device:
   • A user logs into the management interface using Telnet or SSH
   • A user enters a command for which accounting has been configured
• A system event occurs, such as a reboot or reloading of the configuration file

2. The Brocade device checks the configuration to see if the event is one for which TACACS+ accounting is required.

3. If the event requires TACACS+ accounting, the Brocade device sends a TACACS+ Accounting Start packet to the TACACS+ accounting server, containing information about the event.

4. The TACACS+ accounting server acknowledges the Accounting Start packet.

5. The TACACS+ accounting server records information about the event.

6. When the event is concluded, the Brocade device sends an Accounting Stop packet to the TACACS+ accounting server.

7. The TACACS+ accounting server acknowledges the Accounting Stop packet.

**AAA operations for TACACS/TACACS+**

The following table lists the sequence of authentication, authorization, and accounting operations that take place when a user gains access to a Brocade device that has TACACS/TACACS+ security configured.

<table>
<thead>
<tr>
<th>User action</th>
<th>Applicable AAA operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>User attempts to gain access to the Privileged EXEC and CONFIG levels of the CLI</td>
<td>Enable authentication:</td>
</tr>
<tr>
<td></td>
<td>aaa authentication enable default &lt;method-list&gt;</td>
</tr>
<tr>
<td></td>
<td>Exec authorization (TACACS+):</td>
</tr>
<tr>
<td></td>
<td>aaa authorization exec default tacacs+</td>
</tr>
<tr>
<td></td>
<td>System accounting start (TACACS+):</td>
</tr>
<tr>
<td></td>
<td>aaa accounting system default start-stop &lt;method-list&gt;</td>
</tr>
<tr>
<td>User logs in using Telnet/SSH</td>
<td>Login authentication:</td>
</tr>
<tr>
<td></td>
<td>aaa authentication login default &lt;method-list&gt;</td>

<td>aaa accounting exec default start-stop &lt;method-list&gt;</td>
</tr>
</tbody>
</table>
Configuring TACACS/TACACS+ security

If AAA security is enabled on the device, commands pasted into the running-config are subject to the same AAA operations as if they were entered manually.

When you paste commands into the running-config, and AAA command authorization or accounting, or both, are configured on the device, AAA operations are performed on the pasted commands. The AAA operations are performed before the commands are actually added to the running-config. The server performing the AAA operations should be reachable when you paste the commands into the running-config file. If the device determines that a pasted command is invalid, AAA operations are halted on the remaining commands. The remaining commands may not be executed if command authorization is configured.

**AAA security for commands pasted into the running-config**

**TACACS/TACACS+ configuration considerations**

- You must deploy at least one TACACS/TACACS+ server in your network.
- Brocade devices support authentication using up to eight TACACS/TACACS+ servers. The device tries to use the servers in the order you add them to the device configuration.
- You can select only one primary authentication method for each type of access to a device (CLI through Telnet, CLI Privileged EXEC and CONFIG levels). For example, you can select TACACS+ as the primary authentication method for Telnet CLI access, but you cannot also select RADIUS authentication as a primary method for the same type of access. However, you can configure backup authentication methods for each access type.
- You can configure the Brocade device to authenticate using a TACACS or TACACS+ server, not both.
TACACS configuration procedure

Follow the procedure given below for TACACS configurations.

1. Identify TACACS servers. Refer to “Identifying the TACACS/TACACS+ servers” on page 1448.
2. Set optional parameters. Refer to “Setting optional TACACS/TACACS+ parameters” on page 1450.

TACACS+ configuration procedure

Follow the procedure given below for TACACS+ configurations.

1. Identify TACACS+ servers. Refer to “Identifying the TACACS/TACACS+ servers” on page 1448.
2. Set optional parameters. Refer to “Setting optional TACACS/TACACS+ parameters” on page 1450.
4. Optionally configure TACACS+ authorization. Refer to “Configuring TACACS+ authorization” on page 1453.
5. Optionally configure TACACS+ accounting. Refer to “Configuring TACACS+ accounting” on page 1456.

Enabling TACACS

TACACS is disabled by default. To configure TACACS/TACACS+ authentication parameters, you must enable TACACS by entering the following command.

FastIron(config)# enable snmp config-tacacs

Syntax: [no] enable snmp <config-radius | config-tacacs>

The <config-radius> parameter specifies the RADIUS configuration mode. RADIUS is disabled by default.

The <config-tacacs> parameter specifies the TACACS configuration mode. TACACS is disabled by default.

Identifying the TACACS/TACACS+ servers

To use TACACS/TACACS+ servers to authenticate access to a Brocade device, you must identify the servers to the Brocade device.

For example, to identify three TACACS/TACACS+ servers, enter commands such as the following.

FastIron(config)# tacacs-server host 207.94.6.161
FastIron(config)# tacacs-server host 207.94.6.191
FastIron(config)# tacacs-server host 207.94.6.122

Syntax: tacacs-server host <ip-addr> | <ipv6-addr> | <hostname> [auth-port <number>]
The <ip-addr> | <ipv6-addr> | <hostname> parameter specifies the IP address or host name of the server. You can enter up to eight tacacs-server host commands to specify up to eight different servers.

**NOTE**
To specify the server's host name instead of its IP address, you must first identify a DNS server using the ip dns server-address <ip-addr> command at the global CONFIG level.

If you add multiple TACACS/TACACS+ authentication servers to the Brocade device, the device tries to reach them in the order you add them. For example, if you add three servers in the following order, the software tries the servers in the same order.

1. 207.94.6.161
2. 207.94.6.191
3. 207.94.6.122

You can remove a TACACS/TACACS+ server by entering no followed by the tacacs-server command. For example, to remove 207.94.6.161, enter the following command.

FastIron(config)# no tacacs-server host 207.94.6.161

**NOTE**
If you erase a tacacs-server command (by entering "no" followed by the command), make sure you also erase the aaa commands that specify TACACS/TACACS+ as an authentication method. (Refer to “Configuring authentication-method lists for TACACS/TACACS+” on page 1451.) Otherwise, when you exit from the CONFIG mode or from a Telnet session, the system continues to believe it is TACACS/TACACS+ enabled and you will not be able to access the system.

The auth-port parameter specifies the UDP (for TACACS) or TCP (for TACACS+) port number of the authentication port on the server. The default port number is 49.

### Specifying different servers for individual AAA functions

In a TACACS+ configuration, you can designate a server to handle a specific AAA task. For example, you can designate one TACACS+ server to handle authorization and another TACACS+ server to handle accounting. You can set the TACACS+ key for each server.

To specify different TACACS+ servers for authentication, authorization, and accounting, enter the command such as following.

FastIron(config)# tacacs-server host 1.2.3.4 auth-port 49 authentication-only key abc
FastIron(config)# tacacs-server host 1.2.3.5 auth-port 49 authorization-only key def
FastIron(config)# tacacs-server host 1.2.3.6 auth-port 49 accounting-only key ghi

**Syntax:**
```
tacacs-server host <ip-addr> | <ipv6-addr> | <server-name> [auth-port <num>]
authentication-only | authorization-only | accounting-only | default] [key 0 | 1 <string>]
```

The default parameter causes the server to be used for all AAA functions.

After authentication takes place, the server that performed the authentication is used for authorization and accounting. If the authenticating server cannot perform the requested function, then the next server in the configured list of servers is tried; this process repeats until a server that can perform the requested function is found, or every server in the configured list has been tried.
Setting optional TACACS/TACACS+ parameters

You can set the following optional parameters in a TACACS/TACACS+ configuration:

- **TACACS+ key** – This parameter specifies the value that the Brocade device sends to the TACACS+ server when trying to authenticate user access.
- **Retransmit interval** – This parameter specifies how many times the Brocade device will resend an authentication request when the TACACS/TACACS+ server does not respond. The retransmit value can be from 1 – 5 times. The default is 3 times.
- **Dead time** – This parameter specifies how long the Brocade device waits for the primary authentication server to reply before deciding the server is dead and trying to authenticate using the next server. The dead-time value can be from 1 – 5 seconds. The default is 3 seconds.
- **Timeout** – This parameter specifies how many seconds the Brocade device waits for a response from a TACACS/TACACS+ server before either retrying the authentication request, or determining that the TACACS/TACACS+ servers are unavailable and moving on to the next authentication method in the authentication-method list. The timeout can be from 1 – 15 seconds. The default is 3 seconds.
- **TACACS/TACACS+ over IPv6** – This parameter enables the Brocade device to send TACACS/TACACS+ packets over IPv6.

**Setting the TACACS+ key**

The `key` parameter in the `tacacs-server` command is used to encrypt TACACS+ packets before they are sent over the network. The value for the `key` parameter on the Brocade device should match the one configured on the TACACS+ server. The key can be from 1 – 32 characters in length and cannot include any space characters.

**NOTE**

The `tacacs-server key` command applies only to TACACS+ servers, not to TACACS servers. If you are configuring TACACS, do not configure a key on the TACACS server and do not enter a key on the Brocade device.

To specify a TACACS+ server key, enter a command such as following.

```
FastIron(config)# tacacs-server key rkwong
```

**Syntax: tacacs-server key [0 | 1] <string>**

When you display the configuration of the Brocade device, the TACACS+ keys are encrypted. For example.

```
FastIron(config)# tacacs-server key 1 abc
FastIron(config)# write terminal
...
```
```
tacacs-server host 1.2.3.5 auth-port 49
  tacacs key 1 $!2d
```

**NOTE**

Encryption of the TACACS+ keys is done by default. The 0 parameter disables encryption. The 1 parameter is not required; it is provided for backwards compatibility.
Setting the retransmission limit

The retransmit parameter specifies how many times the Brocade device will resend an authentication request when the TACACS/TACACS+ server does not respond. The retransmit limit can be from 1 – 5 times. The default is 3 times.

To set the TACACS/TACACS+ retransmit limit, enter a command such as the following.

FastIron(config)# tacacs-server retransmit 5

Syntax: tacacs-server retransmit <number>

Setting the timeout parameter

The timeout parameter specifies how many seconds the Brocade device waits for a response from the TACACS/TACACS+ server before either retrying the authentication request, or determining that the TACACS/TACACS+ server is unavailable and moving on to the next authentication method in the authentication-method list. The timeout can be from 1 – 15 seconds. The default is 3 seconds.

FastIron(config)# tacacs-server timeout 5

Syntax: tacacs-server timeout <number>

TACACS/TACACS+ over IPv6

Platform Support:
- FESX and FSX devices running software release 02.5.00 and later

To enable this feature, enter a command such as the following at the Global CONFIG level of the CLI.

FastIron(config)# tacacs-server host ipv6 3000::200

Syntax: tacacs-server host ipv6 <ipv6-host address>

The <ipv6-host address> is the IPv6 address of the TACACS server. When you enter the IPv6 host address, you do not need to specify the prefix length. A prefix length of 128 is implied.

Configuring authentication-method lists for TACACS/TACACS+

You can use TACACS/TACACS+ to authenticate Telnet/SSH access and access to Privileged EXEC level and CONFIG levels of the CLI. When configuring TACACS/TACACS+ authentication, you create authentication-method lists specifically for these access methods, specifying TACACS/TACACS+ as the primary authentication method.

Within the authentication-method list, TACACS/TACACS+ is specified as the primary authentication method and up to six backup authentication methods are specified as alternates. If TACACS/TACACS+ authentication fails due to an error, the device tries the backup authentication methods in the order they appear in the list.

When you configure authentication-method lists for TACACS/TACACS+ authentication, you must create a separate authentication-method list for Telnet/SSH CLI access, and for access to the Privileged EXEC level and CONFIG levels of the CLI.

To create an authentication method list that specifies TACACS/TACACS+ as the primary authentication method for securing Telnet/SSH access to the CLI.
Configuring TACACS/TACACS+ security

FastIron(config)# enable telnet authentication
FastIron(config)# aaa authentication login default tacacs local

The commands above cause TACACS/TACACS+ to be the primary authentication method for securing Telnet/SSH access to the CLI. If TACACS/TACACS+ authentication fails due to an error with the server, authentication is performed using local user accounts instead.

To create an authentication-method list that specifies TACACS/TACACS+ as the primary authentication method for securing access to Privileged EXEC level and CONFIG levels of the CLI.

FastIron(config)# aaa authentication enable default tacacs local none

The command above causes TACACS/TACACS+ to be the primary authentication method for securing access to Privileged EXEC level and CONFIG levels of the CLI. If TACACS/TACACS+ authentication fails due to an error with the server, local authentication is used instead. If local authentication fails, no authentication is used; the device automatically permits access.

Syntax: [no] aaa authentication enable | login default <method1> [<method2>] [<method3>] [<method4>] [<method5>] [<method6>] [<method7>]

The web-server | enable | login parameter specifies the type of access this authentication-method list controls. You can configure one authentication-method list for each type of access.

NOTE
If you configure authentication for Web management access, authentication is performed each time a page is requested from the server. When frames are enabled on the Web Management Interface, the browser sends an HTTP request for each frame. The Brocade device authenticates each HTTP request from the browser. To limit authentications to one per page, disable frames on the Web Management Interface.

The <method1> parameter specifies the primary authentication method. The remaining optional <method> parameters specify additional methods to try if an error occurs with the primary method. A method can be one of the values listed in the Method Parameter column in the following table.

### TABLE 234 Authentication method values

<table>
<thead>
<tr>
<th>Method parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>line</td>
<td>Authenticate using the password you configured for Telnet access. The Telnet password is configured using the <code>enable telnet password</code> command. Refer to “Setting a Telnet password” on page 1426.</td>
</tr>
<tr>
<td>enable</td>
<td>Authenticate using the password you configured for the Super User privilege level. This password is configured using the <code>enable super-user-password</code> command. Refer to “Setting passwords for management privilege levels” on page 1426.</td>
</tr>
<tr>
<td>local</td>
<td>Authenticate using a local user name and password you configured on the device. Local user names and passwords are configured using the <code>username</code> command. Refer to “Configuring a local user account” on page 1436.</td>
</tr>
<tr>
<td>tacacs</td>
<td>Authenticate using the database on a TACACS server. You also must identify the server to the device using the <code>tacacs-server</code> command.</td>
</tr>
<tr>
<td>tacacs+</td>
<td>Authenticate using the database on a TACACS+ server. You also must identify the server to the device using the <code>tacacs-server</code> command.</td>
</tr>
<tr>
<td>radius</td>
<td>Authenticate using the database on a RADIUS server. You also must identify the server to the device using the <code>radius-server</code> command.</td>
</tr>
<tr>
<td>none</td>
<td>Do not use any authentication method. The device automatically permits access.</td>
</tr>
</tbody>
</table>
Configuring TACACS/TACACS+ security

NOTE
For examples of how to define authentication-method lists for types of authentication other than TACACS/TACACS+, refer to “Configuring authentication-method lists” on page 1477.

Entering privileged EXEC mode after a Telnet or SSH login

By default, a user enters User EXEC mode after a successful login through Telnet or SSH. Optionally, you can configure the device so that a user enters Privileged EXEC mode after a Telnet or SSH login. To do this, use the following command.

\[ \text{FastIron(config)}\# \text{aaa authentication login privilege-mode} \]

Syntax: \text{aaa authentication login privilege-mode}

The user privilege level is based on the privilege level granted during login.

Configuring enable authentication to prompt for password only

If Enable authentication is configured on the device, when a user attempts to gain Super User access to the Privileged EXEC and CONFIG levels of the CLI, by default he or she is prompted for a username and password. You can configure the Brocade device to prompt only for a password. The device uses the username entered at login, if one is available. If no username was entered at login, the device prompts for both username and password.

To configure the Brocade device to prompt only for a password when a user attempts to gain Super User access to the Privileged EXEC and CONFIG levels of the CLI.

\[ \text{FastIron(config)}\# \text{aaa authentication enable implicit-user} \]

Syntax: [no] \text{aaa authentication enable implicit-user}

Telnet/SSH prompts when the TACACS+ Server is unavailable

When TACACS+ is the first method in the authentication method list, the device displays the login prompt received from the TACACS+ server. If a user attempts to login through Telnet or SSH, but none of the configured TACACS+ servers are available, the following takes place:

- If the next method in the authentication method list is "enable", the login prompt is skipped, and the user is prompted for the Enable password (that is, the password configured with the enable super-user-password command).
- If the next method in the authentication method list is "line", the login prompt is skipped, and the user is prompted for the Line password (that is, the password configured with the enable telnet password command).

Configuring TACACS+ authorization

Brocade devices support TACACS+ authorization for controlling access to management functions in the CLI. Two kinds of TACACS+ authorization are supported:

- Exec authorization determines a user privilege level when they are authenticated
- Command authorization consults a TACACS+ server to get authorization for commands entered by the user
Configuring exec authorization

When TACACS+ exec authorization is performed, the Brocade device consults a TACACS+ server to determine the privilege level of the authenticated user. To configure TACACS+ exec authorization on the Brocade device, enter the following command.

FastIron(config)# aaa authorization exec default tacacs+

Syntax: aaa authorization exec default tacacs+ | none

If you specify none, or omit the aaa authorization exec command from the device configuration, no exec authorization is performed.

A user privilege level is obtained from the TACACS+ server in the “foundry-privlvl” A-V pair. If the aaa authorization exec default tacacs+ command exists in the configuration, the device assigns the user the privilege level specified by this A-V pair. If the command does not exist in the configuration, then the value in the “foundry-privlvl” A-V pair is ignored, and the user is granted Super User access.

NOTE
If the aaa authorization exec default tacacs+ command exists in the configuration, following successful authentication the device assigns the user the privilege level specified by the “foundry-privlvl” A-V pair received from the TACACS+ server. If the aaa authorization exec default tacacs+ command does not exist in the configuration, then the value in the “foundry-privlvl” A-V pair is ignored, and the user is granted Super User access.

Also note that in order for the aaa authorization exec default tacacs+ command to work, either the aaa authentication enable default tacacs+ command, or the aaa authentication login privilege-mode command must also exist in the configuration.

Configuring an Attribute-Value pair on the TACACS+ server

During TACACS+ exec authorization, the Brocade device expects the TACACS+ server to send a response containing an A-V (Attribute-Value) pair that specifies the privilege level of the user. When the Brocade device receives the response, it extracts an A-V pair configured for the Exec service and uses it to determine the user privilege level.

To set a user privilege level, you can configure the “foundry-privlvl” A-V pair for the Exec service on the TACACS+ server.

Example

    user=bob {
      default service = permit
      member admin
      #Global password
      global = cleartext "cat"
      service = exec {
        foundry-privlvl = 0
      }
    }

In this example, the A-V pair foundry-privlvl = 0 grants the user full read-write access. The value in the foundry-privlvl A-V pair is an integer that indicates the privilege level of the user. Possible values are 0 for super-user level, 4 for port-config level, or 5 for read-only level. If a value other than 0, 4, or 5 is specified in the foundry-privlvl A-V pair, the default privilege level of 5 (read-only) is used. The foundry-privlvl A-V pair can also be embedded in the group configuration for the user. See your TACACS+ documentation for the configuration syntax relevant to your server.
If the foundry-privlvl A-V pair is not present, the Brocade device extracts the last A-V pair configured for the Exec service that has a numeric value. The Brocade device uses this A-V pair to determine the user privilege level.

Example

```plaintext
user=bob {
    default service = permit
    member admin
    #Global password
    global = cleartext "cat"
    service = exec {
        priv-lvl = 15
    }
}
```

The attribute name in the A-V pair is not significant; the Brocade device uses the last one that has a numeric value. However, the Brocade device interprets the value for a non-“foundry-privlvl” A-V pair differently than it does for a “foundry-privlvl” A-V pair. The following table lists how the Brocade device associates a value from a non-“foundry-privlvl” A-V pair with a Brocade privilege level.

<table>
<thead>
<tr>
<th>Value for non-“foundry-privlvl” A-V pair</th>
<th>Brocade privilege level</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>0 (super-user)</td>
</tr>
<tr>
<td>From 14 – 1</td>
<td>4 (port-config)</td>
</tr>
<tr>
<td>Any other number or 0</td>
<td>5 (read-only)</td>
</tr>
</tbody>
</table>

In the example above, the A-V pair configured for the Exec service is `priv-lvl = 15`. The Brocade device uses the value in this A-V pair to set the user privilege level to 0 (super-user), granting the user full read-write access.

In a configuration that has both a “foundry-privlvl” A-V pair and a non-“foundry-privlvl” A-V pair for the Exec service, the non-“foundry-privlvl” A-V pair is ignored.

Example

```plaintext
user=bob {
    default service = permit
    member admin
    #Global password
    global = cleartext "cat"
    service = exec {
        foundry-privlvl = 4
        priv-lvl = 15
    }
}
```

In this example, the user would be granted a privilege level of 4 (port-config level). The `priv-lvl = 15` A-V pair is ignored by the Brocade device.

If the TACACS+ server has no A-V pair configured for the Exec service, the default privilege level of 5 (read-only) is used.

**Configuring command authorization**

When TACACS+ command authorization is enabled, the Brocade device consults a TACACS+ server to get authorization for commands entered by the user.
You enable TACACS+ command authorization by specifying a privilege level whose commands require authorization. For example, to configure the Brocade device to perform authorization for the commands available at the Super User privilege level (that is, all commands on the device), enter the following command.

```
FastIron(config)# aaa authorization commands 0 default tacacs+
```

**Syntax:** `aaa authorization commands <privilege-level> default tacacs+ | radius | none`

The `<privilege-level>` parameter can be one of the following:

- **0** – Authorization is performed for commands available at the Super User level (all commands)
- **4** – Authorization is performed for commands available at the Port Configuration level (port-config and read-only commands)
- **5** – Authorization is performed for commands available at the Read Only level (read-only commands)

**NOTE**

TACACS+ command authorization can be performed only for commands entered from Telnet or SSH sessions, or from the console. No authorization is performed for commands entered at the Web Management Interface or IronView Network Manager.

TACACS+ command authorization is not performed for the following commands:

- At all levels: `exit`, `logout`, `end`, and `quit`.
- At the Privileged EXEC level: `enable` or `enable <text>`, where `<text>` is the password configured for the Super User privilege level.

If configured, command accounting is performed for these commands.

**AAA support for console commands**

AAA support for commands entered at the console includes the following:

- Login prompt that uses AAA authentication, using authentication-method Lists
- Exec Authorization
- Exec Accounting
- Command authorization
- Command accounting
- System Accounting

To enable AAA support for commands entered at the console, enter the following command.

```
FastIron(config)# enable aaa console
```

**Syntax:** `[no] enable aaa console`

**Configuring TACACS+ accounting**

Brocade devices support TACACS+ accounting for recording information about user activity and system events. When you configure TACACS+ accounting on a Brocade device, information is sent to a TACACS+ accounting server when specified events occur, such as when a user logs into the device or the system is rebooted.
Configuring TACACS+ accounting for Telnet/SSH (Shell) access

To send an Accounting Start packet to the TACACS+ accounting server when an authenticated user establishes a Telnet or SSH session on the Brocade device, and an Accounting Stop packet when the user logs out.

```bash
FastIron(config)# aaa accounting exec default start-stop tacacs+
```

Syntax: `aaa accounting exec default start-stop radius | tacacs+ | none`

Configuring TACACS+ accounting for CLI commands

You can configure TACACS+ accounting for CLI commands by specifying a privilege level whose commands require accounting. For example, to configure the Brocade device to perform TACACS+ accounting for the commands available at the Super User privilege level (that is; all commands on the device), enter the following command.

```bash
FastIron(config)# aaa accounting commands 0 default start-stop tacacs+
```

An Accounting Start packet is sent to the TACACS+ accounting server when a user enters a command, and an Accounting Stop packet is sent when the service provided by the command is completed.

**NOTE**

If authorization is enabled, and the command requires authorization, then authorization is performed before accounting takes place. If authorization fails for the command, no accounting takes place.

Syntax: `aaa accounting commands <privilege-level> default start-stop radius | tacacs+ | none`

The `<privilege-level>` parameter can be one of the following:

- **0** – Records commands available at the Super User level (all commands)
- **4** – Records commands available at the Port Configuration level (port-config and read-only commands)
- **5** – Records commands available at the Read Only level (read-only commands)

Configuring TACACS+ accounting for system events

You can configure TACACS+ accounting to record when system events occur on the Brocade device. System events include rebooting and when changes to the active configuration are made.

The following command causes an Accounting Start packet to be sent to the TACACS+ accounting server when a system event occurs, and a Accounting Stop packet to be sent when the system event is completed.

```bash
FastIron(config)# aaa accounting system default start-stop tacacs+
```

Syntax: `aaa accounting system default start-stop radius | tacacs+ | none`
Configuring an interface as the source for all TACACS/TACACS+ packets

You can designate the lowest-numbered IP address configured an Ethernet port, loopback interface, or virtual interface as the source IP address for all TACACS/TACACS+ packets from the Layer 3 Switch. Identifying a single source IP address for TACACS/TACACS+ packets provides the following benefits:

- If your TACACS/TACACS+ server is configured to accept packets only from specific links or IP addresses, you can use this feature to simplify configuration of the TACACS/TACACS+ server by configuring the Brocade device to always send the TACACS/TACACS+ packets from the same link or source address.

- If you specify a loopback interface as the single source for TACACS/TACACS+ packets, TACACS/TACACS+ servers can receive the packets regardless of the states of individual links. Thus, if a link to the TACACS/TACACS+ server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

The software contains separate CLI commands for specifying the source interface for Telnet, TACACS/TACACS+, and RADIUS packets. You can configure a source interface for one or more of these types of packets.

To specify an Ethernet, loopback, or virtual interface as the source for all TACACS/TACACS+ packets from the device, use the following CLI method. The software uses the lowest-numbered IP address configured on the port or interface as the source IP address for TACACS/TACACS+ packets originated by the device.

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all TACACS/TACACS+ packets, enter commands such as the following.

```
FastIron(config)# int ve 1
FastIron(config-vif-1)# ip address 10.0.0.3/24
FastIron(config-vif-1)# exit
FastIron(config)# ip tacacs source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface as the source for all TACACS/TACACS+ packets from the Layer 3 Switch.

**Syntax:** `ip tacacs source-interface ethernet [<slotnum>/]<portnum> | loopback <num> | ve <num>`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The `<num>` parameter is a loopback interface or virtual interface number.
Displaying TACACS/TACACS+ statistics and configuration information

The **show aaa** command displays information about all TACACS+ and RADIUS servers identified on the device.

```
FastIron# show aaa
Tacacs+ key: foundry
Tacacs+ retries: 1
Tacacs+ timeout: 15 seconds
Tacacs+ dead-time: 3 minutes
Tacacs+ Server: 207.95.6.90 Port:49:
              opens=6 closes=3 timeouts=3 errors=0
              packets in=4 packets out=4
no connection
Radius key: networks
Radius retries: 3
Radius timeout: 3 seconds
Radius dead-time: 3 minutes
Radius Server:  207.95.6.90 Auth Port=1645 Acct Port=1646:
              opens=2 closes=1 timeouts=1 errors=0
              packets in=1 packets out=4
no connection

The following table describes the TACACS/TACACS+ information displayed by the **show aaa** command.

**TABLE 236** Output of the show aaa command for TACACS/TACACS+

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tacacs+ key</td>
<td>The setting configured with the <code>tacacs-server key</code> command. At the Super User privilege level, the actual text of the key is displayed. At the other privilege levels, a string of periods (....) is displayed instead of the text.</td>
</tr>
<tr>

The **show web** command displays the privilege level of Web Management Interface users.
Configuring RADIUS security

You can use a Remote Authentication Dial In User Service (RADIUS) server to secure the following types of access to the Brocade Layer 2 Switch or Layer 3 Switch:

- Telnet access
- SSH access
- Web management access
- Access to the Privileged EXEC level and CONFIG levels of the CLI

**NOTE**
Brocade devices do not support RADIUS security for SNMP (IronView Network Manager) access.

**RADIUS authentication, authorization, and accounting**

When RADIUS authentication is implemented, the Brocade device consults a RADIUS server to verify user names and passwords. You can optionally configure RADIUS authorization, in which the Brocade device consults a list of commands supplied by the RADIUS server to determine whether a user can execute a command he or she has entered, as well as accounting, which causes the Brocade device to log information on a RADIUS accounting server when specified events occur on the device.

**RADIUS authentication**

When RADIUS authentication takes place, the following events occur.

1. A user attempts to gain access to the Brocade device by doing one of the following:
   - Logging into the device using Telnet, SSH, or the Web Management Interface
   - Entering the Privileged EXEC level or CONFIG level of the CLI
2. The user is prompted for a username and password.
3. The user enters a username and password.
4. The Brocade device sends a RADIUS Access-Request packet containing the username and password to the RADIUS server.
5. The RADIUS server validates the Brocade device using a shared secret (the RADIUS key).
6. The RADIUS server looks up the username in its database.
7. If the username is found in the database, the RADIUS server validates the password.

---

**Example**

```bash
FastIron# show web
User                             Privilege       IP address
set                                     0        192.168.1.234
```

**Syntax:** show web
8. If the password is valid, the RADIUS server sends an Access-Accept packet to the Brocade device, authenticating the user. Within the Access-Accept packet are three Brocade vendor-specific attributes that indicate:
   • The privilege level of the user
   • A list of commands
   • Whether the user is allowed or denied usage of the commands in the list
   The last two attributes are used with RADIUS authorization, if configured.

9. The user is authenticated, and the information supplied in the Access-Accept packet for the user is stored on the Brocade device. The user is granted the specified privilege level. If you configure RADIUS authorization, the user is allowed or denied usage of the commands in the list.

**RADIUS authorization**

When RADIUS authorization takes place, the following events occur.

1. A user previously authenticated by a RADIUS server enters a command on the Brocade device.
2. The Brocade device looks at its configuration to see if the command is at a privilege level that requires RADIUS command authorization.
3. If the command belongs to a privilege level that requires authorization, the Brocade device looks at the list of commands delivered to it in the RADIUS Access-Accept packet when the user was authenticated. (Along with the command list, an attribute was sent that specifies whether the user is permitted or denied usage of the commands in the list.)

**NOTE**

After RADIUS authentication takes place, the command list resides on the Brocade device. The RADIUS server is not consulted again once the user has been authenticated. This means that any changes made to the user command list on the RADIUS server are not reflected until the next time the user is authenticated by the RADIUS server, and the new command list is sent to the Brocade device.

4. If the command list indicates that the user is authorized to use the command, the command is executed.

**RADIUS accounting**

RADIUS accounting works as follows.

1. One of the following events occur on the Brocade device:
   • A user logs into the management interface using Telnet or SSH
   • A user enters a command for which accounting has been configured
   • A system event occurs, such as a reboot or reloading of the configuration file
2. The Brocade device checks its configuration to see if the event is one for which RADIUS accounting is required.
3. If the event requires RADIUS accounting, the Brocade device sends a RADIUS Accounting Start packet to the RADIUS accounting server, containing information about the event.
4. The RADIUS accounting server acknowledges the Accounting Start packet.
5. The RADIUS accounting server records information about the event.
6. When the event is concluded, the Brocade device sends an Accounting Stop packet to the RADIUS accounting server.
7. The RADIUS accounting server acknowledges the Accounting Stop packet.

**AAA operations for RADIUS**

The following table lists the sequence of authentication, authorization, and accounting operations that take place when a user gains access to a Brocade device that has RADIUS security configured.

<table>
<thead>
<tr>
<th>User action</th>
<th>Applicable AAA operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>User attempts to gain access to the Privileged EXEC and CONFIG levels of the CLI</td>
<td>Enable authentication: aaa authentication enable default &lt;method-list&gt; System accounting start: aaa accounting system default start-stop &lt;method-list&gt;</td>
</tr>
<tr>
<td>User logs into the Web Management Interface</td>
<td>Web authentication: aaa authentication web-server default &lt;method-list&gt;</td>
</tr>
<tr>
<td>User enters system commands (for example, <code>reload</code>, <code>boot system</code>)</td>
<td>Command authorization: aaa authorization commands &lt;privilege-level&gt; default &lt;method-list&gt; Command accounting: aaa accounting commands &lt;privilege-level&gt; default start-stop &lt;method-list&gt; System accounting stop: aaa accounting system default start-stop &lt;method-list&gt;</td>
</tr>
<tr>
<td>User enters other commands</td>
<td>Command authorization: aaa authorization commands &lt;privilege-level&gt; default &lt;method-list&gt; Command accounting: aaa accounting commands &lt;privilege-level&gt; default start-stop &lt;method-list&gt;</td>
</tr>
</tbody>
</table>
AAA security for commands pasted into the running-config

If AAA security is enabled on the device, commands pasted into the running-config are subject to the same AAA operations as if they were entered manually.

When you paste commands into the running-config, and AAA command authorization or accounting, or both, are configured on the device, AAA operations are performed on the pasted commands. The AAA operations are performed before the commands are actually added to the running-config. The server performing the AAA operations should be reachable when you paste the commands into the running-config file. If the device determines that a pasted command is invalid, AAA operations are halted on the remaining commands. The remaining commands may not be executed if command authorization is configured.

NOTE
Since RADIUS command authorization relies on a list of commands received from the RADIUS server when authentication is performed, it is important that you use RADIUS authentication when you also use RADIUS command authorization.

RADIUS configuration considerations

- You must deploy at least one RADIUS server in your network.
- Brocade devices support authentication using up to eight RADIUS servers, including those used for 802.1X authentication and for management. The device tries to use the servers in the order you add them to the device configuration. If one RADIUS server times out (does not respond), the Brocade device tries the next one in the list. Servers are tried in the same sequence each time there is a request.
- Starting in software release FSX 04.0.00, you can optionally configure a RADIUS server as a port server, indicating that the server will be used only to authenticate users on ports to which it is mapped, as opposed to globally authenticating users on all ports of the device. In earlier releases, all configured RADIUS servers are “global” servers and apply to users on all ports of the device. Refer to “Configuring a RADIUS server per port” on page 1466.
- Starting in software release FSX 04.0.00, you can map up to eight RADIUS servers to each port on the Brocade device. The port will authenticate users using only the RADIUS servers to which it is mapped. If there are no RADIUS servers mapped to a port, it will use the “global” servers for authentication. In earlier releases, all RADIUS servers are “global” servers and cannot be bound to individual ports. Refer to “Mapping a RADIUS server to individual ports” on page 1467.
- You can select only one primary authentication method for each type of access to a device (CLI through Telnet, CLI Privileged EXEC and CONFIG levels). For example, you can select RADIUS as the primary authentication method for Telnet CLI access, but you cannot also select TACACS+ authentication as the primary method for the same type of access. However, you can configure backup authentication methods for each access type.

RADIUS configuration procedure

Follow the procedure given below to configure a Brocade device for RADIUS.

2. Identify the RADIUS server to the Brocade device. Refer to “Identifying the RADIUS server to the Brocade device” on page 1466.

3. Optionally specify different servers for individual AAA functions. Refer to “Specifying different servers for individual AAA functions” on page 1466.

4. Optionally configure the RADIUS server as a “port only” server. Refer to “Configuring a RADIUS server per port” on page 1466.

5. Optionally bind the RADIUS servers to ports on the Brocade device. Refer to “Mapping a RADIUS server to individual ports” on page 1467.

8. Optionally configure RADIUS authorization. Refer to “Configuring RADIUS authorization” on page 1472.

Configuring Brocade-specific attributes on the RADIUS server

NOTE
For all Brocade devices, RADIUS Challenge is supported for 802.1x authentication but not for login authentication.

During the RADIUS authentication process, if a user supplies a valid username and password, the RADIUS server sends an Access-Accept packet to the Brocade device, authenticating the user. Within the Access-Accept packet are three Brocade vendor-specific attributes that indicate:

- The privilege level of the user
- A list of commands
- Whether the user is allowed or denied usage of the commands in the list

You must add these three Brocade vendor-specific attributes to your RADIUS server configuration, and configure the attributes in the individual or group profiles of the users that will access the Brocade device.

Brocade Vendor-ID is 1991, with Vendor-Type 1. The following table describes the Brocade vendor-specific attributes.
Enabling SNMP to configure RADIUS

To enable SNMP access to RADIUS MIB objects on the device, enter a command such as the following.

```
FastIron(config)# enable snmp config-radius
```

**Syntax:** `[no] enable snmp <config-radius | config-tacacs>

The `<config-radius>` parameter specifies the RADIUS configuration mode. RADIUS is disabled by default.

The `<config-tacacs>` parameter specifies the TACACS configuration mode. TACACS is disabled by default.

### TABLE 237  Brocade vendor-specific attributes for RADIUS

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Attribute ID</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foundry-privilege-level</td>
<td>1</td>
<td>integer</td>
<td>Specifies the privilege level for the user. This attribute can be set to one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• 0 - Super User level – Allows complete read-and-write access to the system. This is generally for system administrators and is the only management privilege level that allows you to configure passwords.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• 4 - Port Configuration level – Allows read-and-write access for specific ports but not for global (system-wide) parameters.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• 5 - Read Only level – Allows access to the Privileged EXEC mode and CONFIG mode of the CLI but only with read access.</td>
</tr>
</tbody>
</table>

| foundry-command-string     | 2            | string    | Specifies a list of CLI commands that are permitted or denied to the user when RADIUS authorization is configured. The commands are delimited by semi-colons (;). You can specify an asterisk (*) as a wildcard at the end of a command string. For example, the following command list specifies all show and debug ip commands, as well as the write terminal command: show *; debug ip *; write term* |

| foundry-command-exception-flag | 3      | integer | Specifies whether the commands indicated by the foundry-command-string attribute are permitted or denied to the user. This attribute can be set to one of the following: |
|                                |        |         | • 0 - Permit execution of the commands indicated by foundry-command-string, deny all other commands. |
|                                |        |         | • 1 - Deny execution of the commands indicated by foundry-command-string, permit all other commands. |
Identifying the RADIUS server to the Brocade device

To use a RADIUS server to authenticate access to a Brocade device, you must identify the server to the Brocade device.

**Example**

FastIron(config)# radius-server host 209.157.22.99

**Syntax:** `radius-server host <ip-addr> | <ipv6-addr> | <server-name> [auth-port <number>] [acct-port <number>]`

The `<ip-addr> | <ipv6-addr> | <server-name>` parameter is either an IP address or an ASCII text string.

The `<auth-port>` parameter is the Authentication port number. The default is 1645.

The `<acct-port>` parameter is the Accounting port number. The default is 1646.

Specifying different servers for individual AAA functions

In a RADIUS configuration, you can designate a server to handle a specific AAA task. For example, you can designate one RADIUS server to handle authorization and another RADIUS server to handle accounting. You can specify individual servers for authentication and accounting, but not for authorization. You can set the RADIUS key for each server.

To specify different RADIUS servers for authentication, authorization, and accounting, enter commands such as the following.

FastIron(config)# radius-server host 1.2.3.4 authentication-only key abc
FastIron(config)# radius-server host 1.2.3.5 authorization-only key def
FastIron(config)# radius-server host 1.2.3.6 accounting-only key ghi

**Syntax:** `radius-server host <ip-addr> | <ipv6-addr> | <server-name> [auth-port <number>] [acct-port <number>] [authentication-only | accounting-only | default] [key 0 | 1 <string>]`

The `default` parameter causes the server to be used for all AAA functions.

After authentication takes place, the server that performed the authentication is used for authorization and accounting. If the authenticating server cannot perform the requested function, then the next server in the configured list of servers is tried; this process repeats until a server that can perform the requested function is found, or every server in the configured list has been tried.

Configuring a RADIUS server per port

**Platform Support:**

- FastIron X Series devices running software release 04.0.00 and later – L2, BL3, L3
- TurboIron X Series devices running software release 04.1.00 and later

You can optionally configure a RADIUS server per port, indicating that it will be used only to authenticate users on ports to which it is mapped. A RADIUS server that is not explicitly configured as a RADIUS server per port is a **global server**, and can be used to authenticate users on ports to which no RADIUS servers are mapped.
Configuration notes

- This feature works with 802.1X and multi-device port authentication only.
- As in previous releases, you can define up to eight RADIUS servers per Brocade device.

Configuration example and command syntax

The following shows an example configuration.

```
FastIron(config)# radius-server host 10.10.10.103 auth-port 1812 acct-port 1813
default key mykeyword dot1x port-only
FastIron(config)# radius-server host 10.10.10.104 auth-port 1812 acct-port 1813
default key mykeyword dot1x port-only
FastIron(config)# radius-server host 10.10.10.105 auth-port 1812 acct-port 1813
default key mykeyword dot1x
FastIron(config)# radius-server host 10.10.10.106 auth-port 1812 acct-port 1813
default key mykeyword dot1x
```

The above configuration has the following affect:

- RADIUS servers 10.10.10.103 and 10.10.10.104 will be used only to authenticate users on ports to which the servers are mapped. To map a RADIUS server to a port, refer to “Mapping a RADIUS server to individual ports” on page 1467.
- RADIUS servers 10.10.10.105 and 10.10.10.106 will be used to authenticate users on ports to which no RADIUS servers are mapped. For example, port e 9, to which no RADIUS servers are mapped, will send a RADIUS request to the first configured RADIUS server, 10.10.10.105. If the request fails, it will go to the second configured RADIUS server, 10.10.10.106. It will not send requests to 10.10.10.103 or 10.10.10.104, since these servers are configured as port servers.

Syntax: `radius-server host <ip-addr> | <server-name> [auth-port <number>] [acct-port <number>] [default key <string> dot1x] [port-only]`

The `host <ip-addr>` is the IPv4 address.

The `auth-port <number>` parameter is the Authentication port number; it is an optional parameter. The default is 1645.

The `acct-port <number>` parameter is the Accounting port number; it is an optional parameter. The default is 1646.

The `default key <string> dot1x` parameter indicates that this RADIUS server supports the 802.1X standard. A RADIUS server that supports the 802.1X standard can also be used to authenticate non-802.1X authentication requests.

The `port-only` parameter is optional and specifies that the server will be used only to authenticate users on ports to which it is mapped.

Mapping a RADIUS server to individual ports

Platform Support:

- FastIron X Series devices running software release 04.0.00 and later – L2, BL3, L3
- Turbolron X Series devices running software release 04.1.00 and later
You can map up to eight RADIUS servers to each port on the Brocade device. The port will authenticate users using only the RADIUS servers to which the port is mapped. If there are no RADIUS servers mapped to a port, it will use the “global” servers for authentication.

As in previous releases, a port goes through the list of servers in the order in which it was mapped or configured, until a server that can perform the requested function is found, or until every server in the list has been tried.

**Configuration notes**

- This feature works with 802.1X and multi-device port authentication only.
- You can map a RADIUS server to a physical port only. You cannot map a RADIUS server to a VE.

**Configuration example and command syntax**

To map a RADIUS server to a port, enter commands such as the following.

```plaintext
FastIron(config)# int e 3
FastIron(config-if-e1000-3)# dot1x port-control auto
FastIron(config-if-e1000-3)# use-radius-server 10.10.10.103
FastIron(config-if-e1000-3)# use-radius-server 10.10.10.110
```

With the above configuration, port e 3 would send a RADIUS request to 10.10.10.103 first, since it is the first server mapped to the port. If it fails, it will go to 10.10.10.110.

**Syntax:** `use-radius-server <ip-addr>`

The `host <ip-addr>` is an IPv4 address.

**Setting RADIUS parameters**

You can set the following parameters in a RADIUS configuration:

- **RADIUS key** – This parameter specifies the value that the Brocade device sends to the RADIUS server when trying to authenticate user access.
- **Retransmit interval** – This parameter specifies how many times the Brocade device will resend an authentication request when the RADIUS server does not respond. The retransmit value can be from 1 – 5 times. The default is 3 times.
- **Timeout** – This parameter specifies how many seconds the Brocade device waits for a response from a RADIUS server before either retrying the authentication request, or determining that the RADIUS servers are unavailable and moving on to the next authentication method in the authentication-method list. The timeout can be from 1 – 15 seconds. The default is 3 seconds.

**Setting the RADIUS key**

The `key` parameter in the `radius-server` command is used to encrypt RADIUS packets before they are sent over the network. The value for the `key` parameter on the Brocade device should match the one configured on the RADIUS server. The key can be from 1 – 32 characters in length and cannot include any space characters.

To specify a RADIUS server key, enter a command such as the following.

```plaintext
FastIron(config)# radius-server key mirabeau
```
Syntax: `radius-server key [0 | 1] <string>`

When you display the configuration of the Brocade device, the RADIUS key is encrypted.

Example

```
FastIron(config)# radius-server key 1 abc
FastIron(config)# write terminal
...
radius-server host 1.2.3.5
radius key 1 $!2d
```

**NOTE**

Encryption of the RADIUS keys is done by default. The 0 parameter disables encryption. The 1 parameter is not required; it is provided for backwards compatibility.

**Setting the retransmission limit**

The `retransmit` parameter specifies the maximum number of retransmission attempts. When an authentication request times out, the Brocade software will retransmit the request up to the maximum number of retransmissions configured. The default retransmit value is 3 retries. The range of retransmit values is from 1 – 5.

To set the RADIUS retransmit limit, enter a command such as the following.

```
FastIron(config)# radius-server retransmit 5
```

**Syntax: `radius-server retransmit <number>`**

**Setting the timeout parameter**

The `timeout` parameter specifies how many seconds the Brocade device waits for a response from the RADIUS server before either retrying the authentication request, or determining that the RADIUS server is unavailable and moving on to the next authentication method in the authentication-method list. The timeout can be from 1 – 15 seconds. The default is 3 seconds.

```
FastIron(config)# radius-server timeout 5
```

**Syntax: `radius-server timeout <number>`**

**RADIUS over IPv6**

**Platform Support:**

- FastIron X Series devices running software release 02.5.00 and later

Brocade devices support the ability to send RADIUS packets over an IPv6 network.

To enable the Brocade device to send RADIUS packets over IPv6, enter a command such as the following at the Global CONFIG level of the CLI.

```
FastIron(config)# radius-server host ipv6 3000::300
```

**Syntax: `radius-server host ipv6 <ipv6-host address>`**

The `<ipv6-host address>` is the IPv6 address of the RADIUS server. When you enter the IPv6 host address, you do not need to specify the prefix length. A prefix length of 128 is implied.
Configuring authentication-method lists for RADIUS

You can use RADIUS to authenticate Telnet/SSH access and access to Privileged EXEC level and CONFIG levels of the CLI. When configuring RADIUS authentication, you create authentication-method lists specifically for these access methods, specifying RADIUS as the primary authentication method.

Within the authentication-method list, RADIUS is specified as the primary authentication method and up to six backup authentication methods are specified as alternates. If RADIUS authentication fails due to an error, the device tries the backup authentication methods in the order they appear in the list.

When you configure authentication-method lists for RADIUS, you must create a separate authentication-method list for Telnet or SSH CLI access and for CLI access to the Privileged EXEC level and CONFIG levels of the CLI.

To create an authentication-method list that specifies RADIUS as the primary authentication method for securing Telnet access to the CLI.

```
FastIron(config)# enable telnet authentication
FastIron(config)# aaa authentication login default radius local
```

The commands above cause RADIUS to be the primary authentication method for securing Telnet access to the CLI. If RADIUS authentication fails due to an error with the server, local authentication is used instead.

To create an authentication-method list that specifies RADIUS as the primary authentication method for securing access to Privileged EXEC level and CONFIG levels of the CLI.

```
FastIron(config)# aaa authentication enable default radius local none
```

The command above causes RADIUS to be the primary authentication method for securing access to Privileged EXEC level and CONFIG levels of the CLI. If RADIUS authentication fails due to an error with the server, local authentication is used instead. If local authentication fails, no authentication is used; the device automatically permits access.

**Syntax:**

```
[no] aaa authentication enable | login default <method1> [<method2>] [<method3>]
[<method4>] [<method5>] [<method6>] [<method7>]
```

The `web-server | enable | login` parameter specifies the type of access this authentication-method list controls. You can configure one authentication-method list for each type of access.

**NOTE**

If you configure authentication for Web management access, authentication is performed each time a page is requested from the server. When frames are enabled on the Web Management Interface, the browser sends an HTTP request for each frame. The Brocade device authenticates each HTTP request from the browser. To limit authentications to one per page, disable frames on the Web Management Interface.

The `<method1>` parameter specifies the primary authentication method. The remaining optional `<method>` parameters specify additional methods to try if an error occurs with the primary method. A method can be one of the values listed in the Method Parameter column in the following table.
Configuring RADIUS security

### Entering privileged EXEC mode after a Telnet or SSH login

By default, a user enters User EXEC mode after a successful login through Telnet or SSH. Optionally, you can configure the device so that a user enters Privileged EXEC mode after a Telnet or SSH login. To do this, use the following command.

```
FastIron(config)# aaa authentication login privilege-mode
```

**Syntax:** `aaa authentication login privilege-mode`

The user privilege level is based on the privilege level granted during login.

### Configuring enable authentication to prompt for password only

If Enable authentication is configured on the device, when a user attempts to gain Super User access to the Privileged EXEC and CONFIG levels of the CLI, by default he or she is prompted for a username and password. In this release, you can configure the Brocade device to prompt only for a password. The device uses the username entered at login, if one is available. If no username was entered at login, the device prompts for both username and password.

To configure the Brocade device to prompt only for a password when a user attempts to gain Super User access to the Privileged EXEC and CONFIG levels of the CLI.

```
FastIron(config)# aaa authentication enable implicit-user
```

**Syntax:** `[no] aaa authentication enable implicit-user`

---

**TABLE 238 Authentication method values**

<table>
<thead>
<tr>
<th>Method parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>line</td>
<td>Authenticate using the password you configured for Telnet access. The Telnet password is configured using the <code>enable telnet password...</code> command. Refer to “Setting a Telnet password” on page 1426.</td>
</tr>

<tr>
<td>none</td>
<td>Do not use any authentication method. The device automatically permits access.</td>
</tr>
</tbody>
</table>

**NOTE**

For examples of how to define authentication-method lists for types of authentication other than RADIUS, refer to “Configuring authentication-method lists” on page 1477.
Configuring RADIUS authorization

Brocade devices support RADIUS authorization for controlling access to management functions in the CLI. Two kinds of RADIUS authorization are supported:

- Exec authorization determines a user privilege level when they are authenticated
- Command authorization consults a RADIUS server to get authorization for commands entered by the user

Configuring exec authorization

When RADIUS exec authorization is performed, the Brocade device consults a RADIUS server to determine the privilege level of the authenticated user. To configure RADIUS exec authorization on the Brocade device, enter the following command.

```
FastIron(config)# aaa authorization exec default radius
```

Syntax: `aaa authorization exec default radius` | `none`

If you specify `none`, or omit the `aaa authorization exec` command from the device configuration, no exec authorization is performed.

**NOTE**

If the `aaa authorization exec default radius` command exists in the configuration, following successful authentication the device assigns the user the privilege level specified by the foundry-privilege-level attribute received from the RADIUS server. If the `aaa authorization exec default radius` command does not exist in the configuration, then the value in the foundry-privilege-level attribute is ignored, and the user is granted Super User access.

Also note that in order for the `aaa authorization exec default radius` command to work, either the `aaa authentication enable default radius` command, or the `aaa authentication login privilege-mode` command must also exist in the configuration.

Configuring command authorization

When RADIUS command authorization is enabled, the Brocade device consults the list of commands supplied by the RADIUS server during authentication to determine whether a user can execute a command he or she has entered.

You enable RADIUS command authorization by specifying a privilege level whose commands require authorization. For example, to configure the Brocade device to perform authorization for the commands available at the Super User privilege level (that is; all commands on the device), enter the following command.

```
FastIron(config)# aaa authorization commands 0 default radius
```

Syntax: `aaa authorization commands <privilege-level> default radius` | `tacacs+` | `none`

The `<privilege-level>` parameter can be one of the following:

- **0** – Authorization is performed (that is, the Brocade device looks at the command list) for commands available at the Super User level (all commands)
- **4** – Authorization is performed for commands available at the Port Configuration level (port-config and read-only commands)
Configuring RADIUS security

- Authorization is performed for commands available at the Read Only level (read-only commands)

NOTE
RADIUS command authorization can be performed only for commands entered from Telnet or SSH sessions, or from the console. No authorization is performed for commands entered at the Web Management Interface or IronView Network Manager.

NOTE
Since RADIUS command authorization relies on the command list supplied by the RADIUS server during authentication, you cannot perform RADIUS authorization without RADIUS authentication.

Command authorization and accounting for console commands

The Brocade device supports command authorization and command accounting for CLI commands entered at the console. To configure the device to perform command authorization and command accounting for console commands, enter the following.

FastIron(config)# enable aaa console

Syntax: enable aaa console

CAUTION
If you have previously configured the device to perform command authorization using a RADIUS server, entering the enable aaa console command may prevent the execution of any subsequent commands entered on the console.

This happens because RADIUS command authorization requires a list of allowable commands from the RADIUS server. This list is obtained during RADIUS authentication. For console sessions, RADIUS authentication is performed only if you have configured Enable authentication and specified RADIUS as the authentication method (for example, with the aaa authentication enable default radius command). If RADIUS authentication is never performed, the list of allowable commands is never obtained from the RADIUS server. Consequently, there would be no allowable commands on the console.

Configuring RADIUS accounting

Brocade devices support RADIUS accounting for recording information about user activity and system events. When you configure RADIUS accounting on a Brocade device, information is sent to a RADIUS accounting server when specified events occur, such as when a user logs into the device or the system is rebooted.

Configuring RADIUS accounting for Telnet/SSH (Shell) access

To send an Accounting Start packet to the RADIUS accounting server when an authenticated user establishes a Telnet or SSH session on the Brocade device, and an Accounting Stop packet when the user logs out.

FastIron(config)# aaa accounting exec default start-stop radius

Syntax: aaa accounting exec default start-stop radius  |  tacacs+  |  none
Configuring RADIUS accounting for CLI commands

You can configure RADIUS accounting for CLI commands by specifying a privilege level whose commands require accounting. For example, to configure the Brocade device to perform RADIUS accounting for the commands available at the Super User privilege level (that is; all commands on the device), enter the following command.

```
FastIron(config)# aaa accounting commands 0 default start-stop radius
```

An Accounting Start packet is sent to the RADIUS accounting server when a user enters a command, and an Accounting Stop packet is sent when the service provided by the command is completed.

**NOTE**
If authorization is enabled, and the command requires authorization, then authorization is performed before accounting takes place. If authorization fails for the command, no accounting takes place.

Syntax: `aaa accounting commands <privilege-level> default start-stop radius | tacacs | none`

The `<privilege-level>` parameter can be one of the following:

- **0** – Records commands available at the Super User level (all commands)
- **4** – Records commands available at the Port Configuration level (port-config and read-only commands)
- **5** – Records commands available at the Read Only level (read-only commands)

Configuring RADIUS accounting for system events

You can configure RADIUS accounting to record when system events occur on the Brocade device. System events include rebooting and when changes to the active configuration are made.

The following command causes an Accounting Start packet to be sent to the RADIUS accounting server when a system event occurs, and a Accounting Stop packet to be sent when the system event is completed.

```
FastIron(config)# aaa accounting system default start-stop radius
```

Syntax: `aaa accounting system default start-stop radius | tacacs+ | none`

Configuring an interface as the source for all RADIUS packets

You can designate the lowest-numbered IP address configured an Ethernet port, loopback interface, or virtual interface as the source IP address for all RADIUS packets from the Layer 3 Switch. Identifying a single source IP address for RADIUS packets provides the following benefits:

- If your RADIUS server is configured to accept packets only from specific links or IP addresses, you can use this feature to simplify configuration of the RADIUS server by configuring the Brocade device to always send the RADIUS packets from the same link or source address.
• If you specify a loopback interface as the single source for RADIUS packets, RADIUS servers can receive the packets regardless of the states of individual links. Thus, if a link to the RADIUS server becomes unavailable but the client or server can be reached through another link, the client or server still receives the packets, and the packets still have the source IP address of the loopback interface.

The software contains separate CLI commands for specifying the source interface for Telnet, TACACS/TACACS+, and RADIUS packets. You can configure a source interface for one or more of these types of packets.

To specify an Ethernet, loopback or virtual interface as the source for all RADIUS packets from the device, use the following CLI method. The software uses the lowest-numbered IP address configured on the port or interface as the source IP address for RADIUS packets originated by the device.

To specify the lowest-numbered IP address configured on a virtual interface as the device source for all RADIUS packets, enter commands such as the following.

```
FastIron(config)# int ve 1
FastIron(config-vif-1)# ip address 10.0.0.3/24
FastIron(config-vif-1)# exit
FastIron(config)# ip radius source-interface ve 1
```

The commands in this example configure virtual interface 1, assign IP address 10.0.0.3/24 to the interface, then designate the interface as the source for all RADIUS packets from the Layer 3 Switch.

**Syntax:**  
```
ip radius source-interface ethernet [<slotnum>]<portnum> | loopback <num> | ve <num>
```

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The `<num>` parameter is a loopback interface or virtual interface number. If you specify an Ethernet port, the `<portnum>` is the port number (including the slot number, if you are configuring a device).

**Displaying RADIUS configuration information**

The `show aaa` command displays information about all TACACS/TACACS+ and RADIUS servers identified on the device.
Configuring RADIUS security

Example

FastIron# show aaa
Tacacs+ key: foundry
Tacacs+ retries: 1
Tacacs+ timeout: 15 seconds
Tacacs+ dead-time: 3 minutes
Tacacs+ Server: 207.95.6.90 Port:49:
  opens=6 closes=3 timeouts=3 errors=0
  packets in=4 packets out=4
no connection
Radius key: networks
Radius retries: 3
Radius timeout: 3 seconds
Radius dead-time: 3 minutes
Radius Server: 207.95.6.90 Auth Port=1645 Acct Port=1646:
  opens=2 closes=1 timeouts=1 errors=0
  packets in=1 packets out=4
no connection

The following table describes the RADIUS information displayed by the show aaa command.

**TABLE 239  Output of the show aaa command for RADIUS**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Radius key</td>
<td>The setting configured with the <code>radius-server key</code> command. At the Super User privilege level, the actual text of the key is displayed. At the other privilege levels, a string of periods (....) is displayed instead of the text.</td>
</tr>
<tr>
<td>Radius retries</td>
<td>The setting configured with the <code>radius-server retransmit</code> command.</td>
</tr>
<tr>
<td>Radius timeout</td>
<td>The setting configured with the <code>radius-server timeout</code> command.</td>
</tr>
<tr>
<td>Radius dead-time</td>
<td>The setting configured with the <code>radius-server dead-time</code> command.</td>
</tr>
<tr>
<td>Radius Server</td>
<td>For each RADIUS server, the IP address, and the following statistics are displayed: Auth Port RADIUS authentication port number (default 1645) Acct Port RADIUS accounting port number (default 1646)</td>
</tr>
<tr>
<td></td>
<td>• opens - Number of times the port was opened for communication with the server</td>
</tr>
<tr>
<td></td>
<td>• closes - Number of times the port was closed normally</td>
</tr>
<tr>
<td></td>
<td>• timeouts - Number of times port was closed due to a timeout</td>
</tr>
<tr>
<td></td>
<td>• errors - Number of times an error occurred while opening the port</td>
</tr>
<tr>
<td></td>
<td>• packets in - Number of packets received from the server</td>
</tr>
<tr>
<td></td>
<td>• packets out - Number of packets sent to the server</td>
</tr>
<tr>
<td>connection</td>
<td>The current connection status. This can be “no connection” or “connection active”.</td>
</tr>
</tbody>
</table>

The `show web` command displays the privilege level of Web Management Interface users.

Example

FastIron# show web
User set                   Privilege 0 IP address 192.168.1.234

Syntax: show web
Configuring authentication-method lists

To implement one or more authentication methods for securing access to the device, you configure authentication-method lists that set the order in which the authentication methods are consulted.

In an authentication-method list, you specify the access method (Telnet, Web, SNMP, and so on) and the order in which the device tries one or more of the following authentication methods:

- Local Telnet login password
- Local password for the Super User privilege level
- Local user accounts configured on the device
- Database on a TACACS or TACACS+ server
- Database on a RADIUS server
- No authentication

**NOTE**
The TACACS/TACACS+, RADIUS, and Telnet login password authentication methods are not supported for SNMP access.

**NOTE**
To authenticate Telnet access to the CLI, you also must enable the authentication by entering the `enable telnet authentication` command at the global CONFIG level of the CLI. You cannot enable Telnet authentication using the Web Management Interface.

**NOTE**
You do not need an authentication-method list to secure access based on ACLs or a list of IP addresses. Refer to “Using ACLs to restrict remote access” on page 1414 or “Restricting remote access to the device to specific IP addresses” on page 1417.

In an authentication-method list for a particular access method, you can specify up to seven authentication methods. If the first authentication method is successful, the software grants access and stops the authentication process. If the access is rejected by the first authentication method, the software denies access and stops checking.

However, if an error occurs with an authentication method, the software tries the next method on the list, and so on. For example, if the first authentication method is the RADIUS server, but the link to the server is down, the software will try the next authentication method in the list.

**NOTE**
If an authentication method is working properly and the password (and user name, if applicable) is not known to that method, this is not an error. The authentication attempt stops, and the user is denied access.

The software will continue this process until either the authentication method is passed or the software reaches the end of the method list. If the Super User level password is not rejected after all the access methods in the list have been tried, access is granted.
Configuration considerations for authentication-method lists

- For CLI access, you must configure authentication-method lists if you want the device to authenticate access using local user accounts or a RADIUS server. Otherwise, the device will authenticate using only the locally based password for the Super User privilege level.

- When no authentication-method list is configured specifically for Web management access, the device performs authentication using the SNMP community strings:
  - For read-only access, you can use the user name “get” and the password “public”. The default read-only community string is “public”.
  - There is no default read-write community string. Thus, by default, you cannot open a read-write management session using the Web Management Interface. You first must configure a read-write community string using the CLI. Then you can log on using “set” as the user name and the read-write community string you configure as the password. Refer to “Configuring TACACS/TACACS+ security” on page 1441.

- If you configure an authentication-method list for Web management access and specify “local” as the primary authentication method, users who attempt to access the device using the Web Management Interface must supply a user name and password configured in one of the local user accounts on the device. The user cannot access the device by entering “set” or “get” and the corresponding SNMP community string.

- For devices that can be managed using IronView Network Manager, the default authentication method (if no authentication-method list is configured for SNMP) is the CLI Super User level password. If no Super User level password is configured, then access through IronView Network Manager is not authenticated.

Examples of authentication-method lists

The following examples show how to configure authentication-method lists. In these examples, the primary authentication method for each is “local”. The device will authenticate access attempts using the locally configured usernames and passwords.

The command syntax for each of the following examples is provided in “Command Syntax” on page 1479.

Example 1

To configure an authentication-method list for the Web Management Interface, enter a command such as the following.

```
FastIron(config)# aaa authentication web-server default local
```

This command configures the device to use the local user accounts to authenticate access to the device through the Web Management Interface. If the device does not have a user account that matches the user name and password entered by the user, the user is not granted access.

Example 2

To configure an authentication-method list for SNMP, enter a command such as the following.

```
FastIron(config)# aaa authentication snmp-server default local
```
This command allows certain incoming SNMP SET operations to be authenticated using the locally configured usernames and passwords. When this command is enabled, community string validation is not performed for incoming SNMP V1 and V2c packets. This command takes effect as long as the first varbind for SNMP packets is set to one of the following:

- `snAgGblPassword"<username> <password>"` (for AAA method local)
- `snAgGblPassword"<password>"` (for AAA method line, enable)

**NOTE**
Certain SNMP objects need additional validation. These objects include but are not limited to: `snAgReload`, `snAgWriteNVRAM`, `snAgConfigFromNVRAM`, `snAgImgLoad`, `snAgCfgLoad` and `snAgGblTelnetPassword`. For more information, see `snAgGblPassword` in the IronWare MIB Reference.

If AAA is set up to check both the username and password, the string contains the username, followed by a space then the password. If AAA is set up to authenticate with the current Enable or Line password, the string contains the password only.

Note that the above configuration can be overridden by the command `no snmp-server pw-check`, which disables password checking for SNMP SET requests.

**Example 3**
To configure an authentication-method list for the Privileged EXEC and CONFIG levels of the CLI, enter the following command.

```
FastIron(config)# aaa authentication enable default local
```

This command configures the device to use the local user accounts to authenticate attempts to access the Privileged EXEC and CONFIG levels of the CLI.

**Example 4**
To configure the device to consult a RADIUS server first to authenticate attempts to access the Privileged EXEC and CONFIG levels of the CLI, then consult the local user accounts if the RADIUS server is unavailable, enter the following command.

```
FastIron(config)# aaa authentication enable default radius local
```

**Command Syntax**
The following is the command syntax for the preceding examples.

```
Syntax: [no] aaa authentication snmp-server | web-server | enable | login default <method1> [<method2>] [<method3>] [<method4>] [<method5>] [<method6>] [<method7>]
```

The `snmp-server` | `web-server` | `enable` | `login` parameter specifies the type of access this authentication-method list controls. You can configure one authentication-method list for each type of access.

**NOTE**
TACACS/TACACS+ and RADIUS are supported only with the `enable` and `login` parameters.

The `<method1>` parameter specifies the primary authentication method. The remaining optional `<method>` parameters specify additional methods to try if an error occurs with the primary method. A method can be one of the values listed in the Method Parameter column in the following table.
TCP Flags - edge port security

FastIron GS and FastIron LS devices support edge port security. This feature works in combination with IP ACL rules, and supports all 6 TCP flags present in the offset 13 of the TCP header:

- +|- urg = Urgent
- +|- ack = Acknowledge
- +|- psh = Push
- +|- rst = Reset
- +|- syn = Synchronize
- +|- fin = Finish

TCP flags can be combined with other ACL functions (such as dscp-marking and traffic policies), giving you greater flexibility when designing ACLs.

The TCP flags feature offers two options, match-all and match-any:

- **Match-any** - Indicates that incoming TCP traffic must be matched against any of the TCP flags configured as part of the match-any ACL rule. In CAM hardware, the number of ACL rules will match the number of configured flags.

- **Match-all** - Indicates that incoming TCP traffic must be matched against all of the TCP flags configured as part of the match-all ACL rule. In CAM hardware, there will be only one ACL rule for all configured flags.

**Example**

```
FastIron(config-ext-nACL)# permit tcp 1.1.1.1 0.0.0.255 eq 100 2.2.2.2 0.0.0.255 eq 300 match-all +urg +ack +syn -rst
```
This command configures a single rule in CAM hardware. This rule will contain all of the configured TCP flags (urg, ack, syn, and rst).

**Using TCP Flags in combination with other ACL features**

The TCP Flags feature has the added capability of being combined with other ACL features.

**Example**

FastIron(config-ext-nACL)# permit tcp any any match-all +urg +ack +syn -rst
traffic-policy test

This command configures the ACL to match incoming traffic with the TCP Flags urg, ack, and syn and also to apply the traffic policy (rate, limit, etc.) to the matched traffic.

FastIron(config-ext-nACL)# permit tcp any any match-all +urg +ack +syn -rst tos normal

This command configures the ACL to match incoming traffic with the flags urg, ack, and syn, and also sets the tos bit to normal when the traffic exits the device.

**NOTE**

TCP Flags combines the functionality of older features such as TCP Syn Attack and TCP Establish. Avoid configuring these older features on a port where you have configured TCP Flags. TCP Flags can perform all of the functions of TCP Syn Attack and TCP Establish, and more. However, if TCP Syn Attack is configured on a port along with TCP Flags, TCP Syn Attack will take precedence.

**NOTE**

If an ACL clause with match-any exists, and the system runs out of CAM, if the total number of TCP rules to TCP Flags will not fit within 1021 entries (the maximum rules allowed per device), then none of the TCP Flag rules will be programmed into the CAM hardware.

**NOTE**

If a range option and match-any TCP-flags are combined in the same ACL, the total number of rules will be calculated as: Total number of rules in CAM hardware = (number of rules for range) * (number of rules for match-any TCP-flags).
Chapter 40

Configuring SSH1 and SCP

NOTE
Secure Shell (SSH) version 1 is supported in pre-release 03.0.00 software for the FastIron X Series devices and in pre-release 02.4.00 for the FastIron GS and FastIron LS

In succeeding releases, SSH1 is no longer supported and SSH2 is supported. TurboIron X Series devices support SSH2 only. For SSH2 configuration procedures, refer to Chapter 41, “Configuring SSH2 and SCP”.

Configuring SSH1

Secure Shell (SSH) is a mechanism for allowing secure remote access to management functions on a Brocade device. SSH provides a function similar to Telnet. Users can log into and configure the device using a publicly or commercially available SSH client program, just as they can with Telnet. However, unlike Telnet which provides no security, SSH provides a secure, encrypted connection to the device.

SSH supports Arcfour, IDEA, Blowfish, DES (56-bit) and Triple DES (168-bit) data encryption methods. Nine levels of data compression are available. You can configure your SSH client to use any one of these data compression levels when connecting to a Brocade device.

Brocade devices also support Secure Copy (SCP) for securely transferring files between a Brocade device and SCP-enabled remote hosts. Refer to “Using secure copy with SSH1” on page 1494 for more information.

The Brocade implementation of SSH supports two kinds of user authentication:

- **RSA challenge-response authentication**, where a collection of public keys are stored on the device. Only clients with a private key that corresponds to one of the stored public keys can gain access to the device using SSH.

- **Password authentication**, where users attempting to gain access to the device using an SSH client are authenticated with passwords stored on the device or on a TACACS/TACACS+ or RADIUS server.

Both kinds of user authentication are enabled by default. You can configure the device to use one or both of them.

Follow the steps given below to configure Secure Shell on a Brocade device.

1. Set the host name and domain name on the Brocade device.
2. Generate a host RSA public and private key pair for the device.
4. Set optional parameters.

You can also view information about active SSH connections on the device as well as terminate them.
Setting the host name and domain name

If you have not already done so, establish a host name and domain name for the Brocade device.

Example

FastIron(config)#hostname BrcdRouter
FastIron(config)#ip dns domain-name home.com

Syntax: hostname <name>
Syntax: ip dns domain-name <name>

Generating a host I key pair

When SSH is configured, a public and private host RSA key pair is generated for the Brocade device. The SSH server on the Brocade device uses this host RSA key pair, along with a dynamically generated server RSA key pair, to negotiate a session key and encryption method with the client trying to connect to it.

The host RSA key pair is stored in the system-config file in the Brocade device. Only the public key is readable. The public key should be added to a “known hosts” file (for example, $HOME/.ssh/known_hosts on UNIX systems) on the clients who want to access the device. Some SSH client programs add the public key to the known hosts file automatically; in other cases, you must manually create a known hosts file and place the public key (for the Brocade device) in it. Refer to “Providing the public key to clients” on page 1485 for an example of what to place in the known hosts file.

To generate a public and private RSA host key pair for the most Brocade devices, enter the following commands.

FastIron(config)#crypto key generate rsa
FastIron(config)#write memory

The crypto key generate [rsa] command places an RSA host key pair in the running-config file and enables SSH on the device.

To disable SSH, you must delete the RSA host key pair. To do this in SSH1, enter the following commands.

FastIron(config)#crypto key zeroize rsa
FastIron(config)#write memory

The crypto key zeroize [rsa] command deletes the RSA host key pair in the running-config file and disables SSH on the device.

Syntax: crypto key generate | zeroize rsa

You can optionally configure the Brocade device to hide the RSA host key pair in the running-config file. To do this, enter the following command.

FastIron#ssh no-show-host-keys

Syntax: ssh no-show-host-keys

After entering the ssh no-show-host-keys command, you can display the RSA host key pair in the running-config file with the following command.

FastIron#ssh show-host-keys

Syntax: ssh show-host-keys
Configuration notes

- If the Brocade device does not have internal memory, the RSA host key pair is stored in the startup-config file. In this case, the `ssh show-host-keys` command allows the RSA host key pair to be viewed, and the `ssh no-show-host-keys` command prevents the RSA host key pair from being viewed.
- If an RSA host key pair is stored in internal memory on the Brocade device, it is used even if the startup-config file contains a different RSA host key pair.
- If no RSA host key pair is stored in internal memory, but the startup-config file contains an RSA host key pair, the key pair in the startup-config file is used. If you later generate an RSA host key pair with the `crypto key generate` command, the new key pair takes effect only after you store it in internal memory with the `write memory` command and reboot the Brocade device.
- If no RSA host key pair is stored in internal memory, and the startup-config file contains an RSA host key pair, the first time you enter the `write memory` command, it will save the RSA host key pair in the startup-config file to internal memory and remove it from the startup-config file.
- If no RSA host key pair is stored in internal memory, the startup-config file contains an RSA host key pair, and you generate an RSA host key pair with the `crypto key generate` command, the new pair is stored in internal memory the first time you enter the `write memory` command.
- The `crypto key zeroize` command disables the currently active RSA host key pair. If you subsequently enter the `write memory` command without generating another RSA host key pair, the RSA host key pair stored in internal memory is removed.
- If you enter the `ssh no-show-host-keys` command to hide the RSA host key pair in the running-config file, then reload the software, the RSA host key pair is once again visible in the running-config file. The setting to hide the RSA host key pair is not carried across software reloads.
- In a configuration using redundant management modules, if the active module has an RSA host key pair, but the standby module does not, the RSA host key pair is not carried over when switchover occurs. You must create an RSA host key pair on the standby module manually.
- The SSH key generation process causes UDLD-enabled interfaces to go down instantaneously. This in turn requires the re-convergence of the route tables on the routers across the network. Non-UDLD-enabled interfaces do not experience this issue.

Providing the public key to clients

If you are using SSH to connect to a Brocade device from a UNIX system, you may need to add the public key on the Brocade device to a “known hosts” file; for example, `$HOME/.ssh/known_hosts`. The following is an example of an entry in a known hosts file:

```
10.10.20.10 1024 37 118771881862677030464851288737258046856031640635887679230111
84247022636117580489663384620574930068397650231698985431857279323745963240790218
03229084221453472515782437007702806627934784079949643404159653290224014833380339
09542147367974638560060162945329037563502804231039654388220432832662804242569361
58342816331
```

In this example, 10.10.20.10 is the IP address of an SSH-enabled Brocade Layer 2 Switch or Layer 3 Switch. The second number, 1024, is the size of the host key, and the third number, 37, is the encoded public exponent. The remaining text is the encoded modulus.
Configuring RSA challenge-response authentication

With RSA challenge-response authentication, a collection of clients’ public keys are stored on the Brocade device. Clients are authenticated using these stored public keys. Only clients that have a private key that corresponds to one of the stored public keys can gain access to the device using SSH.

When RSA challenge-response authentication is enabled, the following events occur when a client attempts to gain access to the device using SSH.

1. The client sends its public key to the Brocade device.
2. The Brocade device compares the client public key to those stored in memory.
3. If there is a match, the Brocade device uses the public key to encrypt a random sequence of bytes.
4. The Brocade device sends these encrypted bytes to the client.
5. The client uses its private key to decrypt the bytes.
6. The client sends the decrypted bytes back to the Brocade device.
7. The Brocade device compares the decrypted bytes to the original bytes it sent to the client. If the two sets of bytes match, it means that the client private key corresponds to an authorized public key, and the client is authenticated.

Setting up RSA challenge-response authentication consists of the following steps.

1. Importing authorized public keys into the Brocade device.
2. Enabling RSA challenge response authentication

**Importing authorized public keys into the Brocade device**

SSH clients that support RSA authentication normally provide a utility to generate an RSA key pair. The private key is usually stored in a password-protected file on the local host; the public key is stored in another file and is not protected. You should collect one public key from each client to be granted access to the Brocade device and place all of these keys into one file. This public key file is imported into the Brocade device.

The following is an example of a public key file containing two public keys

```
1024 65537 16256605067838000614946055028651406123030679778280561661106866485485749495733923225996315737968192484763461453274217865276723199574694144160471468268000644536790333042029124905690771828865418396565665679025432881477252978135992782167540629478392662275128774861815448523997023618173312328476660721888873946758201user@csp_client
1024 35 1526761998898567696935561556145872915538263123280953004284214941643609247620745545234679268443237622953129794188335259756957577051018052125410080748772658611985742270289700411216885214507408796984064240845174271445585923616937059087483787559940550347960302428713132793895007927438074972787423695977635251943root@unix_machine
```

You can import the authorized public keys into the active configuration by loading them from a file on a TFTP server. Once the authorized public keys are loaded, you can optionally save them to the startup-config file. If you import a public key file from a TFTP server or PCMCIA flash card, the file is automatically loaded into the active configuration the next time the device is booted.
Brocade devices support Secure Copy (SCP) for securely transferring files between hosts on a network. Note that when you copy files using SCP, you enter the commands on the SCP-enabled client, rather than the console on the Brocade device.

For example, to copy a public key file called pkeys.txt from an SCP-enabled client, enter a command such as the following on the SCP-enabled client.

```
C:\> scp c:\pkeys.txt user@FastIron:a:/pkeys.txt
```

If password authentication is enabled for SSH, the user will be prompted for a password in order to copy the file. Refer to “Using secure copy with SSH1” on page 1494 for more information on SCP.

After the file is loaded onto the TFTP server or PCMCIA flash card, it can be imported into the active configuration each time the device is booted.

To cause a public key file called pkeys.txt to be loaded from a TFTP server each time the Brocade device is booted, enter a command such as the following.

```
FastIron(config)#ip ssh pub-key-file tftp 192.168.1.234 pkeys.txt
```

**Syntax:** `ip ssh pub-key-file tftp <tftp-server-ip-addr> <filename>`

The `<tftp-server-ip-addr>` variable is the IP address of the tftp server that contains the public key file that you want to import into the Brocade device.

The `<filename>` variable is the name of the dsa public key file that you want to import into the Brocade device.

To display the currently loaded public keys, enter the following command.

```
FastIron#show ip client-pub-key
1024 65537 162560506783800614946050286514061230306797782065166110686648548574

```

There are 2 authorized client public keys configured

**Syntax:** `show ip client-pub-key`

To clear the public keys from the active configuration, enter the following command.

```
FastIron#clear public-key
```

**Syntax:** `clear public-key`

To reload the public keys from the file on the TFTP server or PCMCIA flash card, enter the following command.

```
FastIron(config)#ip ssh pub-key-file reload
```

**Syntax:** `ip ssh pub-key-file reload`
Once the public keys are part of the active configuration, you can make them part of the startup-config file. The startup-config file can contain a maximum of 10 public keys. If you want to store more than 10 public keys, keep them in a file on a TFTP server or PCMCIA flash card, where they will be loaded into the active configuration when the device is booted.

To make the public keys in the active configuration part of the startup-config file, enter the following commands.

```
FastIron(config)#ip ssh pub-key-file flash-memory
FastIron(config)#write memory
```

**Syntax:** `ip ssh pub-key-file flash-memory`

To clear the public keys from the startup-config file (if they are located there), enter the following commands.

```
FastIron#clear public-key
FastIron#write memory
```

**Enabling RSA challenge-response authentication**

RSA challenge-response authentication is enabled by default. You can disable or re-enable it manually.

To enable RSA challenge-response authentication, enter the following command.

```
FastIron(config)#ip ssh rsa-authentication yes
```

To disable RSA challenge-response authentication, enter the following command.

```
FastIron(config)#ip ssh rsa-authentication no
```

**Syntax:** `ip ssh rsa-authentication yes | no`

**Setting optional parameters**

You can adjust the following SSH settings on the Brocade device:

- The number of SSH authentication retries
- The server RSA key size
- The user authentication method the Brocade device uses for SSH connections
- Whether the Brocade device allows users to log in without supplying a password
- The port number for SSH connections
- The SSH login timeout value
- A specific interface to be used as the source for all SSH traffic from the device
- The maximum idle time for SSH sessions

**Setting the number of SSH authentication retries**

By default, the Brocade device attempts to negotiate a connection with the connecting host three times. The number of authentication retries can be changed to between 1 –– 5.

For example, the following command changes the number of authentication retries to 5.

```
FastIron(config)#ip ssh authentication-retries 5
```

**Syntax:** `ip ssh authentication-retries <number>`
Setting the server RSA key size

The default size of the dynamically generated server RSA key is 768 bits. The size of the server RSA key can be between 512 –– 896 bits.

For example, the following command changes the server RSA key size to 896 bits.

```
FastIron(config)#ip ssh key-size 896
```

Syntax: `ip ssh key-size <number>`

**NOTE**
The `ip ssh key-size` command is not applicable to SSH2 implementation.

**NOTE**
The size of the host RSA key that resides in the system-config file is always 1024 bits and cannot be changed.

Deactivating user authentication

After the SSH server on the Brocade device negotiates a session key and encryption method with the connecting client, user authentication takes place. The Brocade implementation of SSH supports RSA challenge-response authentication and password authentication.

With RSA challenge-response authentication, a collection of clients’ public keys are stored on the Brocade device. Clients are authenticated using these stored public keys. Only clients that have a private key that corresponds to one of the stored public keys can gain access to the device using SSH.

With password authentication, users are prompted for a password when they attempt to log into the device (provided empty password logins are not allowed; refer to “Enabling empty password logins” on page 1489). If there is no user account that matches the user name and password supplied by the user, the user is not granted access.

You can deactivate one or both user authentication methods for SSH. Note that deactivating both authentication methods essentially disables the SSH server entirely.

To disable RSA challenge-response authentication, enter the following command.

```
FastIron(config)#ip ssh rsa-authentication no
```

Syntax: `ip ssh rsa-authentication no | yes`

To deactivate password authentication, enter the following command.

```
FastIron(config)#ip ssh password-authentication no
```

Syntax: `ip ssh password-authentication no | yes`

Enabling empty password logins

By default, empty password logins are not allowed. This means that users with an SSH client are always prompted for a password when they log into the device. To gain access to the device, each user must have a user name and password. Without a user name and password, a user is not granted access. Refer to “Setting up local user accounts” on page 1430 for information on setting up user names and passwords on Brocade devices.
If you enable empty password logins, users are not prompted for a password when they log in. Any user with an SSH client can log in without being prompted for a password.

To enable empty password logins, enter the following command.

```
FastIron(config)#ip ssh permit-empty-passwd yes
```

**Syntax:** `ip ssh permit-empty-passwd no | yes`

### Setting the SSH port number

By default, SSH traffic occurs on TCP port 22. You can change this port number. For example, the following command changes the SSH port number to 2200.

```
FastIron(config)#ip ssh port 2200
```

Note that if you change the default SSH port number, you must configure SSH clients to connect to the new port. Also, you should be careful not to assign SSH to a port that is used by another service. If you change the SSH port number, Brocade recommends that you change it to a port number greater than 1024.

**Syntax:** `ip ssh port <number>`

### Setting the SSH login timeout value

When the SSH server attempts to negotiate a session key and encryption method with a connecting client, it waits a maximum of 120 seconds for a response from the client. If there is no response from the client after 120 seconds, the SSH server disconnects. You can change this timeout value to between 1 – 120 seconds. For example, to change the timeout value to 60 seconds.

```
FastIron(config)#ip ssh timeout 60
```

**Syntax:** `ip ssh timeout <seconds>`

### Designating an interface as the source for all SSH packets

You can designate a loopback interface, virtual interface, or Ethernet port as the source for all SSH packets from the device. The software uses the IP address with the numerically lowest value configured on the port or interface as the source IP address for SSH packets originated by the device.

**NOTE**

When you specify a single SSH source, you can use only that source address to establish SSH management sessions with the Brocade device.

To specify the numerically lowest IP address configured on a loopback interface as the device source for all SSH packets, enter commands such as the following.

```
FastIron(config)#int loopback 2
FastIron(config-lbif-2)#ip address 10.0.0.2/24
FastIron(config-lbif-2)#exit
FastIron(config)#ip ssh source-interface loopback 2
```

The commands in this example configure loopback interface 2, assign IP address 10.0.0.2/24 to the interface, then designate the interface as the source for all SSH packets from the Layer 3 Switch.

**Syntax:** `ip ssh source-interface ethernet [<slotnum>] | portnum> | loopback <num> | ve <num>`
The `<slotnum>` parameter is required on chassis devices.
The `<portnum>` parameter is a valid port number.
The `<num>` parameter is a loopback interface or virtual interface number. If you specify an Ethernet port, the `<portnum>` is the port number (including the slot number, if you are configuring a Chassis device).

**Example**

```
FastIron(config)#interface ethernet 1/4
FastIron(config-if-1/4)#ip address 209.157.22.110/24
FastIron(config-if-1/4)#exit
FastIron(config)#ip ssh source-interface ethernet 1/4
```

**Configuring maximum idle time for SSH sessions**

By default, SSH sessions do not time out. Optionally, you can set the amount of time an SSH session can be inactive before the Brocade device closes it. For example, to set the maximum idle time for SSH sessions to 30 minutes, enter the following command.

```
FastIron(config)#ip ssh idle-time 30
```

**Syntax:** `ip ssh idle-time <minutes>`

If an established SSH session has no activity for the specified number of minutes, the Brocade device closes it. An idle time of 0 minutes (the default value) means that SSH sessions never timeout. The maximum idle time for SSH sessions is 240 minutes.

**Terminating an SSH session**

To terminate an active SSH connection, enter the following command.

```
FastIron#kill ssh 1
```

**Syntax:** `kill ssh <connection-id>`

**Displaying SSH connection information**

Up to five SSH connections can be active on the Brocade device. To display information about SSH connections, enter the following command.

```
FastIron#show ip ssh
```

<table>
<thead>
<tr>
<th>Connection</th>
<th>Version</th>
<th>Encryption</th>
<th>State</th>
<th>Username</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.5</td>
<td>ARCFOUR</td>

<tr>
<td>5</td>
<td>1.5</td>
<td>none</td>
<td>0x00</td>
<td></td>
</tr>
</tbody>
</table>

**Syntax:** `show ip ssh`

This display shows the following information about the active SSH connections.
TABLE 241  SSH connection information

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection</td>
<td>The SSH connection ID. This can be from 1 – 5.</td>
</tr>
<tr>
<td>Version</td>
<td>The SSH version number. This should always be 1.5.</td>
</tr>
<tr>
<td>Encryption</td>
<td>The encryption method used for the connection. This can be IDEA, ARCFOUR, DES, 3DES, AES, or BLOWFISH.</td>
</tr>
</tbody>
</table>
| State         | The connection state. This can be one of the following:  
|               | • 0x00 - Server started to send version number to client.  
|               | • 0x01 - Server sent version number to client.  
|               | • 0x02 - Server received version number from client.  
|               | • 0x20 - Server sent public key to client.  
|               | • 0x21 - Server is waiting for client session key.  
|               | • 0x22 - Server received session key from client.  
|               | • 0x23 - Server is verifying client session key.  
|               | • 0x24 - Client session key is verified.  
|               | • 0x25 - Server received client name.  
|               | • 0x40 - Server is authenticating client.  
|               | • 0x41 - Server is continuing to authenticate client after one or more failed attempts.  
|               | • 0x80 - Server main loop started after successful authentication.  
|               | • 0x81 - Server main loop sent a message to client.  
|               | • 0x82 - Server main loop received a message from client. |
| Username      | The user name for the connection. |

The `show who` command also displays information about SSH connections.

Example

```
FastIron#show who
Console connections:  
established, active
Telnet connections:  
  1 closed
  2 closed
  3 closed
  4 closed
  5 closed
SSH connections:  
  1 established, client ip address 209.157.22.8  
  16 seconds in idle
  2 established, client ip address 209.157.22.21  
  42 seconds in idle
  3 established, client ip address 209.157.22.68  
  49 seconds in idle
  4 closed
  5 closed
```

Syntax: show who

Sample SSH configuration

The following is a sample SSH configuration for a Brocade device.
hostname FastIron
ip dns domain-name home.com
!
aaa authentication login default local
username neville password ......
username lynval password ..... 
username terry password ..... 
!
ip ssh permit-empty-passwd no
!
ip ssh pub-key-file tftp 192.168.1.234 pkeys.txt 
!
crypto key generate rsa public_key "1024 35 144460146631716543532035011163035196 41193195125205894452637462409522275505020845087302985209960346239172995676329357 2477753018866626789819564825318155162468139452068167261082818831043962242301296 2688393717676977618498409310098401707536938707100663796650877224677979486802651 458324218055083313313948534902409 FastIron@home.com"
!
crypto key generate rsa private_key "**************************
!
ip ssh authentication-retries 5

This **aaa authentication login default local** command configures the device to use the local user accounts to authenticate users attempting to log in.

Three user accounts are configured on the device. The **ip ssh permit-empty-passwd no** command causes users always to be prompted for a password when they attempt to establish an SSH connection. Since the device uses local user accounts for authentication, only these three users are allowed to connect to the device using SSH.

The **ip ssh pub-key-file tftp** command causes a public key file called pkeys.txt to be loaded from a TFTP server at 192.168.1.234. To gain access to the Brocade device using SSH, a user must have a private key that corresponds to one of the public keys in this file.

The **crypto key generate rsa public_key** and **crypto key generate rsa private_key** statements are both generated by the **crypto key generate rsa** command. By default, the RSA host key pair appears in the running-config file, but not in the startup-config file. You can optionally configure the Brocade device to hide the RSA host key pair in the running-config file with the **ssh no-show-host-keys** command. The actual private key is never visible in either the running-config file or the startup-config file.

You may need to copy the public key to a “known hosts” file (for example, $HOME/.ssh/known_hosts on UNIX systems) on the clients who want to access the device. Refer to “Providing the public key to clients” on page 1485 for an example of what to place in the known hosts file.

The **ip ssh authentication-retries 5** command sets the number of times the Brocade device attempts to negotiate a connection with the connecting host to 5.
Using secure copy with SSH1

Secure Copy (SCP) uses security built into SSH to transfer image and configuration files to and from the device. SCP automatically uses the authentication methods, encryption algorithm, and data compression level configured for SSH. For example, if password authentication is enabled for SSH, the user is prompted for a user name and password before SCP allows a file to be transferred. No additional configuration is required for SCP on top of SSH.

You can use SCP to copy files on the FastIron device, including the startup configuration and running configuration files, to or from an SCP-enabled remote host.

**NOTE**
in an IronStack topology, Secure Copy will only copy files to the Active Controller. It will not copy files to other stack members.

SCP is enabled by default and can be disabled. To disable SCP, enter the following command.

```
FastIron(config)# ip ssh scp disable
```

**Syntax:** `ip ssh scp disable | enable`

**NOTE**
If you disable SSH, SCP is also disabled.

The following are examples of using SCP to transfer files from and to a Brocade device.

**NOTE**
When using SCP, you enter the `scp` commands on the SCP-enabled client, rather than the console on the Brocade device.

**NOTE**
Certain SCP client options, including `-p` and `-r`, are ignored by the SCP server on the Brocade device. If an option is ignored, the client is notified.

To copy a configuration file `c:\cfg\cfg` to the running configuration file on a Brocade device at 192.168.1.50 and log in as user terry, enter the following command on the SCP-enabled client.

```
C:\> scp c:\cfg\cfg terry@192.168.1.50:runConfig
```

If password authentication is enabled for SSH, the user is prompted for user terry’s password before the file transfer takes place.

To copy the configuration file to the startup configuration file.

```
C:\> scp c:\cfg\cfg terry@192.168.1.50:startConfig
```

To copy the running configuration file on a Brocade device to a file called `c:\cfg\run.cfg` on the SCP-enabled client.

```
C:\> scp terry@192.168.1.50:runConfig c:\cfg\brcdrun.cfg
```

To copy the startup configuration file on a Brocade device to a file called `c:\cfg\brcdstart.cfg` on the SCP-enabled client.

```
C:\> scp terry@192.168.1.50:startConfig c:\cfg\brcdstart.cfg
```
Chapter 41

Configuring SSH2 and SCP

SSH version 2 support

Secure Shell (SSH) is a mechanism for allowing secure remote access to management functions on a Brocade device. SSH provides a function similar to Telnet. Users can log into and configure the device using a publicly or commercially available SSH client program, just as they can with Telnet. However, unlike Telnet, which provides no security, SSH provides a secure, encrypted connection to the device.

The Brocade SSH2 implementation is compatible with all versions of the SSH2 protocol (2.1, 2.2, and so on). At the beginning of an SSH session, the Brocade device negotiates the version of SSH2 to be used. The highest version of SSH2 supported by both the Brocade device and the client is the version that is used for the session. Once the SSH2 version is negotiated, the encryption algorithm with the highest security ranking is selected to be used for the session.

Brocade devices also support Secure Copy (SCP) for securely transferring files between a Brocade device and SCP-enabled remote hosts.

NOTE
With the introduction of SSH2, SSH1 is no longer supported. For example, if you are running a FastIron X Series release prior to 03.0.00 and are using SSH1, your keys will no longer be valid when you upgrade to FastIron X Series 03.0.00 or later. You must obtain new keys for SSH2.

NOTE
The SSH feature includes software that is copyright Allegro Software Development Corporation.

SSH2 is supported in the Layer 2 and Layer 3 codes, and SSH version 1 (SSH1) is no longer supported. Refer to Chapter 40, “Configuring SSH1 and SCP”.

SSH2 is a substantial revision of Secure Shell, comprising the following hybrid protocols and definitions:

- SSH Transport Layer Protocol
- SSH Authentication Protocol
- SSH Connection Protocol
- SECSH Public Key File Format
- SSH Fingerprint Format
- SSH Protocol Assigned Numbers
- SSH Transport Layer Encryption Modes
- SCP/SFTP/SSH URI Format

Tested SSH2 clients

The following SSH clients have been tested with SSH2:
• SSH Secure Shell 3.2.3
• Van Dyke SecureCRT 4.0 and 4.1
• F-Secure SSH Client 5.3 and 6.0
• PuTTY 0.54 and 0.56
• OpenSSH 3.5_p1 and 3.6.1p2
• Solaris Sun-SSH-1.0

NOTE
The FastIron GS and FastIron LS devices support client public key sizes of 2048 bits or less. This also applies to TurboIron X Series devices, and to FastIron X Series devices running software release 03.0.00 or later.

Supported features
SSH2 (Secure Shell version 2 protocol) provides an SSH server. The SSH server allows secure remote access management functions on a Brocade device. SSH provides a function that is similar to Telnet, but unlike Telnet, SSH provides a secure, encrypted connection.

Brocade SSH2 support includes the following:
• Key exchange methods are diffie-hellman-group1-sha1
• The public key algorithm is ssh-dss.
• Encryption is provided with 3des-cbc, aes128-cbc, aes192-cbc or aes256-cbc. AES encryption has been adopted by the U.S. Government as an encryption standard. Refer to “AES encryption for SSH2” on page 1496.
• Data integrity is ensured with hmac-sha1.
• Supported authentication methods are Password and publickey.

Unsupported features
The following are not supported with SSH2
• Compression
• TCP/IP port forwarding, X11 forwarding, and secure file transfer
• SSH version 1

AES encryption for SSH2

NOTE
On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

Encryption is provided with 3des-cbc, aes128-cbc, aes192-cbc or aes256-cbc. AES encryption has been adopted by the U.S. Government as an encryption standard.

A total of five SSH connections can be active on a Brocade device. To display information about SSH connections, enter the following command.
Configuring SSH2

The Brocade implementation of SSH2 supports two kinds of user authentication:

- **DSA challenge-response authentication**, where a collection of public keys are stored on the device. Only clients with a private key that corresponds to one of the stored public keys can gain access to the device using SSH.

  **NOTE**
  SSH2 supports and validates DSA keys only. It does not support or validate SSH1 RSA keys.

- **Password authentication**, where users attempting to gain access to the device using an SSH client are authenticated with passwords stored on the device or on a TACACS/TACACS+ or RADIUS server.

Both kinds of user authentication are enabled by default. You can configure the device to use one or both of them.

Follow the steps given below to configure Secure Shell on a Brocade device.

1. If necessary, recreate the SSH keys
2. Generate a host DSA public and private key pair for the device
3. Configure DSA challenge-response authentication
4. Set optional parameters

You can also view information about active SSH connections on the device as well as terminate them.

**Recreating SSH keys**

You must recreate SSH keys after any one of the following events:

- After upgrading from a software release that supports SSH1, to a software release that supports SSH2.
- After downgrading a software release that supports SSH2, to a software release that supports SSH1

To recreate SSH keys, enter the following command.

```
FastIron(config)# crypto key generate
```

**Generating a host key pair**

When SSH is configured, a public and private **host DSA key pair** is generated for the Brocade device. The SSH server on the Brocade device uses this host DSA key pair, along with a dynamically generated **server DSA key pair**, to negotiate a session key and encryption method with the client trying to connect to it.

The host DSA key pair is stored in the system-config file of the Brocade device. Only the public key is readable. The public key should be added to a “known hosts” file (for example, `$HOME/.ssh/known_hosts` on UNIX systems) on the clients who want to access the device. Some SSH client programs add the public key to the known hosts file automatically; in other cases, you must manually create a known hosts file and place the public key of the Brocade device in it.

While the SSH listener exists at all times, sessions cannot be started from clients until a key is generated. Once a key is generated, clients can start sessions. The keys are also not displayed in the configuration file by default. To display the keys, use the **ssh show-host-keys** command in Privileged EXEC mode.

To generate a public and private DSA host key pair on a Brocade device, enter the following command.

```
FastIron(config)# crypto key generate
```

When a host key pair is generated, it is saved to the flash memory of all management modules.

To disable SSH2 on a Brocade device, enter the following command.

```
FastIron(config)# crypto key zeroize
```

When SSH is disabled, it is deleted from the flash memory of all management modules.

**Syntax:** crypto key generate | zeroize

The **generate** keyword places a DSA host key pair in the flash memory and enables SSH on the device.

The **zeroize** keyword deletes the DSA host key pair from the flash memory and disables SSH on the device.
By default, public keys are hidden in the running configuration. You can optionally configure the Brocade device to display the DSA host key pair in the running configuration file, by entering the following command.

FastIron# ssh show-host-keys

Syntax: ssh show-host-keys

To hide the public keys in the running configuration file, enter the following command.

FastIron# ssh no-show-host-keys

Syntax: ssh no-show-host-keys

**Providing the public key to clients**

If you are using SSH to connect to a Brocade device from a UNIX system, you may need to add the public key on the Brocade device to a "known hosts" file; for example, $HOME/.ssh/known_hosts. The following is an example of an entry in a known hosts file.

```
AAAAB3NzaC1kc3MAAACBAPY8ZOHY2yFSJA6XYC9HRwNHxahvVx5wOJ0zzDzoSOXxbET676Cv8dIUJ/

```

**Configuring DSA challenge-response authentication**

With DSA challenge-response authentication, a collection of clients’ public keys are stored on the Brocade device. Clients are authenticated using these stored public keys. Only clients that have a private key that corresponds to one of the stored public keys can gain access to the device using SSH.

When DSA challenge-response authentication is enabled, the following events occur when a client attempts to gain access to the device using SSH.

1. The client sends its public key to the Brocade device.
2. The Brocade device compares the client public key to those stored in memory.
3. If there is a match, the Brocade device uses the public key to encrypt a random sequence of bytes.
4. The Brocade device sends these encrypted bytes to the client.
5. The client uses its private key to decrypt the bytes.
6. The client sends the decrypted bytes back to the Brocade device.
7. The Brocade device compares the decrypted bytes to the original bytes it sent to the client. If the two sets of bytes match, it means that the client private key corresponds to an authorized public key, and the client is authenticated.

Setting up DSA challenge-response authentication consists of the following steps.
1. Importing authorized public keys into the Brocade device.
2. Enabling DSA challenge response authentication

**Importing authorized public keys into the Brocade device**

SSH clients that support DSA authentication normally provide a utility to generate an DSA key pair. The private key is usually stored in a password-protected file on the local host; the public key is stored in another file and is not protected. You should collect one public key from each client to be granted access to the Brocade device and place all of these keys into one file. This public key file is imported into the Brocade device.

The following is an example of a public key file containing one public key.

```
----- BEGIN SSH2 PUBLIC KEY ----- 
Comment: DSA Public Key

sY29ouezv4Xz2PuMch5VGPP+CDqzCM4loWgV 
----- END SSH2 PUBLIC KEY ----- 
```

You can import the authorized public keys into the active configuration by loading them from a file on a TFTP server. If you import a public key file from a TFTP server, the file is automatically loaded into the active configuration the next time the device is booted.

To cause a public key file called pkeys.txt to be loaded from a TFTP server each time the Brocade device is booted, enter a command such as the following.

```
FastIron(config)# ip ssh pub-key-file tftp 192.168.1.234 pkeys.txt 
```

**Syntax:** `ip ssh pub-key-file tftp | <tftp-server-ip-addr> <filename> [remove]`

The `<tftp-server-ip-addr>` variable is the IP address of the tftp server that contains the public key file that you want to import into the Brocade device.

The `<filename>` variable is the name of the dsa public key file that you want to import into the Brocade device.

The `remove` parameter deletes the key from the system.

To display the currently loaded public keys, enter the following command.

```
FastIron(config)# show ip ssh pub-key-file 
```
Setting optional parameters

You can adjust the following SSH settings on the Brocade device:

- The number of SSH authentication retries
- The user authentication method the Brocade device uses for SSH connections
- Whether the Brocade device allows users to log in without supplying a password
- The port number for SSH connections
- The SSH login timeout value
- A specific interface to be used as the source for all SSH traffic from the device
- The maximum idle time for SSH sessions

Syntax: **ip ssh key-authentication yes** | **no**

Enabling DSA challenge-response authentication

DSA challenge-response authentication is enabled by default. You can disable or re-enable it manually.

To enable DSA challenge-response authentication.

FastIron(config)# ip ssh key-authentication yes

To disable DSA challenge-authentication.

FastIron(config)# ip ssh key-authentication no

Syntax: **ip ssh key-authentication yes** | **no**
Setting the number of SSH authentication retries

By default, the Brocade device attempts to negotiate a connection with the connecting host three times. The number of authentication retries can be changed to between 1 – 5.

For example, the following command changes the number of authentication retries to 5.

```
FastIron(config)# ip ssh authentication-retries 5
```

Syntax: `ip ssh authentication-retries <number>`

Deactivating user authentication

After the SSH server on the Brocade device negotiates a session key and encryption method with the connecting client, user authentication takes place. The Brocade implementation of SSH supports DSA challenge-response authentication and password authentication.

With DSA challenge-response authentication, a collection of clients’ public keys are stored on the Brocade device. Clients are authenticated using these stored public keys. Only clients that have a private key that corresponds to one of the stored public keys can gain access to the device using SSH.

With password authentication, users are prompted for a password when they attempt to log into the device (provided empty password logins are not allowed). If there is no user account that matches the user name and password supplied by the user, the user is not granted access.

You can deactivate one or both user authentication methods for SSH. Note that deactivating both authentication methods essentially disables the SSH server entirely.

To disable DSA challenge-response authentication, enter the following command.

```
FastIron(config)# ip ssh key-authentication no
```

Syntax: `ip ssh key-authentication yes | no`

The default is `yes`.

To deactivate password authentication, enter the following command.

```
FastIron(config)# ip ssh password-authentication no
```

Syntax: `ip ssh password-authentication no | yes`

The default is `yes`.

Enabling empty password logins

By default, empty password logins are not allowed. This means that users with an SSH client are always prompted for a password when they log into the device. To gain access to the device, each user must have a user name and password. Without a user name and password, a user is not granted access.

If you enable empty password logins, users are not prompted for a password when they log in. Any user with an SSH client can log in without being prompted for a password.

To enable empty password logins, enter the following command.

```
FastIron(config)# ip ssh permit-empty-passwd yes
```

Syntax: `ip ssh permit-empty-passwd no | yes`
Setting the SSH port number

By default, SSH traffic occurs on TCP port 22. You can change this port number. For example, the following command changes the SSH port number to 2200.

```
FastIron(config)# ip ssh port 2200
```

Note that if you change the default SSH port number, you must configure SSH clients to connect to the new port. Also, you should be careful not to assign SSH to a port that is used by another service. If you change the SSH port number, Brocade recommends that you change it to a port number greater than 1024.

Syntax: `ip ssh port <number>`

Setting the SSH login timeout value

When the SSH server attempts to negotiate a session key and encryption method with a connecting client, it waits a maximum of 120 seconds for a response from the client. If there is no response from the client after 120 seconds, the SSH server disconnects. You can change this timeout value to between 1 – 120 seconds. For example, to change the timeout value to 60 seconds, enter the following command.

```
FastIron(config)# ip ssh timeout 60
```

Syntax: `ip ssh timeout <seconds>`

Designating an interface as the source for all SSH packets (Layer 3 code only)

You can designate a loopback interface, virtual interface, or Ethernet port as the source for all SSH packets from the device. The software uses the IP address with the numerically lowest value configured on the port or interface as the source IP address for SSH packets originated by the device.

**NOTE**

When you specify a single SSH source, you can use only that source address to establish SSH management sessions with the Brocade device.

To specify the numerically lowest IP address configured on a loopback interface as the device source for all SSH packets, enter commands such as the following.

```
FastIron(config)# int loopback 2
FastIron(config-lbif-2)# ip address 10.0.0.2/24
FastIron(config-lbif-2)# exit
FastIron(config)# ip ssh source-interface loopback 2
```

The commands in this example configure loopback interface 2, assign IP address 10.0.0.2/24 to the interface, then designate the interface as the source for all SSH packets from the Brocade device.

Syntax: `ip ssh source-interface ethernet <slot/port> | loopback <num> | ve <num>`

The `<num>` parameter is a loopback interface or virtual interface number. The `<slot/port>` parameter specifies an ethernet port number.
Example

FastIron(config)# interface ethernet 1/4
FastIron(config-if-e10000-1/4)# ip address 209.157.22.110/24
FastIron(config-if-e10000-1/4)# exit
FastIron(config)# ip ssh source-interface ethernet 1/4

Configuring the maximum idle time for SSH sessions

By default, SSH sessions do not time out. Optionally, you can set the amount of time an SSH session can be inactive before the Brocade device closes it. For example, to set the maximum idle time for SSH sessions to 30 minutes, enter the following command.

FastIron(config)# ip ssh idle-time 30

Syntax: ip ssh idle-time <minutes>

If an established SSH session has no activity for the specified number of minutes, the Brocade device closes it. An idle time of 0 minutes (the default value) means that SSH sessions never time out. The maximum idle time for SSH sessions is 240 minutes.

Filtering SSH access using ACLs

You can permit or deny SSH access to the Brocade device using ACLs. To use ACLs, first create the ACLs you want to use. You can specify a numbered standard IPv4 ACL, a named standard IPv4 ACL, or a standard numbered ACL.

Enter commands such as the following.

FastIron(config)# access-list 10 permit host 192.168.144.241
FastIron(config)# access-list 10 deny host 192.168.144.242 log
FastIron(config)# access-list 10 permit host 192.168.144.243
FastIron(config)# access-list 10 deny any
FastIron(config)# ssh access-group 10

Syntax: ssh access-group <standard-named-acl> | <standard-numbered-acl>

Terminating an active SSH connection

To terminate one of the active SSH connections, enter the following command.

FastIron# kill ssh 1

Syntax: kill ssh <connection-id>
Displaying SSH connection information

Up to five SSH connections can be active on the Brocade device. To display information about SSH connections, enter the following command.

Syntax: show ip ssh [begin <expression> | exclude <expression> | include <expression>]

This display shows the following information about the active SSH connections.

<table>
<thead>
<tr>
<th>Connection</th>
<th>Version</th>
<th>Encryption</th>
<th>Username</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SSH-2</td>
<td>3des-cbc</td>
<td>Hanuma</td>
</tr>
<tr>
<td>2</td>
<td>SSH-2</td>
<td>3des-cbc</td>
<td>Mikaila</td>
</tr>
<tr>
<td>3</td>
<td>SSH-2</td>
<td>3des-cbc</td>
<td>Jenny</td>
</tr>
<tr>
<td>4</td>
<td>SSH-2</td>
<td>3des-cbc</td>
<td>Mariah</td>
</tr>
<tr>
<td>5</td>
<td>SSH-2</td>
<td>3des-cbc</td>
<td>Logan</td>
</tr>
</tbody>
</table>

The show who command also displays information about SSH connections.

Example

FastIron# show who
Console connections:
established, monitor enabled, in config mode
2 minutes 17 seconds in idle
Telnet connections (inbound):
1 closed
2 closed
3 closed
4 closed
5 closed
Telnet connection (outbound):
6 closed
SSH connections:
1 established, client ip address 192.168.144.241, user is hanuma
1 minutes 16 seconds in idle
2 established, client ip address 192.168.144.241, user is Mikaila
you are connecting to this session
18 seconds in idle
3 established, client ip address 192.168.144.241, user is Jenny
1 minutes 39 seconds in idle
4 established, client ip address 192.168.144.242, user is Mariah
41 seconds in idle
5 established, client ip address 192.168.144.241, user is Logan
23 seconds in idle

Syntax: show who [begin <expression> | exclude <expression> | include <expression>]

DRAFT: BROCADE CONFIDENTIAL
Using Secure copy with SSH2

Secure Copy (SCP) uses security built into SSH to transfer image and configuration files to and from the device. SCP automatically uses the authentication methods, encryption algorithm, and data compression level configured for SSH. For example, if password authentication is enabled for SSH, the user is prompted for a user name and password before SCP allows a file to be transferred. No additional configuration is required for SCP on top of SSH.

You can use SCP to copy files on the Brocade device, including the startup configuration and running configuration files, to or from an SCP-enabled remote host.

NOTE
On Turbolron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

Enabling and disabling SCP

SCP is enabled by default and can be disabled. To disable SCP, enter the following command.

```
FastIron(config)# ip ssh scp disable
```

Syntax: `ip ssh scp disable | enable`

NOTE
If you disable SSH, SCP is also disabled.

NOTE
When using SCP, enter the `scp` commands on the SCP-enabled client, rather than the console on the Brocade device.

NOTE
Certain SCP client options, including `-p` and `-r`, are ignored by the SCP server on the Brocade device. If an option is ignored, the client is notified.

Example file transfers using SCP

The following are examples of using SCP to transfer files to and from a Brocade device.

Copying a file to the running config

To copy a configuration file (c:\cfg\brocade.cfg) to the running configuration file on a Brocade device at 192.168.1.50 and log in as user terry, enter the following command on the SCP-enabled client.

```
C:\> scp c:\cfg\brocade.cfg terry@192.168.1.50:runConfig
```

If password authentication is enabled for SSH, the user is prompted for user terry password before the file transfer takes place.

Copying a file to the startup config

To copy the configuration file to the startup configuration file, enter the following command.
C:\> scp c:\cfg\brocade.cfg terry@192.168.1.50:startConfig

**Copying the running config file to an SCP-enabled client**

To copy the running configuration file on the Brocade device to a file called c:\cfg\fdryrun.cfg on the SCP-enabled client, enter the following command.

C:\> scp terry@192.168.1.50:runConfig c:\cfg\fdryrun.cfg

**Copying the startup config file to an SCP-enabled client**

To copy the startup configuration file on the Brocade device to a file called c:\cfg\fdrystart.cfg on the SCP-enabled client, enter the following command.

C:\> scp terry@192.168.1.50:startConfig c:\cfg\fdry

To overwrite the running configuration file

C:\> scp c:\cfg\brocade.cfg terry@192.168.1.50:runConfig-overwrite

**Copying a software image file to flash memory**

To copy a software image file from an SCP-enabled client to the primary flash on a FastIron LS device, FastIron GS device, or FastIron SuperX device, enter the following command.

C:\> scp SXL03200.bin terry@192.168.1.50:flash:primary.bin

or

C:\> scp SXL03200.bin terry@192.168.1.50:flash:primary.bin

To copy a software image file from an SCP-enabled client to the primary flash on a FastIron CX device or Turbolron device use the following command.

C:\> scp TIR04200.bin terry@192.168.1.50:flash:primary

To copy a software image file from an SCP-enabled client to the secondary flash on a FastIron LS device, FastIron GS device, or FastIron SuperX device, enter the following command.

C:\> scp SXL03200.bin terry@192.168.1.50:flash:secondary.bin

or

C:\> scp SXL03200.bin terry@192.168.1.50:flash:secondary.bin

To copy a software image file from an SCP-enabled client to the secondary flash on a FastIron CX device or Turbolron device, enter the following command.

C:\> scp TIR04200.bin terry@192.168.1.50:flash:secondary

---

**NOTE**

The Brocade device supports only one SCP copy session at a time.
Copying a Software Image file from flash memory

To copy a software image from the primary flash on the FastIron LS device, FastIron GS device, or FastIron SuperX device to an SCP-enabled client, enter a command such as the following.

C:\ scp terry@192.168.1.50:flash:primary.bin SXL03200.bin

To copy a software image from the primary flash on the FastIron CX device or TurboIron device to an SCP-enabled client, enter a command such as the following.

C:\ scp terry@192.168.1.50:flash:primary TIR04200.bin

To copy a software image from the secondary flash on the FastIron LS device, FastIron GS device, or FastIron SuperX device to an SCP-enabled client, enter a command such as the following.

C:\ scp terry@192.168.1.50:flash:secondary.bin SXL03200.bin

To copy a software image from the secondary flash on the FastIron CX device or TurboIron device to an SCP-enabled client, enter a command such as the following.

C:\ scp terry@192.168.1.50:flash:secondary TIR04200.bin

NOTE
The Brocade device supports only one SCP copy session at a time.
Configuring 802.1X Port Security

NOTE
On TurboIron X Series devices, the 802.1X port security feature is supported on devices running software release 04.2.00 and later.

IETF RFC support

Brocade FastIron devices support the IEEE 802.1X standard for authenticating devices attached to LAN ports. Using 802.1X port security, you can configure a FastIron device to grant access to a port based on information supplied by a client to an authentication server.

When a user logs on to a network that uses 802.1X port security, the Brocade device grants (or does not grant) access to network services after the user is authenticated by an authentication server. The user-based authentication in 802.1X port security provides an alternative to granting network access based on a user IP address, MAC address, or subnetwork.

The Brocade implementation of 802.1X port security supports the following RFCs:

- RFC 2284 PPP Extensible Authentication Protocol (EAP)
- RFC 2865 Remote Authentication Dial In User Service (RADIUS)
- RFC 2869 RADIUS Extensions

How 802.1X port security works

This section explains the basic concepts behind 802.1X port security, including device roles, how the devices communicate, and the procedure used for authenticating clients.

NOTE
802.1X Port Security cannot be configured on MAC Port Security-enabled ports.

Device roles in an 802.1X configuration

The 802.1X standard defines the roles of Client/Supplicant, Authenticator, and Authentication Server in a network.

The Client (known as a Supplicant in the 802.1X standard) provides username/password information to the Authenticator. The Authenticator sends this information to the Authentication Server. Based on the Client's information, the Authentication Server determines whether the Client can use services provided by the Authenticator. The Authentication Server passes this information to the Authenticator, which then provides services to the Client, based on the authentication result.
How 802.1X port security works

**Figure 160** illustrates these roles.

**FIGURE 160** Authenticator, client/supplicant, and authentication server in an 802.1X configuration

**Authenticator** – The device that controls access to the network. In an 802.1X configuration, the Brocade device serves as the Authenticator. The Authenticator passes messages between the Client and the Authentication Server. Based on the identity information supplied by the Client, and the authentication information supplied by the Authentication Server, the Authenticator either grants or does not grant network access to the Client.

**Client/Supplicant** – The device that seeks to gain access to the network. Clients must be running software that supports the 802.1X standard (for example, the Windows XP operating system). Clients can either be directly connected to a port on the Authenticator, or can be connected by way of a hub.

**Authentication server** – The device that validates the Client and specifies whether or not the Client may access services on the device. Brocade supports Authentication Servers running RADIUS.

**Communication between the devices**

For communication between the devices, 802.1X port security uses the *Extensible Authentication Protocol* (EAP), defined in RFC 2284. The 802.1X standard specifies a method for encapsulating EAP messages so that they can be carried over a LAN. This encapsulated form of EAP is known as EAP over LAN (EAPOL). The standard also specifies a means of transferring the EAPOL information between the Client/Supplicant, Authenticator, and Authentication Server.
EAPOL messages are passed between the Port Access Entity (PAE) on the Supplicant and the Authenticator. Figure 161 shows the relationship between the Authenticator PAE and the Supplicant PAE.

**FIGURE 161  Authenticator PAE and supplicant PAE**

Authenticator PAE – The Authenticator PAE communicates with the Supplicant PAE, receiving identifying information from the Supplicant. Acting as a RADIUS client, the Authenticator PAE passes the Supplicant information to the Authentication Server, which decides whether the Supplicant can gain access to the port. If the Supplicant passes authentication, the Authenticator PAE grants it access to the port.

Supplicant PAE – The Supplicant PAE supplies information about the Client to the Authenticator PAE and responds to requests from the Authenticator PAE. The Supplicant PAE can also initiate the authentication procedure with the Authenticator PAE, as well as send log off messages.

**Controlled and uncontrolled ports**

A physical port on the device used with 802.1X port security has two virtual access points a **controlled** port and an **uncontrolled** port. The controlled port provides full access to the network. The uncontrolled port provides access only for EAPOL traffic between the Client and the Authentication Server. When a Client is successfully authenticated, the controlled port is opened to the Client. Figure 162 illustrates this concept.
Before a Client is authenticated, only the uncontrolled port on the Authenticator is open. The uncontrolled port allows only EAPOL frames to be exchanged between the Client and the Authentication Server. The controlled port is in the unauthorized state and allows no traffic to pass through.

During authentication, EAPOL messages are exchanged between the Supplicant PAE and the Authenticator PAE, and RADIUS messages are exchanged between the Authenticator PAE and the Authentication Server. Refer to “Message exchange during authentication” on page 1512 for an example of this process. If the Client is successfully authenticated, the controlled port becomes authorized, and traffic from the Client can flow through the port normally.

By default, all controlled ports on the Brocade device are placed in the authorized state, allowing all traffic. When authentication is activated on an 802.1X-enabled interface, the interface controlled port is placed initially in the unauthorized state. When a Client connected to the port is successfully authenticated, the controlled port is then placed in the authorized state until the Client logs off. Refer to “Enabling 802.1X port security” on page 1530 for more information.

**Message exchange during authentication**

*Figure 163* illustrates a sample exchange of messages between an 802.1X-enabled Client, a FastIron switch acting as Authenticator, and a RADIUS server acting as an Authentication Server.
How 802.1X port security works

In this example, the Authenticator (the FastIron switch) initiates communication with an 802.1X-enabled Client. When the Client responds, it is prompted for a username (255 characters maximum) and password. The Authenticator passes this information to the Authentication Server, which determines whether the Client can access services provided by the Authenticator. When the Client is successfully authenticated by the RADIUS server, the port is authorized. When the Client logs off, the port becomes unauthorized again.

The Brocade 802.1X implementation supports dynamic VLAN assignment. If one of the attributes in the Access-Accept message sent by the RADIUS server specifies a VLAN identifier, and this VLAN is available on the Brocade device, the client port is moved from its default VLAN to the specified VLAN. When the client disconnects from the network, the port is placed back in its default VLAN. Refer to “Configuring dynamic VLAN assignment for 802.1X ports” on page 1523 for more information.

If a Client does not support 802.1X, authentication cannot take place. The Brocade device sends EAP-Request/Identity frames to the Client, but the Client does not respond to them.

When a Client that supports 802.1X attempts to gain access through a non-802.1X-enabled port, it sends an EAP start frame to the Brocade device. When the device does not respond, the Client considers the port to be authorized, and starts sending normal traffic.

Brocade devices support Identity and MD5-challenge requests in EAP Request/Response messages. However, FESX release 02.1.01 and FSX release 02.3.01 support the following 802.1X authentication challenge types:

**NOTE**
Refer to also “EAP pass-through support” on page 1514.
How 802.1X port security works

- **EAP-TLS (RFC 2716)** – EAP Transport Level Security (TLS) provides strong security by requiring both client and authentication server to be identified and validated through the use of public key infrastructure (PKI) digital certificates. EAP-TLS establishes a tunnel between the client and the authentication server to protect messages from unauthorized users’ eavesdropping activities. Since EAP-TLS requires PKI digital certificates on both the clients and the authentication servers, the roll out, maintenance, and scalability of this authentication method is much more complex than other methods. EAP-TLS is best for installations with existing PKI certificate infrastructures.

- **EAP-TTLS (Internet-Draft)** – The EAP Tunneled Transport Level Security (TTLS) is an extension of EAP-TLS Like TLS, EAP-TTLS provides strong authentication; however it requires only the authentication server to be validated by the client through a certificate exchange between the server and the client. Clients are authenticated by the authentication server using user names and passwords.

  A TLS tunnel can be used to protect EAP messages and existing user credential services such as Active Directory, RADIUS, and LDAP. Backward compatibility for other authentication protocols such as PAP, CHAP, MS-CHAP, and MS-CHAP-V2 are also provided by EAP-TTLS. EAP-TTLS is not considered foolproof and can be fooled into sending identity credentials if TLS tunnels are not used. EAP-TTLS is suited for installations that require strong authentication without the use of mutual PKI digital certificates.

- **PEAP (Internet-Draft)** – Protected EAP Protocol (PEAP) is an Internet-Draft that is similar to EAP-TTLS. PEAP client authenticates directly with the backend authentication server. The authenticator acts as a pass-through device, which does not need to understand the specific EAP authentication protocols.

  Unlike EAP-TTLS, PEAP does not natively support user name and password to authenticate clients against an existing user database such as LDAP. PEAP secures the transmission between the client and authentication server with a TLS encrypted tunnel. PEAP also allows other EAP authentication protocols to be used. It relies on the mature TLS keying method for its key creation and exchange. PEAP is best suited for installations that require strong authentication without the use of mutual certificates.

**NOTE**

If the 802.1X Client will be sending a packet that is larger than 1500 bytes, you must enable jumbo at the Global config level of the CLI.

Configuration for these challenge types is the same as for the EAP-MD5 challenge type.

**EAP pass-through support**

EAP pass-through support is fully compliant with RFC 3748, in which, by default, compliant pass-through authenticator implementations forward EAP challenge request packets of any type. Previous software releases were limited to MD5, EAP-TTLS, EAP-PEAP, and EAP-TLS challenge request types for 802.1X authentication.

**Configuration notes**

- If the 802.1X supplicant or authentication server will be sending packets that are greater than 1500 MTU, you should configure the device to accommodate a bigger buffer size.

- EAP pass-through is supported on the Turbolron X Series devices running software release 04.2.00 and later.
Support for RADIUS user-name attribute in access-accept messages

Platform Support:

- FastIron X Series devices running software release 04.0.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later
- FCX-S devices running software release 06.0.00 and later

Brocade 802.1X-enabled ports support the RADIUS User-name (type 1) attribute in the Access-Accept message returned during 802.1X authentication.

This feature is useful when the client/supplicant does not provide its user-name in the EAP-response/identity frame, and the username is key to providing useful information. For example, when the User-name attribute is sent in the Access-Accept message, it is then available for display in sFlow sample messages sent to a collector, and in the output of some show dot1x CLI commands, such as show dot1x mac-sessions.

To enable this feature, add the following attribute on the RADIUS server.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>User-name</td>
<td>1</td>
<td>&lt;name&gt; (string)</td>
</tr>
</tbody>
</table>

Authenticating multiple hosts connected to the same port

Brocade devices support 802.1X authentication for ports with more than one host connected to them. Figure 164 illustrates a sample configuration where multiple hosts are connected to a single 802.1X port.
How 802.1X port security works

The way the Brocade device authenticates clients in a multiple-host configuration depends on the software release running on the device.

Starting in release 02.2.00 for the FESX and FWSX and release 02.3.01 for the FSX, if there are multiple hosts connected to a single 802.1X-enabled port, the Brocade device authenticates each of them individually. Each host authentication status is independent of the others, so that if one authenticated host disconnects from the network, it has no effect on the authentication status of any of the other authenticated hosts.

By default, traffic from hosts that cannot be authenticated by the RADIUS server is dropped in hardware. You can optionally configure the Brocade device to assign the port to a “restricted” VLAN if authentication of the Client is unsuccessful.

How 802.1X Multiple-host authentication works

When multiple hosts are connected to a single 802.1X-enabled port on a Brocade device (as in Figure 164), 802.1X authentication is performed in the following way.

1. One of the 802.1X-enabled Clients attempts to log into a network in which a Brocade device serves as an Authenticator.

2. The Brocade device creates an internal session (called a dot1x-mac-session) for the Client. A dot1x-mac-session serves to associate a Client MAC address and username with its authentication status.

3. The Brocade device performs 802.1X authentication for the Client. Messages are exchanged between the Brocade device and the Client, and between the device and the Authentication Server (RADIUS server). The result of this process is that the Client is either successfully authenticated or not authenticated, based on the username and password supplied by the client.
4. If the Client is successfully authenticated, the Client dot1x-mac-session is set to “access-is-allowed”. This means that traffic from the Client can be forwarded normally.

5. If authentication for the Client is unsuccessful the first time, multiple attempts to authenticate the client will be made as determined by the attempts variable in the auth-fail-max-attempts command.
   - Refer to “Specifying the number of authentication attempts the device makes before dropping packets” on page 1536 for information on how to do this.

6. If authentication for the Client is unsuccessful more than the number of times specified by the attempts variable in the auth-fail-max-attempts command, an authentication-failure action is taken. The authentication-failure action can be either to drop traffic from the Client, or to place the port in a “restricted” VLAN:
   - If the authentication-failure action is to drop traffic from the Client, then the Client dot1x-mac-session is set to “access-denied”, causing traffic from the Client to be dropped in hardware.
   - If the authentication-failure action is to place the port in a “restricted” VLAN, if the Client dot1x-mac-session is set to “access-restricted” then the port is moved to the specified restricted VLAN, and traffic from the Client is forwarded normally.

7. When the Client disconnects from the network, the Brocade device deletes the Client dot1x-mac-session. This does not affect the dot1x-mac-session or authentication status (if any) of the other hosts connected on the port.

Configuration notes

- The Client dot1x-mac-session establishes a relationship between the username and MAC address used for authentication. If a user attempts to gain access from different Clients (with different MAC addresses), he or she would need to be authenticated from each Client.

- If a Client has been denied access to the network (that is, the Client dot1x-mac-session is set to “access-denied”), then you can cause the Client to be re-authenticated by manually disconnecting the Client from the network, or by using the clear dot1x mac-session command. Refer to “Clearing a dot1x-mac-session for a MAC address” on page 1537 for information on this command.

- When a Client has been denied access to the network, its dot1x-mac-session is aged out if no traffic is received from the Client MAC address over a fixed hardware aging period (70 seconds), plus a configurable software aging period. You can optionally change the software aging period for dot1x-mac-sessions or disable aging altogether. After the denied Client dot1x-mac-session is aged out, traffic from that Client is no longer blocked, and the Client can be re-authenticated.

  In addition, you can configure disable aging for the dot1x-mac-session of Clients that have been granted either full access to the network, or have been placed in a restricted VLAN. After a Client dot1x-mac-session ages out, the Client must be re-authenticated. Refer to “Disabling aging for dot1x-mac-sessions” on page 1536 for more information.

- Dynamic IP ACL and MAC address filter assignment is supported in an 802.1X multiple-host configuration. Refer to “Dynamically applying IP ACLs and MAC filters to 802.1X ports” on page 1527.

- 802.1X multiple-host authentication has the following additions:
  - Configurable hardware aging period for denied client dot1x-mac-sessions. Refer to “Configurable hardware aging period for denied client dot1x-mac-sessions” on page 1518.
How 802.1X port security works

- Dynamic ACL and MAC address filter assignment in 802.1X multiple-host configurations. Refer to “Dynamically applying IP ACLs and MAC filters to 802.1X ports” on page 1527.
- Dynamic multiple VLAN assignment for 802.1X ports. Refer “Dynamic multiple VLAN assignment for 802.1X ports” on page 1524.
- Configure a restriction to forward authenticated and unauthenticated tagged and untagged clients to a restricted VLAN.
- Configure an override to send failed dot1x and non-dot1x clients to a restricted VLAN.
- Configure VLAN assignments for clients attempting to gain access through dual-mode ports.
- Enhancements to some show commands.
- Differences in command syntax for saving dynamic VLAN assignments to the startup-config file.

**Configurable hardware aging period for denied client dot1x-mac-sessions**

When one of the 802.1X-enabled Clients in a multiple-host configuration attempts to log into a network in which a Brocade device serves as an Authenticator, the device creates a dot1x-mac-session for the Client.

When a Client has been denied access to the network, its dot1x-mac-session is aged out if no traffic is received from the Client MAC address over a period of time. After a denied Client dot1x-mac-session ages out, the Client can be re-authenticated. Aging of a denied Client's dot1x-mac-session occurs in two phases, known as hardware aging and software aging.

The hardware aging period for a denied Client's dot1x-mac-session is not fixed at 70 seconds. The hardware aging period for a denied Client's dot1x-mac-session is equal to the length of time specified with the dot1x timeout quiet-period command. By default, the hardware aging time is 60 seconds. Once the hardware aging period ends, the software aging period begins. When the software aging period ends, the denied Client's dot1x-mac-session ages out, and the Client can be authenticated again.

**802.1X port security and sFlow**

sFlow is a standards-based protocol that allows network traffic to be sampled at a user-defined rate for the purpose of monitoring traffic flow patterns and identifying packet transfer rates on user-specified interfaces.

When you enable sFlow forwarding on an 802.1X-enabled interface, the samples taken from the interface include the user name string at the inbound or outbound port, or both, if that information is available.

For more information on sFlow, refer to Appendix A, “Network Monitoring”.

**802.1X accounting**

When 802.1X port security is enabled on the Brocade device, you can enable 802.1X accounting. This feature enables the Brocade device to log information on the RADIUS server about authenticated 802.1X clients. The information logged on the RADIUS server includes the 802.1X client session ID, MAC address, and authenticating physical port number.
NOTE
On TurboIron devices running software release 04.2.00, the 802.1X accounting feature is not supported.

802.1X accounting works as follows.

1. A RADIUS server successfully authenticates an 802.1X client.
2. If 802.1X accounting is enabled, the Brocade device sends an 802.1X Accounting Start packet to the RADIUS server, indicating the start of a new session.
3. The RADIUS server acknowledges the Accounting Start packet.
4. The RADIUS server records information about the client.
5. When the session is concluded, the Brocade device sends an Accounting Stop packet to the RADIUS server, indicating the end of the session.
6. The RADIUS server acknowledges the Accounting Stop packet.

To enable 802.1X accounting, refer to “Configuring 802.1X accounting” on page 1539.

Configuring 802.1X port security

Configuring 802.1X port security on a Brocade device consists of the following tasks.

1. Configure the device interaction with the Authentication Server:
   - “Configuring an authentication method list for 802.1X” on page 1520
   - “Setting RADIUS parameters” on page 1520
   - “Configuring dynamic VLAN assignment for 802.1X ports” on page 1523 (optional)
   - “Dynamically applying IP ACLs and MAC filters to 802.1X ports” on page 1527

2. Configure the device role as the Authenticator:
   - “Enabling 802.1X port security” on page 1530
   - “Initializing 802.1X on a port” on page 1535 (optional)

3. Configure the device interaction with Clients:
   - “Configuring periodic re-authentication” on page 1532 (optional)
   - “Re-authenticating a port manually” on page 1532 (optional)
   - “Setting the quiet period” on page 1533 (optional)
   - “Setting the wait interval for EAP frame retransmissions” on page 1533 (optional)
   - “Setting the maximum number of EAP frame retransmissions” on page 1534 (optional)
   - “Specifying a timeout for retransmission of messages to the authentication server” on page 1535 (optional)
   - “Allowing access to multiple hosts” on page 1535 (optional)
   - “Defining MAC filters for EAP frames” on page 1537 (optional)
Configuring an authentication method list for 802.1X

To use 802.1X port security, you must specify an authentication method to be used to authenticate Clients. Brocade supports RADIUS authentication with 802.1X port security. To use RADIUS authentication with 802.1X port security, you create an authentication method list for 802.1X and specify RADIUS as an authentication method, then configure communication between the Brocade device and RADIUS server.

Example

FastIron(config)# aaa authentication dot1x default radius

Syntax: [no] aaa authentication dot1x default <method-list>

For the <method-list>, enter at least one of the following authentication methods

radius – Use the list of all RADIUS servers that support 802.1X for authentication.

none – Use no authentication. The Client is automatically authenticated without the device using information supplied by the Client.

NOTE
If you specify both radius and none, make sure radius comes before none in the method list.

Setting RADIUS parameters

To use a RADIUS server to authenticate access to a Brocade device, you must identify the server to the Brocade device.

Example

FastIron(config)# radius-server host 209.157.22.99 auth-port 1812 acct-port 1813 default key mirabeau dot1x

Syntax: radius-server host <ip-addr> | <ipv6-addr> | <server-name> [auth-port <num> | acct-port <num> | default] [key 0 | 1 <string>] [dot1x]

The host <ip-addr> | <ipv6-addr> | <server-name> parameter is either an IP address or an ASCII text string.

The dot1x parameter indicates that this RADIUS server supports the 802.1X standard. A RADIUS server that supports the 802.1X standard can also be used to authenticate non-802.1X authentication requests.

NOTE
To implement 802.1X port security, at least one of the RADIUS servers identified to the Brocade device must support the 802.1X standard.

Supported RADIUS attributes

Many IEEE 802.1X Authenticators will function as RADIUS clients. Some of the RADIUS attributes may be received as part of IEEE 802.1X authentication. Brocade devices support the following RADIUS attributes for IEEE 802.1X authentication:

• Username (1) – RFC 2865
• NAS-IP-Address (4) – RFC 2865
• NAS-Port (5) – RFC 2865
• Service-Type (6) – RFC 2865
• FilterId (11) – RFC 2865
• Framed-MTU (12) – RFC 2865
• State (24) – RFC 2865
• Vendor-Specific (26) – RFC 2865
• Session-Timeout (27) – RFC 2865
• Termination-Action (29) – RFC 2865
• Calling-Station-ID (31) – RFC 2865
• NAS-Port-Type (61) – RFC 2865
• Tunnel-Type (64) – RFC 2868
• Tunnel-Medium-Type (65) – RFC 2868
• EAP Message (79) – RFC 2579
• Message-Authenticator (80) RFC 3579
• Tunnel-Private-Group-Id (81) – RFC 2868
• NAS-Port-id (87) – RFC 2869

**Specifying the RADIUS timeout action**

A RADIUS timeout occurs when the Brocade device does not receive a response from a RADIUS server within a specified time limit and after a certain number of retries. The time limit and number of retries can be manually configured using the CLI commands `radius-server timeout` and `radius-server retransmit`, respectively. If the parameters are not manually configured, the Brocade device applies the default value of three seconds time limit with a maximum of three retries.

In releases prior to FSX software release 03.2.00 and FGS and FLS software release 04.1.00, when a RADIUS timeout occurs, the Brocade device will automatically reset the authentication process then retry to authenticate the user.

In FSX software release 03.2.00, and FGS software release 04.1.00, you can better control port behavior when a RADIUS timeout occurs. That is, you can configure a port on the Brocade device to automatically pass or fail users being authenticated. A **pass** essentially bypasses the authentication process and permits user access to the network. A **fail** bypasses the authentication process and blocks user access to the network, unless restrict-vlan is configured, in which case, the user is placed into a VLAN with restricted or limited access. By default, the Brocade device will reset the authentication process and retry to authenticate the user.

Specify the RADIUS timeout action at the Interface level of the CLI.

**Permit user access to the network after a RADIUS timeout**

To set the RADIUS timeout behavior to bypass 802.1X authentication and **permit** user access to the network, enter commands such as the following:

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# dot1x auth-timeout-action success
```

**Syntax:** `[no] dot1x auth-timeout-action success`

Once the success timeout action is enabled, use the **no** form of the command to reset the RADIUS timeout behavior to **retry**.
Re-authenticate a user
To configure RADIUS timeout behavior to bypass multi-device port authentication and permit user access to the network, enter commands similar to the following:

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# dot1x re-auth-timeout-success 60
```

Syntax: `[no] dot1x re-auth-timeout-success <seconds>`

The `<seconds>` parameter specifies the number of seconds the device will wait to re-authenticate a user after a timeout. The minimum value is 10 seconds. The maximum value is $2^{16} - 1$ (maximum unsigned 16-bit value).

Deny user access to the network after a RADIUS timeout
To set the RADIUS timeout behavior to bypass 802.1X authentication and block user access to the network, enter commands such as the following:

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# dot1x auth-timeout-action failure
```

Syntax: `[no] dot1x auth-timeout-action failure`

Once the failure timeout action is enabled, use the `no` form of the command to reset the RADIUS timeout behavior to retry.

**NOTE**
If `restrict-vlan` is configured along with `auth-timeout-action failure`, the user will be placed into a VLAN with restricted or limited access. Refer to “Allow user access to a restricted VLAN after a RADIUS timeout” on page 1522.

Allow user access to a restricted VLAN after a RADIUS timeout
To set the RADIUS timeout behavior to bypass 802.1X authentication and place the user in a VLAN with restricted or limited access, enter commands such as the following:

```
FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# dot1x auth-fail-action restrict-vlan 100
FastIron(config-if-e100-3/1)# dot1x auth-timeout-action failure
```

Syntax: `[no] dot1x auth-fail-action restrict-vlan [<vlan-id>]`

Syntax: `[no] dot1x auth-timeout-action failure`

Send a failed Dot1X client to a restricted VLAN
In Figure 165, a VoIP phone sends both tagged and untagged traffic to dual-mode port e 1/3. Assuming the VoIP phone is authenticated to a voice VLAN as tagged, a MAC session for the VoIP phone is learned on the voice VLAN. In addition, since the phone sends untagged traffic, a MAC session is also learned on the native untagged VLAN (based on the VLAN dual-mode configuration).

In previous releases, if a dot1x client tries to obtain access through the VoIP phone, and authentication fails for the client, the client is blocked in the native untagged VLAN because a MAC session for the VoIP phone is in place.

Use the `auth-fail-force-restrict` command to override the VoIP MAC session on the native VLAN, and move the PVID for the port to the restricted VLAN. Future untagged traffic from both phone and client establishes MAC sessions on the restricted VLAN, for restricted access.
NOTE
FCX devices do not support the auth-fail-force-restrict command.

This command is configured under the global dot1x-enable command as follows:

```
FastIron(config)# dot1x-enable
FastIron(config-dot1x)# auth-fail-force-restrict
```

Syntax: auth-fail-force-restrict

**FIGURE 165** Redirecting clients to a restricted VLAN

![Diagram](image)

**User 1 (IP Phone) Profile:**
Authentication: RADIUS assigned to tagged VLAN A
MAC sessions exist on untagged native VLAN, and VLAN A

**User 2 (PC) Profile:**
Authentication: failed
PVID moved to restricted VLAN

After authentication fails for User 2, and the PVID moves to the restricted VLAN, there will be a total of 3 MAC sessions on port e1/3:
- one tagged MAC session on VLAN A for the phone
- one untagged MAC session on the restricted VLAN for the phone
- one untagged MAC session on the restricted VLAN for the client

**Configuring dynamic VLAN assignment for 802.1X ports**

When a client successfully completes the EAP authentication process, the Authentication Server (the RADIUS server) sends the Authenticator (the Brocade device) a RADIUS Access-Accept message that grants the client access to the network. The RADIUS Access-Accept message contains attributes set for the user in the user’s access profile on the RADIUS server.

If one of the attributes in the Access-Accept message specifies a VLAN identifier, and if this VLAN is available on the Brocade device, the client port is moved from its default VLAN to this specified VLAN.

**NOTE**
This feature is supported on port-based VLANs only. This feature cannot be used to place an 802.1X-enabled port into a Layer 3 protocol VLAN.
Automatic removal of dynamic VLAN assignments for 802.1X ports

For increased security, this feature removes any association between a port and a dynamically-assigned VLAN when all 802.1x sessions for that VLAN have expired on the port.

NOTE
When a show run command is issued during a session, the dynamically-assigned VLAN is not displayed.

Enable 802.1X VLAN ID support by adding the following attributes to a user profile on the RADIUS server.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel-Type</td>
<td>064</td>
<td>13 (decimal) – VLAN</td>
</tr>
<tr>
<td>Tunnel-Medium-Type</td>
<td>065</td>
<td>6 (decimal) – 802</td>
</tr>
<tr>
<td>Tunnel-Private-Group-ID</td>
<td>081</td>
<td>&lt;vlan-name&gt; (string) – either the name or the number of a VLAN configured on the Brocade device.</td>
</tr>
</tbody>
</table>

The device reads the attributes as follows:

- If the Tunnel-Type or the Tunnel-Medium-Type attributes in the Access-Accept message do not have the values specified above, the Brocade device ignores the three Attribute-Value pairs. The client becomes authorized, but the client port is not dynamically placed in a VLAN.
- If the Tunnel-Type or the Tunnel-Medium-Type attributes in the Access-Accept message do have the values specified above, but there is no value specified for the Tunnel-Private-Group-ID attribute, the client will not become authorized.
- When the Brocade device receives the value specified for the Tunnel-Private-Group-ID attribute, it checks whether the <vlan-name> string matches the name of a VLAN configured on the device. If there is a VLAN on the device whose name matches the <vlan-name> string, then the client port is placed in the VLAN whose ID corresponds to the VLAN name.
- If the <vlan-name> string does not match the name of a VLAN, the Brocade device checks whether the string, when converted to a number, matches the ID of a VLAN configured on the device. If it does, then the client port is placed in the VLAN with that ID.
- If the <vlan-name> string does not match either the name or the ID of a VLAN configured on the device, then the client will not become authorized.

The show interface command displays the VLAN to which an 802.1X-enabled port has been dynamically assigned, as well as the port from which it was moved (that is, the port default VLAN). Refer to “Displaying dynamically assigned VLAN information” on page 1544 for sample output indicating the port dynamically assigned VLAN.

Dynamic multiple VLAN assignment for 802.1X ports

When you add attributes to a user profile on the RADIUS server, the <vlan-name> value for the Tunnel-Private-Group-ID attribute can specify the name or number of one or more VLANs configured on the Brocade device.

For example, to specify one VLAN, configure the following for the <vlan-name> value in the Tunnel-Private-Group-ID attribute on the RADIUS server.

"10" or "marketing"
In this example, the port on which the Client is authenticated is assigned to VLAN 10 or the VLAN named "marketing". The VLAN to which the port is assigned must have previously been configured on the Brocade device.

To specify an untagged VLAN, use the following.

"U:10" or "U:marketing"

When the RADIUS server specifies an untagged VLAN ID, the port default VLAN ID (or PVID) is changed from the system DEFAULT-VLAN (VLAN 1) to the specified VLAN ID. The port transmits only untagged traffic on its PVID. In this example, the port PVID is changed from VLAN 1 (the DEFAULT-VLAN) to VLAN 10 or the VLAN named "marketing".

The PVID for a port can be changed only once through RADIUS authentication. For example, if RADIUS authentication for a Client causes a port PVID to be changed from 1 to 10, and then RADIUS authentication for another Client on the same port specifies that the port PVID be moved to 20, then the second PVID assignment from the RADIUS server is ignored.

If the link goes down, or the dot1x-mac-session for the Client that caused the initial PVID assignment ages out, then the port reverts back to its original (non-RADIUS-specified) PVID, and subsequent RADIUS authentication can change the PVID assignment for the port.

If a port PVID is assigned through the multi-device port authentication feature, and 802.1X authentication subsequently specifies a different PVID, then the PVID specified through 802.1X authentication overrides the PVID specified through multi-device port authentication.

To specify tagged VLANs, use the following.

"T:12;T:20" or "T:12;T:marketing"

In this example, the port is added to VLANs 12 and 20 or VLANs 12 and the VLAN named "marketing". When a tagged packet is authenticated, and a list of VLANs is specified on the RADIUS server for the MAC address, then the packet tag must match one of the VLANs in the list in order for the Client to be successfully authenticated. If authentication is successful, then the port is added to all of the VLANs specified in the list.

Unlike with a RADIUS-specified untagged VLAN, if the dot1x-mac-session for the Client ages out, the port membership in RADIUS-specified tagged VLANs is not changed. In addition, if multi-device port authentication specifies a different list of tagged VLANs, then the port is added to the specified list of VLANs. Membership in the VLANs specified through 802.1X authentication is not changed.

To specify an untagged VLAN and multiple tagged VLANs, use the following.

"U:10;T:12;T:marketing"

When the RADIUS server returns a value specifying both untagged and tagged VLAN IDs, the port becomes a dual-mode port, accepting and transmitting both tagged traffic and untagged traffic at the same time. A dual-mode port transmits only untagged traffic on its default VLAN (PVID) and only tagged traffic on all other VLANs.

In this example, the port VLAN configuration is changed so that it transmits untagged traffic on VLAN 10, and transmits tagged traffic on VLAN 12 and the VLAN named "marketing".

For a configuration example, refer to "802.1X Authentication with dynamic VLAN assignment" on page 1554.
**Saving dynamic VLAN assignments to the running-config file**

You can configure the Brocade device to save the RADIUS-specified VLAN assignments to the device's running-config file. Enter commands such as the following.

```
FastIron(config)# dot1x-enable
FastIron(config-dot1x)# save-dynamicvlan-to-config
```

**Syntax:** `save-dynamicvlan-to-config`

By default, the dynamic VLAN assignments are not saved to the running-config file. Entering the `show running-config` command does not display dynamic VLAN assignments, although they can be displayed with the `show vlan` and `show authenticated-mac-address detail` commands.

---

**NOTE**

When this feature is enabled, issuing the command `write mem` will save any dynamic VLAN assignments to the startup configuration file.

---

**Considerations for dynamic VLAN assignment in an 802.1X multiple-host configuration**

The following considerations apply when a Client in a 802.1X multiple-host configuration is successfully authenticated, and the RADIUS Access-Accept message specifies a VLAN for the port:

- If the port is not already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of a valid VLAN on the Brocade device, then the port is placed in that VLAN.
- If the port is already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of a different VLAN, then it is considered an authentication failure. The port VLAN membership is not changed.
- If the port is already a member of a RADIUS-specified VLAN, and the RADIUS Access-Accept message specifies the name or ID of that same VLAN, then traffic from the Client is forwarded normally.
- If the RADIUS Access-Accept message specifies the name or ID of a VLAN that does not exist on the Brocade device, then it is considered an authentication failure.
- If the port is a tagged or dual-mode port, and the RADIUS Access-Accept message specifies the name or ID of a valid VLAN on the Brocade device, then the port is placed in that VLAN. If the port is already a member of the RADIUS-specified VLAN, no further action is taken. Note that the Client dot1x-mac-session is set to “access-is-allowed” for the RADIUS-specified VLAN only. If traffic from the Client MAC address is received on any other VLAN, it is dropped.
- If the RADIUS Access-Accept message does not contain any VLAN information, the Client dot1x-mac-session is set to “access-is-allowed”. If the port is already in a RADIUS-specified VLAN, it remains in that VLAN.

---

**Using dynamic VLAN assignment with the MAC port security feature**

MAC port security allows the Brocade device to learn a limited number of “secure” MAC addresses on an interface. The interface forwards only packets with source MAC addresses that match these secure addresses. If the interface receives a packet with a source MAC address that is different from any of the secure addresses, it is considered a security violation, and subsequent packets from the violating MAC address can be dropped, or the port can be disabled entirely.
If a port is disabled due to a MAC port security violation, 802.1X clients attempting to connect over the port cannot be authorized. In addition, 802.1X clients connecting from non-secure MAC addresses cannot be authorized.

To use 802.1X dynamic VLAN assignment with the MAC port security feature on an interface, you must set the number of secure MAC addresses to two or more.

**Example**

```bash
FastIron(config)# int e 3/2
FastIron(config-if-e1000-3/2)# port security
FastIron(config-port-security-e1000-3/2)# maximum 2
FastIron(config-port-security-e1000-3/2)# exit
```

**NOTE**

FGS-STK, FLS-STK and TurboIron devices do not support:
- dot1x with port security configured on the same port
- dot1x with lock-address configured on the same port.

Refer to Chapter 43, “Using the MAC Port Security Feature” for more information.

**Dynamically applying IP ACLs and MAC filters to 802.1X ports**

The Brocade 802.1X implementation supports dynamically applying an IP ACL or MAC address filter to a port, based on information received from an Authentication Server.

When a client/supplicant successfully completes the EAP authentication process, the Authentication Server (the RADIUS server) sends the Authenticator (the Brocade device) a RADIUS Access-Accept message that grants the client access to the network. The RADIUS Access-Accept message contains attributes set for the user in the user's access profile on the RADIUS server.

If the Access-Accept message contains Filter-ID (type 11) or Vendor-Specific (type 26), or both attributes, the Brocade device can use information in these attributes to apply an IP ACL or MAC address filter to the authenticated port. This IP ACL or MAC address filter applies to the port for as long as the client is connected to the network. When the client disconnects from the network, the IP ACL or MAC address filter is no longer applied to the port. If an IP ACL or MAC address filter had been applied to the port prior to 802.1X authentication, it is then re-applied to the port.

The Brocade device uses information in the Filter ID and Vendor-Specific attributes as follows:

- The Filter-ID attribute can specify the number of an existing IP ACL or MAC address filter configured on the Brocade device. In this case, the IP ACL or MAC address filter with the specified number is applied to the port.
- The Vendor-Specific attribute can specify actual syntax for a Brocade IP ACL or MAC address filter, which is then applied to the authenticated port. Configuring a Vendor-Specific attribute in this way allows you to create IP ACLs and MAC filters that apply to individual users; that is, per-user IP ACLs or MAC address filters.

**Configuration considerations**

The following restrictions apply to dynamic IP ACLs or MAC address filters:

- Inbound dynamic IP ACLs are supported. Outbound dynamic ACLs are not supported.
Inbound Vendor-Specific attributes are supported. Outbound Vendor-Specific attributes are not supported.

A maximum of one IP ACL can be configured in the inbound direction on an interface.

MAC address filters cannot be configured in the outbound direction on an interface.

Concurrent operation of MAC address filters and IP ACLs is not supported.

Disabling and enabling strict security mode for dynamic filter assignment

By default, 802.1X dynamic filter assignment operates in strict security mode. When strict security mode is enabled, 802.1X authentication for a port fails if the Filter-ID attribute contains invalid information, or if insufficient system resources are available to implement the per-user IP ACLs or MAC address filters specified in the Vendor-Specific attribute.

When strict security mode is enabled:

- If the Filter-ID attribute in the Access-Accept message contains a value that does not refer to an existing filter (that is, a MAC address filter or IP ACL configured on the device), then the port will not be authenticated, regardless of any other information in the message (for example, if the Tunnel-Private-Group-ID attribute specifies a VLAN on which to assign the port).

- If the Vendor-Specific attribute specifies the syntax for a filter, but there are insufficient system resources to implement the filter, then the port will not be authenticated.

- If the device does not have the system resources available to dynamically apply a filter to a port, then the port will not be authenticated.

NOTE
If the Access-Accept message contains values for both the Filter-ID and Vendor-Specific attributes, then the value in the Vendor-Specific attribute (the per-user filter) takes precedence.

Also, if authentication for a port fails because the Filter-ID attribute referred to a non-existent filter, or there were insufficient system resources to implement the filter, then a Syslog message is generated.

When strict security mode is disabled:

- If the Filter-ID attribute in the Access-Accept message contains a value that does not refer to an existing filter (that is, a MAC address filter or IP ACL configured on the device), then the port is still authenticated, but no filter is dynamically applied to it.

- If the Vendor-Specific attribute specifies the syntax for a filter, but there are insufficient system resources to implement the filter, then the port is still authenticated, but the filter specified in the Vendor-Specific attribute is not applied to the port.

By default, strict security mode is enabled for all 802.1X-enabled interfaces, but you can manually disable or enable it, either globally or for specific interfaces.

To disable strict security mode globally, enter the following commands.

```
FastIron(config)# dot1x-enable
FastIron(config-dot1x)# no global-filter-strict-security
```

After you globally disable strict security mode, you can re-enable it by entering the following command.

```
FastIron(config-dot1x)# global-filter-strict-security
```

Syntax: [no] global-filter-strict-security
To disable strict security mode for a specific interface, enter commands such as the following.

```
FastIron(config)# interface e 1
FastIron(config-if-e1000-1)# dot1x disable-filter-strict-security
```

To re-enable strict security mode for an interface, enter the following command.

```
FastIron(config-if-e1000-1)# no dot1x disable-filter-strict-security
```

**Syntax:** `[no] dot1x disable-filter-strict-security`

The output of the `show dot1x` and `show dot1x config` commands has been enhanced to indicate whether strict security mode is enabled or disabled globally and on an interface. Refer to “Displaying the status of strict security mode” on page 1547.

**Dynamically applying existing ACLs or MAC address filters**

When a port is authenticated using 802.1X security, an IP ACL or MAC address filter that exists in the running-config on the Brocade device can be dynamically applied to the port. To do this, you configure the Filter-ID (type 11) attribute on the RADIUS server. The Filter-ID attribute specifies the name or number of the Brocade IP ACL or MAC address filter.

The following is the syntax for configuring the Filter-ID attribute to refer to a Brocade IP ACL or MAC address filter.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip.&lt;number&gt;.in</code></td>
<td>Applies the specified numbered ACL to the 802.1X authenticated port in the inbound direction.</td>
</tr>
<tr>
<td><code>ip.&lt;name&gt;.in</code></td>
<td>Applies the specified named ACL to the 802.1X authenticated port in the inbound direction.</td>
</tr>
<tr>
<td><code>mac.&lt;number&gt;.in</code></td>
<td>Applies the specified numbered MAC address filter to the 802.1X authenticated port in the inbound direction.</td>
</tr>
</tbody>
</table>

The following table lists examples of values you can assign to the Filter-ID attribute on the RADIUS server to refer to IP ACLs and MAC address filters configured on a Brocade device.

<table>
<thead>
<tr>
<th>Possible values for the filter ID attribute on the RADIUS server</th>
<th>ACL or MAC address filter configured on the Brocade device</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip.2.in</code></td>
<td>access-list 2 permit host 36.48.0.3</td>
</tr>
<tr>
<td></td>
<td>access-list 2 permit 36.0.0.0 0.255.255.255</td>
</tr>
<tr>
<td><code>ip.102.in</code></td>
<td>access-list 102 permit ip 36.0.0.0 0.255.255.255 any</td>
</tr>
<tr>
<td><code>ip.fdry_filter.in</code></td>
<td>ip access-list standard fdry_filter</td>
</tr>
<tr>
<td></td>
<td>permit host 36.48.0.3</td>
</tr>
<tr>
<td><code>mac.2.in</code></td>
<td>mac filter 2 permit 3333.3333.3333 ffff.ffff.ffff any etype eq 0800</td>
</tr>
<tr>
<td><code>mac.3.in</code></td>
<td>mac filter 2 permit 3333.3333.3333 ffff.ffff.ffff any etype eq 0800</td>
</tr>
<tr>
<td><code>mac.3.in</code></td>
<td>mac filter 3 permit 2222.2222.2222 ffff.ffff.ffff any etype eq 0800</td>
</tr>
</tbody>
</table>

**Notes**

- The `<name>` in the Filter ID attribute is case-sensitive.
- You can specify only numbered MAC address filters in the Filter ID attribute. Named MAC address filters are not supported.
• Dynamic ACL filters are supported only for the inbound direction. Dynamic outbound ACL filters are not supported.
• MAC address filters are supported only for the inbound direction. Outbound MAC address filters are not supported.
• Dynamically assigned IP ACLs and MAC address filters are subject to the same configuration restrictions as non-dynamically assigned IP ACLs and MAC address filters.

**Configuring per-user IP ACLs or MAC address filters**

Per-user IP ACLs and MAC address filters make use of the Vendor-Specific (type 26) attribute to dynamically apply filters to ports. Defined in the Vendor-Specific attribute are Brocade ACL or MAC address filter statements. When the RADIUS server returns the Access-Accept message granting a client access to the network, the Brocade device reads the statements in the Vendor-Specific attribute and applies these IP ACLs or MAC address filters to the client port. When the client disconnects from the network, the dynamically applied filters are no longer applied to the port. If any filters had been applied to the port previous to the client connecting, then those filters are reapplied to the port.

**NOTE**
Dynamic IP ACL filters and MAC address filters are not supported on the same port at the same time.

The following table shows the syntax for configuring the Brocade Vendor-Specific attributes with ACL or MAC address filter statements.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipACL.e.in=&lt;extended-ACL-entries&gt;</td>
<td>Applies the specified extended ACL entries to the 802.1X authenticated port in the inbound direction.</td>
</tr>
<tr>
<td>macfilter.in=&lt;mac-filter-entries&gt;</td>
<td>Applies the specified MAC address filter entries to the 802.1X authenticated port in the inbound direction.</td>
</tr>
</tbody>
</table>

The following table shows examples of IP ACLs and MAC address filters configured in the Brocade Vendor-Specific attribute on a RADIUS server. These IP ACLs and MAC address filters follow the same syntax as other Brocade ACLs and MAC address filters. Refer to the related chapters in this book for information on syntax.

<table>
<thead>
<tr>
<th>ACL or MAC address filter</th>
<th>Vendor-specific attribute on RADIUS server</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAC address filter with one entry</td>
<td>macfilter.in= deny any any</td>
</tr>
<tr>
<td>MAC address filter with two entries</td>
<td>macfilter.in= permit 0000.0000.3333 ffff.ffff.0000 any, macfilter.in= permit 0000.0000.4444 ffff.ffff.0000 any</td>
</tr>
</tbody>
</table>

The RADIUS server allows one instance of the Vendor-Specific attribute to be sent in an Access-Accept message.

**Enabling 802.1X port security**

By default, 802.1X port security is disabled on Brocade devices. To enable the feature on the device and enter the dot1x configuration level, enter the following command.

```
FastIron(config)# dot1x-enable
FastIron(config-dot1x)#
```
Syntax: [no] dot1x-enable
At the dot1x configuration level, you can enable 802.1X port security on all interfaces at once, on individual interfaces, or on a range of interfaces.

For example, to enable 802.1X port security on all interfaces on the device, enter the following command.

FastIron(config-dot1x)# enable all

Syntax: [no] enable all
To enable 802.1X port security on interface 3/11, enter the following command.

FastIron(config-dot1x)# enable ethernet 3/11

Syntax: [no] enable ethernet [<slotnum>]/<portnum>
The <slotnum> parameter is required on chassis devices.
The <portnum> parameter is a valid port number.

To enable 802.1X port security on interfaces 3/11 through 3/16, enter the following command.

FastIron(config-dot1x)# enable ethernet 3/11 to 3/16

Syntax: [no] enable ethernet [<slotnum>]/<portnum> to <portnum>
The <slotnum> parameter is required on chassis devices.
The <portnum> parameter is a valid port number.

Setting the port control
To activate authentication on an 802.1X-enabled interface, you specify the kind of port control to be used on the interface. An interface used with 802.1X port security has two virtual access points: a controlled port and an uncontrolled port:

• The controlled port can be either the authorized or unauthorized state. In the authorized state, it allows normal traffic to pass between the Client and the Authenticator. In the unauthorized state, no traffic is allowed to pass.
• The uncontrolled port allows only EAPOL traffic between the Client and the Authentication Server.

Refer to Figure 162 for an illustration of this concept.

By default, all controlled ports on the device are in the authorized state, allowing all traffic. When you activate authentication on an 802.1X-enabled interface, its controlled port is placed in the unauthorized state. When a Client connected to the interface is successfully authenticated, the controlled port is then placed in the authorized state. The controlled port remains in the authorized state until the Client logs off.

To activate authentication on an 802.1X-enabled interface, you configure the interface to place its controlled port in the authorized state when a Client is authenticated by an Authentication Server. To do this, enter commands such as the following.

FastIron(config)# interface e 3/1
FastIron(config-if-3/1)# dot1x port-control auto

Syntax: [no] dot1x port-control [force-authorized | force-unauthorized | auto]
When an interface control type is set to **auto**, the controlled port is initially set to unauthorized, but is changed to authorized when the connecting Client is successfully authenticated by an Authentication Server.

The port control type can be one of the following:

- **force-authorized** – The controlled port is placed unconditionally in the authorized state, allowing all traffic. This is the default state for ports on the Brocade device.
- **force-unauthorized** – The controlled port is placed unconditionally in the unauthorized state.
- **auto** – The controlled port is unauthorized until authentication takes place between the Client and Authentication Server. Once the Client passes authentication, the port becomes authorized. This activates authentication on an 802.1X-enabled interface.

**NOTE**

You cannot enable 802.1X port security on ports that have any of the following features enabled:

- Link aggregation
- Metro Ring Protocol (MRP)
- Mirror port
- Trunk port

### Configuring periodic re-authentication

You can configure the device to periodically re-authenticate Clients connected to 802.1X-enabled interfaces. When you enable periodic re-authentication, the device re-authenticates Clients every 3,600 seconds by default. You can optionally specify a different re-authentication interval of between 1 – 4294967295 seconds.

To configure periodic re-authentication using the default interval of 3,600 seconds, enter the following command.

```
FastIron(config-dot1x)# re-authentication
```

**Syntax:** `[no] re-authentication`

To configure periodic re-authentication with an interval of 2,000 seconds, enter the following commands.

```
FastIron(config-dot1x)# re-authentication
FastIron(config-dot1x)# timeout re-authperiod 2000
```

**Syntax:** `[no] timeout re-authperiod <seconds>`

The re-authentication interval is a global setting, applicable to all 802.1X-enabled interfaces. To re-authenticate Clients connected to a specific port manually, use the **dot1x re-authenticate** command. Refer to “Re-authenticating a port manually”, below.

### Re-authenticating a port manually

When periodic re-authentication is enabled, by default the Brocade device re-authenticates Clients connected to an 802.1X-enabled interface every 3,600 seconds (or the time specified by the **dot1x timeout re-authperiod** command). You can also manually re-authenticate Clients connected to a specific port.
For example, to re-authenticate Clients connected to interface 3/1, enter the following command.

```
FastIron# dot1x re-authenticate e 3/1
```

**Syntax:** `dot1x re-authenticate ethernet [slotnum]/portnum`

The `<slotnum>` parameter is required on chassis devices.
The `<portnum>` parameter is a valid port number.

**Setting the quiet period**

If the Brocade device is unable to authenticate the Client, the Brocade device waits a specified amount of time before trying again. The amount of time the Brocade device waits is specified with the `quiet-period` parameter. The `quiet-period` parameter can be from 1 – 4294967295 seconds. The default is 60 seconds.

For example, to set the quiet period to 30 seconds, enter the following command.

```
FastIron(config-dot1x)# timeout quiet-period 30
```

**Syntax:** `[no] timeout quiet-period <seconds>`

**Specifying the wait interval and number of EAP-request/identity frame retransmissions from the Brocade device**

When the Brocade device sends an EAP-request/identity frame to a Client, it expects to receive an EAP-response/identity frame from the Client. By default, if the Brocade device does not receive an EAP-response/identity frame from a Client, the device waits 30 seconds, then retransmits the EAP-request/identity frame. Also by default, the Brocade device retransmits the EAP-request/identity frame a maximum of two times. You can optionally configure the amount of time the device will wait before retransmitting an EAP-request/identity frame, and the number of times the EAP-request/identity frame will be transmitted. This section provides the command syntax for these features.

**Setting the wait interval for EAP frame retransmissions**

By default, if the Brocade device does not receive an EAP-response/identity frame from a Client, the device waits 30 seconds, then retransmits the EAP-request/identity frame. You can optionally change the amount of time the Brocade device waits before retransmitting the EAP-request/identity frame to the Client.

For example, to cause the Brocade device to wait 60 seconds before retransmitting an EAP-request/identity frame to a Client, enter the following command.

```
FastIron(config-dot1x)# timeout tx-period 60
```

If the Client does not send back an EAP-response/identity frame within 60 seconds, the device will transmit another EAP-request/identity frame.

**Syntax:** `[no] timeout tx-period <seconds>`

where `<seconds>` is a value from 1 – 4294967295. The default is 30 seconds.
Configuring 802.1X port security

Setting the maximum number of EAP frame retransmissions

The Brocade device retransmits the EAP-request/identity frame a maximum of two times. If no EAP-response/identity frame is received from the Client after two EAP-request/identity frame retransmissions (or the amount of time specified with the auth-max command), the device restarts the authentication process with the Client.

You can optionally change the number of times the Brocade device should retransmit the EAP-request/identity frame. You can specify between 1 – 10 frame retransmissions. For example, to configure the device to retransmit an EAP-request/identity frame to a Client a maximum of three times, enter the following command:

```
FastIron(config-dot1x)# auth-max 3
```

Syntax: `auth-max <value>`

<value> is a number from 1 – 10. The default is 2.

Specifying the wait interval and number of EAP-request/identity frame retransmissions from the RADIUS server

Acting as an intermediary between the RADIUS Authentication Server and the Client, the Brocade device receives RADIUS messages from the RADIUS server, encapsulates them as EAPOL frames, and sends them to the Client. By default, when the Brocade device relays an EAP-Request frame from the RADIUS server to the Client, it expects to receive a response from the Client within 30 seconds. If the Client does not respond within the allotted time, the device retransmits the EAP-Request frame to the Client. Also by default, the Brocade device retransmits the EAP-request frame twice. If no EAP-response frame is received from the Client after two EAP-request frame retransmissions, the device restarts the authentication process with the Client.

You can optionally configure the amount of time the device will wait before retransmitting an EAP-request/identity frame, and the number of times the EAP-request/identity frame will be transmitted. This section provides the command syntax for these features.

Setting the wait interval for EAP frame retransmissions

By default, when the Brocade device relays an EAP-Request frame from the RADIUS server to the Client, it expects to receive a response from the Client within 30 seconds. You can optionally specify the wait interval using the supptimeout command.

For example, to configure the device to retransmit an EAP-Request frame if the Client does not respond within 45 seconds, enter the following command.

```
FastIron(config-dot1x)# supptimeout 45
```

Syntax: `supptimeout <seconds>`

<seconds> is a number from 1 – 4294967295 seconds. The default is 30 seconds.

Setting the maximum number of EAP frame retransmissions

You can optionally specify the number of times the Brocade device will retransmit the EAP-request frame. You can specify between 1 – 10 frame retransmissions. For example, to configure the device to retransmit an EAP-request frame to a Client a maximum of three times, enter the following command.
FastIron(config-dot1x)# max-req 3

Syntax: max-req <value>

<value> is a number from 1 – 10. The default is 2.

Specifying a timeout for retransmission of messages to the authentication server

When performing authentication, the Brocade device receives EAPOL frames from the Client and passes the messages on to the RADIUS server. The device expects a response from the RADIUS server within 30 seconds. If the RADIUS server does not send a response within 30 seconds, the Brocade device retransmits the message to the RADIUS server. The time constraint for retransmission of messages to the Authentication Server can be between 0 – 4294967295 seconds.

For example, to configure the device to retransmit a message if the Authentication Server does not respond within 45 seconds, enter the following command.

FastIron(config-dot1x)# server-timeout 45

Syntax: server-timeout <seconds>

Initializing 802.1X on a port

To initialize 802.1X port security on a port, enter a command such as the following.

FastIron# dot1x initialize e 3/1

Syntax: dot1x initialize ethernet [<slotnum>/]<portnum>

The <slotnum> parameter is required on chassis devices.
The <portnum> parameter is a valid port number.

Allowing access to multiple hosts

Brocade devices support 802.1X authentication for ports with more than one host connected to them. If there are multiple hosts connected to a single 802.1X-enabled port, the Brocade device authenticates each of them individually. Refer to “Configuring 802.1X multiple-host authentication” on page 1535.

Configuring 802.1X multiple-host authentication

When multiple hosts are connected to the same 802.1X-enabled port, the functionality described in “How 802.1X Multiple-host authentication works” on page 1516 is enabled by default. You can optionally do the following:

- Specify the authentication-failure action
- Specify the number of authentication attempts the device makes before dropping packets
- Disabling aging for dot1x-mac-sessions
- Configure aging time for blocked Clients
- Clear the dot1x-mac-session for a MAC address
Specifying the authentication-failure action

In an 802.1X multiple-host configuration, if RADIUS authentication for a Client is unsuccessful, traffic from that Client is either dropped in hardware (the default), or the Client port is placed in a “restricted” VLAN. You can specify which of these two authentication-failure actions is to be used. If the authentication-failure action is to place the port in a restricted VLAN, you can specify the ID of the restricted VLAN.

To specify that the authentication-failure action is to place the Client port in a restricted VLAN, enter the following command.

```
FastIron(config)# dot1x-enable
FastIron(config-dot1x)# auth-fail-action restricted-vlan
```

Syntax: `[no] auth-fail-action restricted-vlan`

To specify the ID of the restricted VLAN as VLAN 300, enter the following command.

```
FastIron(config-dot1x)# auth-fail-vlanid 300
```

Syntax: `[no] auth-fail-vlanid <vlan-id>`

Specifying the number of authentication attempts the device makes before dropping packets

When the authentication-failure action is to drop traffic from the Client, and the initial authentication attempt made by the device to authenticate the Client is unsuccessful, the Brocade device immediately retries to authenticate the Client. After three unsuccessful authentication attempts, the Client dot1x-mac-session is set to “access-denied”, causing traffic from the Client to be dropped in hardware.

You can optionally configure the number of authentication attempts the device makes before dropping traffic from the Client. To do so, enter a command such as the following.

```
FastIron(config-dot1x)# auth-fail-max-attempts 2
```

Syntax: `[no] auth-fail-max-attempts <attempts>`

By default, the device makes 3 attempts to authenticate a Client before dropping packets from the Client. You can specify between 1 – 10 authentication attempts.

Disabling aging for dot1x-mac-sessions

The dot1x-mac-sessions for Clients authenticated or denied by a RADIUS server are aged out if no traffic is received from the Client MAC address for a certain period of time. After a Client dot1x-mac-session is aged out, the Client must be re-authenticated:

- **Permitted** dot1x-mac-sessions, which are the dot1x-mac-sessions for authenticated Clients, as well as for non-authenticated Clients whose ports have been placed in the restricted VLAN, are aged out if no traffic is received from the Client MAC address over the normal MAC aging interval on the Brocade device.

- **Denied** dot1x-mac-sessions, which are the dot1x-mac-sessions for non-authenticated Clients that are blocked by the Brocade device are aged out over a configurable software aging period. (Refer to the next section for more information on configuring the software aging period).

You can optionally disable aging of the permitted or denied dot1x-mac-sessions, or both, on the Brocade device.

To disable aging of the permitted dot1x-mac-sessions, enter the following command.

```
FastIron(config-dot1x)# mac-session-aging no-aging permitted-mac-only
```

Syntax: `[no] mac-session-aging no-aging permitted-mac-only`
To disable aging of the denied dot1x-mac-sessions, enter the following command.

```
FastIron(config-dot1x)# mac-session-aging no-aging denied-mac-only
```

**Syntax:** `[no] mac-session-aging no-aging denied-mac-only`

**NOTE**
This command enables aging of permitted sessions.

As a shortcut, use the command `[no] mac-session-aging` to enable or disable aging for permitted and denied sessions.

**Specifying the aging time for blocked clients**

When the Brocade device is configured to drop traffic from non-authenticated Clients, traffic from the blocked Clients is dropped in hardware, without being sent to the CPU. A Layer 2 CAM entry is created that drops traffic from the blocked Client MAC address in hardware. If no traffic is received from the blocked Client MAC address for a certain amount of time, this Layer 2 CAM entry is aged out. If traffic is subsequently received from the Client MAC address, then an attempt can be made to authenticate the Client again.

Aging of the Layer 2 CAM entry for a blocked Client MAC address occurs in two phases, known as `hardware aging` and `software aging`. The hardware aging period is fixed at 70 seconds and is non-configurable. The software aging time is configurable through the CLI.

Once the Brocade device stops receiving traffic from a blocked Client MAC address, the hardware aging begins and lasts for a fixed period of time. After the hardware aging period ends, the software aging period begins. The software aging period lasts for a configurable amount of time (by default 120 seconds). After the software aging period ends, the blocked Client MAC address ages out, and can be authenticated again if the Brocade device receives traffic from the Client MAC address.

Change the length of the software aging period for a blocked Client MAC address by entering a command such as the following.

```
FastIron(config)# mac-session-aging max-age 180
```

**Syntax:** `[no] mac-session-aging max-age <seconds>`

You can specify from 1 – 65535 seconds. The default is 120 seconds.

**Clearing a dot1x-mac-session for a MAC address**

You can clear the dot1x-mac-session for a specified MAC address, so that the Client with that MAC address can be re-authenticated by the RADIUS server.

```
FastIron# clear dot1x mac-session 00e0.1234.abd4
```

**Syntax:** `clear dot1x mac-session <mac-address>`

**Defining MAC filters for EAP frames**

You can create MAC address filters to permit or deny EAP frames. To do this, you specify the Brocade device 802.1X group MAC address as the destination address in a MAC filter, then apply the filter to an interface.
MAC filters for EAPS on most devices

For example, the following command creates a MAC filter that denies frames with the destination MAC address of 0180.c200.0003, which is the 802.1X group MAC address on the Brocade device.

FastIron(config)# mac filter 1 deny any 0180.c200.0003 ffff.ffff.ffff

The following commands apply this filter to interface e 3/1.

FastIron(config)# interface e 3/1
FastIron(config-if-3/1)# mac filter-group 1

Refer to “Defining MAC address filters” on page 1578 for more information.

NOTE
This feature is not supported on Turbolron devices.

Configuring VLAN access for non-EAP-capable clients

You can configure the Brocade device to grant "guest" or restricted VLAN access to clients that do not support Extensible EAP. The restricted VLAN limits access to the network or applications, instead of blocking access to these services altogether.

When the Brocade device receives the first packet (non-EAP packet) from a client, the device waits for 10 seconds or the amount of time specified with the timeout restrict-fwd-period command. If the Brocade device does not receive subsequent packets after the timeout period, the device places the client on the restricted VLAN.

This feature is disabled by default. To enable this feature and change the timeout period, enter commands such as the following.

FastIron(config)# dot1x-enable
FastIron(config-dot1x)# restrict-forward-non-dot1x
FastIron(config-dot1x)# timeout restrict-fwd-period 15

Once the success timeout action is enabled, use the no form of the command to reset the RADIUS timeout behavior to retry.

Syntax: timeout restrict-fwd-period <num>

The <num> parameter is a value from 0 to 32767. The default value is 10.

Configuring a timeout action to cancel 802.1X authentication for Non-802.1X clients

Normally, the Brocade-specific attribute obtained from the RADIUS server identifies a client as not 802.1X-capable and tells the switch not to perform 802.1X authentication for this client.

However, if you configure an auth-timeout-action at the global level, the Brocade-specific attribute from the RADIUS server is no longer required to cancel 802.1X authentication for a non-802.1X user. To configure the timeout action, enter commands similar to the following at the global level.

FastIron(config)# dot1x-enable
FastIron(config-dot1x)# restrict-forward-non-dot1x auth-timeout-action

NOTE
FCX devices do not support the auth-timeout-action portion of the previous command.
Syntax: restrict-forward-non-dot1x [auth-timeout-action]

To set the RADIUS timeout behavior to bypass dot.1X authentication and permit client access to the network, enter commands similar to the following (at the interface level).

FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# dot1x auth-timeout-action success

To set the RADIUS timeout behavior to bypass 802.1X authentication and return a failure, which limits access to the network and moves the client to the restricted VLAN, enter commands similar to the following (at the interface level).

FastIron(config)# interface ethernet 3/1
FastIron(config-if-e100-3/1)# dot1x auth-timeout-action failure

Syntax: [no] dot1x auth-timeout-action success
Syntax: [no] dot1x auth-timeout-action failure

NOTE
The success or failure of multi-device port authentication can change the effect of these commands.

Configuring 802.1X accounting

Platform Support:
- FastIron X Series devices running software release 04.3.00 and later – L2, BL3, L3

802.1X accounting enables the recording of information about 802.1X clients who were successfully authenticated and allowed access to the network. When 802.1X accounting is enabled on the Brocade device, it sends the following information to a RADIUS server whenever an authenticated 802.1X client (user) logs into or out of the Brocade device:
  - The session ID
  - The user MAC address
  - The authenticating physical port number

An Accounting Start packet is sent to the RADIUS server when a user is successfully authenticated. The Start packet indicates the start of a new session and contains the user MAC address and physical port number. The 802.1X session state will change to Authenticated and Permit after receiving a response from the accounting server for the accounting Start packet. If the Accounting service is not available, the 802.1X session status will change to Authenticated and Permit after a RADIUS timeout. The device will retry authentication requests three times (the default), or the number of times configured on the device.

An Accounting Stop packet is sent to the RADIUS server when one of the following events occur:
  - The user logs off
  - The port goes down
  - The port is disabled
  - The user fails to re-authenticate after a RADIUS timeout
  - The 802.1X port control-auto configuration changes
  - The MAC session clears (through use of the clear dot1x mac-session CLI command)

The Accounting Stop packet indicates the end of the session and the time the user logged out.
802.1X Accounting attributes for RADIUS

Brocade devices support the following RADIUS attributes for 802.1X accounting.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Attribute ID</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acct-Session-ID</td>
<td>44</td>
<td>Integer</td>
<td>The account session ID, which is a number from 1 to 4294967295.</td>
</tr>
<tr>
<td>Acct-Status-Type</td>
<td>40</td>
<td>integer</td>
<td>Indicates whether the accounting request marks the beginning (start) or end (stop) of the user service. 1 – Start 2 – Stop</td>
</tr>
<tr>
<td>Calling-Station-Id</td>
<td>31</td>
<td>string</td>
<td>The supplicant MAC address in ASCII format (upper case only), with octet values separated by a dash (-). For example 00-10-A4-23-19-C0</td>
</tr>
<tr>
<td>NAS-Port</td>
<td>5</td>
<td>integer</td>
<td>The physical port number.</td>
</tr>
<tr>
<td>NAS-Port-Type</td>
<td>61</td>
<td>integer</td>
<td>The physical port type.</td>
</tr>
</tbody>
</table>

Enabling 802.1X accounting

To enable 802.1X accounting, enter the following command.

```
FastIron(config)# aaa accounting dot1x default start-stop radius none
```

**Syntax:** `aaa accounting dot1x default start-stop radius | none`

`radius` – Use the list of all RADIUS servers that support 802.1X for authentication.

`none` – Use no authentication. The client is automatically authenticated without the device using information supplied by the client.

**NOTE**

If you specify both `radius` and `none`, make sure `radius` comes before `none`.

Displaying 802.1X information

You can display the following 802.1X-related information:

- The 802.1X configuration on the device and on individual ports
- Statistics about the EAPOL frames passing through the device
- 802.1X-enabled ports dynamically assigned to a VLAN
- User-defined and dynamically applied MAC filters and IP ACLs currently active on the device
- The 802.1X multiple-host configuration

Displaying 802.1X configuration information

To display information about the 802.1X configuration on the Brocade device, enter the following command.
Displaying 802.1X information

Syntax: show dot1x

The following table describes the information displayed by the show dot1x command.

<table>
<thead>
<tr>
<th>TABLE 244 Output from the show dot1x command</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field...</strong></td>
</tr>
<tr>
<td>PAE Capability</td>

<tr>
<td>quiet-period</td>
</tr>
<tr>
<td>tx-period</td>
</tr>
<tr>
<td>supp-timeout</td>
</tr>
<tr>
<td>server-timeout</td>
</tr>
<tr>
<td>max-req</td>
</tr>
</tbody>
</table>

FastIron# show dot1x
PAE Capability: Authenticator Only
system-auth-control: Enable
re-authentication: Disable
global-filter-strict-security: Enable
quiet-period: 60 Seconds
tx-period: 30 Seconds
supp-timeout: 30 Seconds
server-timeout: 30 Seconds
max-req: 2
re-authperiod: 3600 Seconds
Protocol Version: 1
To display information about the 802.1X configuration on an individual port, enter a command such as the following.

```
FastIron# show dot1x configuration ethernet 1/3
```

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>re-authperiod</td>
<td>How often the device automatically re-authenticates Clients when periodic re-authentication is enabled (default 3,600 seconds). Refer to “Configuring periodic re-authentication” on page 1532 for information on how to change this setting.</td>
</tr>
<tr>
<td>Protocol Version</td>
<td>The version of the 802.1X protocol in use on the device.</td>
</tr>
</tbody>
</table>

The following additional information is displayed in the `show dot1x config` command for an interface.

```
<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authenticator PAE state</td>
<td>The current status of the Authenticator PAE state machine. This can be INITIALIZE, DISCONNECTED, CONNECTING, AUTHENTICATING, AUTHENTICATED, ABORTING, HELD, FORCE_AUTH, or FORCE_UNAUTH.</td>
</tr>
<tr>
<td>Backend Authentication state</td>
<td>The current status of the Backend Authentication state machine. This can be REQUEST, RESPONSE, SUCCESS, FAIL, TIMEOUT, IDLE, or INITIALIZE.</td>
</tr>
</tbody>
</table>
```

**Syntax:** `show dot1x config ethernet [<slotnum>/]<portnum>`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The following additional information is displayed in the `show dot1x config` command for an interface.
Displaying 802.1X information

To display 802.1X statistics for an individual port, enter a command such as the following:

```
FastIron# show dot1x statistics e 3/3
```

Port 3/3 Statistics:
RX EAPOL Start: 0
RX EAPOL Logoff: 0
RX EAPOL Invalid: 0
RX EAPOL Total: 0
RX EAP Resp/Id: 0
RX EAP Resp other than Resp/Id: 0
RX EAP Length Error: 0
Last EAPOL Version: 0
Last EAPOL Source: 0007.9550.0B83
TX EAPOL Total: 217
TX EAP Req/Id: 163
TX EAP Req other than Req/Id: 0

Syntax: `show dot1x statistics ethernet [<slotnum>]/<portnum>`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The following table describes the information displayed by the `show dot1x statistics` command for an interface.

**TABLE 245** Output from the `show dot1x config` command for an interface (Continued)

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>AdminControlledDirections</td>
<td>Indicates whether an unauthorized controlled port exerts control over communication in both directions (disabling both reception of incoming frames and transmission of outgoing frames), or just in the incoming direction (disabling only reception of incoming frames). On Brocade devices, this parameter is set to BOTH.</td>
</tr>
<tr>
<td>OperControlledDirections</td>
<td>The setting for the OperControlledDirections parameter, as defined in the 802.1X standard. According to the 802.1X standard, if the AdminControlledDirections parameter is set to BOTH, the OperControlledDirections parameter is unconditionally set to BOTH. Since the AdminControlledDirections parameter on Brocade devices is always set to BOTH, the OperControlledDirections parameter is also set to BOTH.</td>
</tr>
<tr>
<td>AuthControlledPortControl</td>
<td>The port control type configured for the interface. If set to auto, authentication is activated on the 802.1X-enabled interface.</td>
</tr>
<tr>
<td>AuthControlledPortStatus</td>
<td>The current status of the interface controlled port either authorized or unauthorized.</td>
</tr>
<tr>
<td>multiple-hosts</td>
<td>Whether the port is configured to allow multiple Supplicants accessing the interface on the Brocade device through a hub. Refer to “Allowing access to multiple hosts” on page 1535 for information on how to change this setting.</td>
</tr>
</tbody>
</table>
Clearing 802.1X statistics

You can clear the 802.1X statistics counters on all interfaces at once, on individual interfaces, or on a range of interfaces.

For example, to clear the 802.1X statistics counters on all interfaces on the device, enter the following command.

```
FastIron# clear dot1x statistics all
```

**Syntax: clear dot1x statistics all**

To clear the 802.1X statistics counters on interface e 3/11, enter the following command.

```
FastIron# clear dot1x statistics e 3/11
```

**Syntax: clear dot1x statistics ethernet [<slotnum>/]<portnum>**

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

Displaying dynamically assigned VLAN information

The `show interface` command displays the VLAN to which an 802.1X-enabled port has been dynamically assigned, as well as the port from which it was moved (that is, the port default VLAN).

The following example of the `show interface` command indicates the port dynamically assigned VLAN. Information about the dynamically assigned VLAN is shown in bold type.
FastIron# show interface e 12/2
FastEthernet12/2 is up, line protocol is up
  Hardware is FastEthernet, address is 0204.80a0.4681 (bia 0204.80a0.4681)
  Configured speed auto, actual 100Mbit, configured duplex fdx, actual fdx
  Member of L2 VLAN ID 2 (dotix-RADIUS assigned), original L2 VLAN ID is 1,
  port is untagged, port state is FORWARDING
  STP configured to ON, priority is level0, flow control enabled
  mirror disabled, monitor disabled
  Not member of any active trunks
  Not member of any configured trunks
  No port name
  MTU 1518 bytes
  300 second input rate: 0 bits/sec, 0 packets/sec, 0.00% utilization
  300 second output rate: 256 bits/sec, 0 packets/sec, 0.00% utilization
  3 packets input, 192 bytes, 0 no buffer
  Received 0 broadcasts, 0 multicasts, 3 unicasts
  0 input errors, 0 CRC, 0 frame, 0 ignored
  0 runts, 0 giants, DMA received 3 packets
  919 packets output, 58816 bytes, 0 underruns
  Transmitted 1 broadcasts, 916 multicasts, 2 unicasts
  0 output errors, 0 collisions, DMA transmitted 919 packets

In this example, the 802.1X-enabled port has been moved from VLAN 1 to VLAN 2. When the client disconnects, the port will be moved back to VLAN 1.

The **show run** command also indicates the VLAN to which the port has been dynamically assigned. The output can differ depending on whether GARP VLAN Registration Protocol (GVRP) is enabled on the device:

- **Without GVRP** – When you enter the **show run** command, the output indicates that the port is a member of the VLAN to which it was dynamically assigned through 802.1X. If you then enter the **write memory** command, the VLAN to which the port is currently assigned becomes the port default VLAN in the device configuration.

- **With GVRP** – When you enter the **show run** command, if the VLAN name supplied by the RADIUS server corresponds to a VLAN learned through GVRP, then the output indicates that the port is a member of the VLAN to which it was originally assigned (not the VLAN to which it was dynamically assigned).

  If the VLAN name supplied by the RADIUS server corresponds to a statically configured VLAN, the output indicates that the port is a member of the VLAN to which it was dynamically assigned through 802.1X. If you then enter the **write memory** command, the VLAN to which the port is currently assigned becomes the port default VLAN in the device configuration.

### Displaying information about dynamically applied MAC filters and IP ACLs

You can display information about currently active user-defined and dynamically applied MAC filters and IP ACLs.

**Displaying user-defined MAC filters and IP ACLs**

To display the user-defined MAC filters active on the device, enter the following command.
Displaying 802.1X information

FastIron# show dot1x mac-address filter

Port 1/3 (User defined MAC Address Filter):
  mac filter 1 permit any any

Syntax: show dot1x mac-address-filter

To display the user-defined IP ACLs active on the device, enter the following command.

FastIron# show dot1x ip-ACL

Port 1/3 (User defined IP ACLs):

Extended IP access list Port_1/3_E_IN
  permit udp any any

Extended IP access list Port_1/3_E_OUT
  permit udp any any

Syntax: show dot1x ip-ACL

Displaying dynamically applied MAC filters and IP ACLs

To display the dynamically applied MAC address filters active on an interface, enter a command such as the following.

FastIron# show dot1x mac-address-filter e 1/3

Port 1/3 MAC Address Filter information:
  802.1X Dynamic MAC Address Filter:
    mac filter-group 2
  Port default MAC Address Filter:
    No mac address filter is set

Syntax: show dot1x mac-address-filter all | ethernet [slotnum]/<portnum>

The all keyword displays all dynamically applied MAC address filters active on the device.
The <slotnum> parameter is required on chassis devices.
The <portnum> parameter is a valid port number.
To display the dynamically applied IP ACLs active on an interface, enter a command such as the following.

FastIron# show dot1x ip-ACL e 1/3

Port 1/3 IP ACL information:
  802.1X dynamic IP ACL (user defined) in:
    ip access-list extended Port_1/3_E_IN in
  Port default IP ACL in:
    No inbound ip access-list is set
  802.1X dynamic IP ACL (user defined) out:
    ip access-list extended Port_1/3_E_OUT out
  Port default IP ACL out:
    No outbound ip access-list is set

Syntax: show dot1x ip-ACL all | ethernet [slotnum]/<portnum>
The **all** keyword displays all dynamically applied IP ACLs active on the device.
The **<slotnum>** parameter is required on chassis devices.
The **<portnum>** parameter is a valid port number.

### Displaying the status of strict security mode

**Platform Support:**
- FastIron X Series devices running software release 02.2.00 and later

The output of the `show dot1x` and `show dot1x config` commands indicate whether strict security mode is enabled or disabled globally and on an interface.

**Displaying the status of strict security mode globally on the device**

To display the status of strict security mode globally on the device, enter the following command.

```
FastIron# show dot1x
```

```
PAE Capability: Authenticator Only
system-auth-control: Enable
re-authentication: Disable
global-filter-strict-security: Enable
quiet-period:  60 Seconds
tx-period:  30 Seconds
supptimeout:  30 Seconds
servertimeout:  30 Seconds
maxreq:  2
re-authperiod:  3600 Seconds
security-hold-time:  60 Seconds
Protocol Version:  1
```

**Syntax:** `show dot1x`

**Displaying the status of strict security mode on an interface**

To display the status of strict security mode on an interface, enter a command such as the following:

```
FastIron# show dot1x config e 1/3
```

```
Port 1/3 Configuration:
Authenticator PAE state: AUTHENTICATED
Backend Authentication state: IDLE
AdminControlledDirections: BOTH
OperControlledDirections: BOTH
AuthControlledPortControl: Auto
AuthControlledPortStatus: authorized
quiet-period:  60 Seconds
tx-period:  30 Seconds
supptimeout:  30 Seconds
servertimeout:  30 Seconds
maxreq:  2
re-authperiod:  3600 Seconds
security-hold-time:  60 Seconds
re-authentication: Disable
multiple-hosts: Disable
global-filter-strict-security: Enable
Protocol Version:  1
```
Syntax: `show dot1x config ethernet [<slotnum>/]<portnum>`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

**Displaying 802.1X multiple-host authentication information**

You can display the following information about 802.1X multiple-host authentication:

- Information about the 802.1X multiple-host configuration
- The dot1x-mac-sessions on each port
- The number of users connected on each port in a 802.1X multiple-host configuration

**Displaying 802.1X multiple-host configuration information**

The output of the `show dot1x` and `show dot1x config` commands displays information related to 802.1X multiple-host authentication.

The following is an example of the output of the `show dot1x` command. The information related to multiple-host authentication is highlighted in bold.

FastIron# show dot1x

<table>
<thead>

</tr>
</tbody>
</table>
Displaying 802.1X information

The output of the `show dot1x config` command for an interface displays the configured port control for the interface. Starting in release 02.2.00, this command also displays information related to 802.1X multiple host-authentication.

The following is an example of the output of the `show dot1x config` command for an interface.

```
FastIron# show dot1x config e 3/1

Port-Control                   : control-auto
filter strict security         : Enable
PVID State                     : Restricted (10)
Original PVID                  : 10
PVID mac total                 : 1
PVID mac authorized            : 0
num mac sessions               : 1
num mac authorized             : 0
```

**Syntax: show dot1x config ethernet [<slotnum>/]<portnum>**

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The following table lists the fields in the display.

<table>
<thead>
<tr>
<th>This field</th>
<th>Displays</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port-Control</td>
<td>The configured port control type for the interface. This can be one of the following: force-authorized – The controlled port is placed unconditionally in the authorized state, allowing all traffic. This is the default state for ports on the Brocade device. force-unauthorized – The controlled port is placed unconditionally in the unauthorized state. No authentication takes place for any connected 802.1X Clients. auto – The authentication status for each 802.1X Client depends on the authentication status returned from the RADIUS server.</td>
</tr>
<tr>
<td>filter strict security</td>
<td>Whether strict security mode is enabled or disabled on the interface.</td>
</tr>
<tr>
<td>PVID State</td>
<td>The port default VLAN ID (PVID) and the state of the port PVID. The PVID state can be one of the following: Normal – The port PVID is not set by a RADIUS server, nor is it the restricted VLAN. RADIUS - The port PVID was dynamically assigned by a RADIUS server. RESTRICTED – The port PVID is the restricted VLAN.</td>
</tr>
<tr>
<td>Original PVID</td>
<td>The originally configured (not dynamically assigned) PVID for the port.</td>
</tr>
<tr>
<td>PVID mac total</td>
<td>The number of devices transmitting untagged traffic on the port PVID.</td>
</tr>
<tr>
<td>PVID mac authorized</td>
<td>The number of devices transmitting untagged traffic on the port PVID as a result of dynamic VLAN assignment.</td>
</tr>
</tbody>
</table>
Displaying information about the dot1x MAC sessions on each port

The `show dot1x mac-session` command displays information about the dot1x-mac-sessions on each port on the device. Starting in software release 02.2.00, the output also shows the authenticator PAE state.

Example

```
FastIron# show dot1x mac-session
```

```
Port    MAC/(username)                  Vlan Auth ACL Age PAE State
-------- ------------------------------- ------- ---- ---- ---------------
1        0010.a498.24f7 :User          10      permit none 520 AUTHENTICATED
```

Syntax: `show dot1x mac-session`

Table 249 lists the new fields in the display.

**TABLE 249** Output from the `show dot1x mac-session` command

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The port on which the dot1x-mac-session exists.</td>
</tr>
<tr>
<td>MAC/ (username)</td>
<td>The MAC address of the Client and the username used for RADIUS authentication.</td>
</tr>
<tr>
<td>Vlan</td>
<td>The VLAN to which the port is currently assigned.</td>
</tr>
<tr>
<td>Auth-State</td>
<td>The authentication state of the dot1x-mac-session. This can be one of the following: permit – The Client has been successfully authenticated, and traffic from the Client is being forwarded normally; blocked – Authentication failed for the Client, and traffic from the Client is being dropped in hardware; restricted – Authentication failed for the Client, but traffic from the Client is allowed in the restricted VLAN only; init - The Client is in is in the process of 802.1X authentication, or has not started the authentication process.</td>
</tr>
<tr>
<td>Age</td>
<td>The software age of the dot1x-mac-session.</td>
</tr>
<tr>
<td>PAE State</td>
<td>The current status of the Authenticator PAE state machine. This can be INITIALIZE, DISCONNECTED, CONNECTING, AUTHENTICATING, AUTHENTICATED, ABORTING, HELD, FORCE_AUTH, or FORCE_UNAUTH.</td>
</tr>
</tbody>
</table>

**NOTE:** When the Authenticator PAE state machine is in the AUTHENTICATING state, if the reAuthenticate, eapStart, eapLogoff, or authTimeout parameters are set to TRUE, it may place the Authenticator PAE state machine indefinitely in the ABORTING state. If this should happen, use the dot1x initialize command to initialize 802.1X port security on the port, or unplug the Client or hub connected to the port, then reconnect it.
Displaying information about the ports in an 802.1X multiple-host configuration

To display information about the ports in an 802.1X multiple-host configuration, enter the following command.

```
FastIron(config-dot1x)# sh dot1x mac-s br
```

## Table

Sample 802.1X configurations

This section illustrates a sample point-to-point configuration and a sample hub configuration that use 802.1X port security.
Point-to-point configuration

Figure 166 illustrates a sample 802.1X configuration with Clients connected to three ports on the Brocade device. In a point-to-point configuration, only one 802.1X Client can be connected to each port.

FIGURE 166 Sample point-to-point 802.1X configuration

The following commands configure the Brocade device in Figure 166:

```
FastIron(config)# aaa authentication dot1x default radius
FastIron(config)# radius-server host 192.168.9.22 auth-port 1812 acct-port 1813
default key mirabeau dot1x
FastIron(config)# dot1x-enable e 1 to 3
FastIron(config-dot1x)# re-authentication
FastIron(config-dot1x)# timeout re-authperiod 2000
FastIron(config-dot1x)# timeout quiet-period 30
FastIron(config-dot1x)# timeout tx-period 60
FastIron(config-dot1x)# max-req 6
FastIron(config-dot1x)# exit
FastIron(config)# interface e 1
FastIron(config-if-e1000-1)# dot1x port-control auto
FastIron(config-if-e1000-1)# exit
FastIron(config)# interface e 2
FastIron(config-if-e1000-2)# dot1x port-control auto
FastIron(config-if-e1000-2)# exit
FastIron(config)# interface e 3
FastIron(config-if-e1000-3)# dot1x port-control auto
FastIron(config-if-e1000-3)# exit
```
Hub configuration

Figure 167 illustrates a configuration where three 802.1X-enabled Clients are connected to a hub, which is connected to a port on the Brocade device. The configuration is similar to that in Figure 166, except that 802.1X port security is enabled on only one port, and the `multiple-hosts` command is used to allow multiple Clients on the port.

**FIGURE 167** Sample 802.1X configuration using a hub

The following commands configure the Brocade device in Figure 167:

```
FastIron(config)# aaa authentication dot1x default radius
FastIron(config)# radius-server host 192.168.9.22 auth-port 1812 acct-port 1813
default key mirabeau dot1x
FastIron(config)# dot1x-enable e 1
FastIron(config-dot1x)# re-authentication
FastIron(config-dot1x)# timeout re-authperiod 2000
FastIron(config-dot1x)# timeout quiet-period 30
FastIron(config-dot1x)# timeout tx-period 60
FastIron(config-dot1x)# max-req 6
FastIron(config-dot1x)# exit
FastIron(config)# interface e 1
FastIron(config-if-e1000-1)# dot1x port-control auto
FastIron(config-if-e1000-1)# dot1x multiple-hosts
FastIron(config-if-e1000-1)# exit
```
802.1X Authentication with dynamic VLAN assignment

Figure 168 illustrates 802.1X authentication with dynamic VLAN assignment. In this configuration, two user PCs are connected to a hub, which is connected to port e2. Port e2 is configured as a dual-mode port. Both PCs transmit untagged traffic. The profile for User 1 on the RADIUS server specifies that User 1 PC should be dynamically assigned to VLAN 3. The RADIUS profile for User 2 on the RADIUS server specifies that User 2 PC should be dynamically assigned to VLAN 20.

**FIGURE 168** Sample configuration using 802.1X authentication with dynamic VLAN assignment

In this example, the PVID for port e2 would be changed based on the first host to be successfully authenticated. If User 1 is authenticated first, then the PVID for port e2 is changed to VLAN 3. If User 2 is authenticated first, then the PVID for port e2 is changed to VLAN 20. Since a PVID cannot be changed by RADIUS authentication after it has been dynamically assigned, if User 2 is authenticated after the port PVID was changed to VLAN 3, then User 2 would not be able to gain access to the network.

If there were only one device connected to the port, and authentication failed for that device, it could be placed into the restricted VLAN, where it could gain access to the network.

The part of the running-config related to 802.1X authentication would be as follows.

```
dot1x-enable
re-authentication
server-timeout 10
timeout re-auth-period 10
auth-fail-action restricted-vlan
auth-fail-vlanid 1023
mac-session-aging no-aging permitted-mac-only
enable ethe 2 to 4
```

```
Using multi-device port authentication and 802.1X security on the same port

You can configure the Brocade device to use multi-device port authentication and 802.1X security on the same port:

- The multi-device port authentication feature allows you to configure a Brocade device to forward or block traffic from a MAC address based on information received from a RADIUS server. Incoming traffic originating from a given MAC address is switched or forwarded by the device only if the source MAC address is successfully authenticated by a RADIUS server. The MAC address itself is used as the username and password for RADIUS authentication. A connecting user does not need to provide a specific username and password to gain access to the network.

- The IEEE 802.1X standard is a means for authenticating devices attached to LAN ports. Using 802.1X port security, you can configure a Brocade device to grant access to a port based on information supplied by a client to an authentication server.

For information on configuring the multi-device port authentication feature and 802.1X security on Brocade devices, Refer to the related chapters in this book.

When both of these features are enabled on the same port, multi-device port authentication is performed prior to 802.1X authentication. If multi-device port authentication is successful, 802.1X authentication may be performed, based on the configuration of a vendor-specific attribute (VSA) in the profile for the MAC address on the RADIUS server.

When both features are configured on a port, a device connected to the port is authenticated as follows.

1. Multi-device port authentication is performed on the device to authenticate the device MAC address.

2. If multi-device port authentication is successful for the device, then the Brocade device checks whether the RADIUS server included the Foundry-802_1x-enable VSA (described in Table 251) in the Access-Accept message that authenticated the device.

3. If the Foundry-802_1x-enable VSA is not present in the Access-Accept message, or is present and set to 1, then 802.1X authentication is performed for the device.

4. If the Foundry-802_1x-enable VSA is present in the Access-Accept message, and is set to 0, then 802.1X authentication is skipped. The device is authenticated, and any dynamic VLANs specified in the Access-Accept message returned during multi-device port authentication are applied to the port.

```bash
! interface ethernet 2
dot1x port-control auto
dual-mode

If User 1 is successfully authenticated before User 2, the PVID for port e2 would be changed from the default VLAN to VLAN 3.

Had User 2 been the first to be successfully authenticated, the PVID would be changed to 20, and User 1 would not be able to gain access to the network. If there were only one device connected to the port that was sending untagged traffic, and 802.1X authentication failed for that device, it would be placed in the restricted VLAN 1023, and would be able to gain access to the network.
```
5. If 802.1X authentication is performed on the device, and is successful, then dynamic VLANs or ACLs specified in the Access-Accept message returned during 802.1X authentication are applied to the port.

If multi-device port authentication fails for a device, then by default traffic from the device is either blocked in hardware, or the device is placed in a restricted VLAN. You can optionally configure the Brocade device to perform 802.1X authentication on a device when it fails multi-device port authentication. Refer to “Example 2” on page 1559 for a sample configuration where this is used.

**Configuring Brocade-specific attributes on the RADIUS server**

If the RADIUS authentication process is successful, the RADIUS server sends an Access-Accept message to the Brocade device, authenticating the device. The Access-Accept message can include Vendor-Specific Attributes (VSAs) that specify additional information about the device. If you are configuring multi-device port authentication and 802.1X authentication on the same port, then you can configure the Brocade VSAs listed in Table 251 on the RADIUS server.

Add these Brocade vendor-specific attributes to your RADIUS server configuration, and configure the attributes in the individual or group profiles of the devices that will be authenticated. The Brocade Vendor-ID is 1991, with Vendor-Type 1.

**TABLE 251** Brocade vendor-specific attributes for RADIUS

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Attribute ID</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Foundry-802_1x-enable</td>
<td>6</td>
<td>integer</td>
<td>Specifies whether 802.1X authentication is performed when multi-device port authentication is successful for a device. This attribute can be set to one of the following: 0 Do not perform 802.1X authentication on a device that passes multi-device port authentication. Set the attribute to zero for devices that do not support 802.1X authentication. 1 Perform 802.1X authentication when a device passes multi-device port authentication. Set the attribute to one for devices that support 802.1X authentication.</td>
</tr>
<tr>
<td>Foundry-802_1x-valid</td>
<td>7</td>
<td>integer</td>
<td>Specifies whether the RADIUS record is valid only for multi-device port authentication, or for both multi-device port authentication and 802.1X authentication. This attribute can be set to one of the following: 0 The RADIUS record is valid only for multi-device port authentication. Set this attribute to zero to prevent a user from using their MAC address as username and password for 802.1X authentication 1 The RADIUS record is valid for both multi-device port authentication and 802.1X authentication.</td>
</tr>
</tbody>
</table>
If neither of these VSAs exist in a device profile on the RADIUS server, then by default the device is subject to multi-device port authentication (if configured), then 802.1X authentication (if configured). The RADIUS record can be used for both multi-device port authentication and 802.1X authentication.

**Example configurations**

The following examples show configurations that use multi-device port authentication and 802.1X authentication on the same port.

**Example 1**

Figure 169 illustrates an example configuration that uses multi-device port authentication and 802.1X authentication on the same port. In this configuration, a PC and an IP phone are connected to port e 1/3 on a Brocade device. Port e 1/3 is configured as a dual-mode port.

The profile for the PC MAC address on the RADIUS server specifies that the PC should be dynamically assigned to VLAN "Login-VLAN", and the RADIUS profile for the IP phone specifies that it should be dynamically assigned to the VLAN named "IP-Phone-VLAN". When User 1 is successfully authenticated using 802.1X authentication, the PC is then placed in the VLAN named "User-VLAN".

**NOTE**

This example assumes that the IP phone initially transmits untagged packets (for example, CDP or DHCP packets), which trigger the authentication process on the Brocade device and client lookup on the RADIUS server. If the phone sends only tagged packets and the port (e 1/3) is not a member of that VLAN, authentication would not occur. In this case, port e 1/3 must be added to that VLAN prior to authentication.
When the devices attempt to connect to the network, they are first subject to multi-device port authentication.

When the MAC address of the IP phone is authenticated, the Access-Accept message from the RADIUS server specifies that the IP phone port be placed into the VLAN named “IP-Phone-VLAN”, which is VLAN 7. The Foundry-802_1x-enable attribute is set to 0, meaning that 802.1X authentication is skipped for this MAC address. Port 1/3 is placed in VLAN 7 as a tagged port. No further authentication is performed.

When the PC MAC address is authenticated, the Access-Accept message from the RADIUS server specifies that the PVID for the PC port be changed to the VLAN named “Login-VLAN”, which is VLAN 1024. The Foundry-802_1x-enable attribute is set to 1, meaning that 802.1X authentication is required for this MAC address. The PVID of the port 1/3 is temporarily changed to VLAN 1024, pending 802.1X authentication.

When User 1 attempts to connect to the network from the PC, he is subject to 802.1X authentication. If User 1 is successfully authenticated, the Access-Accept message from the RADIUS server specifies that the PVID for User 1 port be changed to the VLAN named “User-VLAN”, which is VLAN 3. If 802.1X authentication for User 1 is unsuccessful, the PVID for port 1/3 is changed to that of the restricted VLAN, which is VLAN 1023, or untagged traffic from port e 1/3 can be blocked in hardware.

The part of the running-config related to port e 1/3 would be as follows.

```plaintext
interface ethernet 1/3
   dot1x port-control auto
   mac-authentication enable
dual-mode
```
When the PC is authenticated using multi-device port authentication, the port PVID is changed to “Login-VLAN”, which is VLAN 1024 in this example.

When User 1 is authenticated using 802.1X authentication, the port PVID is changed to “User-VLAN”, which is VLAN 3 in this example.

**Example 2**

The configuration in Figure 169 requires that you create a profile on the RADIUS server for each MAC address to which a device or user can connect to the network. In a large network, this can be difficult to implement and maintain.

As an alternative, you can create MAC address profiles only for those devices that do not support 802.1X authentication, such as IP phones and printers, and configure the Brocade device to perform 802.1X authentication for the other devices that do not have MAC address profiles, such as user PCs. To do this, you configure the Brocade device to perform 802.1X authentication when a device fails multi-device port authentication.

Figure 170 shows a configuration where multi-device port authentication is performed for an IP phone, and 802.1X authentication is performed for a user PC. There is a profile on the RADIUS server for the IP phone MAC address, but not for the PC MAC address.

**FIGURE 170 802.1X Authentication is performed when a device fails multi-device port authentication**

Multi-device port authentication is initially performed for both devices. The IP phone MAC address has a profile on the RADIUS server. This profile indicates that 802.1X authentication should be skipped for this device, and that the device port be placed into the VLAN named “IP-Phone-VLAN”.

![Diagram of network configuration](image-url)
Since there is no profile for the PC MAC address on the RADIUS server, multi-device port authentication for this MAC address fails. Ordinarily, this would mean that the PVID for the port would be changed to that of the restricted VLAN, or traffic from this MAC would be blocked in hardware. However, the FastIron switch is configured to perform 802.1X authentication when a device fails multi-device port authentication, so when User 1 attempts to connect to the network from the PC, he is subject to 802.1X authentication. If User 1 is successfully authenticated, the PVID for port e 1/4 is changed to the VLAN named “User-VLAN”.

**NOTE**
This example assumes that the IP phone initially transmits untagged packets (for example, CDP or DHCP packets), which trigger the authentication process on the Brocade device and client lookup on the RADIUS server. If the phone sends only tagged packets and the port (e 1/4) is not a member of that VLAN, authentication would not occur. In this case, port e 1/4 must be added to that VLAN prior to authentication.

To configure the Brocade device to perform 802.1X authentication when a device fails multi-device port authentication, enter the following command.

```
FastIron(config)# mac-authentication auth-fail-dot1x-override
```

**Syntax:** `[no] mac-authentication auth-fail-dot1x-override`
Using the MAC Port Security Feature

This chapter describes how to configure Brocade devices to learn “secure” MAC addresses on an interface so that the interface will forward only packets that match the secure addresses.

NOTE
On TurboIron X Series devices, this feature is supported on devices running software release 04.2.00 and later.

Overview

You can configure the Brocade device to learn “secure” MAC addresses on an interface. The interface will forward only packets with source MAC addresses that match these learned secure addresses. The secure MAC addresses can be specified manually, or the Brocade device can learn them automatically. After the device reaches the limit for the number of secure MAC addresses it can learn on the interface, if the interface then receives a packet with a source MAC address that does not match the learned addresses, it is considered a security violation.

When a security violation occurs, a Syslog entry and an SNMP trap are generated. In addition, the device takes one of two actions; it either drops packets from the violating address (and allows packets from the secure addresses), or disables the port for a specified amount of time. You specify which of these actions takes place.

The secure MAC addresses are not flushed when an interface is disabled and re-enabled. The secure addresses can be kept secure permanently (the default), or can be configured to age out, at which time they are no longer secure. You can configure the device to automatically save the secure MAC address list to the startup-config file at specified intervals, allowing addresses to be kept secure across system restarts.

Local and global resources

The port security feature uses a concept of local and global “resources” to determine how many MAC addresses can be secured on each interface. In this context, a “resource” is the ability to store one secure MAC address entry. Each interface is allocated 64 local resources. Additional global resources are shared among all interfaces on the device.

When the port security feature is enabled on an interface, the interface can store one secure MAC address. You can increase the number of MAC addresses that can be secured using local resources to a maximum of 64.

Besides the maximum of 64 local resources available to an interface, there are additional global resources. Depending on flash memory size, a device can have 1024, 2048, or 4096 global resources available. When an interface has secured enough MAC addresses to reach its limit for local resources, it can secure additional MAC addresses by using global resources. Global resources are shared among all the interfaces on a first-come, first-served basis.
The maximum number of MAC addresses any single interface can secure is 64 (the maximum number of local resources available to the interface), plus the number of global resources not allocated to other interfaces.

**Configuration notes and feature limitations**

The following limitations apply to this feature:

- **MAC port security applies only to Ethernet interfaces.**
- **MAC port security is not supported on static trunk group members or ports that are configured for link aggregation.**
- **MAC port security is not supported on 802.1X port security-enabled ports.**
- **Brocade devices do not support the `reserved-vlan-id <num>` command, which changes the default VLAN ID for the MAC port security feature.**
- **The SNMP trap generated for restricted MAC addresses indicates the VLAN ID associated with the MAC address, as well as the port number and MAC address.**
- **MAC port security is not supported on ports that have multi-device port authentication enabled.**

**Configuring the MAC port security feature**

To configure the MAC port security feature, perform the following tasks:

- Enable the MAC port security feature
- Set the maximum number of secure MAC addresses for an interface
- Set the port security age timer
- Specify secure MAC addresses
- Configure the device to automatically save secure MAC addresses to the startup-config file
- Specify the action taken when a security violation occurs
- Deny specific MAC addresses

**Enabling the MAC port security feature**

By default, the MAC port security feature is disabled on all interfaces. You can enable or disable the feature globally on all interfaces at once, or on individual interfaces.

To enable the feature on all interfaces at once, enter the following commands.

```
FastIron(config)# port security
FastIron(config-port-security)# enable
```

To disable the feature on all interfaces at once, enter the following commands.

```
FastIron(config)# port security
FastIron(config-port-security)# no enable
```

To enable the feature on a specific interface, enter the following commands.

```
FastIron(config)# int e 7/11
FastIron(config-if-e1000-7/11)# port security
FastIron(config-port-security-e1000-7/11)# enable
```
Syntax: port security
Syntax: [no] enable

Setting the maximum number of secure MAC addresses for an interface

When port security is enabled, an interface can store one secure MAC address. You can increase the number of MAC addresses that can be stored to a maximum of 64, plus the total number of global resources available.

For example, to configure interface 7/11 to have a maximum of 10 secure MAC addresses, enter the following commands.

```
FastIron(config)# int e 7/11
FastIron(config-if-e1000-7/11)# port security
FastIron(config-port-security-e1000-7/11)# maximum 10
```
Syntax: maximum <number-of-addresses>

The <number-of-addresses> parameter can be set to a number from 0 – (64 + the total number of global resources available). The total number of global resources is 2048 or 4096, depending on flash memory size. Setting the parameter to 0 prevents any addresses from being learned. The default is 1.

Setting the port security age timer

By default, learned MAC addresses stay secure indefinitely. You can optionally configure the device to age out secure MAC addresses after a specified amount of time.

To set the port security age timer to 10 minutes on all interfaces, enter the following commands.

```
FastIron(config)# port security
FastIron(config-port-security)# age 10
```
To set the port security age timer to 10 minutes on a specific interface, enter the following commands.

```
FastIron(config)# int e 7/11
FastIron(config-if-e1000-7/11)# port security
FastIron(config-port-security-e1000-7/11)# age 10
```
Syntax: [no] age <minutes>

The default is 0 (never age out secure MAC addresses).

Specifying secure MAC addresses

This section describes how to configure secure MAC addresses on tagged and untagged interfaces.

On an untagged interface

To specify a secure MAC address on an untagged interface, enter commands such as the following.
Configuring the MAC port security feature

FastIron(config)# int e 7/11
FastIron(config-if-e1000-7/11)# port security
FastIron(config-port-security-e1000-7/11)# secure-mac-address 0050.DA18.747C

Syntax: [no] secure-mac-address <mac-address>

On a tagged interface

When specifying a secure MAC address on a tagged interface, you must also specify the VLAN ID. To do so, enter commands such as the following.

FastIron(config)# int e 7/11
FastIron(config-if-e1000-7/11)# port security
FastIron(config-port-security-e1000-7/11)# secure-mac-address 0050.DA18.747C 2

Syntax: [no] secure-mac-address <mac-address> <vlan-ID>

NOTE
If MAC port security is enabled on a port and you change the VLAN membership of the port, make sure that you also change the VLAN ID specified in the secure-mac-address configuration statement for the port.

When a secure MAC address is applied to a tagged port, the vlan-id is generated for both tagged and untagged ports. When you display the configuration, you will see an entry for the secure MAC addresses secure-mac-address <address> <vlan>. For example, you may see the following line.

secure-mac-address 0000.1111.2222 10

This line means that MAC address 0000.1111.2222 on VLAN 10 is a secure MAC address.

Autosaving secure MAC addresses to the startup-config file

Learned MAC addresses can automatically be saved to the startup-config file at specified intervals. For example, to automatically save learned secure MAC addresses every twenty minutes, enter the following commands.

FastIron(config)# port security
FastIron(config-port-security)# autosave 20

Syntax: [no] autosave <minutes>

You can specify from 15 – 1440 minutes. By default, secure MAC addresses are not autosaved to the startup-config file.

Specifying the action taken when a security violation occurs

A security violation can occur when a user tries to connect to a port where a MAC address is already locked, or the maximum number of secure MAC addresses has been exceeded. When a security violation occurs, an SNMP trap and Syslog message are generated.
You can configure the device to take one of two actions when a security violation occurs; either drop packets from the violating address (and allow packets from secure addresses), or disable the port for a specified time.

**Dropping packets from a violating address**

To configure the device to drop packets from a violating address and allow packets from secure addresses, enter the following commands.

```bash
FastIron(config)# int e 7/11
FastIron(config-if-e1000-7/11)# port security
FastIron(config-port-security-e1000-7/11)# violation restrict
```

**Syntax: violation restrict**

**NOTE**

When the `restrict` option is used, the maximum number of MAC addresses that can be restricted is 128. If the number of violating MAC addresses exceeds this number, the port is shut down. An SNMP trap and the following Syslog message are generated "Port Security violation restrict limit 128 exceeded on interface ethernet `<port_id>`". This is followed by a port shutdown Syslog message and trap.

**Specifying the period of time to drop packets from a violating address**

To specify the number of minutes that the device drops packets from a violating address, use commands similar to the following.

```bash
FastIron(config)# int e 7/11
FastIron(config-if-e1000-7/11)# port security
FastIron(config-port-security-e1000-7/11)# violation restrict 5
```

**Syntax: violation restrict <age>**

`<age>` can be from 0 – 1440 minutes. The default is 5 minutes. Specifying 0 drops packets from the violating address permanently.

Aging for restricted MAC addresses is done in software. There can be a worst case inaccuracy of one minute from the specified time.

The restricted MAC addresses are denied in hardware.

**Disabling the port for a specified amount of time**

You can configure the device to disable the port for a specified amount of time when a security violation occurs.

To shut down the port for 5 minutes when a security violation occurs, enter the following commands.

```bash
FastIron(config)# int e 7/11
FastIron(config-if-e1000-7/11)# port security
FastIron(config-port-security-e1000-7/11)# violation shutdown 5
```

**Syntax: violation shutdown <minutes>**

You can specify from 0 – 1440 minutes. Specifying 0 shuts down the port permanently when a security violation occurs.
Clearing port security statistics

You can clear restricted MAC addresses and violation statistics from ports globally (on all ports) or on individual ports.

Clearing restricted MAC addresses

To clear all restricted MAC addresses globally, enter the following command.

```
FastIron#clear port security restricted-macs all
```

To clear restricted MAC addresses on a specific port, enter a command such as the following.

```
FastIron#clear port security restricted-macs e 5
```

**Syntax:** `clear port security restricted-macs all | ethernet [<slot-num>]/<port-num>`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

Clearing violation statistics

To clear violation statistics globally, enter the following command.

```
FastIron#clear port security statistics all
```

To clear violation statistics on a specific port, enter a command such as the following.

```
FastIron#clear port security statistics e 1/5
```

**Syntax:** `clear port security statistics all | ethernet [<slot-num>]/<port-num>`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

Displaying port security information

You can display the following information about the port security feature:

- The port security settings for an individual port or for all the ports on a specified module
- The secure MAC addresses configured on the device
- Port security statistics for an interface or for a module

Displaying port security settings

You can display the port security settings for an individual port or for all the ports on a specified module. For example, to display the port security settings for port 7/11, enter the following command.

```
```
Displaying port security information

Syntax: show port security ethernet [<slotnum>]/<portnum>

The <slotnum> parameter is required on chassis devices.

The <portnum> parameter is a valid port number.

<table>
<thead>
<tr>
<th>TABLE 252</th>
<th>Output from the <code>show port security</code> command</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field...</strong></td>
<td><strong>Displays...</strong></td>
</tr>
<tr>
<td>Port</td>
<td>The slot and port number of the interface.</td>
</tr>
<tr>
<td>Security</td>
<td>Whether the port security feature has been enabled on the interface.</td>
</tr>
<tr>
<td>Violation</td>
<td>The action to be undertaken when a security violation occurs, either “shutdown” or “restrict”.</td>
</tr>
<tr>
<td>Shutdown-Time</td>
<td>The number of seconds a port is shut down following a security violation, if the port is set to “shutdown” when a violation occurs.</td>
</tr>
<tr>
<td>Age-Time</td>
<td>The amount of time, in minutes, MAC addresses learned on the port will remain secure.</td>
</tr>
<tr>
<td>Max-MAC</td>
<td>The maximum number of secure MAC addresses that can be learned on the interface.</td>
</tr>
</tbody>
</table>

Displaying the secure MAC addresses

To list the secure MAC addresses configured on the device, enter the following command.

FastIron# show port security mac

<table>
<thead>
<tr>
<th>TABLE 253</th>
<th>Output from the <code>show port security mac</code> command</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field...</strong></td>
<td><strong>Displays...</strong></td>
</tr>
<tr>
<td>Port</td>
<td>The slot and port number of the interface.</td>
</tr>
<tr>
<td>Num-Addr</td>
<td>The number of MAC addresses secured on this interface.</td>
</tr>
<tr>
<td>Secure-Src-Addr</td>
<td>The secure MAC address.</td>
</tr>
<tr>
<td>Resource</td>
<td>Whether the address was secured using a local or global resource. Refer to “Local and global resources” on page 1561 for more information.</td>
</tr>
<tr>
<td>Age-Left</td>
<td>The number of minutes the MAC address will remain secure.</td>
</tr>
<tr>
<td>Shutdown/Time-Left</td>
<td>Whether the interface has been shut down due to a security violation and the number of seconds before it is enabled again.</td>
</tr>
</tbody>
</table>
Displaying port security statistics

You can display port security statistics for an interface or for a module.

For example, to display port security statistics for interface 7/11, enter the following command.

```
FastIron# show port security statistics e 7/11
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Total-Addrs</th>
<th>Maximum-Addrs</th>
<th>Violation</th>
<th>Shutdown/Time-Left</th>
</tr>
</thead>
<tbody>
<tr>
<td>7/11</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>no</td>
</tr>
</tbody>
</table>

**Syntax:** `show port security statistics [<slotnum>/]<portnum>`

The `<slotnum>` parameter is required on chassis devices. The `<portnum>` parameter is a valid port number.

**TABLE 254** Output from the `show port security statistics <portnum>` command

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The slot and port number of the interface.</td>
</tr>
<tr>
<td>Total-Addrs</td>
<td>The total number of secure MAC addresses on the interface.</td>
</tr>
<tr>
<td>Maximum-Addrs</td>
<td>The maximum number of secure MAC addresses on the interface.</td>
</tr>
<tr>
<td>Violation</td>
<td>The number of security violations on the port.</td>
</tr>
<tr>
<td>Shutdown/Time-Left</td>
<td>Whether the port has been shut down due to a security violation and the number of seconds before it is enabled again.</td>
</tr>
</tbody>
</table>

To display port security statistics for an interface module, enter the following command.

```
FastIron# show port security statistics e 7
```

Module 7:
- Total ports: 0
- Total MAC address(es): 0
- Total violations: 0
- Total shutdown ports 0

**Syntax:** `show port security statistics <module>`

**TABLE 255** Output from the `show port security statistics <module>` command

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total ports</td>
<td>The number of ports on the module.</td>
</tr>
<tr>
<td>Total MAC address(es)</td>
<td>The total number of secure MAC addresses on the module.</td>
</tr>
<tr>
<td>Total violations</td>
<td>The number of security violations encountered on the module.</td>
</tr>
<tr>
<td>Total shutdown ports</td>
<td>The number of ports on the module shut down as a result of security violations.</td>
</tr>
</tbody>
</table>

Displaying restricted MAC addresses on a port

To display a list of restricted MAC addresses on a port, enter a command such as the following.

```
FastIron# show port security ethernet e 1/5 restricted-macs
```

**Syntax:** `show port security ethernet [<slotnum>/]<portnum> restricted-macs`

The `<slotnum>` parameter is required on chassis devices.
The `<portnum>` parameter is a valid port number.
Displaying port security information
Configuring Multi-Device Port Authentication

Multi-device port authentication is a way to configure a Brocade device to forward or block traffic from a MAC address based on information received from a RADIUS server.

NOTE
On TurboIron X Series devices, multi-device port authentication is supported on devices running software release 04.2.00 and later.

How multi-device port authentication works

Multi-device port authentication is a way to configure a Brocade device to forward or block traffic from a MAC address based on information received from a RADIUS server.

The multi-device port authentication feature is a mechanism by which incoming traffic originating from a specific MAC address is switched or forwarded by the device only if the source MAC address is successfully authenticated by a RADIUS server. The MAC address itself is used as the username and password for RADIUS authentication; the user does not need to provide a specific username and password to gain access to the network. If RADIUS authentication for the MAC address is successful, traffic from the MAC address is forwarded in hardware.

If the RADIUS server cannot validate the user's MAC address, then it is considered an authentication failure, and a specified authentication-failure action can be taken. The default authentication-failure action is to drop traffic from the non-authenticated MAC address in hardware. You can also configure the device to move the port on which the non-authenticated MAC address was learned into a restricted or “guest” VLAN, which may have limited access to the network.

NOTE
FGS-STK, FLS-STK, and FCX devices do not support:
- multi-device authentication on dynamic (LACP) and static trunk ports
- multi-device authentication and port security configured on the same port
- multi-device authentication and lock-address configured on the same port

NOTE
TurboIron devices do not support:
- multi-device authentication and port security configured on the same port
- multi-device authentication and lock-address configured on the same port

NOTE
FCX devices do not support multi-device authentication denial of service (DoS) attack protection.
RADIUS authentication

The multi-device port authentication feature communicates with the RADIUS server to authenticate a newly found MAC address. The Brocade device supports multiple RADIUS servers; if communication with one of the RADIUS servers times out, the others are tried in sequential order. If a response from a RADIUS server is not received within a specified time (by default, 3 seconds) the RADIUS session times out, and the device retries the request up to three times. If no response is received, the next RADIUS server is chosen, and the request is sent for authentication.

The RADIUS server is configured with the usernames and passwords of authenticated users. For multi-device port authentication, the username and password is the MAC address itself; that is, the device uses the MAC address for both the username and the password in the request sent to the RADIUS server. For example, given a MAC address of 0007e90feaa1, the users file on the RADIUS server would be configured with a username and password both set to 0007e90feaa1. When traffic from this MAC address is encountered on a MAC-authentication-enabled interface, the device sends the RADIUS server an Access-Request message with 0007e90feaa1 as both the username and password. The format of the MAC address sent to the RADIUS server is configurable through the CLI.

The request for authentication from the RADIUS server is successful only if the username and password provided in the request matches an entry in the users database on the RADIUS server. When this happens, the RADIUS server returns an Access-Accept message back to the Brocade device. When the RADIUS server returns an Access-Accept message for a MAC address, that MAC address is considered authenticated, and traffic from the MAC address is forwarded normally by the Brocade device.

Authentication-failure actions

If the MAC address does not match the username and password of an entry in the users database on the RADIUS server, then the RADIUS server returns an Access-Reject message. When this happens, it is considered an authentication failure for the MAC address. When an authentication failure occurs, the Brocade device can either drop traffic from the MAC address in hardware (the default), or move the port on which the traffic was received to a restricted VLAN.

Supported RADIUS attributes

Brocade devices support the following RADIUS attributes for multi-device port authentication:

- Username (1) – RFC 2865
- NAS-IP-Address (4) – RFC 2865
- NAS-Port (5) – RFC 2865
- Service-Type (6) – RFC 2865
- FilterId (11) – RFC 2865
- Framed-MTU (12) – RFC 2865
- State (24) – RFC 2865
- Vendor-Specific (26) – RFC 2865
- Session-Timeout (27) – RFC 2865
- Termination-Action (29) – RFC 2865
- Calling-Station-ID (31) – RFC 2865
How multi-device port authentication works

- NAS-Port-Type (61) – RFC 2865
- Tunnel-Type (64) – RFC 2868
- Tunnel-Medium-Type (65) – RFC 2868
- EAP Message (79) – RFC 2579
- Message-Authenticator (80) RFC 3579
- Tunnel-Private-Group-Id (81) – RFC 2868
- NAS-Port-id (87) – RFC2869

Support for dynamic VLAN assignment

The Brocade multi-device port authentication feature supports dynamic VLAN assignment, where a port can be placed in one or more VLANs based on the MAC address learned on that interface. For details about this feature, refer to “Configuring the RADIUS server to support dynamic VLAN assignment” on page 1580.

Support for dynamic ACLs

The Brocade multi-device port authentication implementation supports the assignment of a MAC address to a specific ACL, based on the MAC address learned on the interface. For details about this feature, refer to “Dynamically applying IP ACLs to authenticated MAC addresses” on page 1582.

Support for authenticating multiple MAC addresses on an interface

The multi-device port authentication feature allows multiple MAC addresses to be authenticated or denied authentication on each interface. The maximum number of MAC addresses that can be authenticated on each interface is limited only by the amount of system resources available on the Brocade device.

Support for dynamic ARP inspection with dynamic ACLs

Starting in software release FSX 04.2.00, multi-device port authentication and Dynamic ARP Inspection (DAI) are supported in conjunction with dynamic ACLs. Support is available in the Layer 3 software codes only, and not in the Layer 2 software code. Releases prior to FSX 04.2.00 do not support DAI and multi-device port authentication when dynamic ACLs are in effect.

DAI is supported together with multi-device port authentication as long as ACL-per-port-per-vlan is enabled. Otherwise, you do not need to perform any extra configuration steps to enable support with dynamic ACLs. When these features are enabled on the same port/VLAN, support is automatically enabled.
Support for DHCP snooping with dynamic ACLs

Starting in software release FSX 04.2.00, multi-device port authentication and DHCP snooping are supported in conjunction with dynamic ACLs. Support is available in the Layer 3 software codes only, and not in the Layer 2 software code. Releases prior to FSX 04.2.00 do not support DHCP Snooping and multi-device port authentication when dynamic ACLs are in effect.

DHCP Snooping is supported together with multi-device port authentication as long as \texttt{ACL-per-port-per-vlan} is enabled. Otherwise, you do not need to perform any extra configuration steps to enable support with dynamic ACLs. When these features are enabled on the same port/VLAN, support is automatically enabled.

Support for source guard protection

The Brocade proprietary \textit{Source Guard Protection} feature, a form of IP Source Guard, can be used in conjunction with multi-device port authentication. For details, refer to “Enabling source guard protection” on page 1586.

Using multi-device port authentication and 802.1X security on the same port

On some Brocade devices, multi-device port authentication and 802.1X security can be configured on the same port. When both of these features are enabled on the same port, multi-device port authentication is performed prior to 802.1X authentication. If multi-device port authentication is successful, 802.1X authentication may be performed, based on the configuration of a vendor-specific attribute (VSA) in the profile for the MAC address on the RADIUS server.

\begin{itemize}
\item \textbf{NOTE}
\end{itemize}

When multi-device port authentication and 802.1X security are configured together on the same port, Brocade recommends that dynamic VLANs and dynamic ACLs are done at the multi-device port authentication level, and not at the 802.1X level.

When both features are configured on a port, a device connected to the port is authenticated as follows.

1. Multi-device port authentication is performed on the device to authenticate the device MAC address.
2. If multi-device port authentication is successful for the device, then the device checks whether the RADIUS server included the Foundry-802_1x-enable VSA (described in Table 256) in the Access-Accept message that authenticated the device.
3. If the Foundry-802_1x-enable VSA is not present in the Access-Accept message, or is present and set to 1, then 802.1X authentication is performed for the device.
4. If the Foundry-802_1x-enable VSA is present in the Access-Accept message, and is set to 0, then 802.1X authentication is skipped. The device is authenticated, and any dynamic VLANs specified in the Access-Accept message returned during multi-device port authentication are applied to the port.
5. If 802.1X authentication is performed on the device, and is successful, then dynamic VLANs or ACLs specified in the Access-Accept message returned during 802.1X authentication are applied to the port.

If multi-device port authentication fails for a device, then by default traffic from the device is either blocked in hardware, or the device is placed in a restricted VLAN. You can optionally configure the Brocade device to perform 802.1X authentication on a device when it fails multi-device port authentication. Refer to “Example 2” on page 1604 for a sample configuration where this is used.

### Configuring Brocade-specific attributes on the RADIUS server

If the RADIUS authentication process is successful, the RADIUS server sends an Access-Accept message to the Brocade device, authenticating the device. The Access-Accept message can include Vendor-Specific Attributes (VSAs) that specify additional information about the device. If you are configuring multi-device port authentication and 802.1X authentication on the same port, then you can configure the Brocade VSAs listed in Table 256 on the RADIUS server.

You add these Brocade vendor-specific attributes to your RADIUS server configuration, and configure the attributes in the individual or group profiles of the devices that will be authenticated. The Brocade Vendor-ID is 1991, with Vendor-Type 1.

### TABLE 256  Brocade vendor-specific attributes for RADIUS

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Attribute ID</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Foundry-802_1x-enable| 6            | integer   | Specifies whether 802.1X authentication is performed when multi-device port authentication is successful for a device. This attribute can be set to one of the following:
|                      |              |           | 0 - Do not perform 802.1X authentication on a device that passes multi-device port authentication. Set the attribute to zero for devices that do not support 802.1X authentication.
|                      |              |           | 1 - Perform 802.1X authentication when a device passes multi-device port authentication. Set the attribute to one for devices that support 802.1X authentication. |
| Foundry-802_1x-valid | 7            | integer   | Specifies whether the RADIUS record is valid only for multi-device port authentication, or for both multi-device port authentication and 802.1X authentication. This attribute can be set to one of the following:
|                      |              |           | 0 - The RADIUS record is valid only for multi-device port authentication. Set this attribute to zero to prevent a user from using their MAC address as username and password for 802.1X authentication
|                      |              |           | 1 - The RADIUS record is valid for both multi-device port authentication and 802.1X authentication. |
Configuring multi-device port authentication

If neither of these VSAs exist in a device profile on the RADIUS server, then by default the device is subject to multi-device port authentication (if configured), then 802.1X authentication (if configured). The RADIUS record can be used for both multi-device port authentication and 802.1X authentication.

An example configuration is shown in “Examples of multi-device port authentication and 802.1X authentication configuration on the same port” on page 1602.

Configuring multi-device port authentication

Configuring multi-device port authentication on the Brocade device consists of the following tasks:

- Enabling multi-device port authentication globally and on individual interfaces
- Specifying the format of the MAC addresses sent to the RADIUS server (optional)
- Specifying the authentication-failure action (optional)
- Enabling and disabling SNMP traps for multi-device port authentication
- Defining MAC address filters (optional)
- Configuring dynamic VLAN assignment (optional)
- Dynamically Applying IP ACLs to authenticated MAC addresses
- Enabling denial of service attack protection (optional)
- Clearing authenticated MAC addresses (optional)
- Disabling aging for authenticated MAC addresses (optional)
- Configuring the hardware aging period for blocked MAC addresses
- Specifying the aging time for blocked MAC addresses (optional)

**NOTE**
On TurboIron X Series devices, the 802.1X port security feature is supported on devices running software release 04.2.00 and later.

**Enabling multi-device port authentication**

To enable multi-device port authentication, you first enable the feature globally on the device. On some Brocade devices, you can then enable the feature on individual interfaces.

**Globally enabling multi-device port authentication**

To globally enable multi-device port authentication on the device, enter the following command.

```
FastIron(config)# mac-authentication enable
```

**Syntax:** `[no] mac-authentication enable`

**Enabling multi-device port authentication on an interface**

To enable multi-device port authentication on an individual interface, enter a command such as the following.

```
FastIron(config)# mac-authentication enable ethernet 3/1
```
Configuring multi-device port authentication

Syntax:  [no] mac-authentication enable [slotnum]/portnum | all

The <slotnum> parameter is required on chassis devices.
The <portnum> parameter is a valid port number.
The all option enables the feature on all interfaces at once.
You can enable the feature on an interface at the interface CONFIG level.

Example
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication enable

Syntax:  [no] mac-authentication enable

You can also configure multi-device port authentication commands on a range of interfaces.

Example
FastIron(config)# int e 3/1 to 3/12
FastIron(config-mif-3/1-3/12)# mac-authentication enable

Specifying the format of the MAC addresses sent to the RADIUS server

When multi-device port authentication is configured, the Brocade device authenticates MAC addresses by sending username and password information to a RADIUS server. The username and password is the MAC address itself; that is, the device uses the MAC address for both the username and the password in the request sent to the RADIUS server.

By default, the MAC address is sent to the RADIUS server in the format xxxxxxxxxxxx. You can optionally configure the device to send the MAC address to the RADIUS server in the format xx-xx-xx-xx-xx, or the format xxxx.xxxxxx.xxxx. To do this, enter a command such as the following.

FastIron(config)# mac-authentication auth-passwd-format xxxx.xxxxxx.xxxx

Syntax:  [no] mac-authentication auth-passwd-format xxxx.xxxxxx | xx-xx-xx-xx-xx | xxxxxxxxxxxx

Specifying the authentication-failure action

When RADIUS authentication for a MAC address fails, you can configure the device to perform one of two actions:

- Drop traffic from the MAC address in hardware (the default)
- Move the port on which the traffic was received to a restricted VLAN

To configure the device to move the port to a restricted VLAN when multi-device port authentication fails, enter commands such as the following.

FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication auth-fail-action restrict-vlan 100

Syntax:  [no] mac-authentication auth-fail-action restrict-vlan [vlan-id]

If the ID for the restricted VLAN is not specified at the interface level, the global restricted VLAN ID applies for the interface.
To specify the VLAN ID of the restricted VLAN globally, enter the following command.

```
FastIron(config)# mac-authentication auth-fail-vlan-id 200
```

**Syntax:**

```
[no] mac-authentication auth-fail-vlan-id <vlan-id>
```

The command above applies globally to all MAC-authentication-enabled interfaces.

Note that the restricted VLAN must already exist on the device. You cannot configure the restricted VLAN to be a non-existent VLAN. If the port is a tagged or dual-mode port, you cannot use a restricted VLAN as the authentication-failure action.

To configure the device to drop traffic from non-authenticated MAC addresses in hardware, enter commands such as the following.

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication auth-fail-action block-traffic
```

**Syntax:**

```
[no] mac-authentication auth-fail-action block-traffic
```

Dropping traffic from non-authenticated MAC addresses is the default behavior when multi-device port authentication is enabled.

### Generating traps for multi-device port authentication

You can enable and disable SNMP traps for multi-device port authentication. SNMP traps are enabled by default.

To enable SNMP traps for multi-device port authentication after they have been disabled, enter the following command.

```
FastIron(config)# snmp-server enable traps mac-authentication
```

**Syntax:**

```
[no] snmp-server enable traps mac-authentication
```

Use the **no** form of the command to disable SNMP traps for multi-device port authentication.

### Defining MAC address filters

You can specify MAC addresses that do not have to go through multi-device port authentication. These MAC addresses are considered pre-authenticated, and are not subject to RADIUS authentication. To do this, you can define MAC address filters that specify the MAC addresses to exclude from multi-device port authentication.

You should use a MAC address filter when the RADIUS server itself is connected to an interface where multi-device port authentication is enabled. If a MAC address filter is not defined for the MAC address of the RADIUS server and applied on the interface, the RADIUS authentication process would fail since the device would drop all packets from the RADIUS server itself.

For example, the following command defines a MAC address filter for address 0010.dc58.aca4.

```
FastIron(config)# mac-authentication mac-filter 1 0010.dc58.aca4
```

**Syntax:**

```
[no] mac-authentication mac-filter <filter>
```

The following commands apply the MAC address filter on an interface so that address 0010.dc58.aca4 is excluded from multi-device port authentication.

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication apply-mac-auth-filter 1
```
Configuring multi-device port authentication

Syntax: [no] mac-authentication apply-mac-auth-filter <filter-id>

Configuring dynamic VLAN assignment

An interface can be dynamically assigned to one or more VLANs based on the MAC address learned on that interface. When a MAC address is successfully authenticated, the RADIUS server sends the Brocade device a RADIUS Access-Accept message that allows the Brocade device to forward traffic from that MAC address. The RADIUS Access-Accept message can also contain attributes set for the MAC address in its access profile on the RADIUS server.

If one of the attributes in the Access-Accept message specifies one or more VLAN identifiers, and the VLAN is available on the Brocade device, the port is moved from its default VLAN to the specified VLAN.

To enable dynamic VLAN assignment for authenticated MAC addresses, you must add attributes to the profile for the MAC address on the RADIUS server, then enable dynamic VLAN assignment on multi-device port authentication-enabled interfaces. Refer to “Configuring the RADIUS server to support dynamic VLAN assignment” on page 1580 for a list of the attributes that must be set on the RADIUS server.

To enable dynamic VLAN assignment on a multi-device port authentication-enabled interface, enter commands such as the following.

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication enable-dynamic-vlan
```

Syntax: [no] mac-authentication enable-dynamic-vlan

Configuring a port to remain in the restricted VLAN after a successful authentication attempt

If a previous authentication attempt for a MAC address failed, and as a result the port was placed in the restricted VLAN, but a subsequent authentication attempt was successful, the RADIUS Access-Accept message may specify a VLAN for the port. By default, the Brocade device moves the port out of the restricted VLAN and into the RADIUS-specified VLAN. You can optionally configure the device to leave the port in the restricted VLAN. To do this, enter the following command.

```
FastIron(config-if-e1000-3/1)# mac-authentication no-override-restrict-vlan
```

When the above command is applied, if the RADIUS-specified VLAN configuration is tagged (e.g., T:1024) and the VLAN is valid, then the port is placed in the RADIUS-specified VLAN as a tagged port and left in the restricted VLAN. If the RADIUS-specified VLAN configuration is untagged (e.g., U:1024), the configuration from the RADIUS server is ignored, and the port is left in the restricted VLAN.

Syntax: [no] mac-authentication no-override-restrict-vlan

Configuration notes

- If you configure dynamic VLAN assignment on a multi-device port authentication enabled interface, and the Access-Accept message returned by the RADIUS server contains a Tunnel-Type and Tunnel-Medium-Type, but does not contain a Tunnel-Private-Group-ID attribute, then it is considered an authentication failure, and the configured authentication failure action is performed for the MAC address.
• If the `<vlan-name>` string does not match either the name or the ID of a VLAN configured on the device, then it is considered an authentication failure, and the configured authentication failure action is performed for the MAC address.

• For tagged or dual-mode ports, if the VLAN ID provided by the RADIUS server does not match the VLAN ID in the tagged packet that contains the authenticated MAC address as its source address, then it is considered an authentication failure, and the configured authentication failure action is performed for the MAC address.

• If an untagged port had previously been assigned to a VLAN through dynamic VLAN assignment, and then another MAC address is authenticated on the same port, but the RADIUS Access-Accept message for the second MAC address specifies a different VLAN, then it is considered an authentication failure for the second MAC address. Note that this applies only if the first MAC address has not yet aged out. If the first MAC address has aged out, then dynamic VLAN assignment would work as expected for the second MAC address.

• For dual mode ports, if the RADIUS server returns T:<vlan-name>, the traffic will still be forwarded in the statically assigned PVID. If the RADIUS server returns U:<vlan-name>, the traffic will not be forwarded in the statically assigned PVID.

Configuring the RADIUS server to support dynamic VLAN assignment

To specify VLAN identifiers on the RADIUS server, add the following attributes to the profile for the MAC address on the RADIUS server, then enable dynamic VLAN assignment on multi-device port authentication-enabled interfaces.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel-Type</td>
<td>064</td>
<td>13 (decimal) – VLAN</td>
</tr>
<tr>
<td>Tunnel-Medium-Type</td>
<td>065</td>
<td>6 (decimal) – 802</td>
</tr>
<tr>
<td>Tunnel-Private-Group-ID</td>
<td>081</td>
<td><code>&lt;vlan-name&gt;</code> (string)</td>
</tr>
</tbody>
</table>

The `<vlan-name>` value can specify either the name or the number of one or more VLANs configured on the Brocade device.

For information about the attributes, refer to “Dynamic multiple VLAN assignment for 802.1X ports” on page 1524.

Also, refer to the example configuration of “Multi-device port authentication with dynamic VLAN assignment” on page 1600.

Enabling dynamic VLAN support for tagged packets on non-member VLAN ports

Platform Support:

• FastIron X Series devices running software release FSX 04.2.00 and later – L2, BL3, L3

In releases prior to FSX 04.2.00, the Brocade device drops tagged packets that are received on non-member VLAN ports. This process is called ingress filtering. Since the MAC address of the packets are not learned, authentication does not take place.

Starting in software release FSX 04.2.00, the Brocade device can authenticate clients that send tagged packets on non-member VLAN ports. This enables the Brocade device to add the VLAN dynamically. To enable support, enter the following command at the Interface level of the CLI.

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication disable-ingress-filtering
```
If the client MAC address is successfully authenticated and the correct VLAN attribute is sent by the RADIUS server, the MAC address will be successfully authenticated on the VLAN.

Syntax: `mac-authentication disable-ingress-filtering`

**Configuration notes and limitations:**

- This feature works in conjunction with multi-device port authentication with dynamic VLAN assignment only. If this feature is not enabled, authentication works as in pre-release FSX 04.2.00. Refer to the configuration examples in “Multi-device port authentication with dynamic VLAN assignment” on page 1600.

- The port on which ingress filtering is disabled must be tagged to a VLAN.

- If a host sends both tagged and untagged traffic, and ingress filtering is disabled on the port, the port must be configured as a dual-mode port.

**Specifying to which VLAN a port is moved after its RADIUS-specified VLAN assignment expires**

When a port is dynamically assigned to a VLAN through the authentication of a MAC address, and the MAC session for that address is deleted on the Brocade device, then by default the port is removed from its RADIUS-assigned VLAN and placed back in the VLAN where it was originally assigned.

A port can be removed from its RADIUS-assigned VLAN when any of the following occur:

- The link goes down for the port
- The MAC session is manually deleted with the `mac-authentication clear-mac-session` command
- The MAC address that caused the port to be dynamically assigned to a VLAN ages out

For example, say port 1/1 is currently in VLAN 100, to which it was assigned when MAC address 0007.eaa1.e90f was authenticated by a RADIUS server. The port was originally configured to be in VLAN 111. If the MAC session for address 0007.eaa1.e90f is deleted, then port 1/1 is moved from VLAN 100 back into VLAN 111.

You can optionally specify an alternate VLAN to which to move the port when the MAC session for the address is deleted. For example, to place the port in the restricted VLAN, enter commands such as the following.

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-auth move-back-to-old-vlan port-restrict-vlan
```

Syntax: `[no] mac-authentication move-back-to-old-vlan disable | port-configured-vlan | system-default-vlan`

The `disable` keyword disables moving the port back to its original VLAN. The port would stay in its RADIUS-assigned VLAN.

The `port-configured-vlan` keyword removes the port from its RADIUS-assigned VLAN and places it back in the VLAN where it was originally assigned. This is the default.

The `port-restrict-vlan` keyword removes the port from its RADIUS-assigned VLAN and places it in the restricted VLAN.

The `system-default-vlan` keyword removes the port from its RADIUS-assigned VLAN and places it in the DEFAULT-VLAN.
NOTE
When a MAC session is deleted, if the port is moved back to a VLAN that is different than the running-config file, the system will update the running-config file to reflect the changes. This will occur even if `mac-authentication save-dynamicvlan-to-config` is not configured.

Automatic removal of dynamic VLAN assignments for MAC authenticated ports

Platform Support:

- FastIron X Series devices running software release 04.1.00 and later

By default, the Brocade device removes any association between a port and a dynamically-assigned VLAN when all authenticated MAC sessions for that tagged or untagged VLAN have expired on the port. Thus, RADIUS-specified VLAN assignments are not saved to the device running-config file. When the `show run` command is issued during a session, dynamically-assigned VLANs are not displayed, although they can be displayed with the `show vlan`, `show auth-mac-addresses detail`, and `show auth-mac-addresses authorized-mac` commands.

You can optionally configure the Brocade device to save the RADIUS-specified VLAN assignments to the device's running-config file. Refer to “Saving dynamic VLAN assignments to the running-config file”, next.

Saving dynamic VLAN assignments to the running-config file

By default, dynamic VLAN assignments are not saved to the running-config file of the Brocade device. However, you can configure the device to do so by entering the following command.

```
FastIron(config)# mac-authentication save-dynamicvlan-to-config
```

When the above command is applied, dynamic VLAN assignments are saved to the running-config file and are displayed when the `show run` command is issued. Dynamic VLAN assignments can also be displayed with the `show vlan`, `show auth-mac-addresses detail`, and `show auth-mac-addresses authorized-mac` commands.

Syntax: `[no] mac-authentication save-dynamicvlan-to-config`

Dynamically applying IP ACLs to authenticated MAC addresses

The Brocade multi-device port authentication implementation supports the assignment of a MAC address to a specific ACL, based on the MAC address learned on the interface.

When a MAC address is successfully authenticated, the RADIUS server sends the Brocade device a RADIUS Access-Accept message that allows the Brocade device to forward traffic from that MAC address. The RADIUS Access-Accept message can also contain, among other attributes, the Filter-ID (type 11) attribute for the MAC address. When the Access-Accept message containing the Filter-ID (type 11) attribute is received by the Brocade device, it will use the information in these attributes to apply an IP ACL on a per-MAC (per user) basis.

The dynamic IP ACL is active as long as the client is connected to the network. When the client disconnects from the network, the IP ACL is no longer applied to the port. If an IP ACL had been applied to the port prior to multi-device port authentication; it will be re-applied to the port.
The Brocade device uses information in the Filter ID to apply an IP ACL on a per-user basis. The Filter-ID attribute can specify the number of an existing IP ACL configured on the Brocade device. If the Filter-ID is an ACL number, the specified IP ACL is applied on a per-user basis.

**Enhancements to multi-device port authentication with dynamic IP ACLs**

**Platform Support:**
- FastIron X Series devices running software release 04.2.00 and later – BL3, L3

The following enhancements were introduced in software release FSX 04.2.00:
- Multi-device port authentication and dynamic ACLs are supported together with ACL-per-port-per-vlan (ACL filtering based on VLAN membership or VE port membership).
  - Releases prior to FSX 04.2.00 do not support multi-device port authentication together with dynamic ACLs when enable ACL-per-port-per-vlan is in effect.
- Multi-device port authentication and dynamic ACLs are supported on tagged, dual-mode, and untagged ports, with or without virtual Interfaces.

There are no new CLI commands associated with this feature. Support is automatically enabled when all of the required conditions are met.

The following describes the conditions and feature limitations:
- Dynamic IP ACLs are allowed on physical ports when ACL-per-port-per-vlan is enabled.
- Dynamic IP ACLs are allowed on tagged and dual-mode ports when ACL-per-port-per-vlan is enabled. If ACL-per-port-per-vlan is not enabled, dynamic IP ACLs are not allowed on tagged or dual-mode ports.
- Dynamic IP ACLs can be added to tagged/untagged ports in a VLAN with or without a VE, as long as the tagged/untagged ports do not have configured ACLs assigned to them. The following shows some example scenarios where dynamic IP ACLs would not apply:
  - A port is a tagged/untagged member of VLAN 20, VLAN 20 includes VE 20, and an ACL is bound to VE 20.
  - A port is a tagged/untagged member of VLAN 20, VLAN 20 includes VE 20, and a per-port-per-vlan ACL is bound to VE 20 and to a subset of ports in VE 20

In the above scenarios, dynamic IP ACL assignment would not apply in either instance, because a configured ACL is bound to VE 20 on the port. Consequently, the MAC session would fail.

**Configuration considerations and guidelines**
- Software release FSX 04.2.00 introduced enhancements to multi-device port authentication with dynamic ACLs and ACL-per-port-per-vlan. Refer to “Enhancements to multi-device port authentication with dynamic IP ACLs” on page 1583.
- Starting in software release FSX 04.2.00, Dynamic ARP inspection (DAI) and DHCP Snooping are supported together with dynamic ACLs. Releases prior to FSX 04.2.00 do not allow DAI or DHCP snooping in tandem with dynamic ACLs.
- Dynamic IP ACLs with multi-device port authentication are supported. Dynamic MAC filters with multi-device port authentication are not supported.
- In the Layer 2 switch code, dynamic IP ACLs are not supported when ACL-per-port-per-vlan is enabled on a global-basis.
• The RADIUS Filter ID (type 11) attribute is supported. The Vendor-Specific (type 26) attribute is not supported.
• The dynamic ACL must be an extended ACL. Standard ACLs are not supported.
• Multi-device port authentication and 802.1x can be used together on the same port. However, Brocade does not recommend the use of multi-device port authentication and 802.1x with dynamic ACLs together on the same port. If a single supplicant requires both 802.1x and multi-device port authentication, and if both 802.1x and multi-device port authentication try to install different dynamic ACLs for the same supplicant, the supplicant will fail authentication.
• Dynamically assigned IP ACLs are subject to the same configuration restrictions as non-dynamically assigned IP ACLs. One caveat is that ports with VE interfaces cannot have assigned user-defined ACLs. For example, a user-defined ACL bound to a VE or a port on a VE is not allowed. There are no restrictions on ports that do not have VE interfaces.
• Dynamic ACL filters are supported only for the inbound direction. Dynamic outbound ACL filters are not supported.
• Dynamic ACL assignment with multi-device port authentication is not supported in conjunction with any of the following features:
  • IP source guard
  • Rate limiting
  • Protection against ICMP or TCP Denial-of-Service (DoS) attacks
  • Policy-based routing
  • 802.1X dynamic filter
• On TurboIron X Series devices running software release 04.2.00 and later, the dynamic ACLs are not supported on ports that have 802.1x and MAC authentication enabled along with the auth-fail-dot1x-override option enabled.
• On TurboIron devices, MAC authentication and 802.1X authentication can be configured on the same port. When both of these features are enabled on the same port, MAC authentication is performed prior to 802.1X authentication. If MAC authentication is successful, 802.1X authentication may be performed. If 802.1X authentication is successful, dynamic VLAN and ACL filters for 802.1X are applied.
• TurboIron devices authenticate devices attached to VLAN ports. The MAC address is used as the username and password for port authentication. The 802.1X authentication uses the username and password for port authentication.

**Configuring the RADIUS server to support dynamic IP ACLs**

When a port is authenticated using multi-device port authentication, an IP ACL filter that exists in the running-config file on the Brocade device can be dynamically applied to the port. To do this, you configure the Filter-ID (type 11) attribute on the RADIUS server. The Filter-ID attribute specifies the name or number of the Brocade IP ACL.

The following is the syntax for configuring the Filter-ID attribute on the RADIUS server to refer to a Brocade IP ACL.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip.&lt;number&gt;.in&lt;1&gt;</td>
<td>Applies the specified numbered ACL to the authenticated port in the inbound direction.</td>
</tr>
<tr>
<td>ip.&lt;name&gt;.in&lt;1,2&gt;</td>
<td>Applies the specified named ACL to the authenticated port in the inbound direction.</td>
</tr>
</tbody>
</table>

1. The ACL must be an extended ACL. Standard ACLs are not supported.
2. The `<name>` in the Filter ID attribute is case-sensitive

The following table lists examples of values you can assign to the Filter-ID attribute on the RADIUS server to refer to IP ACLs configured on a Brocade device.

<table>
<thead>
<tr>
<th>Possible values for the filter ID attribute on the RADIUS server</th>
<th>ACLs configured on the Brocade device</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip.102.in</td>
<td>access-list 102 permit ip 36.0.0.0 0.255.255.255 any</td>
</tr>
</tbody>
</table>
| ip.fdry_filter.in                                            | ip access-list standard fdry_filter  
|                                                             | permit host 36.48.0.3 |

Enabling denial of service attack protection

**NOTE**

FCX devices do not support multi-device authentication denial of service (DoS) attack prevention.

The Brocade device does not start forwarding traffic from an authenticated MAC address in hardware until the RADIUS server authenticates the MAC address; traffic from the non-authenticated MAC addresses is sent to the CPU. A denial of service (DoS) attack could be launched against the device where a high volume of new source MAC addresses is sent to the device, causing the CPU to be overwhelmed with performing RADIUS authentication for these MAC addresses. In addition, the high CPU usage in such an attack could prevent the RADIUS response from reaching the CPU in time, causing the device to make additional authentication attempts.

To limit the susceptibility of the Brocade device to such attacks, you can configure the device to use multiple RADIUS servers, which can share the load when there are a large number of MAC addresses that need to be authenticated. The Brocade device can run a maximum of 10 RADIUS clients per server and will attempt to authenticate with a new RADIUS server if current one times out.

In addition, you can configure the Brocade device to limit the rate of authentication attempts sent to the RADIUS server. When the multi-device port authentication feature is enabled, it keeps track of the number of RADIUS authentication attempts made per second. When you also enable the DoS protection feature, if the number of RADIUS authentication attempts for MAC addresses learned on an interface per second exceeds a configurable rate (by default 512 authentication attempts per second), the device considers this a possible DoS attack and disables the port. You must then manually re-enable the port.

The DoS protection feature is disabled by default. To enable it on an interface, enter commands such as the following.

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication dos-protection enable
```

To specify a maximum rate for RADIUS authentication attempts, enter commands such as the following.

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication dos-protection mac-limit 256
```

**Syntax:** `[no] mac-authentication dos-protection mac-limit <number>`

You can specify a rate from 1 – 65535 authentication attempts per second. The default is a rate of 512 authentication attempts per second.
Enabling source guard protection

Platform Support:
- FastIron X Series devices running software release FSX 04.2.00 and later – BL3, L3
- FCX-S devices running software release 06.0.00 and later

Source Guard Protection is a form of IP Source Guard used in conjunction with multi-device port authentication. When Source Guard Protection is enabled, IP traffic is blocked until the system learns the IP address. Once the IP address is validated, traffic with that source address is permitted.

NOTE
Source Guard Protection is supported together with multi-device port authentication as long as ACL-per-port-per-vlan is enabled.

When a new MAC session begins on a port that has Source Guard Protection enabled, the session will either apply a dynamically created Source Guard ACL entry, or it will use the dynamic IP ACL assigned by the RADIUS server. If a dynamic IP ACL is not assigned, the session will use the Source Guard ACL entry. The Source Guard ACL entry is permit ip <secure-ip> any, where <secure-ip> is obtained from the ARP Inspection table or from the DHCP Secure table. The DHCP Secure table is comprised of DHCP Snooping and Static ARP Inspection entries.

The Source Guard ACL permit entry is added to the hardware table after all of the following events occur:
- The MAC address is authenticated
- The IP address is learned
- The MAC-to-IP mapping is checked against the Static ARP Inspection table or the DHCP Secure table.

The Source Guard ACL permit entry is not written to the running configuration file. However, you can view the configuration using the show auth-mac-addresses authorized-mac ip-addr. Refer to “Viewing the assigned ACL for ports on which source guard protection is enabled” in the following section.

NOTE
The secure MAC-to-IP mapping is assigned at the time of authentication and remains in effect as long as the MAC session is active. If the DHCP Secure table is updated after the session is authenticated and while the session is still active, it does not affect the existing MAC session.

The Source Guard ACL permit entry is removed when the MAC session expires or is cleared.

To enable Source Guard Protection on a port on which multi-device port authentication is enabled, enter the following command at the Interface level of the CLI.

```
FastIron(config)int e 1/4
FastIron(config-if-e1000-1/4)mac-authentication source-guard-protection enable
```

Syntax: [no] mac-authentication source-guard-protection enable

Enter the no form of the command to disable SG protection.

Viewing the assigned ACL for ports on which source guard protection is enabled

Use the following command to view whether a Source Guard ACL or dynamic ACL is applied to ports on which Source Guard Protection is enabled.
Configuring multi-device port authentication

In the above output, for port 6/12, Source Guard Protection is enabled and the Source Guard ACL is applied to the MAC session, as indicated by **SG** in the **ACL** column. For port 6/13, Source Guard Protection is also enabled, but in this instance, a dynamic ACL (103) is applied to the MAC session.

### Clearing authenticated MAC addresses

The Brocade device maintains an internal table of the authenticated MAC addresses (viewable with the `show authenticated-mac-address` command). You can clear the contents of the authenticated MAC address table either entirely, or just for the entries learned on a specified interface. In addition, you can clear the MAC session for an address learned on a specific interface.

To clear the entire contents of the authenticated MAC address table, enter the following command.

```
FastIron# clear auth-mac-table
```

**Syntax:** `clear auth-mac-table`

To clear the authenticated MAC address table of entries learned on a specified interface, enter a command such as the following.

```
FastIron# clear auth-mac-table e 3/1
```

**Syntax:** `clear auth-mac-table [(<slotnum>)/]<portnum>`

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

To clear the MAC session for an address learned on a specific interface, enter commands such as the following.

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication clear-mac-session 00e0.1234.abd4
```

**Syntax:** `mac-authentication clear-mac-session <mac-address>`

This command removes the Layer 2 CAM entry created for the specified MAC address. If the Brocade device receives traffic from the MAC address again, the MAC address is authenticated again.

### Disabling aging for authenticated MAC addresses

MAC addresses that have been authenticated or denied by a RADIUS server are aged out if no traffic is received from the MAC address for a certain period of time:

- Authenticated MAC addresses or non-authenticated MAC addresses that have been placed in the restricted VLAN are aged out if no traffic is received from the MAC address over the device normal MAC aging interval.
• Non-authenticated MAC addresses that are blocked by the device are aged out if no traffic is received from the address over a fixed hardware aging period (70 seconds), plus a configurable software aging period. (Refer to the next section for more information on configuring the software aging period).

You can optionally disable aging for MAC addresses subject to authentication, either for all MAC addresses or for those learned on a specified interface.

**Globally disabling aging of MAC addresses**

On most devices, you can disable aging for all MAC addresses on all interfaces where multi-device port authentication has been enabled by entering the following command.

```
FastIron(config)# mac-authentication disable-aging
```

**Syntax:** `mac-authentication disable-aging`

Enter the command at the global or interface configuration level.

The `denied-only` parameter prevents denied sessions from being aged out, but ages out permitted sessions.

The `permitted-only` parameter prevents permitted (authenticated and restricted) sessions from being aged out and ages denied sessions.

**Disabling the aging of MAC addresses on interfaces**

To disable aging for all MAC addresses subject to authentication on a specific interface where multi-device port authentication has been enabled, enter the command at the interface level.

**Example**

```
FastIron(config)# interface e 3/1
FastIron(config-if-e1000-3/1)# mac-authentication disable-aging
```

**Syntax:** `[no] mac-authentication disable-aging`

**Changing the hardware aging period for blocked MAC addresses**

The feature was added in release 02.2.00 for the FESX and FWSX, and release 02.3.01 for the FSX.

When the Brocade device is configured to drop traffic from non-authenticated MAC addresses, traffic from the blocked MAC addresses is dropped in hardware, without being sent to the CPU. A Layer 2 hardware entry is created that drops traffic from the MAC address in hardware. If no traffic is received from the MAC address for a certain amount of time, this Layer 2 hardware entry is aged out. If traffic is subsequently received from the MAC address, then an attempt can be made to authenticate the MAC address again.

Aging of the Layer 2 hardware entry for a blocked MAC address occurs in two phases, known as hardware aging and software aging.
On FastIron devices, the hardware aging period for blocked MAC addresses is fixed at 70 seconds and is non-configurable. (The hardware aging time for non-blocked MAC addresses is the length of time specified with the \texttt{mac-age} command.) The software aging period for blocked MAC addresses is configurable through the CLI, with the \texttt{mac-authentication max-age} command. Once the hardware aging period ends, the software aging period begins. When the software aging period ends, the blocked MAC address ages out, and can be authenticated again if the Brocade device receives traffic from the MAC address.

On FastIron X Series devices, the hardware aging period for blocked MAC addresses is not fixed at 70 seconds. The hardware aging period for blocked MAC addresses is equal to the length of time specified with the \texttt{mac-age} command. As on FastIron devices, once the hardware aging period ends, the software aging period begins. When the software aging period ends, the blocked MAC address ages out, and can be authenticated again if the device receives traffic from the MAC address.

To change the hardware aging period for blocked MAC addresses, enter a command such as the following.

\texttt{FastIron(config)# mac-authentication hw-deny-age 10}

\textbf{Syntax:} \texttt{[no] mac-authentication hw-deny-age <num>}

The \texttt{<num>} parameter is a value from 1 to 65535 seconds. The default is 70 seconds.

### Specifying the aging time for blocked MAC addresses

When the Brocade device is configured to drop traffic from non-authenticated MAC addresses, traffic from the blocked MAC addresses is dropped in hardware, without being sent to the CPU. A Layer 2 CAM entry is created that drops traffic from the blocked MAC address in hardware. If no traffic is received from the blocked MAC address for a certain amount of time, this Layer 2 CAM entry is aged out. If traffic is subsequently received from the MAC address, then an attempt can be made to authenticate the MAC address again.

Aging of the Layer 2 CAM entry for a blocked MAC address occurs in two phases, known as \textit{hardware aging} and \textit{software aging}. The hardware aging period is fixed at 70 seconds and is non-configurable. The software aging time is configurable through the CLI.

Once the Brocade device stops receiving traffic from a blocked MAC address, the hardware aging begins and lasts for a fixed period of time. After the hardware aging period ends, the software aging period begins. The software aging period lasts for a configurable amount of time (by default 120 seconds). After the software aging period ends, the blocked MAC address ages out, and can be authenticated again if the Brocade device receives traffic from the MAC address.

To change the length of the software aging period for blocked MAC addresses, enter a command such as the following.

\texttt{FastIron(config)# mac-authentication max-age 180}

\textbf{Syntax:} \texttt{[no] mac-authentication max-age <seconds>}

You can specify from 1 – 65535 seconds. The default is 120 seconds.
Specifying the RADIUS timeout action

A RADIUS timeout occurs when the Brocade device does not receive a response from a RADIUS server within a specified time limit and after a certain number of retries. The time limit and number of retries can be manually configured using the CLI commands `radius-server timeout` and `radius-server retransmit`, respectively. If the parameters are not manually configured, the Brocade device applies the default value of three seconds with a maximum of three retries.

In releases prior to FSX software release 03.2.00 and FGS software release 04.1.00, when a RADIUS timeout occurs, the Brocade device will automatically reset the authentication process then retry to authenticate the user.

With FSX software release 03.2.00, and FGS software release 04.1.00, and later, you can better control port behavior when a RADIUS timeout occurs by configuring a port on the Brocade device to automatically pass or fail user authentication. A `pass` essentially bypasses the authentication process and permits user access to the network. A `fail` bypasses the authentication process and blocks user access to the network, unless `restrict-vlan` is configured, in which case, the user is placed into a VLAN with restricted or limited access. By default, the Brocade device will reset the authentication process and retry to authenticate the user.

Specify the RADIUS timeout action at the Interface level of the CLI.

**Permit User access to the network after a RADIUS timeout**

To set the RADIUS timeout behavior to bypass multi-device port authentication and permit user access to the network, enter commands such as the following.

```
FastIron(config)# interface ethernet 1/3
FastIron(config-if-e100-1/3)# mac-authentication auth-timeout-action success
```

**Syntax:**

`[no] mac-authentication auth-timeout-action success`

Once the `success` timeout action is enabled, use the `no` form of the command to reset the RADIUS timeout behavior to `retry`.

**Deny User access to the network after a RADIUS timeout**

To set the RADIUS timeout behavior to bypass multi-device port authentication and block user access to the network, enter commands such as the following.

```
FastIron(config)# interface ethernet 1/3
FastIron(config-if-e100-1/3)# mac-authentication auth-timeout-action failure
```

**Syntax:**

`[no] mac-authentication auth-timeout-action failure`

Once the failure timeout action is enabled, use the `no` form of the command to reset the RADIUS timeout behavior to `retry`.

**NOTE**

If `restrict-vlan` is configured along with `auth-timeout-action failure`, the user will be placed into a VLAN with restricted or limited access. Refer to “Allow user access to a restricted VLAN after a RADIUS timeout” on page 1591.
**Allow user access to a restricted VLAN after a RADIUS timeout**

To set the RADIUS timeout behavior to bypass multi-device port authentication and place the user in a VLAN with restricted or limited access, enter commands such as the following.

```
FastIron(config)# interface ethernet 1/3
FastIron(config-if-e100-1/3)# mac-authentication auth-fail-action restrict-vlan 100
FastIron(config-if-e100-1/3)# mac-authentication auth-timeout-action failure
```

**Syntax:** `[no] mac-authentication auth-fail-action restrict-vlan [vlan-id]`

**Syntax:** `[no] mac-authentication auth-timeout-action failure`

**Multi-device port authentication password override**

The multi-device port authentication feature communicates with the RADIUS server to authenticate a newly found MAC address. The RADIUS server is configured with the usernames and passwords of authenticated users. For multi-device port authentication, the username and password is the MAC address itself; that is, the device uses the MAC address for both the username and the password in the request sent to the RADIUS server. For example, given a MAC address of 0007e90feaa1, the users file on the RADIUS server would be configured with a username and password both set to 0007e90feaa1. When traffic from this MAC address is encountered on a MAC-authentication-enabled interface, the device sends the RADIUS server an Access-Request message with 0007e90feaa1 as both the username and password.

In FSX software releases prior to 03.2.00, the MAC address is always used as the username and password for multi-device port authentication. The username and password cannot be changed.

Starting in release 03.2.00, the MAC address becomes the default password for multi-device port authentication, and you can optionally configure the device to use a different password. Note that the MAC address is still the username and cannot be changed.

To change the password for multi-device port authentication, enter a command such as the following at the GLOBAL Config Level of the CLI.

```
FastIron(config)# mac-authentication password-override
```

**Syntax:** `[no] mac-authentication password-override <password>`

where `<password>` can have up to 32 alphanumeric characters, but cannot include blank spaces.

**Limiting the number of authenticated MAC addresses**

You cannot enable MAC port security on the same port that has multi-device port authentication enabled. To simulate the function of MAC port security, you can enter a command such as the following.

```
FastIron(config-if-e1000-2)# mac-authentication max-accepted-session 5
```

**Syntax:** `[no] mac-authentication max-accepted-session <session-number>`

This command limits the number of successfully authenticated MAC addresses. Enter a value from 1 - 250 for `session-number`. 
Displaying multi-device port authentication information

You can display the following information about the multi-device port authentication configuration:

- Information about authenticated MAC addresses
- Information about the multi-device port authentication configuration
- Authentication Information for a specific MAC address or port
- Multi-device port authentication settings and authenticated MAC addresses for each port where the multi-device port authentication feature is enabled
- The MAC addresses that have been successfully authenticated
- The MAC addresses for which authentication was not successful

Displaying authenticated MAC address information

To display information about authenticated MAC addresses on the ports where the multi-device port authentication feature is enabled, enter the following command.

```
FastIron# show auth-mac-address
```

The following table describes the information displayed by the `show auth-mac-address` command.

<table>
<thead>
<tr>
<th>Port</th>
<th>Vlan</th>
<th>Accepted MACs</th>
<th>Rejected MACs</th>
<th>Attempted-MACs</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/18</td>
<td>100</td>
<td>1</td>
<td>100</td>
<td>0</td>
</tr>
<tr>
<td>1/20</td>
<td>40</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1/22</td>
<td>100</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4/5</td>
<td>30</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Syntax: show auth-mac-address

```
Syntax: show auth-mac-address
```

The following table describes the information displayed by the `show auth-mac-address` command.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The port number where the multi-device port authentication feature is enabled.</td>
</tr>
<tr>
<td>Vlan</td>
<td>The VLAN to which the port has been assigned.</td>
</tr>
<tr>
<td>Accepted MACs</td>
<td>The number of MAC addresses that have been successfully authenticated</td>
</tr>

<td>Rejected MACs</td>
<td>The number of MAC addresses for which authentication has failed.</td>
</tr>
<tr>
<td>Attempted-MACs</td>
<td>The rate at which authentication attempts are made for MAC addresses.</td>
</tr>
</tbody>
</table>

Displaying multi-device port authentication configuration information

To display information about the multi-device port authentication configuration, enter the following command.
Displaying multi-device port authentication information

For a specific MAC address or port

To display authentication information for a specific MAC address or port, enter a command such as the following.

```
FastIron# show auth-mac-address 0007.e90f.eaa1
```

<table>
<thead>
<tr>
<th>MAC/IP Address</th>
<th>Port</th>
<th>Vlan</th>
<th>Authenticated Time</th>
<th>Age</th>
<th>CAM Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>0007.e90f.eaa1</td>
<td>25.25.25.25</td>
<td>1/18</td>
<td>100</td>
<td>Yes</td>
<td>00d01h10m06s 0</td>
</tr>
</tbody>
</table>

**Syntax:** `show auth-mac-address <mac-address> | <ip-addr> | [<slotnum>/]<portnum>`

The `<ip-addr>` parameter lists the MAC address associated with the specified IP address.

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The following table describes the information displayed by the `show authenticated-mac-address` command for a specified MAC address or port.
Displaying multi-device port authentication information

### TABLE 259  Output from the `show authenticated-mac-address <address> command`

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAC/IP Address</td>
<td>The MAC address for which information is displayed. If the packet for which multi-device port authentication was performed also contained an IP address, then the IP address is displayed as well.</td>
</tr>
<tr>
<td>Port</td>
<td>The port on which the MAC address was learned.</td>

<tr>
<td>Vlan</td>
<td>The VLAN to which the MAC address was assigned.</td>
</tr>
<tr>
<td>Authenticated</td>
<td>Whether the MAC address was authenticated.</td>
</tr>
<tr>
<td>Time</td>
<td>The time at which the MAC address was authenticated. If the clock is set on the Brocade device, then the actual date and time are displayed. If the clock has not been set, then the time is displayed relative to when the device was last restarted.</td>
</tr>
<tr>
<td>Age</td>
<td>The age of the MAC address entry in the authenticated MAC address list.</td>
</tr>
<tr>
<td>CAM Index</td>
<td>If the MAC address is blocked, this is the index entry for the Layer 2 CAM entry created for this MAC address. If the MAC address is not blocked, either through successful authentication or through being placed in the restricted VLAN, then &quot;N/A&quot; is displayed. If the hardware aging period has expired, then &quot;ffff&quot; is displayed for the MAC address during the software aging period.</td>
</tr>
</tbody>
</table>

### Displaying the authenticated MAC addresses

To display the MAC addresses that have been successfully authenticated, enter the `show auth-mac-addresses authorized-mac` command.

The following example output is from a FastIron X Series device running software release 04.1.00. The display output on your device may differ, depending on the software version running on the device.

```
FastIron# show auth-mac-addresses authorized-mac
   +-------------------+---------+--------+---------------+-----------+------------+-----------+
   | MAC Address        | Port    | Vlan   | Authenticated | Time      | Age        | dot1x     |
   +-------------------+---------+--------+---------------+-----------+------------+-----------+
   | 0030.4874.3181     | 15/23   | 101    | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.0001     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.012d     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.0065     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.0191     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.01f5     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   +-------------------+---------+--------+---------------+-----------+------------+-----------+
```

Syntax: `show auth-mac-addresses authorized-mac`

### Displaying the non-authenticated MAC addresses

To display the MAC addresses for which authentication was not successful, enter the following command:

```
FastIron# show auth-mac-addresses non-authorized-mac
   +-------------------+---------+--------+---------------+-----------+------------+-----------+
   | MAC Address        | Port    | Vlan   | Authenticated | Time      | Age        | dot1x     |
   +-------------------+---------+--------+---------------+-----------+------------+-----------+
   | 0030.4874.3181     | 15/23   | 101    | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.0001     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.012d     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.0065     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.0191     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   | 000f.ed00.01f5     | 18/1    | 87     | Yes           | 00d01h03m17s | Ena        | Ena       |
   +-------------------+---------+--------+---------------+-----------+------------+-----------+
```

Syntax: `show auth-mac-addresses non-authorized-mac`
Displaying multi-device port authentication information for a port

To display a summary of Multi-Device Port Authentication for ports on a device, enter the following command:

```
FastIron# show auth-mac-addresses ethernet 18/1

Displaying multi-device port authentication settings and authenticated MAC addresses

To display the multi-device port authentication settings and authenticated MAC addresses for a port where the feature is enabled, enter the following command.

**Syntax:** show auth-mac-address [detail] [ethernet [<slotnum>/]<portnum>]

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

Omitting the `<portnum>` parameter displays information for all interfaces where the multi-device port authentication feature is enabled.

FastIron# show auth-mac-addresses detailed ethernet 15/23

Displaying multi-device port authentication information

For FCX devices, there are three commands you can use to display MAC authentication information:

- `show table <mac address>`
- `show table allowed-mac`
- `show table denied-mac`

This section describes the output for these commands.

To display MAC authentication information for FCX devices, enter the `show table <mac address>` command as shown:

```
FCX648 Switch# show table 0000.0010.1002
Syntax: show table <mac address>
<mac address> - the specified mac address
```

Output from this command resembles the following:
Displaying multi-device port authentication information

FCX648S Switch# show table 0000.0010.1002

MAC Address Port Vlan Authenticated Time Age dot1x
0000.0010.1002 2/1/48 2 Yes 00d00h30m57s Ena Dis

FCX648S Switch#

To display the table of allowed (authenticated) mac addresses enter the show table allowed-mac command as shown.

Syntax: show table allowed-mac

Output from this command resembles the following:

```
FCX648S Switch# show table allowed-mac

MAC Address Port Vlan Authenticated Time Age dot1x
0000.0010.100a 1/1/1 2 Yes 00d00h30m57s Ena Dis
0000.0010.100b 1/1/1 2 Yes 00d00h31m00s Ena Dis
0000.0010.1002 2/1/48 2 Yes 00d00h30m57s Ena Dis
0000.0010.1003 2/1/48 2 Yes 00d00h30m57s Ena Dis
0000.0010.1004 2/1/48 2 Yes 00d00h30m57s Ena Dis

FCX648S Switch#
```

To display the table of allowed mac addresses enter the show table denied-mac command as shown.

Syntax: show table <mac address>

<mac address> - the specified mac adderss

Output from this command resembles the following:

```
FCX648S Switch# show table denied-mac

MAC Address Port Vlan Authenticated Time Age dot1x
0000.0010.1021 2/1/48 4092 No 00d00h32m48s H8 Dis
0000.0010.1022 2/1/48 4092 No 00d00h32m48s H8 Dis

FCX648S Switch#
```

To display MAC authentication for a specific port, enter the show table ethernet <stack-unit/slot/port> command as shown.

```
FCX648S Switch# show table eth 2/1/48

MAC Address Port Vlan Authenticated Time Age CAM MAC Dot1x Type Pri Index Index

```
Example configurations

This section includes configuration examples of multi-device port authentication with dynamic VLAN assignment, and multi-device port authentication and 802.1X authentication.

Multi-device port authentication with dynamic VLAN assignment

Depending on the software version running on the Brocade device, support for multi-device port authentication with dynamic VLAN assignment may have certain limitations. Refer to the appropriate section below, according to the software version running on your device.

Example 1 – Software releases FSX 04.2.00 and later

Figure 172 illustrates multi-device port authentication with dynamic VLAN assignment on a Brocade device running software release FSX 04.2.00. In this configuration, a PC and an IP phone are connected to a hub, which is connected to port e1 on a Brocade device. The profile for the PC MAC address on the RADIUS server specifies that the PC should be dynamically assigned to VLAN 102, and the RADIUS profile for the IP phone specifies that it should be dynamically assigned to VLAN 3.

In this example, multi-device port authentication is performed for both devices. If the PC is successfully authenticated, port e1 PVID is changed from VLAN 1 (the DEFAULT-VLAN) to VLAN 102. If authentication for the PC fails, then the PC can be placed in a specified “restricted” VLAN, or traffic from the PC can be blocked in hardware. In this example, if authentication for the PC fails, the PC would be placed in VLAN 1023, the restricted VLAN.
If authentication for the IP phone is successful, then port e1 is added to VLAN 3. If authentication for the IP phone fails, then traffic from the IP phone would be blocked in hardware. (Devices sending tagged traffic cannot be placed in the restricted VLAN.)

The part of the running-config related to multi-device port authentication would be as follows.

```plaintext
mac-authentication enable
mac-authentication auth-fail-vlan-id 1023

interface ethernet 1
dual-mode
mac-authentication enable
mac-authentication auth-fail-action restrict-vlan
mac-authentication enable-dynamic-vlan
mac-authentication disable-ingress-filtering
```

The `mac-authentication disable-ingress-filtering` configuration is new in software release FSX 04.2.00. This command enables tagged packets on the port, even if the port is not a member of the VLAN. If this feature is not enabled, authentication works as in pre-release FSX 04.2.00. Refer to the configuration example in "Example 2 – Software releases prior to FSX 04.2.00" on page 1601.

**Example 2 – Software releases prior to FSX 04.2.00**

**Figure 172** illustrates multi-device port authentication with dynamic VLAN assignment on a Brocade device running a release prior to FSX 04.2.00. In this configuration, a PC and an IP phone are connected to a hub, which is connected to port e1 on a Brocade device. Port e1 is configured as a dual-mode port. The profile for the PC MAC address on the RADIUS server specifies that the PC should be dynamically assigned to VLAN 102, and the RADIUS profile for the IP phone specifies that it should be dynamically assigned to VLAN 3.

**FIGURE 172** Using multi-device port authentication with dynamic VLAN assignment
In this example, multi-device port authentication is performed for both devices. If the PC is successfully authenticated, dual-mode port e1 PVID is changed from the VLAN 1 (the DEFAULT-VLAN) to VLAN 102. If authentication for the PC fails, then the PC can be placed in a specified “restricted” VLAN, or traffic from the PC can be blocked in hardware. In this example, if authentication for the PC fails, the PC would be placed in VLAN 1023, the restricted VLAN.

If authentication for the IP phone is successful, then dual-mode port e1 is added to VLAN 3. If authentication for the IP phone fails, then traffic from the IP phone would be blocked in hardware. (Devices sending tagged traffic cannot be placed in the restricted VLAN.)

NOTE
This example assumes that the IP phone initially transmits untagged packets (for example, CDP or DHCP packets), which trigger the authentication process on the Brocade device and client lookup on the RADIUS server. If the phone sends only tagged packets and the port (e1) is not a member of that VLAN, authentication would not occur. In this case, port e1 must be added to that VLAN prior to authentication.

The part of the running-config related to multi-device port authentication would be as follows.

```
mac-authentication enable
mac-authentication auth-fail-vlan-id 1023

interface ethernet 1
  mac-authentication enable
  mac-authentication auth-fail-action restrict-vlan
  mac-authentication enable-dynamic-vlan
dual-mode
```

Examples of multi-device port authentication and 802.1X authentication configuration on the same port

The following examples use multi-device port authentication and 802.1X authentication on the same port.

**Example 1**

Figure 173 illustrates an example configuration that uses multi-device port authentication and 802.1X authentication on the same port. In this configuration, a PC and an IP phone are connected to port e 1/3 on an FSX. Port e 1/3 is configured as a dual-mode port.

The profile for the PC MAC address on the RADIUS server specifies that the PC should be dynamically assigned to VLAN "Login-VLAN", and the profile for the IP phone specifies that it should be dynamically assigned to the VLAN named "IP-Phone-VLAN". When User 1 is successfully authenticated using 802.1X authentication, the PC is then placed in the VLAN named "User-VLAN".

NOTE
This example assumes that the IP phone initially transmits untagged packets (for example, CDP or DHCP packets), which trigger the authentication process on the Brocade device and client lookup on the RADIUS server. If the phone sends only tagged packets and the port (e 1/3) is not a member of that VLAN, authentication would not occur. In this case, port e 1/3 must be added to that VLAN prior to authentication.
When the devices attempt to connect to the network, they are first subject to multi-device port authentication.

When the IP phone MAC address is authenticated, the Access-Accept message from the RADIUS server specifies that the IP phone port be placed into the VLAN named “IP-Phone-VLAN”, which is VLAN 7. The Foundry-802_1x-enable attribute is set to 0, meaning that 802.1X authentication is skipped for this MAC address. Port e1/3 is placed in VLAN 7 as a tagged port. No further authentication is performed.

When the PC MAC address is authenticated, the Access-Accept message from the RADIUS server specifies that the PVID for the PC port be changed to the VLAN named “Login-VLAN”, which is VLAN 1024. The Foundry-802_1x-enable attribute is set to 1, meaning that 802.1X authentication is required for this MAC address. The PVID of the port e1/3 is temporarily changed to VLAN 1024, pending 802.1X authentication.

When User 1 attempts to connect to the network from the PC, he is subject to 802.1X authentication. If User 1 is successfully authenticated, the Access-Accept message from the RADIUS server specifies that the PVID for User 1 port be changed to the VLAN named “User-VLAN”, which is VLAN 3. If 802.1X authentication for User 1 is unsuccessful, the PVID for port e1/3 is changed to that of the restricted VLAN, which is VLAN 1023, or untagged traffic from port e1/3 can be blocked in hardware.

The part of the running-config related to port e1/3 would be as follows.

```
interface ethernet 1/3
  dot1x port-control auto
  mac-authentication enable
dual-mode
```
When the PC is authenticated using multi-device port authentication, the port PVID is changed to “Login-VLAN”, which is VLAN 1024 in this example.

When User 1 is authenticated using 802.1X authentication, the port PVID is changed to “User-VLAN”, which is VLAN 3 in this example.

**Example 2**

The configuration in Figure 174 requires that you create a profile on the RADIUS server for each MAC address to which a device or user can connect to the network. In a large network, this can be difficult to implement and maintain.

As an alternative, you can create MAC address profiles only for those devices that do not support 802.1X authentication, such as IP phones and printers, and configure the device to perform 802.1X authentication for the other devices that do not have MAC address profiles, such as user PCs. To do this, you configure the device to perform 802.1X authentication when a device fails multi-device port authentication.

Figure 174 shows a configuration where multi-device port authentication is performed for an IP phone, and 802.1X authentication is performed for a user PC. There is a profile on the RADIUS server for the IP phone MAC address, but not for the PC MAC address.

**FIGURE 174  802.1X Authentication is performed when a device fails multi-device port authentication**

Multi-device port authentication is initially performed for both devices. The IP phone MAC address has a profile on the RADIUS server. This profile indicates that 802.1X authentication should be skipped for this device, and that the device port be placed into the VLAN named “IP-Phone-VLAN”.
Since there is no profile for the PC MAC address on the RADIUS server, multi-device port authentication for this MAC address fails. Ordinarily, this would mean that the PVID for the port would be changed to that of the restricted VLAN, or traffic from this MAC would be blocked in hardware. However, the device is configured to perform 802.1X authentication when a device fails multi-device port authentication, so when User 1 attempts to connect to the network from the PC, he is subject to 802.1X authentication. If User 1 is successfully authenticated, the PVID for port e 1/4 is changed to the VLAN named “User-VLAN”.

**NOTE**

This example assumes that the IP phone initially transmits untagged packets (for example, CDP or DHCP packets), which trigger the authentication process on the Brocade device and client lookup on the RADIUS server. If the phone sends only tagged packets and the port (e 1/4) is not a member of that VLAN, authentication would not occur. In this case, port e 1/4 must be added to that VLAN prior to authentication.

To configure the device to perform 802.1X authentication when a device fails multi-device port authentication, enter the following command.

```
FastIron(config)# mac-authentication auth-fail-dot1x-override
```

**Syntax:** `[no] mac-authentication auth-fail-dot1x-override`
Chapter 45

Configuring Web Authentication

Overview

**Platform Support:** FastIron X Series devices running software release 05.0.00 and later – L2, BL3, L3

Authentication is important in enterprise networks because the network is considered a secure area: it contains sensitive data and a finite amount of resources. Unauthorized users must be prevented from accessing the network to protect the sensitive data and prevent the unnecessary consumption of resources.

The ideal authentication method blocks unauthorized users at the earliest possible opportunity. For internal enterprise networks, this can be controlled at the edge switch port. Two popular forms of port-based security authentication used at the edge switch are multi-device port authentication and 802.1x. Multi-device port authentication authenticates the MAC addresses of hosts or users that are attempting to access the network. This type of authentication requires no intervention from the host or user who is attempting to be authenticated. It is easy to use, but it can only authorize hosts; it cannot be used to authorize users. 802.1x authentication can authorize users or hosts. It is more flexible than the multi-device port authentication method; however, it requires more support, configuration, maintenance and user intervention than multi-device port authentication.

The Brocade Web authentication method provides an ideal port-based authentication alternative to multi-device port authentication without the complexities and cost of 802.1x authentication. Hosts gain access to the network by opening a Web browser and entering a valid URL address using HTTP or HTTPS services. Instead of being routed to the URL, the host browser is directed to an authentication Web page on the FastIron switch. The Web page prompts the host to enter a user ID and password or a passcode. The credentials a host enters are used by a trusted source to authenticate the host MAC address. (Multiple MAC addresses can be authenticated with the same user name and password.)

If the authentication is unsuccessful, the appropriate page is displayed on the host browser. The host is asked to try again or call for assistance, depending on what message is configured on the Web page. If the host MAC address is authenticated by the trusted source, a Web page is displayed with a hyperlink to the URL the host originally entered. If the user clicks on the link, a new window is opened and the the user is directed to the requested URL.

While a MAC address is in the authenticated state, the host can forward data through the FastIron switch. The MAC address remains authenticated until one of the following events occurs:

- The host MAC address is removed from a list of MAC addresses that are automatically authenticated. (Refer to “Specifying hosts that are permanently authenticated” on page 1621).
- The re-authentication timer expires and the host is required to re-authenticate (Refer to “Configuring the re-authentication period” on page 1622).
- The host has remained inactive for a period of time and the inactive period timer has expired. (Refer to “Forcing re-authentication after an inactive period” on page 1625.)
Configuration considerations

- All the ports on the VLAN on which Web Authentication has been configured are in a down state. All MAC addresses that are currently authenticated are de-authenticated (Refer to “Forcing re-authentication when ports are down” on page 1624.)
- The authenticated client is cleared from the Web Authentication table. (Refer to “Clearing authenticated hosts from the web authentication table” on page 1623).

The FastIron switch can be configured to automatically authenticate a host MAC address. The host will not be required to login or re-authenticate (depending on the re-authentication period) once the MAC address passes authentication.

A host that is logged in and authenticated remains logged in indefinitely, unless a re-authentication period is configured. When the re-authentication period ends, the host is logged out. A host can log out at any time by pressing the Logout button in the Web Authentication Success page.

NOTE
The host can log out as long as the Logout window (Success page) is visible. If the window is accidentally closed, the host cannot log out unless the re-authentication period ends or the host is manually cleared from the Web Authentication table.

Configuration considerations

Web Authentication is modeled after other RADIUS-based authentication methods currently available on Brocade edge switches. However, Web Authentication requires a Layer 3 protocol (TCP/IP) between the host and the authenticator. Therefore, to implement Web Authentication, you must consider the following configuration and topology configuration requirements:

- Web Authentication works only on the default HTTP or HTTPS port.
- The host must have an IP address prior to Web Authentication. This IP address can be configured statically on the host; however, DHCP addressing is also supported.
- If you are using DHCP addressing, a DHCP server must be in the same broadcast domain as the host. This DHCP server does not have to be physically connected to the switch. Also, DHCP assist from a router may be used.
- Web Authentication, 802.1X port security, and multi-device port authentication are not supported concurrently on the same port.

The following applies to Web Authentication in the Layer 2 switch image:

- If the management VLAN and Web Authentication VLAN are in different IP networks, make sure there is at least one routing element in the network topology that can route between these IP networks.

The following are required for Web Authentication in the base Layer 3 and full Layer 3 images:

- Each Web Authentication VLAN must have a virtual interface (VE).
- The VE must have at least one assigned IPv4 address.

Web Authentication is enabled on a VLAN. That VLAN becomes a Web Authentication VLAN that does the following:

- Forwards traffic from authenticated hosts, just like a regular VLAN.
- Blocks traffic from unauthenticated hosts except from ARP, DHCP, DNS, HTTP, and HTTPs that are required to perform Web Authentication.
**Figure 175** shows the basic components of a network topology where Web Authentication is used. You will need:

- A Brocade FastIron switch running a software release that supports Web Authentication
- DHCP server, if dynamic IP addressing is to be used
- Computer/host with a web browser

Your configuration may also require a RADIUS server with some Trusted Source such as LDAP or Active Directory.

**NOTE**
The Web server, RADIUS server, and DHCP server can all be the same server.

**FIGURE 175** Basic topology for web authentication

---

**Configuration tasks**

Follow the steps given below to configure Web Authentication on a device.

   - On a Layer 2 FastIron switch, make sure the FastIron switch has an IP address.
     
     FastIron# configure terminal
     FastIron(config)#ip address 10.1.1.10/24

   - On a Layer 3 FastIron switch, assign an IP address to a virtual interface (VE) for each VLAN on which Web Authentication will be enabled.
     
     FastIron#configure terminal
     FastIron(config)#vlan 10
     FastIron(config-vlan-10)#router-interface vel
     FastIron(config-vlan-10)#untagged e 1/1/1 to 1/1/10
     FastIron(config-vlan-10)#interface vel
     FastIron(config-vif-1)#ip address 1.1.2.1/24
2. By default, Web Authentication will use a RADIUS server to authenticate host usernames and passwords, unless it is configured to use a local user database. If Web Authentication will use a RADIUS server, you must configure the RADIUS server and other servers. For example, if your RADIUS server has an IP address of 192.168.1.253, then use the CLI to configure the following global CLI commands on the FastIron switch.

```
FastIron(config)# radius-server host 10.1.1.8
FastIron(config)# radius-server key $GSig@U\n```

**NOTE**
Remember the RADIUS key you entered. You will need this key when you configure your RADIUS server.

3. Web authentication can be configured to use secure (HTTPS) or non-secure (HTTP) login and logout pages. By default, HTTPS is used.

To enable the non-secure Web server on the FastIron switch, enter the following command.

```
FastIron(config)# web-management HTTP
FastIron(config)#vlan 10
FastIron(config-vlan-10)#webauth
FastIron(config-vlan-10-webauth)#no secure-login
```

To enable the secure Web server on the FastIron switch, enter the following command.

```
FastIron(config)# web-management HTTPS
FastIron(config)#vlan 10
FastIron(config-vlan-10)#webauth
FastIron(config-vlan-10-webauth)#secure-login
```

4. If the secure Web server is used, in order to access a secure Web page, the Web server needs to provide a key. This key is exchanged using a certificate. A certificate is a digital document that is issued by a trusted source that can validate the authenticity of the certificate and the Web server that is presenting it. Therefore the switch must have a certificate for web authentication to work. There are two choices for providing the switch with a certificate:

- Upload one using the following global CLI command.
  
  ```
  FastIron(config)# ip ssl private-key-file tftp <ip-addr> <key-filename>
  ```

- Generate one using the following global CLI command.
  
  ```
  FastIron(config)#crypto-ssl certificate generate default_cert
  ```

5. Create a Web Authentication VLAN and enable Web Authentication on that VLAN.

```
FastIron(config)#vlan 10
FastIron(config-vlan-10)#webauth
FastIron(config-vlan-10-webauth)#enable
```

Once enabled, the CLI changes to the "webauth" configuration level. In the example above, VLAN 10 will require hosts to be authenticated using Web Authentication before they can forward traffic.

6. Configure the Web Authentication mode:

- **Username and password** – Blocks users from accessing the switch until they enter a valid username and password on a web login page.
- **Passcode** – Blocks users from accessing the switch until they enter a valid passcode on a web login page.
Enabling and disabling web authentication

Web Authentication is disabled by default. To enable it, enter the following commands.

```
FastIron(config)#vlan 10
FastIron(config-vlan-10)webauth
FastIron(config(config-vlan-10-webauth)#enable
```

The first command changes the CLI level to the VLAN configuration level. The second command changes the configuration level to the Web Authentication VLAN level. The last command enables Web Authentication. In the example above, VLAN 10 will require hosts to be authenticated using Web Authentication before they can forward traffic.

**Syntax:** `webauth`

FastIron devices support a maximum of two Web Authentication VLANs.

**Syntax:** `[no] enable`

Enter the `no enable` command to disable Web Authentication.

Configuring the web authentication mode

You can configure the FastIron switch to use one of three Web Authentication modes:

- **Username and password** – Block users from accessing the switch until they enter a valid username and password on a web login page. Refer to “Using local user databases” on page 1611.
- **Passcode** – Blocks users from accessing the switch until they enter a valid passcode on a web login page. Refer to “Using passcodes” on page 1615.
- **None** – Blocks users from accessing the switch until they press the ‘Login’ button. A username and password or passcode is not required. Refer to “Using automatic authentication” on page 1619.

This following sections describe how to configure these Web Authentication modes.

Using local user databases

Web Authentication supports the use of local user databases consisting of usernames and passwords, to authenticate devices. Users are blocked from accessing the switch until they enter a valid username and password on a web login page.
Once a user successfully authenticates through username and password, the user is subjected to the same policies as for RADIUS-authenticated devices (for example, the re-authentication period, maximum number of users allowed, etc.). Similarly, once a user fails username and password authentication, the user is subjected to the same policies as for devices that fail RADIUS authentication.

You can create up to ten local user databases on the FastIron switch either by entering a series of CLI commands, or by uploading a list of usernames and passwords from a TFTP file to the FastIron switch. The user databases are stored locally, on the FastIron switch.

Configuration steps

Follow the steps given below to configure a local user database.

1. Create the local user database.
2. Add records to the local user database either by entering a series of CLI commands, or by importing a list of user records from an ASCII text file on the TFTP server to the FastIron switch.
3. Set the local user database authentication mode.
4. If desired, set the authentication method (RADIUS/local) failover sequence.
5. Assign a local user database to a Web Authentication VLAN.

Creating a local user database

The FastIron switch supports a maximum of ten local user databases, each containing up to 30 user records. Each user record consists of a username and password.

To create a local user database, enter a command such as the following:

```plaintext
FastIron#(config)#local-userdb userdb1
FastIron#(config-localuserdb-userdb1)#
```

This command creates a local user database named `userdb1`. To add user records to this database, refer to "Adding a User record to a local user database" on page 1612.

Syntax: `local-userdb <db-name>`

You can create up to ten local user databases for Web Authentication.

For `<db-name>`, enter up to 31 alphanumeric characters.

Adding a User record to a local user database

To add a user record, enter commands such as the following:

```plaintext
FastIron#(config)#local-userdb userdb1
FastIron#(config-localuserdb-userdb1)#username marcia password bunch4
```

The first command changes the configuration level to the local user database level for `userdb1`. If the database does not already exist, it is created. The second command adds the user record `marcia` to the `userdb1` database.

Syntax: `username <username> password <password>`

For `<username>`, enter up to 31 ASCII characters.

For `<password>`, enter up to 29 ASCII characters.
You can add up to 30 usernames and passwords to a local user database.

To view a list of users in a local user database, use the CLI command `vlan-mod-port-userdb`. Refer to “Displaying a list of local user databases” on page 1637.

**Deleting a user record from a local user database**

To delete a user record from the local user database, enter commands such as the following.

```
FastIron#(config)#local-userdb userdb1
FastIron#(config-localuserdb-userdb1)#no username marcia
```

The first command changes the configuration level to the local user database level for `userdb1`. The second command deletes the user record `marcia` from the `userdb1` database.

**Deleting All user records from a local user database**

To delete all user records from a local user database, enter the following command.

```
FastIron#(config-localuserdb-userdb1)#delete-all
```

**Creating a text file of user records**

If desired, you can use the TFTP protocol to import a list of usernames and passwords from a text file on a TFTP server to the FastIron switch. The text file to be imported must be in the following ASCII format.

```
[delete-all]
[no]  username <username1> password <password1> <cr>
[no]  username <username2> password <password2> <cr>
...
```

The `[delete-all]` keyword indicates that the user records in the text file will replace the user records in the specified local user database on the FastIron switch. If the `[delete-all]` keyword is not present, the new user records will be added to the specified local user database on the FastIron switch. The `[delete-all]` keyword is optional. If present, it must appear on the first line, before the first user record in the text file.

The optional `[no]` keyword indicates that the user entry will be deleted from the specified local user database on the FastIron switch.

User records that already exist in the local user database will be updated with the information in the text file when it is uploaded to the switch.

For `<username1>`, `<username2>`, etc., enter up to 31 ASCII characters.

For `<password1>`, `<password2>`, etc., enter up to 29 ASCII characters.

Be sure to insert a cursor return (`<cr>`) after each user record.

You can enter up to 30 user records per text file.
Importing a text file of user records from a TFTP server

**NOTE**
Before importing the file, make sure it adheres to the ASCII text format described in the previous section, “Creating a text file of user records” on page 1613.

To import a text file of user records from a TFTP server to the FastIron switch, enter a command such as the following.

```
FastIron#(config-localuserdb-userdb1)#import-users tftp 192.168.1.1 filename userdb1
```

Syntax: `import-users tftp <ip-address> filename <filename>`

The `<ip-address>` parameter specifies the IPv4 address of the TFTP server on which the desired text file resides.

The `<filename>` parameter specifies the name of the image on the TFTP server.

Using a RADIUS server as the web authentication method

By default, Web Authentication will use a RADIUS server to authenticate hosts’ usernames and passwords, unless the device is configured to use the local user database (see the previous section). To configure the FastIron switch to use a RADIUS server, refer to “Configuring RADIUS security” on page 1460. You must also do the following.

1. Configure the RADIUS server information on the FastIron switch. Enter a command such as the following.

   ```
   FastIron(config)#radius-server host 10.1.1.8 auth-port 1812 acct-port 1813 default key $GSig@U
   ```

   **NOTE**
   Web Authentication will use the first reachable RADIUS server listed in the configuration. The `use-radius-server` on individual ports is not supported for Web Authentication.

2. Enable the username and password authentication mode.

   ```
   FastIron(config-vlan-10-webauth)#auth-mode username-password
   ```

3. Enable the RADIUS authentication method. Refer to “Setting the local user database authentication method” on page 1614 or “Setting the web authentication failover sequence” on page 1615.

Setting the local user database authentication method

By default, the FastIron switch uses a RADIUS server to authenticate users in a VLAN. The previous section describes how to configure a RADIUS server to authenticate users in a VLAN. To configure the switch to instead use a local user database to authenticate users in a VLAN, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#auth-mode username-password auth-methods local
```

Syntax: `auth-mode username-password auth-methods local`

To revert back to using the RADIUS server, enter the following command.

```
FastIron(config-vlan-10-webauth)#auth-mode username-password auth-methods radius
```
Configuring the web authentication mode

Syntax: auth-mode username-password auth-methods radius

Setting the web authentication failover sequence

You can optionally specify a failover sequence for RADIUS and local user database authentication methods. For example, you can configure Web Authentication to first use a local user database to authenticate users in a VLAN. If the local user database is not available, it will use a RADIUS server. Enter the following command.

FastIron(config-vlan-10-webauth)#auth-mode username-password auth-methods local radius

Syntax: auth-mode username-password auth-methods <method1> <method2>

For <method1> <method2>, enter radius local or local radius.

Assigning a local user database to a web authentication VLAN

After creating or importing a local user database on the FastIron switch and setting the local user database authentication method to local, you can configure a Web Authentication VLAN to use the database to authenticate users in a VLAN. To do so, enter a command such as the following.

FastIron(config-vlan-10-webauth)#auth-mode username-password local-user-database userdb1

These commands configure Web Authentication to use the usernames and passwords in the userdb1 database to authenticate users in VLAN 10.

Syntax: [no] auth-mode username-password local-user-database <db-name>

For <db-name>, enter a valid local user database.

Use the no form of the command to remove the database from the Web Authentication VLAN.

Using passcodes

Web Authentication supports the use of passcodes to authenticate users. Users are blocked from accessing the switch until they enter a valid passcode on a web login page. Unlike username and password authentication, passcode authentication uses a simple number to authenticate users. The simplicity of a passcode reduces user errors and lowers the overhead of supporting and managing simple tasks, such as Internet access for guests and visitors in the office.

When passcodes are enabled, the system will automatically generate them every 1440 minutes (24 hours), and when the system boots up. You can optionally create up to four static passcodes which will be used in conjunction with the dynamic passcodes generated by the system.

Configuration steps

Follow the steps given below to configure the device to use the passcode authentication mode.

1. Optionally create up to four static passcodes
2. Enable passcode authentication
3. Configure other options
**Creating static passcodes**

Static passcodes can be used for troubleshooting purposes, or for networks that want to use passcode authentication, but do not have the ability to support automatically-generated passcodes (for example, the network does not fully support the use of SNMP traps or Syslog messages with passcodes).

Manually-created passcodes are used in conjunction with dynamic passcodes. You can configure up to four static passcodes that never expire. Unlike dynamically-created passcodes, static passcodes are saved to flash memory. By default, there are no static passcodes configured on the switch.

To create static passcodes, enter commands such as the following.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode static 3267345
FastIron(config-vlan-10-webauth)#auth-mode passcode static 56127
```

**Syntax:** `auth-mode passcode static <passcode>

For `<passcode>`, enter a number from 4 to 16 digits in length. You can create up to four static passcodes, each with a different length. Static passcodes do not have to be the same length as passcodes that are automatically generated.

After creating static passcodes, you can enable passcode authentication as described in the next section.

To view the passcodes configured on the switch, use the `show webauth vlan <vlan-id> passcode` command. Refer to “Displaying passcodes” on page 1638.

**Enabling passcode authentication**

To enable passcode authentication, enter the following command.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode
```

This command enables Web Authentication to use dynamically-created passcodes to authenticate users in the VLAN. If the configuration includes static passcodes, they are used in conjunction with dynamically-created passcodes.

**Syntax:** `[no]auth-mode passcode

Enter `no auth-mode passcode` to disable passcode authentication.

**Configuring the length of dynamically-generated passcodes**

By default, dynamically-generated passcodes are 4 digits in length, for example, 0123. If desired, you can increase the passcode length to up to 16 digits. To do so, enter a command such as the following at the Web Authentication level of the CLI.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode length 10
```

The next dynamically-created passcode will be 10 digits in length, for example, 0123456789.

**Syntax:** `auth-mode passcode length <value>

For `<value>`, enter a number from 4 to 16.
**Configuring the passcode refresh method**

Passcode authentication supports two passcode refresh methods:

- **Duration of time** – By default, dynamically-created passcodes are refreshed every 1440 minutes (24 hours). When refreshed, a new passcode is generated and the old passcode expires. You can increase or decrease the duration of time after which passcodes are refreshed, or you can configure the device to refresh passcodes at a certain time of day instead of after a duration of time.

- **Time of day** – When initially enabled, the time of day method will cause passcodes to be refreshed at 0:00 (12:00 midnight). If desired, you can change this time of day, and you can add up to 24 refresh periods in a 24-hour period.

When a passcode is refreshed, the old passcode will no longer work, unless a grace period is configured (refer to “Configuring a Grace Period for an expired passcode” on page 1618).

If a user changes the passcode refresh value, the configuration is immediately applied to the current passcode. For example, if the passcode duration is 100 minutes and the passcode was last generated 60 minutes prior, a new passcode will be generated in 40 minutes. However, if the passcode duration is changed from 100 to 75 minutes, and the passcode was last generated 60 minutes prior, a new passcode will be generated in 15 minutes. Similarly, if the passcode duration is changed from 100 to 50 minutes, and the passcode was last generated 60 minutes prior, the passcode will immediately expire and a new passcode will be generated. The same principles apply to the time of day passcode refresh method.

If you configure both duration of time and time of day passcode refresh values, they are saved to the configuration file. You can switch back and forth between the passcode refresh methods, but only one method can be enabled at a time.

**NOTE**

Passcodes are not stateful, meaning a software reset or reload will cause the system to erase the passcode. When the FastIron switch comes back up, a new passcode will be generated.

**Changing the passcode refresh duration**

To change the duration of time after which passcodes are refreshed, enter commands such as the following.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode refresh-type duration 4320
```

The passcode will be refreshed after 4320 minutes (72 hours).

**Syntax:** auth-mode passcode refresh-type duration <value>

For <value>, enter a number from 5 to 9999 minutes. The default is 1440 minutes (24 hours).

**Refreshing passcodes at a certain time of the day**

You can configure the FastIron switch to refresh passcodes at a certain time of day, up to 24 times each day, instead of after a duration of time. When this feature is enabled, by default passcodes will be refreshed at 00:00 (12 midnight).

To configure the switch to refresh passcodes at a certain time of day, enter commands such as the following.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode refresh-type time 6:00
FastIron(config-vlan-10-webauth)#auth-mode passcode refresh-type time 14:30
```

The passcode will be refreshed at 6:00am, 2:30pm, and 0:00 (12 midnight).
Syntax:  [no] auth-mode passcode refresh-type time <hh:mm>.

<hh:mm> is the hour and minutes. If you do not enter a value for <hh:mm>, by default, passcodes will be refreshed at 00:00 (12:00 midnight). You can configure up to 24 refresh times. Each must be at least five minutes apart.

Enter the no form of the command to remove the passcode refresh time of day.

Resetting the passcode refresh time of day configuration

If the FastIron switch is configured to refresh passcodes several times during the day (time of day configuration), you can use the following command to delete all of the configured times and revert back to the default time of 00:00 (12 midnight).

FastIron(config-vlan-10-webauth)#auth-mode passcode refresh-type time delete-all

Syntax:  auth-mode passcode refresh-type time delete-all

Configuring a Grace Period for an expired passcode

You can optionally configure a grace period for an expired passcode. The grace period is the period of time that a passcode will remain valid, even after a new passcode is generated. For example, if a five minute grace period is set and the passcode 1234 is refreshed to 5678, both passcodes will be valid for five minutes, after which the 1234 passcode will expire and the 5678 passcode will remain in effect.

To configure the grace period for an expired passcode, enter a command such as the following.

FastIron(config-vlan-10-webauth)#auth-mode passcode grace-period 5

Syntax:  auth-mode passcode grace-period <value>

<value> is a number between 0 and 5 minutes. 0 means there is no grace period.

NOTE

If the grace period is re-configured while a passcode is already in the grace period, the passcode is not affected by the configuration change. The new grace period will apply only to passcodes that expire after the new grace period is set.

Flushing all expired passcodes that are in the grace period

You can delete old passcodes that have expired but are still valid because they are in the grace period. This feature is useful in situations where the old passcodes have been compromised but are still valid because of the grace period. This feature does not affect current valid passcodes or passcodes that newly expire.

To flush out all expired passcodes that are currently in the grace period, enter the following command.

FastIron(config-vlan-10-webauth)#auth-mode passcode flush-expired

Syntax:  auth-mode passcode flush-expired

Disabling and re-enabling passcode logging

The software generates a Syslog message and SNMP trap message every time a new passcode is generated and passcode authentication is attempted. This is the default behavior. If desired, you can disable passcode-related Syslog messages or SNMP trap messages, or both.
Configuring the web authentication mode

The following shows an example Syslog message and SNMP trap message related to passcode authentication.

New passcode: 01234567. Expires in 1440 minutes. Old passcode is valid for another 5 minutes.

To disable Syslog messages for passcodes, enter the following command.

```
FastIron(config-vlan-10-webauth)#no auth-mode passcode log syslog
```

Enter the following command to disable SNMP trap messages for passcodes.

```
FastIron(config-vlan-10-webauth)#no auth-mode passcode log snmp-trap
```

Enter the following command to re-enable Syslog messages for passcodes after they have been disabled.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode log syslog
```

Enter the following command to re-enable SNMP trap messages for passcodes after they have been disabled.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode log snmp-trap
```

**Syntax:** `[no] auth-mode passcode log syslog | snmp-trap`

**Re-sending the passcode log message**

If passcode logging is enabled, you can enter a CLI command to retransmit the current passcode to a Syslog message or SNMP trap. To do so, enter the following command.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode resend-log
```

**Syntax:** `auth-mode passcode resend-log`

**NOTE**

The switch retransmits the current passcode only. Passcodes that are in the grace period are not sent.

**Manually refreshing the passcode**

You can manually refresh the passcode instead of waiting for the system to automatically generate one. When manually refreshed, the old passcode will no longer work, even if a grace period is configured. Also, if the passcode refresh method `duration of time` is used, the duration counter is reset when the passcode is manually refreshed. The passcode refresh method `time of day` is not affected when the passcode is manually refreshed.

To immediately refresh the passcode, enter the following CLI command.

```
FastIron(config-vlan-10-webauth)#auth-mode passcode generate
```

**Syntax:** `auth-mode passcode generate`

**Using automatic authentication**

By default, if Web Authentication is enabled, hosts need to login and enter authentication credentials in order to gain access to the network. If a re-authentication period is configured, the host will be asked to re-enter authentication credentials once the re-authentication period ends.
You can configure Web Authentication to authenticate a host when the user presses the ‘Login’ button. When a host enters a valid URL address, Web Authentication checks the list of blocked MAC addresses. If the hosts’ MAC address is not on the list and the number of allowable hosts has not been reached, after pressing the ‘Login’ button, the host is automatically authenticated for the duration of the configured re-authentication period, if one is configured. Once the re-authentication period ends, the host is logged out and needs to enter the URL address again.

**NOTE**
Automatic authentication is not the same as permanent authentication. (Refer to “Specifying hosts that are permanently authenticated” on page 1621). You must still specify devices that are to be permanently authenticated even if automatic authentication is enabled.

To enable automatic authentication, enter the following command.

```
FastIron(config)#vlan 10
FastIron(config-vlan-10)#webauth
FastIron(config-vlan-10-webauth)#auth-mode none
```

**Syntax:** `[no] auth-mode none`  
If automatic authentication is enabled and a host address is not in the blocked MAC address list, Web Authentication authenticates the host and displays the Login page without user credentials, then provides a hyperlink to the requested URL site.

To determine if automatic authentication is enabled on your device, issue the `show webauth vlan <vlan-id>` command at the VLAN configuration level.

Syslog messages are generated under the following conditions:

- The feature is enabled
- The feature is disabled
- A MAC address is successfully authenticated
- Automatic authentication cannot occur because the maximum number of hosts allowed has been reached

### Configuring web authentication options

The sections below explain other configuration options for Web Authentication.

#### Enabling RADIUS accounting for web authentication

When Web Authentication is enabled, you can enable RADIUS accounting to record login (start) and logout (stop) events per host. The information is sent to a RADIUS server. Note that packet/byte count is not supported.

To enable RADIUS accounting, enter the following command.

```
FastIron(config-vlan-10-webauth)#accounting
```

**Syntax:** `[no] accounting`  
Enter the `no accounting` command to disable RADIUS accounting for Web Authentication.
Changing the login mode (HTTPS or HTTP)

Web Authentication can be configured to use secure (HTTPS) or non-secure (HTTP) login and logout pages. By default, HTTPS is used. Figure 177 shows an example Login page.

To change the login mode to non-secure (HTTP), enter the following command.

```
FastIron(config-vlan-10-webauth)#no secure-login
```

To revert back to secure mode, enter the following command.

```
FastIron(config-vlan-10-webauth)#secure-login
```

Syntax: [no] secure-login

Specifying trusted ports

You can configure certain ports of a Web Authentication VLAN as trusted ports. All hosts connected to the trusted ports need not authenticate and are automatically allowed access to the network.

To create a list of trusted ports, enter commands such as the following.

```
FastIron(config-vlan-10-webauth)#trust-port ethernet 3
FastIron(config-vlan-10-webauth)#trust port ethernet 6 to 10
```

The above commands configure ports 3 and 6 – 10 as trusted ports.

Syntax: trust-port ethernet [<slotnum>/]<portnum> [to [<slotnum>/]<portnum>]

Specifying hosts that are permanently authenticated

Certain hosts, such as DHCP server, gateway, printers, may need to be permanently authenticated. Typically, these hosts are managed by the network administrator and are considered to be authorized hosts. Also, some of these hosts (such as printers) may not have a Web browser and will not be able to perform the Web Authentication.

To permanently authenticate these types of hosts, enter a command such as the following at the "webauth" configuration level.

```
FastIron(config-vlan-10-webauth)#add mac 0004.80eb.2d14 duration 0
FastIron(config-vlan-10-webauth)#add mac 0007.e90e.de3b duration 0
```

Syntax: [no] add mac <mac-address> duration <seconds> | ethernet <port-number> duration <seconds>

```
Syntax: no add mac <mac-address>
```

<seconds> specifies how long the MAC address remains authenticated. Enter 0 – 128000 seconds. The default is the current value of reauth-time. A value of "0" means that Web Authentication for the MAC address will not expire.

Instead of just entering a duration for how long the MAC address remains authenticated, you can specify the MAC address to be added by the specified port that is a member of the VLAN. To do this, enter values for the ethernet <port-number> duration <seconds> option. Enter the port number and the number of seconds the MAC address remains authenticated.

Entering a no add mac <mac-address> duration <seconds> | ethernet <port-number> duration <seconds> command sets duration and ethernet to their default values. If you want to remove a host, enter the no add mac <mac-address> command.
NOTE
If a MAC address is statically configured, this MAC address will not be allowed to be dynamically configured on any port.

Configuring the re-authentication period

After a successful authentication, a user remains authenticated for a duration of time. At the end of this duration, the host is automatically logged off. The user must be re-authenticated again. To set the number of seconds a host remains authenticated before being logged off, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#reauth-time 10
```

Syntax: `[no] reauth-time <seconds>`

You can specify 0 – 128000 seconds. The default is 28800 seconds, and 0 means the user is always authenticated and will never have to re-authenticate, except if an inactive period less than the re-authentication period is configured on the Web Authentication VLAN. If this is the case, the user becomes de-authenticated if there is no activity and the timer for the inactive period expires.

Defining the web authentication cycle

You can set a limit as to how many seconds users have to be Web Authenticated by defining a cycle time. This time begins at a user first Login attempt on the Login page. If the user has not been authenticated successfully when this time expires, the user must enter a valid URL again to display the Web Authentication Welcome page.

To define a cycle time, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#cycle time 20
```

Syntax: `[no] cycle time <seconds>`

Enter 0 – 3600 seconds, where 0 means there is no time limit. The default is 600 seconds.

Limiting the number of web authentication attempts

You can set a limit on the number of times a user enters an invalid user name and password during the specified cycle time. If the user exceeds the limit, the user is blocked for a duration of time, which is defined by the `block duration` command. Also, the Web browser will be redirected to the Exceeded Allowable Attempts webpage.

To limit the number of Web Authentication attempts, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#attempt-max-num 4
```

Syntax: `[no] attempt-max-num <number>`

Enter a number from 0 to 64, where 0 means there is no limit to the number of Web Authentication attempts. The default is 5.
Clearing authenticated hosts from the web authentication table

Use the following commands to clear dynamically-authenticated hosts from the Web Authentication table.

To clear all authenticated hosts in a Web authentication VLAN, enter a command such as the following.

```
FastIron#clear webauth vlan 25 authenticated-mac
```

This command clears all the authenticated hosts in VLAN 25.

To clear a particular host in a Web authentication VLAN, enter a command such as the following.

```
FastIron#clear webauth vlan 25 authenticated-mac 1111.2222.3333
```

This command clears host 1111.2222.3333 from VLAN 25.

**Syntax:** `clear webauth vlan <vlan-id> authenticated-mac [<mac-address>]`

Setting and clearing the block duration for web authentication attempts

After users exceed the limit for Web Authentication attempts, specify how many seconds users must wait before the next cycle of Web Authenticated begins. Enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#block duration 4
```

**Syntax:** `[no] block duration <seconds>`

Users cannot attempt Web Authentication during this time.

Enter 0–128000 seconds. The default is 90 seconds, and entering 0 means that the MAC address is infinitely blocked.

To unblock the MAC address, wait until the block duration timer expires or enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#clear webauth vlan 10 block-mac 000.000.1234
```

**Syntax:** `clear webauth vlan <vlan-id> block-mac [<mac-address>]`

If you do not enter a `<mac-address>`, then all the entries for the specified VLAN will be cleared.

Manually blocking and unblocking a specific host

A host can be temporarily or permanently blocked from attempting Web Authentication by entering a command such as the following.

```
FastIron(config-vlan-10-webauth)#block mac 0123.17d1.0a3d duration 4
```

**Syntax:** `[no] block mac <mac-address> duration <seconds>`

**Syntax:** `no block mac <mac-address>`

Enter 0 – 128000 for `<seconds>`. The default is the current value of `block duration` command. Entering a value of "0" means the MAC address is blocked permanently.
Configuring web authentication options

Entering **no block mac** `<mac-address>` **duration** `<seconds>` resets duration to its default value.

You can unblock a host by entering the **no block mac** `<mac-address>` command.

**Limiting the number of authenticated hosts**

You can limit the number of hosts that are authenticated at any one time by entering a command such as the following.

```
FastIron(config-vlan-10-webauth)#host-max-num 300
```

**Syntax:** `[no] host-max-num <number>`

You can enter 0 – 8192, where 0 means there is no limit to the number of hosts that can be authenticated. The default is 0. The maximum is 8192 or the maximum number of MAC addresses the device supports.

When the maximum number of hosts has been reached, the FastIron switch redirects any new host that has been authenticated successfully to the Maximum Host webpage.

**Filtering DNS queries**

Many of the Web Authentication solutions allow DNS queries to be forwarded from unauthenticated hosts. To eliminate the threat of forwarding DNS queries from unauthenticated hosts to unknown or untrusted servers (also known as domain-casting), you can restrict DNS queries from unauthenticated hosts to be forwarded explicitly to defined servers by defining DNS filters. Any DNS query from an unauthenticated host to a server that is not defined in a DNS filter are dropped. Only DNS queries from unauthenticated hosts are affected by DNS filters; authenticated hosts are not. If the DNS filters are not defined, then any DNS queries can be made to any server.

You can have up to four DNS filters. Create a filter by entering the following command.

```
FastIron(config-vlan-10-webauth)#dns-filter 1 191.166.2.44/24
```

**Syntax:** `[no] dns-filter <number> <ip-address> <subnet-mask> | <wildcard>`

For `<number>`, enter a number from 1 to 4 to identify the DNS filter.

Enter the IP address and subnet mask of unauthenticated hosts that will be forwarded to the unknown/untrusted servers. Use the `<ip-address> <subnet-mask>` or `<ip-address>/<subnet-mask>` format.

You can use a `<wildcard>` for the filter. The `<wildcard>` is in dotted-decimal notation (IP address format). It is a four-part value, where each part is 8 bits (one byte) separated by dots, and each bit is a one or a zero. Each part is a number ranging from 0 to 255, for example 0.0.0.255. Zeros in the mask mean the packet source address must match the IP address. Ones mean any value matches. For example, the `<ip-address>` and `<subnet-mask>` values 209.157.22.26 0.0.0.255 mean that all hosts in the Class C sub-net 209.157.22.x match the policy.

**Forcing re-authentication when ports are down**

If all ports on the device go down, you may want to force all authenticated hosts to be re-authenticated. You can do this by entering the following command.

```
FastIron(config-vlan-10-webauth)#port-down-auth-mac-cleanup
```

**Syntax:** `[no] port-down-auth-mac-cleanup`
While this command is enabled, the device checks the link state of all ports that are members of the Web Authentication VLAN. If the state of all the ports is down, then the device forces all authenticated hosts to re-authenticate. However, hosts that were authenticated using the add mac command will remain authenticated; they are not affected by the `port-down-auth-mac-cleanup` command.

**Forcing re-authentication after an inactive period**

You can force Web Authenticated hosts to be re-authenticated if they have been inactive for a period of time. The inactive duration is calculated by adding the mac-age-time that has been configured for the device and the configured `authenticated-mac-age-time`. (The `mac-age-time` command defines how long a port address remains active in the address table.) If the authenticated host is inactive for the sum of these two values, the host is forced to be re-authenticated.

To force authenticated hosts to re-authenticate after a period of inactivity, enter commands such as the following.

```
FastIron(config)#mac-age-time 600
FastIron(config)#vlan 23
FastIron(config-vlan-23)webauth
FastIron(config-vlan-23-webauth)#reauth-time 303
FastIron(config-vlan-23-webauth)#authenticated-mac-age-time 300
```

**Syntax:** `[no] authenticated-mac-age-time <seconds>`

You can enter a value from 0 to the value entered for `reauth-time`. The default is 3600.

Refer to “Changing the MAC age time and disabling MAC address learning” on page 363 for details on the `mac-age-time` command. The default `mac-age-time` is 300 seconds and can be configured to be between 60 and 600 on the FastIron switch. If it is configured to be 0, then the MAC address does not age out due to inactivity.

**Defining the web authorization redirect address**

When a user enters a valid URL address (one that exists), the user is redirected to a Web Authentication address and the Welcome page for Web Authentication is displayed. By default, this Web Authentication address is the IP address of the FastIron switch. You can change this address so that the address matches the name on the security certificates.

To change the address on a Layer 2 switch, enter a command such as the following at the global configuration level.

```
FastIron(config)#webauth-redirect-address my.domain.net
```

To change the address on a Layer 3 switch, enter a command such as the following at the Web Authentication VLAN level.

```
FastIron(config-vlan-10-webauth)#webauth-redirect-address my.domain.net
```

Entering "my.domain.net" redirects the browser to https://my.domain.net/ when the user enters a valid URL on the Web browser.

**Syntax:** `[no] webauth-redirect-address <string>`

For `<string>`, enter up to 64 alphanumeric characters. You can enter any value for `<string>`, but entering the name on the security certificate prevents the display of error messages saying that the security certificate does not match the name of the site.
Deleting a web authentication VLAN

To delete a Web Authentication VLAN, enter the following command:

```
FastIron(config)#vlan 10
FastIron(config-vlan-10)#no webauth
```

Syntax: no webauth

Web authentication pages

There are several pages that can be displayed for Web Authentication.

When a user first enters a valid URL address on the Web browser, the browser is redirected to the Web Authentication URL (refer to “Defining the web authorization redirect address” on page 1625).

If Automatic Authentication is enabled, the following Welcome page appears:

**FIGURE 176** Example of a welcome page when automatic authentication is enabled

The browser will then be directed to the requested URL.

If username and password (Local User Database) authentication is enabled, the following Login page appears.
FIGURE 177  Example of a login page when automatic authentication is disabled and local user database is enabled

The user enters a user name and password, which are then sent for authentication.

If passcode authentication is enabled, the following Login page appears.

FIGURE 178  Example of a login page when automatic authentication is disabled and passcode Authentication is Enabled

The user enters a passcode, which is then sent for authentication.

If the Web Authentication fails, the page to try again is displayed (Figure 179).
FIGURE 179  Example of a try again page

If the limit for the number of authenticated users on the network is exceeded, the Maximum Host Limit page is displayed (Figure 180).

FIGURE 180  Example of a maximum Host limit page

If the number of Web Authentication attempts by a user has been exceeded, the Maximum Attempts Limit page is displayed (Figure 181). The user is blocked from attempting any Web Authentication unless either the user MAC address is removed from the blocked list (using the `clear webauth block-mac <mac-address>` command) or when the block duration timer expires.

FIGURE 181  Example of a maximum attempts limit page

If the user Web Authentication attempt is successful, the Success page is displayed (Figure 182).
Once a host is authenticated, that host can manually de-authenticate by clicking the ‘Logout’ button in the Login Success page. The host remains logged in until the re-authentication period expires. At that time, the host is automatically logged out. However, if a re-authentication period is not configured, then the host remains logged in indefinitely.

**NOTE**
If you accidentally close the Success page, you will not be able to log out. If a re-authentication period is configured, you will be logged out once the re-authentication period ends.

The host can log out of the Web session by simply clicking the Logout button. Once logged out, the following window appears.

You can customize the top and bottom text for all of the windows shown in Figure 176 through Figure 182.

**Displaying text for web authentication pages**

Use the `show webauth vlan <vlan-ID> webpage` command to determine what text has been configured for Web Authentication pages.
Configuring web authentication options

FastIron#show webauth vlan 25 webpage

=================================
Web Page Customizations (VLAN 25):
  Top (Header): Default Text
    "<h3>Welcome to Brocade Communications, Inc. Web Authentication Homepage</h3>"
  Bottom (Footer): Custom Text
    "Copyright 2009 SNL"
  Title: Default Text
    "Web Authentication"
  Login Button: Custom Text
    "Sign On"
  Web Page Logo: blogo.gif
    align: left (Default)
  Web Page Terms and Conditions: policy1.txt

Syntax: show webauth vlan <vlan-id> webpage

Customizing web authentication pages

You can customize the following objects in the Web Authentication pages shown in Figure 176 through Figure 182:

- Title bar
- Banner image (the logo)
- Header
- Text box
- Login button
- Footer

You can use the CLI commands `show webauth` and `show webauth vlan <vlan-id> webpage` to determine what text has been configured for Web Authentication pages.

**NOTE**
The banner image does not apply to the Web Authentication Maximum Attempts Limit page (Figure 181). The text box and Login button apply to the Login page only.

Figure 183 shows the placement of these objects in the Login page.
Customizing the title bar
You can customize the title bar that appears on all Web Authentication pages (refer to Figure 183). To do so, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#webpage custom-text title "Brocade Secure Access Page"
```

**Syntax:** `[no] webpage custom-text title "<title>"`

For `<title>`, enter up to 128 alphanumeric characters. The default title bar is "Web Authentication".

To reset the title bar back to the default value, enter the command `no webpage custom-text title`.

Customizing the banner image (Logo)
You can customize the logo that appears on all Web Authentication pages. Figure 183 shows placement of the banner image in the Login page.

**NOTE**
The banner image does not display in the Maximum Attempts Limit page (Figure 181).

To customize the banner image, use the TFTP protocol to upload an image file from a TFTP server to the FastIron switch. The image file can be in the format jpg, bmp, or gif, and its size must be 64K or less. When you upload a new image file, it will overwrite the existing image file.

To replace the existing logo with a new one, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#webpage logo copy tftp 10.10.5.1 brocadelogo.gif
```

**Syntax:** `[no] webpage logo copy tftp <ip-address> <filename>`
Configuring web authentication options

**NOTE**
This command downloads the image file and stores it in the device flash memory. Therefore, it is not necessary to follow this command with a write memory.

The `<ip-address>` parameter specifies the address of the TFTP server on which the image file resides.

The `<filename>` parameter specifies the name of the image file on the TFTP server.

Use the no webpage logo command to delete the logo from all Web Authentication pages and remove it from flash memory.

**Aligning the banner image (Logo)**
You can optionally configure the placement of the logo that appears on all Web Authentication pages (refer to Figure 183). By default, the logo is left-aligned at the top of the page. To center the logo at the top of the page, enter the following command.

```
FastIron(config-vlan-10-webauth)#webpage logo align center
```

To right-justify the logo at the top of the page, enter the following command.

```
FastIron(config-vlan-10-webauth)#webpage logo align right
```

**Syntax:** `[no] webpage logo align center | left | right`

Use the no webpage logo align command to reset the logo back to its default position (left).

**Customizing the header**
You can customize the header that appears on all Web Authentication pages. Figure 183 shows placement of the header in the Login page.

To customize the header, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#webpage custom-text top "Welcome to Network One"
```

**Syntax:** `[no] webpage custom-text top <text>`

For `<text>`, enter up to 255 alphanumeric characters.

To reset the header back to the default text, enter the command no webpage custom-text top. The default text is "Welcome to Brocade Communications, Inc. Web Authentication Homepage".

**Customizing the text box**
You can customize the text box that appears on the Web Authentication Login page. Figure 183 shows placement of the text box in the Login page. By default, the text box is empty and is not visible. To create a text box or to replace the existing one, upload an ASCII text file from a TFTP server to the FastIron switch. The text file size must not exceed 2K.

To create or replace a text box, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#webpage terms copy tftp 10.10.5.1 policy.txt
```

**Syntax:** `[no] webpage terms copy tftp <ip-address> <filename>`

**NOTE**
This command downloads the text file and stores it in the device flash memory. Therefore, it is not necessary to follow this command with a write memory.

The `<ip-address>` parameter is the address of the TFTP server on which the image resides.
The `<filename>` parameter is the name of the text file on the TFTP server.

To revert back to the default text box (none), enter the command **no webpage terms**.

**Customizing the login button**

You can customize the Login button that appears on the bottom of the Web Authentication Login page (refer to **Figure 183**). To do so, enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#webpage custom-text login-button "Press to Log In"
```

**Syntax: [no] webpage custom-text login-button "<text>"**

For `<text>`, enter up to 32 alphanumeric characters.

To reset the Login button back to the default value ("Login"), enter the command **no webpage custom-text login-button**.

**Customizing the footer**

You can customize the footer that appears on all Web Authentication pages. **Figure 183** shows placement of the footer in the Login page.

To customize the footer enter a command such as the following.

```
FastIron(config-vlan-10-webauth)#webpage custom-text bottom "Network One Copyright 2009"
```

**Syntax: [no] webpage custom-text bottom "<text>"**

For `<text>`, enter up to 255 alphanumeric characters.

To reset the footer back to the default text, enter the command **no webpage custom-text bottom**.

The default text is "This network is restricted to authorized users only. Violators may be subjected to legal prosecution. Activity on this network is monitored and may be used as evidence in a court of law. Copyright 2009 Brocade Communications, Inc., Inc."

**Displaying web authentication information**

The following sections present the **show** commands you can use to display information about the Web Authentication feature.

**Displaying the web authentication configuration**

Enter the following command to display the configuration for the Web Authentication feature.

```
FastIron#show webauth
```

```
WEB AUTHENTICATION (VLAN 25): Enable
attempt-max-num: 5 (Default)
host-max-num: 0 (Default)
block duration: 90 (Default)
cycle-time: 600 (Default)
port-down-authenticated-mac-cleanup: Enable (Default)
reauth-time: 28800 (Default)
authenticated-mac-age-time: 3600 (Default)
```
Displaying web authentication information

dns-filter: Disable (Default)
authentication mode: username and password (Default)
   authentication methods: radius
      Local user database name: <none>
Radius accounting: Enable (Default)
Trusted port list: None
Secure Login (HTTPS): Enable (Default)
Web Page Customizations:
   Top (Header): Default Text
   Bottom (Footer): Custom Text
      "SNL Copyright 2009"
   Title: Default Text
   Login Button: Custom Text
      "Sign On"
   Web Page Logo: blogo.gif
      align: left (Default)
   Web Page Terms and Conditions: policy1.txt
Host statistics:
   Number of hosts dynamically authenticated: 0
   Number of hosts statically authenticated: 2
   Number of hosts dynamically blocked: 0
   Number of hosts statically blocked: 0
   Number of hosts authenticating: 1

The display shows the following information.

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>WEB AUTHENTICATION (VLAN 10)</td>
<td>Identifies the VLAN on which Web Authentication is enabled.</td>
</tr>
<tr>
<td>attempt-max-num</td>
<td>The maximum number of Web Authentication attempts during a cycle.</td>
</tr>
<tr>
<td>host-max-num</td>
<td>The maximum number of users that can be authenticated at one time.</td>
</tr>
<tr>
<td>block duration</td>
<td>How many seconds a user who failed Web Authentication must wait before attempting to be authenticated.</td>
</tr>
<tr>
<td>cycle-time</td>
<td>The number of seconds in one Web Authentication cycle.</td>
</tr>
<tr>
<td>port-down-authenticated-mac-clean-up</td>
<td>Indicates if this option is enabled or disabled. If enabled, all authenticated users are de-authenticated if all the ports in the VLAN go down.</td>
</tr>
<tr>
<td>reauth-time</td>
<td>The number of seconds an authenticated user remains authenticated. Once this timer expires, the user must re-authenticate.</td>
</tr>
<tr>
<td>authenticated-mac-age-time</td>
<td>If a user is inactive, this time shows how many seconds a user has before the user associated MAC address is aged out. The user will be forced to re-authenticate.</td>
</tr>
<tr>
<td>dns-filter</td>
<td>Shows the definition of any DNS filter that have been set. (Refer to “Filtering DNS queries” on page 1624</td>
</tr>
</tbody>
</table>
Displaying web authentication information

Syntax: show webauth [vlan <vlan-id>]

The show webauth command by itself displays information for all VLANs on which Web Authentication is enabled. Use the vlan <vlan-id> parameter to display information for a specific VLAN.

Displaying a list of authenticated hosts

Enter the following command to display a list of hosts that are currently authenticated.

```
FastIron#show webauth allowed-list
```

<table>
<thead>
<tr>
<th>VLAN #: Web Authentication</th>
<th>The ID of the VLAN on which Web Authentication is enabled.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web Authenticated List MAC Address</td>
<td>The MAC addresses that have been authenticated.</td>
</tr>
<tr>
<td>User Name</td>
<td>Configuration</td>
</tr>
<tr>
<td>Static/Dynamic</td>
<td>HH:MM:SS</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>00a0.f86c.2807</td>
<td>N/A</td>
</tr>
<tr>
<td>0009.5b69.79ea</td>
<td>fdry1</td>
</tr>
<tr>
<td>000c.db82.8bca</td>
<td>N/A</td>
</tr>
<tr>
<td>0007.e90e.de3b</td>
<td>N/A</td>
</tr>
<tr>
<td>000a.e422.a50e</td>
<td>fdry2</td>
</tr>

Displaying a list of users in a local user database

The following command displays a list of all users in a particular local user database.
Displaying web authentication information

Gas Iron#show local-userdb test

+----------------------------------------------------------+
| Local User Database : test                                |
| Username                  Password                      |
| -----------            -----------                      |
| user1       $e$&Z9'%*&+                                  |
| user2       $e$,)A=)65N,%-3%1?@U                         |
| user3       $e$5%&-5%YO&Al%6%<@U                        |

As shown in the above example, passwords are encrypted in the command output.

Syntax: show local-userdb <db-name>

Displaying passcodes

If the passcode Web authentication mode is enabled, you can use the following command to display current passcodes.

FastIron#show webauth vlan 25 passcode
Current Passcode : 1389
This passcode is valid for 35089 seconds

Syntax: show webauth vlan <vlan-id> passcode
Protecting against Smurf attacks

This chapter explains how to protect your Brocade devices from Denial of Service (DoS) attacks. In a Denial of Service (DoS) attack, a router is flooded with useless packets, hindering normal operation. Brocade devices include measures for defending against two types of DoS attacks: Smurf attacks and TCP SYN attacks.

A **Smurf attack** is a kind of DoS attack where an attacker causes a victim to be flooded with ICMP echo (Ping) replies sent from another network. Figure 184 illustrates how a Smurf attack works.

**FIGURE 184** How a Smurf attack floods a victim with ICMP replies

The attacker sends an ICMP echo request packet to the broadcast address of an intermediary network. The ICMP echo request packet contains the spoofed address of a victim network as its source. When the ICMP echo request reaches the intermediary network, it is converted to a Layer 2 broadcast and sent to the hosts on the intermediary network. The hosts on the intermediary network then send ICMP replies to the victim network.

For each ICMP echo request packet sent by the attacker, a number of ICMP replies equal to the number of hosts on the intermediary network are sent to the victim. If the attacker generates a large volume of ICMP echo request packets, and the intermediary network contains a large number of hosts, the victim can be overwhelmed with ICMP replies.

**Avoiding being an intermediary in a Smurf attack**

A Smurf attack relies on the intermediary to broadcast ICMP echo request packets to hosts on a target subnet. When the ICMP echo request packet arrives at the target subnet, it is converted to a Layer 2 broadcast and sent to the connected hosts. This conversion takes place only when directed broadcast forwarding is enabled on the device.
To avoid being an intermediary in a Smurf attack, make sure forwarding of directed broadcasts is disabled on the Brocade device. Directed broadcast forwarding is disabled by default. To disable directed broadcast forwarding, do one of the following.

FastIron(config)# no ip directed-broadcast

Syntax: [no] ip directed-broadcast

Avoiding being a victim in a Smurf attack

You can configure the Brocade device to drop ICMP packets when excessive numbers are encountered, as is the case when the device is the victim of a Smurf attack. You can set threshold values for ICMP packets that are targeted at the router itself or passing through an interface, and drop them when the thresholds are exceeded.

The syntax to set threshold values for ICMP packets targeted on a FastIron device is as follows.

Syntax: ip icmp burst-normal <value> burst-max <value> lockup <seconds>

The <value> of burst-normal and burst-max is specified in packets per second.

For example, to set threshold values for ICMP packets targeted on the router, enter the following command in the CONFIG mode.

FastIron(config)# ip icmp burst-normal 5000 burst-max 10000 lockup 300

To set threshold values for ICMP packets received on interface 3/11, enter the following command.

FastIron(config)# int e 3/11
FastIron(config-if-e1000-3/11)# ip icmp burst-normal 5000 burst-max 10000 lockup 300

Syntax: ip icmp burst-normal <value> burst-max <value> lockup <seconds>

The burst-normal value can be from 1 – 100000.

The burst-max value can be from 1 – 100000.

The lockup value can be from 1 – 10000.

This command is supported on Ethernet and Layer 3 ATM interfaces.

The number of incoming ICMP packets per second are measured and compared to the threshold values as follows:

- If the number of ICMP packets exceeds the burst-normal value, the excess ICMP packets are dropped.
- If the number of ICMP packets exceeds the burst-max value, all ICMP packets are dropped for the number of seconds specified by the lockup value. When the lockup period expires, the packet counter is reset and measurement is restarted.

In the example above, if the number of ICMP packets received per second exceeds 5,000, the excess packets are dropped. If the number of ICMP packets received per second exceeds 10,000, the device drops all ICMP packets for the next 300 seconds (five minutes).

Protection against ICMP attacks in TurboIron devices

The ICMP flood attack protection is implemented in hardware on TurboIron X series devices running software release 04.2.00 and later. This feature can coexist with port-based rate-limiting, MAC filters, Layer 4 ACLs, and other features.
You can set threshold values for ICMP packets that are targeted at the router itself or passing through an interface, and drop them when the thresholds are exceeded.

The syntax to set threshold values for ICMP packets targeted on a TurboIron device is as follows.

**Syntax:** ip icmp attack-rate burst-normal `<value>` burst-max `<value>` lockup `<seconds>`

The `attack-rate` keyword indicates that the normal burst value and maximum burst values to be specified in kilobits per second (kbps).

The `burst-normal` value ranges from 20 through 10000000.

The `burst-max` value ranges from 20 through 10000000.

The `lockup` value ranges from 1 through 10000.

**Configuration notes**

Consider the following statements when DoS attack protection is implemented at port level or VLAN level.

- The ACL based ingress rate-limiting for ICMP flow on a port is not accurate if ICMP Dos attack protection is enabled on the same port. Non-ICMP flows are not affected.

- ICMP DoS attack protection considers packet marked as drop by port-based ingress rate limiting. In this case, even if the port-based ingress rate-limiting reduces the packet per byte rate, DoS attack is still detected by using actual ingress packet per byte rate on a port.

**NOTE**

If you configure both DoS attack protection and ACL or MAC filter, the DoS attack statistics for dropped ICMP or TCP SYN packet increments even if the ACL or MAC filter denies the traffic.

---

**Protecting against TCP SYN attacks**

**TCP SYN attacks** exploit the process of how TCP connections are established in order to disrupt normal traffic flow. When a TCP connection starts, the connecting host first sends a TCP SYN packet to the destination host. The destination host responds with a SYN ACK packet, and the connecting host sends back an ACK packet. This process, known as a “TCP three-way handshake”, establishes the TCP connection.

While waiting for the connecting host to send an ACK packet, the destination host keeps track of the as-yet incomplete TCP connection in a connection queue. When the ACK packet is received, information about the connection is removed from the connection queue. Usually there is not much time between the destination host sending a SYN ACK packet and the source host sending an ACK packet, so the connection queue clears quickly.

In a TCP SYN attack, an attacker floods a host with TCP SYN packets that have random source IP addresses. For each of these TCP SYN packets, the destination host responds with a SYN ACK packet and adds information to the connection queue. However, since the source host does not exist, no ACK packet is sent back to the destination host, and an entry remains in the connection queue until it ages out (after around a minute). If the attacker sends enough TCP SYN packets, the connection queue can fill up, and service can be denied to legitimate TCP connections.
To protect against TCP SYN attacks, you can configure the Brocade device to drop TCP SYN packets when excessive numbers are encountered. You can set threshold values for TCP SYN packets that are targeted at the router itself or passing through an interface, and drop them when the thresholds are exceeded.

For example, to set threshold values for TCP SYN packets targeted at the router, enter the following command in CONFIG mode.

`FastIron(config)# ip tcp burst-normal 10 burst-max 100 lockup 300`

To set threshold values for TCP SYN packets received on interface 3/11, enter the following command.

`FastIron(config)# int e 3/11
FastIron(config-if-e1000-3/11)# ip tcp burst-normal 10 burst-max 100 lockup 300`

**Syntax:** `ip tcp burst-normal <value> burst-max <value> lockup <seconds>`

**NOTE**
This command is available at the global CONFIG level on both Chassis devices and Stackable devices. On Chassis devices, this command is available at the Interface level as well. This command is supported on Ethernet and Layer 3 ATM interfaces.

The `burst-normal` value ranges from 1 through 100000.

The `burst-max` value ranges from 1 through 100000.

The `lockup` value ranges from 1 through 10000.

The TurboIron X Series device running software release 04.2.00 and later supports the following burst-normal, burst-max, and lockup values.

The `burst-normal` value ranges from 30 through 16000000.

The `burst-max` value ranges from 30 through 16000000.

The `lockup` value ranges from 1 through 10000.

The number of incoming TCP SYN packets per second are measured and compared to the threshold values as follows:

- If the number of TCP SYN packets exceeds the `burst-normal` value, the excess TCP SYN packets are dropped.
- If the number of TCP SYN packets exceeds the `burst-max` value, all TCP SYN packets are dropped for the number of seconds specified by the `lockup` value. When the lockup period expires, the packet counter is reset and measurement is restarted.

In the example above, if the number of TCP SYN packets received per second exceeds 10, the excess packets are dropped. If the number of TCP SYN packets received per second exceeds 100, the device drops all TCP SYN packets for the next 300 seconds (five minutes).

**Protection against TCP-SYN attacks in TurboIron devices**

The TCP-SYN flood attack protection is implemented in hardware on TurboIron X Series devices running software release 04.2.00 and later. The protection against TCP SYN flood assume that the TCP SYN packet size is 74 bytes, which includes L2, IPv4, and TCP header. If packet size of the attack exceeds the limit, the TCP attack protection takes effect faster than the configured burst values.
Configuration notes

Consider the following statements when DoS attack protection is implemented at port level or Virtual Interface (VE) level.

- The ACL based ingress rate-limiting for TCP flow on a port is not accurate if TCP DoS attack protection is enabled on the same port. Non-TCP flows are not affected.
- TCP DoS attack protection considers packet marked as drop by port-based ingress rate limiting. In this case, even if the port-based ingress rate-limiting reduces the packet per byte rate, DoS attack is still detected by using actual ingress packet per byte rate on a port.

TCP security enhancement

TCP security enhancement improves upon the handling of TCP inbound segments. This enhancement eliminates or minimizes the possibility of a TCP reset attack, in which a perpetrator attempts to prematurely terminate an active TCP session, and a data injection attack, wherein an attacker injects or manipulates data in a TCP connection.

In both cases, the attack is blind, meaning the perpetrator does not have visibility into the content of the data stream between two devices, but blindly injects traffic. Also, the attacker does not see the direct effect, the continuing communications between the devices and the impact of the injected packet, but may see the indirect impact of a terminated or corrupted session.

The TCP security enhancement prevents and protects against the following three types of attacks:

- Blind TCP reset attack using the reset (RST) bit.
- Blind TCP reset attack using the synchronization (SYN) bit
- Blind TCP packet injection attack

The TCP security enhancement is automatically enabled.

Protecting against a blind TCP reset attack using the RST bit

In a blind TCP reset attack using the RST bit, a perpetrator attempts to guess the RST segments in order to prematurely terminate an active TCP session.

To prevent a user from using the RST bit to reset a TCP connection, the RST bit is subject to the following rules when receiving TCP segments:

- If the RST bit is set and the sequence number is outside the expected window, the Brocade device silently drops the segment.
- If the RST bit is exactly the next expected sequence number, the Brocade device resets the connection.
- If the RST bit is set and the sequence number does not exactly match the next expected sequence value, but is within the acceptable window, the Brocade device sends an acknowledgement.

Prior software releases apply the following rules to the RST bit when receiving TCP segments:

- If the RST bit is set and the sequence number is outside the expected window, the Brocade device silently drops the segment.
- If the RST bit is set and the sequence number is within the acceptable range, the Brocade device resets the connection.
Protecting against a blind TCP reset attack using the SYN bit

In a blind TCP reset attack, a perpetrator attempts to guess the SYN bits to prematurely terminate an active TCP session.

To prevent a user from using the SYN bit to tear down a TCP connection, in current software releases, the SYN bit is subject to the following rules when receiving TCP segments:

- If the SYN bit is set and the sequence number is outside the expected window, the Brocade device sends an acknowledgement (ACK) back to the peer.
- If the SYN bit is set and the sequence number is an exact match to the next expected sequence, the Brocade device sends an ACK segment to the peer. Before sending the ACK segment, the software subtracts one from the value being acknowledged.
- If the SYN bit is set and the sequence number is acceptable, the Brocade device sends an acknowledgement (ACK) segment to the peer.

Prior software releases apply the following rules to the SYN bit when receiving TCP segments:

- If the SYN bit is set and the sequence number is outside the expected window, the Brocade device sends an ACK back to the sender.
- If the SYN bit is set and the sequence number is acceptable, the Brocade device sends a RST segment to the peer.

Protecting against a blind injection attack

In a blind TCP injection attack, a perpetrator tries to inject or manipulate data in a TCP connection.

To reduce the chances of a blind injection attack, an additional check on all incoming TCP segments is performed.

Displaying statistics about packets dropped because of DoS attacks

To display information about ICMP and TCP SYN packets dropped because burst thresholds were exceeded, enter the following command.

```
FastIron# show statistics dos-attack
```

```
---------------------------- Local Attack Statistics --------------------------
ICMP Drop Count    ICMP Block Count    SYN Drop Count    SYN Block Count
---------------    ----------------    --------------    ---------------
0                   0                 0                  0
--------------------------- Transit Attack Statistics -------------------------
Port   ICMP Drop Count    ICMP Block Count    SYN Drop Count    SYN Block Count
-----  ---------------    ----------------    --------------    ---------------
3/11               0                   0                 0                  0
```

**Syntax:** `show statistics dos-attack`

To clear statistics about ICMP and TCP SYN packets dropped because burst thresholds were exceeded, enter the following command.

```
FastIron# clear statistics dos-attack
```

**Syntax:** `clear statistics dos-attack`
Displaying statistics about packets dropped because of DoS attacks in TurboIron device

To display information about ICMP and TCP SYN packets dropped because burst thresholds were exceeded, enter the following command.

```
TurboIron# show statistics dos-attack
```

Protecting against TCP SYN attacks
Dynamic ARP inspection

For enhanced network security, you can configure the Brocade device to inspect and keep track of Dynamic Host Configuration Protocol (DHCP) assignments.

**NOTE**
TurboIron X Series devices do not support the features in this chapter.

Dynamic ARP Inspection (DAI) enables the Brocade device to intercept and examine all ARP request and response packets in a subnet and discard those packets with invalid IP to MAC address bindings. DAI can prevent common man-in-the-middle (MIM) attacks such as ARP cache poisoning, and disallow mis-configuration of client IP addresses.

ARP poisoning

ARP provides IP communication within a Layer 2 broadcast domain by mapping an IP address to a MAC address. Before a host can talk to another host, it must map the IP address to a MAC address first. If the host does not have the mapping in its ARP table, it creates an ARP request to resolve the mapping. All computers on the subnet will receive and process the ARP requests, and the host whose IP address matches the IP address in the request will send an ARP reply.

An ARP poisoning attack can target hosts, switches, and routers connected to the Layer 2 network by poisoning the ARP caches of systems connected to the subnet and by intercepting traffic intended for other hosts on the subnet. For instance, a malicious host can reply to an ARP request with its own MAC address, thereby causing other hosts on the same subnet to store this information in their ARP tables or replace the existing ARP entry. Furthermore, a host can send gratuitous replies without having received any ARP requests. A malicious host can also send out ARP packets claiming to have an IP address that actually belongs to another host (e.g., the default router). After the attack, all traffic from the device under attack flows through the attacker computer and then to the router, switch, or host.

How DAI works

DAI allows only valid ARP requests and responses to be forwarded.

A Brocade device on which DAI is configured does the following:

- Intercepts ARP packets received by the system CPU
- Inspects all ARP requests and responses received on untrusted ports
- Verifies that each of the intercepted packets has a valid IP-to-MAC address binding before updating the local ARP table, or before forwarding the packet to the appropriate destination
- Drops invalid ARP packets
When you enable DAI on a VLAN, by default, all member ports are untrusted. You must manually configure trusted ports. In a typical network configuration, ports connected to host ports are untrusted. You configure ports connected to other switches or routers as trusted.

DAI inspects ARP packets received on untrusted ports, as shown in Figure 185. DAI carries out the inspection based on IP-to-MAC address bindings stored in a trusted binding database. For the Brocade device, the binding database is the ARP table, which supports DAI, DHCP snooping, and IP Source Guard. To inspect an ARP request packet, DAI checks the source IP and source MAC address against the ARP table. For an ARP reply packet, DAI checks the source IP, source MAC, destination IP, and destination MAC addresses. DAI forwards the valid packets and discards those with invalid IP-to-MAC address bindings.

When ARP packets reach a trusted port, DAI lets them through, as shown in Figure 185.

**FIGURE 185  Dynamic ARP inspection at work**

**ARP entries**

DAI uses the IP/MAC mappings in the ARP table to validate ARP packets received on untrusted ports.

ARP entries in the ARP table derive from the following:

- **Dynamic ARP** – normal ARP learned from trusted ports.
- **Static ARP** – statically configured IP/MAC/port mapping.
- **Inspection ARP** – statically configured IP/MAC mapping, where the port is initially unspecified. The actual physical port mapping will be resolved and updated from validated ARP packets. Refer to “Configuring an inspection ARP entry” on page 1650.
- **DHCP-Snooping ARP** – information collected from snooping DHCP packets when DHCP snooping is enabled on VLANs.

The status of an ARP entry is either pending or valid:

- **Valid** – the mapping is valid, and the port is resolved. This is always the case for static ARP entries.
- **Pending** – for normal dynamic and inspection ARP entries before they are resolved, and the port mapped. Their status changes to valid when they are resolved, and the port mapped.

Refer to also “System reboot and the binding database” on page 1653.
Configuration notes and feature limitations

The following limits and restrictions apply when configuring DAI:

- To run Dynamic ARP Inspection, you must first enable support for ACL filtering based on VLAN membership or VE port membership. To do so, enter the following commands at the Global CONFIG Level of the CLI.

  FastIron(config)#enable ACL-per-port-per-vlan
  FastIron(config)#write memory
  FastIron(config)#exit
  FastIron#reload

  **NOTE**
  You must save the configuration and reload the software to place the change into effect.

- Brocade recommends that you do not enable DAI on a trunk port.

- The maximum number of DHCP and static DAI entries depends on the maximum number of ARP table entries allowed on the device. A FastIron Layer 2 switch can have up to 256 ARP entries and a FastIron Layer 3 switch can have up to 64,000 ARP entries. In a FastIron Layer 3 switch, you can use the `system-max arp` command to change the maximum number of ARP entries for the device.
  However, only up to 1024 DHCP entries can be saved to flash.

- Starting in software release FSX 04.0.01, ACLs are supported on member ports of a VLAN on which DHCP snooping and Dynamic ARP Inspection (DAI) are enabled.

- Starting in software release FSX 04.2.00, DAI is supported together with multi-device port authentication and dynamic ACLs. For details, refer to “Support for dynamic ARP inspection with dynamic ACLs” on page 1573.

- DAI is supported on a VLAN without a VE, or on a VE with or without an assigned IP address.

Configuring DAI

Configuring DAI consists of the following steps.

1. Configure inspection ARP entries for hosts on untrusted ports. Refer to “Configuring an inspection ARP entry” on page 1650.

2. Enable DAI on a VLAN to inspect ARP packets. Refer to “Enabling DAI on a VLAN” on page 1650.

3. Configure the trust settings of the VLAN members. ARP packets received on trusted ports bypass the DAI validation process. ARP packets received on untrusted ports go through the DAI validation process. Refer to “Enabling trust on a port” on page 1650.

4. Enable DHCP snooping to populate the DHCP snooping IP-to-MAC binding database.

The following shows the default settings of DAI.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic ARP Inspection</td>
<td>Disabled</td>
</tr>
<tr>
<td>Trust setting for ports</td>
<td>Untrusted</td>
</tr>
</tbody>
</table>
Configuring an inspection ARP entry

Static ARP and static inspection ARP entries need to be configured for hosts on untrusted ports. Otherwise, when DAI checks ARP packets from these hosts against entries in the ARP table, it will not find any entries for them, and the Brocade device will not allow and learn ARP from an untrusted host.

When the inspection ARP entry is resolved with the correct IP/MAC mapping, its status changes from pending to valid.

To configure an inspection ARP entry, enter a command such as the following.

```
FastIron(config)#arp 20.20.20.12 0001.0002.0003 inspection
```

This command defines an inspection ARP entry, mapping a device IP address 20.20.20.12 with its MAC address 0001.0002.0003. The ARP entry will be in Pend (pending) status until traffic with the matching IP-to-MAC is received on a port.

Syntax: `[no] arp <index> <ip-addr> <mac-addr> inspection`

The `<index>` can be from 1 up to the maximum number of static entries allowed.

The `<ip-addr> <mac-addr>` parameter specifies a device IP address and MAC address pairing.

Enabling DAI on a VLAN

DAI is disabled by default. To enable DAI on an existing VLAN, enter the following command.

```
FastIron(config)#ip arp inspection vlan 2
```

The command enables DAI on VLAN 2. ARP packets from untrusted ports in VLAN 2 will undergo DAI inspection.

Syntax: `[no] ip arp inspection vlan <vlan-number>`

The `<vlan-number>` variable specifies the ID of a configured VLAN.

Enabling trust on a port

The default trust setting for a port is untrusted. For ports that are connected to host ports, leave their trust settings as untrusted.

To enable trust on a port, enter commands such as the following.

```
FastIron(config)#interface ethernet 1/4
FastIron(config-if-e10000-1/4)#arp inspection trust
```

The commands change the CLI to the interface configuration level of port 1/4 and set the trust setting of port 1/4 to trusted.

Syntax: `[no] arp inspection trust`

Displaying ARP inspection status and ports

To display the ARP inspection status for a VLAN and the trusted/untrusted port, enter the following command.
DHCP snooping

Dynamic Host Configuration Protocol (DHCP) snooping enables the Brocade device to filter untrusted DHCP packets in a subnet. DHCP snooping can ward off MiM attacks, such as a malicious user posing as a DHCP server sending false DHCP server reply packets with the intention of misdirecting other users. DHCP snooping can also stop unauthorized DHCP servers and prevent errors due to user mis-configuration of DHCP servers.

Often DHCP snooping is used together with Dynamic ARP Inspection and IP Source Guard.

Syntax: show ip arp inspection [vlan <vlan_id>]

The <vlan_id> variable specifies the ID of a configured VLAN.

Displaying the ARP table

To display the ARP table, enter the following command.

```
FastIron#show arp
```

```
Total number of ARP entries: 2

<table>
<thead>
<tr>
<th>IP Address</th>
<th>MAC Address</th>
<th>Type</th>
<th>Age</th>
<th>Port</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.43.1.1</td>
<td>0004.80a0.4000</td>
<td>Dynamic</td>
<td>0</td>
<td>mgmt1</td>
<td>Valid</td>
</tr>
<tr>
<td>10.43.1.78</td>
<td>00e0.8160.6ab1</td>
<td>Dynamic</td>
<td>2</td>
<td>mgmt1</td>
<td>Valid</td>
</tr>
</tbody>
</table>
```

The command displays all ARP entries in the system. For field definitions, refer to Table 183 on page 1092.

Syntax: show arp
How DHCP snooping works

When enabled on a VLAN, DHCP snooping stands between untrusted ports (those connected to host ports) and trusted ports (those connected to DHCP servers). A VLAN with DHCP snooping enabled forwards DHCP request packets from clients and discards DHCP server reply packets on untrusted ports, and it forwards DHCP server reply packets on trusted ports to DHCP clients, as shown in the following figures.

FIGURE 186  DHCP snooping at work - on an untrusted port

FIGURE 187  DHCP snooping at work - on a trusted port

**DHCP binding database**

When it forwards DHCP server reply packets on trusted ports, the Brocade device saves the client IP-to-MAC address binding information in the DHCP binding database. This is how the DHCP snooping binding table is populated. The information saved includes MAC address, IP address, lease time, VLAN number, and port number.

In the Brocade device, the DHCP binding database is integrated with the enhanced ARP table, which is used by Dynamic ARP Inspection. For more information, refer to “ARP entries” on page 1648.

The lease time will be refreshed when the client renews its IP address with the DHCP server; otherwise the Brocade device removes the entry when the lease time expires.
**About client IP-to-MAC address mappings**

Starting in release FSX 04.2.00, client IP addresses need not be on directly-connected networks, as long as the client MAC address is learned on the client port and the client port is in the same VLAN as the DHCP server port. In this case, the system will learn the client IP-to-MAC port mapping. Therefore, a VLAN with DHCP snooping enabled does not require a VE interface.

In releases prior to FSX 04.2.00, in the Layer 3 software image, DHCP snooping does not learn the secure IP-to-MAC address mapping for a client, if the client port is not a virtual ethernet (VE) interface with an IP subnet address. In other words, the client IP address had to match one of the subnets of the client port in order for DHCP to learn the address mapping.

**System reboot and the binding database**

To allow DAI and DHCP snooping to work smoothly across a system reboot, the binding database is saved to a file in the system flash memory after an update to the binding database, with a 30 second delay. The flash file is written and read only if DHCP snooping is enabled.

**Configuration notes and feature limitations**

The following limits and restrictions apply to DHCP snooping:

- To run DHCP snooping, you must first enable support for ACL filtering based on VLAN membership or VE port membership. To do so, enter the following commands at the Global CONFIG Level of the CLI.

```
FastIron(config)#enable ACL-per-port-per-vlan
FastIron(config)#write memory
FastIron(config)#exit
FastIron#reload
```

**NOTE**

You must save the configuration and reload the software to place the change into effect.

- DHCP snooping is not supported on trunk ports.
- A switch can have up to 256 ARP entries, therefore, DHCP entries are limited to 256. A router, however, can have 64,000 ARP entries, so a router can have up to 64,000 DHCP entries, of which only 1024 entries can be saved to flash on reboot.
- Starting in software release FSX 04.0.01, ACLs are supported on member ports of a VLAN on which DHCP snooping and Dynamic ARP Inspection (DAI) are enabled.
- See also “About client IP-to-MAC address mappings” on page 1653.
- Starting in software release FSX 04.2.00, DHCP snooping is supported together with multi-device port authentication and dynamic ACLs. For details, refer to “Support for DHCP snooping with dynamic ACLs” on page 1574.
- Starting in software release FSX 05.0.00, DHCP snooping supports DHCP relay agent information (DHCP Option 82). For details, refer to “DHCP relay agent information (DHCP Option 82)” on page 1656.

**Configuring DHCP snooping**

Configuring DHCP snooping consists of the following steps.
1. Enable DHCP snooping on a VLAN. Refer to “Enabling DHCP snooping on a VLAN” on page 1654.

2. For ports that are connected to a DHCP server, change their trust setting to trusted. Refer to “Enabling trust on a port” on page 1654.

The following shows the default settings of DHCP snooping.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCP snooping</td>
<td>Disabled</td>
</tr>
<tr>
<td>Trust setting for ports</td>
<td>Untrusted</td>
</tr>
</tbody>
</table>

**Enabling DHCP snooping on a VLAN**

DHCP packets for a VLAN with DHCP snooping enabled are inspected.

DHCP snooping is disabled by default. This feature must be enabled on the client and the DHCP server VLANs. To enable DHCP snooping, enter the following global command for these VLANs.

FastIron(config)#ip dhcp snooping vlan 2

The command enables DHCP snooping on VLAN 2.

**Syntax:** `[no] ip dhcp snooping vlan <vlan-number>`

The `<vlan-number>` variable specifies the ID of a configured client or DHCP server VLAN.

**Enabling trust on a port**

The default trust setting for a port is untrusted. To enable trust on a port connected to a DHCP server, enter commands such as the following.

FastIron(config)#interface ethernet 1/1
FastIron(config-if-e10000-1/1)#dhcp snooping trust

Port 1/1 is connected to a DHCP server. The commands change the CLI to the interface configuration level of port 1/1 and set the trust setting of port 1/1 to trusted.

**Syntax:** `[no] dhcp snooping trust`

**Clearing the DHCP binding database**

You can clear the DHCP binding database using the CLI command `clear dhcp`. You can remove all entries in the database, or remove entries for a specific IP address only.

To remove all entries from the DHCP binding database, enter the following command.

FastIron#clear dhcp

To clear entries for a specific IP address, enter a command such as the following.

FastIron#clear dhcp 10.10.102.4

**Syntax:** `clear dhcp [<ip-addr>]`
Displaying DHCP snooping status and ports

To display the DHCP snooping status for a VLAN and the trusted/untrusted port, use the `show ip dhcp snooping vlan` command.

```
FastIron#show ip dhcp snooping vlan 2
IP DHCP snooping VLAN 2: Enabled
```

**Syntax:** `show ip dhcp snooping [vlan <vlan-id>]`

Displaying the DHCP snooping binding database

To display the DHCP snooping binding database, use the `show ip dhcp snooping info` command.

```
FastIron#show ip dhcp snooping info
DHCP snooping Info
Total learnt entries 1
SAVED DHCP ENTRIES IN FLASH
 IP Address  Mac Address  Port  vlan  lease
 0        10.10.10.20  0001.0002.0003  6/13  1112  361
```

**Syntax:** `show ip dhcp snooping info`

Displaying DHCP binding entry and status

To display the DHCP binding entry and its current status, use the `show arp` command.

```
FastIron#show arp
Total number of ARP entries: 2
 IP Address  MAC Address  Type   Age    Port  Status
 1     10.43.1.1       00e0.0001.c320  Dynamic 0     mgmt1  Valid
 2     10.43.1.199     00e0.0002.b263  Dynamic 7     mgmt1  Valid
```

**Syntax:** `show arp`

For field definitions, refer to Table 183 on page 1092.

DHCP snooping configuration example

The following example configures VLAN 2 and VLAN 20, and changes the CLI to the global configuration level to enable DHCP snooping on the two VLANs. The commands are as follows.

```
FastIron(config)#vlan 2
FastIron(config-vlan-2)#untagged ethe 1/3 to 1/4
FastIron(config-vlan-2)#router-interface ve 2
FastIron(config-vlan-2)#exit
FastIron(config)#ip dhcp snooping vlan 2

FastIron(config)#vlan 20
FastIron(config-vlan-20)#untagged ethe 1/1 to 1/2
FastIron(config-vlan-20)#router-interface ve 20
FastIron(config-vlan-20)#exit
FastIron(config)#ip dhcp snooping vlan 20
```
On VLAN 2, client ports 1/3 and 1/4 are untrusted by default all client ports are untrusted. Hence, only DHCP client request packets received on ports 1/3 and 1/4 are forwarded.

On VLAN 20, ports 1/1 and 1/2 are connected to a DHCP server. DHCP server ports are set to trusted.

FastIron(config)#interface ethernet 1/1
FastIron(config-if-e10000-1/1)#dhcp snooping trust
FastIron(config-if-e10000-1/1)#exit
FastIron(config)#interface ethernet 1/2
FastIron(config-if-e10000-1/2)#dhcp snooping trust
FastIron(config-if-e10000-1/2)#exit

Hence, DHCP server reply packets received on ports 1/1 and 1/2 are forwarded, and client IP/MAC binding information is collected.

The example also sets the DHCP server address for the local relay agent.

FastIron(config)#interface ve 2
FastIron(config-vif-2)#ip address 20.20.20.1/24
FastIron(config-vif-2)#ip helper-address 1 30.30.30.4
FastIron(config-vif-2)#interface ve 20
FastIron(config-vif-20)#ip address 30.30.30.1/24

**DHCP relay agent information (DHCP Option 82)**

DHCP relay agent information, also known as DHCP option 82, enables a DHCP relay agent to insert information about a client's identity into a DHCP client request being sent to a DHCP server.

Starting with software release FSX 05.0.00, when DHCP snooping is enabled on the FastIron switch, DHCP option 82 is automatically enabled. DHCP packets are processed as follows:

- Before relaying a DHCP discovery packet or DHCP request packet from a client to a DHCP server, the FastIron switch will add agent information to the packet.
- Before relaying a DHCP reply packet from a DHCP server to a client, the FastIron switch will remove relay agent information from the packet.

As illustrated in Figure 188, the DHCP relay agent (the FastIron switch), inserts DHCP option 82 attributes when relaying a DHCP request packet to a DHCP server.

**FIGURE 188** DHCP Option 82 attributes added to the DHCP packet

As illustrated in Figure 189, the FastIron switch deletes DHCP option 82 attributes before forwarding a server reply packet back to a DHCP client.
DHCP relay agent information (DHCP Option 82)

The DHCP option 82 insertion/deletion feature is available only when DHCP snooping is enabled for the client/server ports.

**Configuration notes**

- DHCP snooping and DHCP option 82 are supported on a per-VLAN basis.
- DHCP option 82 follows the same configuration rules and limitations as for DHCP snooping. For more information, refer to “Configuration notes and feature limitations” on page 1653.

**DHCP Option 82 sub-options**

The Brocade implementation of DHCP Option 82 supports the following sub-options:

- Sub-Option 1 – Circuit ID
- Sub-Option 2 - Remote ID
- Sub-Option 6 – Subscriber ID

These sub-options are described in the following sections.

**Sub-option 1 – circuit id**

The Circuit ID (CID) identifies the circuit or port from which a DHCP client request was sent. The FastIron switch uses this information to relay DHCP responses back to the proper circuit, for example, the port number on which the DHCP client request packet was received.
Brocade FastIron devices support the **General CID packet format**. This simple format encodes the CID type, actual information length, VLAN ID, slot number, and port number. This format is compatible with the format used by other vendors’ devices. Figure 190 illustrates the general CID packet format.

**FIGURE 190  General CID packet format**

<table>
<thead>
<tr>
<th>1</th>
<th>6</th>
<th>0</th>
<th>4</th>
<th>VLAN ID</th>
<th>Slot ID</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Byte</td>
<td>2 Bytes</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Sub-option 2 – Remote ID**

The Remote ID (RID) identifies the remote host end of the circuit (the relay agent). Brocade devices use the MAC address to identify itself as the relay agent. Figure 191 illustrates the RID packet format.

**FIGURE 191  RID packet format**

<table>
<thead>
<tr>
<th>2</th>
<th>8</th>
<th>0</th>
<th>6</th>
<th>MAC Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Byte</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Sub-option 6 - subscriber id**

The Subscriber ID (SID) is a unique identification number that enables an Internet Service Provider to:

- Identify a subscriber
- Assign specific attributes to that subscriber (for example, host IP address, subnet mask, and domain name server (DNS))
- Trigger accounting

Figure 192 illustrates the SID packet format.

**FIGURE 192  SID packet format**

<table>
<thead>
<tr>
<th>6</th>
<th>N</th>
<th>ASCII String 1.....N</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Byte</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The second byte (N in Figure 192) is the length of the ASCII string that follows. The FastIron switch supports up to 50 ASCII characters.

**Configuring DHCP option 82**

When DHCP snooping is enabled on a VLAN, by default, DHCP option 82 also is enabled. You do not need to perform any extra configuration steps to enable this feature. To enable DHCP snooping, refer to “Enabling DHCP snooping on a VLAN” on page 1654.
When processing DHCP packets, the FastIron switch applies the following default behavior when DHCP option 82 is enabled:

- Subjects all ports in the VLAN to DHCP option 82 processing
- Uses the general CID packet format
- Uses the standard RID packet format
- Replaces relay agent information received in DHCP packets with its own information
- Does not enable SID processing

When DHCP option 82 is enabled, you can optionally:

- Disable DHCP Option 82 processing on individual ports in the VLAN
- Configure the device to drop or keep the relay agent information in a DHCP packet instead of replacing it with its own information
- Enable SID processing

**Disabling and re-enabling DHCP option 82 processing on an individual interface**

By default, when DHCP option 82 is enabled on a VLAN, DHCP packets received on all member ports of the VLAN are subject to DHCP option 82 processing. You can optionally disable and later re-enable DHCP option 82 processing on one or more member ports of the VLAN. To do so, use the commands in this section.

To disable a particular port in a VLAN from adding relay agent information to DHCP packets, enter commands such as the following.

```
FastIron(config)#ip dhcp snooping vlan 1
FastIron(config)#interface ethernet 1/4
FastIron(config-if-e1000-1/4)#no dhcp snooping relay information
```

The first CLI command enables DHCP snooping and DHCP option 82 on VLAN 1. The second command changes the CLI configuration level to the Interface configuration level for port e 1/4. The last command disables DHCP option 82 on interface e 1/4, which is a member of VLAN 1.

To re-enable DHCP option 82 on an interface after it has been disabled, enter the following command at the Interface level of the CLI.

```
FastIron(config-if-e1000-1/4)#dhcp snooping relay information
```

**Syntax:**  `[no] dhcp snooping relay information`

Use the `show ip dhcp snooping vlan` command to view the ports on which DHCP option 82 processing is disabled. For more information, refer to “Viewing the ports on which DHCP option 82 is disabled” on page 1661.

**Changing the forwarding policy**

When the Brocade device receives a DHCP message that contains relay agent information, by default, the device replaces the information with its own relay agent information. If desired, you can configure the device to drop or keep the information instead of replacing it. To do so, use the CLI commands in this section.

For example, to configure the device to keep the relay agent information contained in a DHCP message, enter the following command.

```
FastIron(config)#ip dhcp relay information policy keep
```
To configure the device to drop messages that contain the relay agent information, enter the following command.

```
FastIron(config)#ip dhcp relay information policy drop
```

**Syntax:** `ip dhcp relay information policy <policy-type>`

- `<policy-type>` can be one of the following:
  - **drop** – Configures the device to discard messages containing relay agent information
  - **keep** – Configures the device to keep the existing relay agent information
  - **replace** – Configures the device to overwrite the relay agent information with the information in the Brocade configuration. This is the default behavior.

**NOTE**

This command is not supported on TurboIron X Series devices running software release 04.2.00.

Use the `show ip dhcp relay information` command to view the forwarding policy configured on the switch. Refer to “Viewing the circuit ID, remote id, and forwarding policy” on page 1660.

### Enabling and disabling subscriber ID processing

You can configure a unique subscriber ID (SID) per port. Unlike the CID and RID sub-options, the SID sub-option is not automatically enabled when DHCP option 82 is enabled. To enable SID processing, enter commands such as the following.

```
FastIron(config)#ip dhcp snooping vlan 1
FastIron(config)#interface ethernet 1/4
FastIron(config-if-e1000-1/4)#dhcp snooping relay information subscriber-id Brcd01
```

The first CLI command enables DHCP snooping and DHCP option 82 on VLAN 1. The second command changes the CLI configuration level to the Interface configuration level for port e 1/4. The last command enables interface e 1/4 to insert the SID information in DHCP packets. In this case, the SID is Fdry01. All other ports in VLAN 1 on which SID is not enabled will send the standard relay agent information (CID and RID information) only.

**Syntax:** `[no] dhcp snooping relay information option subscriber-id <ASCII string>`

Enter up to 50 alphanumeric characters for `<ASCII string>`.

Use the `no` form of the command to disable SID processing once it is enabled.

Use the `show interfaces ethernet` command to view the subscriber ID configured on a port. Refer to “Viewing the status of DHCP option 82 and the subscriber id” on page 1661.

### Viewing information about DHCP option 82 processing

Use the commands in this section to view information about DHCP option 82 processing.

**Viewing the circuit Id, remote id, and forwarding policy**

Use the `show ip dhcp relay information` command to obtain information about the circuit ID, remote ID, and forwarding policy for DHCP option 82. The following shows an example output.
DHCP relay agent information (DHCP Option 82)

Syntax: `show ip dhcp relay information`

**NOTE**
This command is not supported on TurboIron X Series devices running software release 04.2.00.

**TABLE 263** Output for the `ip dhcp relay information` command

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays</th>
</tr>
</thead>
</table>
| Circuit-ID    | The agent circuit ID format:  
|               | • `vlan-mod-port` – The default circuit ID format. |
| Remote-ID     | The remote ID format. In software release 05.0.00, this field displays `mac`, which is the default remote ID format. |
| Policy        | How the Brocade switch processes relay agent information it receives in DHCP messages:  
|               | • `drop` – drops the relay agent information  
|               | • `keep` – keeps the relay agent information  
|               | • `replace` – replaces the relay agent information with its own |

**Viewing the ports on which DHCP option 82 is disabled**

Use the following command to refer which port in a DHCP snooping VLAN has DHCP Option 82 disabled.

FastIron# `show ip dhcp snooping vlan 1`

**IP DHCP snooping VLAN 1: Enabled**

```
Trusted Ports : ethe 3
Untrusted Ports : ethe 1 to 2 ethe 4 to 24
Relay Info. disabled Ports: ethe 10
```

Syntax: `show ip dhcp snooping vlan <vlan-id>`

**TABLE 264** Output for the `show ip dhcp snooping vlan` command

<table>
<thead>
<tr>
<th>This field...</th>
<th>Displays</th>
</tr>
</thead>
</table>
| IP DHCP snooping VLAN `<vlan-id>` | The DHCP snooping and DHCP option 82 status for a VLAN:  
|                               | • Enabled  
|                               | • Disabled  |
| Trusted Ports                 | A list of trusted ports in the VLAN.         |
| Untrusted Ports               | A list of untrusted ports in the VLAN.       |
| Relay Info. disabled Ports    | Ports on which DHCP option 82 was disabled.  |

**Viewing the status of DHCP option 82 and the subscriber id**

Use the `show interfaces ethernet` command to obtain information about the status of DHCP option 82 and the configured subscriber ID, if applicable. In the example below, the text in **bold** type displays the information specific to DHCP option 82.
The above output shows that DHCP option 82 is **Enabled** on the device and the configured subscriber ID is **Brocade001**.

**Syntax:** `show interfaces ethernet <slotnum/portnum>`

---

**IP source guard**

You can use IP Source Guard together with Dynamic ARP Inspection on untrusted ports. Refer to “**DHCP snooping**” on page 1651 and “**Dynamic ARP inspection**” on page 1647.

The Brocade implementation of the IP Source Guard feature supports configuration on a port, on specific VLAN memberships on a port (Layer 2 devices only), and on specific ports on a virtual interface (VE) (Layer 3 devices only).

When IP Source Guard is first enabled, only DHCP packets are allowed and all other IP traffic is blocked. When the system learns a valid IP address, IP Source Guard then allows IP traffic. Only the traffic with valid source IP addresses are permitted. The system learns of a valid IP address from DHCP Snooping. When it learns a valid IP address, the system permits the learned source IP address.

When a new IP source entry binding on the port is created or deleted, the ACL will be recalculated and reapplied in hardware to reflect the change in IP source binding. By default, if IP Source Guard is enabled without any IP source binding on the port, an ACL that denies all IP traffic is loaded on the port.
Configuration notes and feature limitations

- To run IP Source Guard, you must first enable support for ACL filtering based on VLAN membership or VE port membership. To do so, enter the following commands at the Global CONFIG Level of the CLI.

  FastIron(config)#enable ACL-per-port-per-vlan
  FastIron(config)#write memory
  FastIron(config)#exit
  FastIron#reload

  **NOTE**
  You must save the configuration and reload the software to place the change into effect.

- Brocade devices support IP Source Guard together with IPv4 ACLs (similar to ACLs for Dot1x), as long as both features are configured at the port-level or per-port-per-VLAN level. Brocade devices do not support IP Source Guard and IPv4 ACLs on the same port if one is configured at the port-level and the other is configured at the per-port-per-VLAN level.

- IP source guard and IPv6 ACLs are supported together on the same device, as long as they are not configured on the same port or virtual interface.

- The following limitations apply when configuring IP Source Guard on Layer 3 devices:
  - You cannot enable IP Source Guard on a tagged port on a Layer 3 device. To enable IP Source Guard on a tagged port, enable it on a per-VE basis.
  - You cannot enable IP Source Guard on an untagged port with VE on a Layer 3 device. To enable IP Source Guard in this configuration, enable it on a per-VE basis.
  - There are no restrictions for Layer 2, either on the port or per-VLAN.

- You cannot enable IP Source Guard on a port that has any of the following features enabled:
  - MAC address filter
  - Rate limiting
  - Trunk port
  - 802.1x with ACLs
  - Multi-device port authentication with ACLs

- A port on which IP Source Guard is enabled limits the support of IP addresses, VLANs, and ACL rules per port. An IP Source Guard port supports a maximum of:
  - 64 IP addresses
  - 64 VLANs
  - 64 rules per ACL

- The number of configured ACL rules affect the rate at which hardware resources are used when IP Source Guard is enabled. Use the `show access-list hw-usage on` command to enable hardware usage for an ACL, followed by a `show access-list <access-list-id>` command to determine the hardware usage for an ACL.

  **Example**

  FastIron#show access-list hw-usage on
  FastIron#show access-list 100
  Extended IP access list 100 (hw usage : 2)
  deny ip any any (hw usage : 1)
To provide more hardware resource for IP Source Guard addresses, modify the ACL rules so that it uses less hardware resource.

- If you enable IP Source Guard in a network topology that has DHCP clients, you must also enable DHCP snooping. Otherwise, all IP traffic including DHCP packets will be blocked.
- When you enable IP Source Guard in a network topology that does not have DHCP clients, you must create an IP source binding for each client that will be allowed access to the network. Otherwise, data packets will be blocked. Refer to “Defining static IP source bindings” on page 1664.
- Software release FSX 04.2.00 introduced a form of IP Source Guard called Source Guard Protection. This feature enables concurrent support with multi-device port authentication. For details, Refer to “Enabling source guard protection” on page 1586.
- IP Source Guard is supported on a VE with or without an assigned IP address.

**Enabling IP source guard on a port**

You can enable IP Source Guard on DHCP snooping untrusted ports. Refer to “DHCP snooping” on page 1651 for how to configure DHCP and DHCP untrusted ports.

By default, IP Source Guard is disabled. To enable IP Source Guard on a DHCP untrusted port, enter the following commands.

```
FastIron(config)#interface ethernet 1/4
FastIron(config-if-e10000-1/4)#source-guard enable
```

The commands change the CLI to the interface configuration level for port 1/4 and enable IP Source Guard on the port.

**Syntax:** `[no] source-guard enable`

**Defining static IP source bindings**

You can manually enter valid IP addresses in the binding database. To do so, enter a command such as the following.

```
FastIron(config)#ip source binding 10.10.10.1 e 2/4 vlan 4
```

**Syntax:** `[no] ip source binding <ip-addr> ethernet [<slotnum>/]<portnum> [vlan <vlannum>]

For `<ip-addr>`, enter a valid IP address.

The `<slotnum>` parameter is required on chassis devices.

The `<portnum>` parameter is a valid port number.

The `[vlan <vlannum>]` parameter is optional. If you enter a VLAN number, the binding applies to that VLAN only. If you do not enter a VLAN number, the static binding applies to all VLANs associated with the port. Note that since static IP source bindings consume system resources, you should avoid unnecessary bindings.

**Enabling IP source guard per-port-per-VLAN**

To enable IP Source Guard per-port-per VLAN, enter commands such as the following.
IP source guard

FastIron(config)#vlan 12 name vlan12
FastIron(config-vlan-12)#untag ethernet 5 to 8
FastIron(config-vlan-12)#tag ethernet 23 to 24
FastIron(config-vlan-12)#exit
FastIron(config)#int e 23
FastIron(config-if-e1000-23)#per-vlan vlan12
FastIron(config-if-e1000-23-vlan-12))#source-guard enable

The commands in this example configure port-based VLAN 12, and add ports e 5 – 8 as untagged ports and ports e 23 – 24 as tagged ports to the VLAN. The last two commands enable IP Source Guard on port e 23, a member of VLAN 12.

Syntax: [no] source-guard enable

Enabling IP source guard on a VE

To enable IP Source Guard on a virtual interface, enter commands such as the following.

FastIron(config)#vlan 2
FastIron(config-vlan-2)#tag e1
Added tagged port(s) ethe 1 to port-vlan 2
FastIron(config-vlan-2)#router-int ve 2
FastIron(config-vlan-2)#int ve 2
FastIron(config-vlan-2)#source-guard enable e 1

Syntax: [no] source-guard enable

Displaying learned IP addresses

To display the learned IP addresses for IP Source Guard ports, use the CLI commands show ip source-guard ethernet.
IP source guard
SNMP overview

SNMP is a set of protocols for managing complex networks. SNMP sends messages, called protocol data units (PDUs), to different parts of a network. SNMP-compliant devices, called agents, store data about themselves in Management Information Bases (MIBs) and return this data to the SNMP requesters.

Chapter 39, “Securing Access to Management Functions” introduced a few methods used to secure SNMP access. They included the following:

- “Using ACLs to restrict SNMP access” on page 1416
- “Restricting SNMP access to a specific IP address” on page 1418
- “Restricting SNMP access to a specific VLAN” on page 1421
- “Disabling SNMP access” on page 1425

This chapter presents additional methods for securing SNMP access to Brocade devices. It contains the following sections:

- “Establishing SNMP community strings”
- “Using the user-based security model”
- “SNMP v3 Configuration examples”
- “SNMP version 3 traps”
- “Displaying SNMP Information”
- “SNMP v3 Configuration examples”

Restricting SNMP access using ACL, VLAN, or a specific IP address constitute the first level of defense when the packet arrives at a Brocade device. The next level uses one of the following methods:

- Community string match In SNMP versions 1 and 2
- User-based model in SNMP version 3

SNMP views are incorporated in community strings and the user-based model.

Establishing SNMP community strings

SNMP versions 1 and 2 use community strings to restrict SNMP access. The default passwords for Web management access are the SNMP community strings configured on the device:

- The default read-only community string is “public”. To open a read-only Web management session, enter “get” and “public” for the user name and password.
• There is no default read-write community string. Thus, by default, you cannot open a read-write management session using the Web Management Interface. You first must configure a read-write community string using the CLI. Then you can log on using “set” as the user name and the read-write community string you configure as the password.

You can configure as many additional read-only and read-write community strings as you need. The number of strings you can configure depends on the memory on the device. There is no practical limit.

The Web Management Interface supports only one read-write session at a time. When a read-write session is open on the Web Management Interface, subsequent sessions are read-only, even if the session login is “set” with a valid read-write password.

**NOTE**
If you delete the startup-config file, the device automatically re-adds the default “public” read-only community string the next time you load the software.

**NOTE**
As an alternative to the SNMP community strings, you can secure Web management access using local user accounts or ACLs. Refer to “Setting up local user accounts” on page 1430 or “Using an ACL to restrict Web management access” on page 1415.

### Encryption of SNMP community strings

The software automatically encrypts SNMP community strings. Users with read-only access or who do not have access to management functions in the CLI cannot display the strings. For users with read-write access, the strings are encrypted in the CLI but are shown in the clear in the Web Management Interface.

Encryption is enabled by default. You can disable encryption for individual strings or trap receivers if desired. Refer to the next section for information about encryption.

### Adding an SNMP community string

When you add a community string, you can specify whether the string is encrypted or clear. By default, the string is encrypted.

To add an encrypted community string, enter commands such as the following.

```
FastIron(config)# snmp-server community private rw
FastIron(config)# write memory
```

**Syntax:** `snmp-server community [0 | 1] <string> [ro | rw [view <viewname>] [ <standard-ACL-name> | <standard-ACL-id> ]]`

The `<string>` parameter specifies the community string name. The string can be up to 32 characters long.

The `ro | rw` parameter specifies whether the string is **read-only (ro)** or **read-write (rw)**.

The `0 | 1` parameter affects encryption for display of the string in the running-config and the startup-config file. Encryption is enabled by default. When encryption is enabled, the community string is encrypted in the CLI regardless of the access level you are using. In the Web Management Interface, the community string is encrypted at the read-only access level but is visible at the read-write access level.
The encryption option can be omitted (the default) or can be one of the following:

- **0** – Disables encryption for the community string you specify with the command. The community string is shown as clear text in the running-config and the startup-config file. Use this option if you do not want the display of the community string to be encrypted.

- **1** – Assumes that the community string you enter is encrypted, and decrypts the value before using it.

**NOTE**
If you want the software to assume that the value you enter is the clear-text form, and to encrypt display of that form, do not enter **0** or **1**. Instead, omit the encryption option and allow the software to use the default behavior.

**NOTE**
If you specify encryption option **1**, the software assumes that you are entering the encrypted form of the community string. In this case, the software decrypts the community string you enter before using the value for authentication. If you accidentally enter option **1** followed by the clear-text version of the community string, authentication will fail because the value used by the software will not match the value you intended to use.

The command in the example above adds the read-write SNMP community string “private”. When you save the new community string to the startup-config file (using the **write memory** command), the software adds the following command to the file.

```
snmp-server community 1 <encrypted-string> rw
```

To add a non-encrypted community string, you must explicitly specify that you do not want the software to encrypt the string. Here is an example.

```
FastIron(config)# snmp-server community 0 private rw
FastIron(config)# write memory
```

The command in this example adds the string “private” in the clear, which means the string is displayed in the clear. When you save the new community string to the startup-config file, the software adds the following command to the file.

```
snmp-server community 0 private rw
```

The **view** <viewname> parameter is optional. It allows you to associate a view to the members of this community string. Enter up to 32 alphanumeric characters. If no view is specified, access to the full MIB is granted. The view that you want must exist before you can associate it to a community string. Here is an example of how to use the view parameter in the community string command.

```
FastIron(config)# snmp-s community myread ro view sysview
```

The command in this example associates the view “sysview” to the community string named “myread”. The community string has read-only access to “sysview”. For information on how to create views, refer to **“SNMP v3 Configuration examples”** on page 1682.

The **<standard-ACL-name>** | **<standard-ACL-id>** parameter is optional. It allows you to specify which ACL group will be used to filter incoming SNMP packets. You can enter either the ACL name or its ID. Here are some examples.

```
FastIron(config)# snmp-s community myread ro view sysview 2
FastIron(config)# snmp-s community myread ro view sysview myACL
```
The command in the first example indicates that ACL group 2 will filter incoming SNMP packets; whereas, the command in the second example uses the ACL group called “myACL” to filter incoming packets. Refer to “Using ACLs to restrict SNMP access” on page 1416 for more information.

NOTE
To make configuration changes, including changes involving SNMP community strings, you must first configure a read-write community string using the CLI. Alternatively, you must configure another authentication method and log on to the CLI using a valid password for that method.

Displaying the SNMP community strings

To display the configured community strings, enter the following command at any CLI level.

```
FastIron# show snmp server
Contact: Marshall
Location: Copy Center
Community(ro): public
Community(rw): private
Traps
  Cold start: Enable
  Link up: Enable
  Link down: Enable
  Authentication: Enable
  Locked address violation: Enable
  Power supply failure: Enable
  Fan failure: Enable
  Temperature warning: Enable
  STP new root: Enable
  STP topology change: Enable
  ospf: Enable

Total Trap-Receiver Entries: 4
Trap-Receiver IP Address    Community
  1   207.95.6.211
  2   207.95.5.21
```

Syntax: show snmp server

NOTE
If display of the strings is encrypted, the strings are not displayed. Encryption is enabled by default.

Using the user-based security model

Platform Support:

- FastIron X Series devices running software release 03.0.00 and later
- FGS and FLS devices running software release 03.2.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX devices running software release 6.0 and later
SNMP version 3 (RFC 2570 through 2575) introduces a User-Based Security model (RFC 2574) for authentication and privacy services.

SNMP version 1 and version 2 use community strings to authenticate SNMP access to management modules. This method can still be used for authentication. In SNMP version 3, the User-Based Security model of SNMP can be used to secure against the following threats:

- Modification of information
- Masquerading the identity of an authorized entity
- Message stream modification
- Disclosure of information

SNMP version 3 also supports View-Based Access Control Mechanism (RFC 2575) to control access at the PDU level. It defines mechanisms for determining whether or not access to a managed object in a local MIB by a remote principal should be allowed. (refer to “SNMP v3 Configuration examples” on page 1682.)

Configuring your NMS

In order to use the SNMP version 3 features.

1. Make sure that your Network Manager System (NMS) supports SNMP version 3.
2. Configure your NMS agent with the necessary users.
3. Configure the SNMP version 3 features in Brocade devices.

Configuring SNMP version 3 on Brocade devices

Follow the steps given below to configure SNMP version 3 on Brocade devices.

1. Enter an engine ID for the management module using the `snmp-server engineid` command if you will not use the default engine ID. Refer to “Defining the engine id” on page 1671.
2. Create views that will be assigned to SNMP user groups using the `snmp-server view` command. Refer to “SNMP v3 Configuration examples” on page 1682 for details.
3. Create ACL groups that will be assigned to SNMP user groups using the `access-list` command.
4. Create user groups using the `snmp-server group` command. Refer to “Defining an SNMP group” on page 1672.
5. Create user accounts and associate these accounts to user groups using the `snmp-server user` command. Refer to “Defining an SNMP user account” on page 1673.

If SNMP version 3 is not configured, then community strings by default are used to authenticate access.

Defining the engine id

A default engine ID is generated during system start up. To determine what the default engine ID of the device is, enter the `show snmp engineid` command and find the following line:

```
Local SNMP Engine ID: 800007c70300e05290ab60
```

See the section “Displaying the Engine ID” on page 1680 for details.
The default engine ID guarantees the uniqueness of the engine ID for SNMP version 3. If you want to change the default engine ID, enter a command such as the following.

```
FastIron(config)# snmp-server engineid local 800007c70300e05290ab60
```

**Syntax:**

```
[no] snmp-server engineid local <hex-string>
```

The `local` parameter indicates that engine ID to be entered is the ID of this device, representing an SNMP management entity.

**NOTE**

Each user localized key depends on the SNMP server engine ID, so all users need to be reconfigured whenever the SNMP server engine ID changes.

**NOTE**

Since the current implementation of SNMP version 3 does not support Notification, remote engine IDs cannot be configured at this time.

The `<hex-string>` variable consists of 11 octets, entered as hexadecimal values. There are two hexadecimal characters in each octet. There should be an even number of hexadecimal characters in an engine ID.

The default engine ID has a maximum of 11 octets:

- Octets 1 through 4 represent the agent's SNMP management private enterprise number as assigned by the Internet Assigned Numbers Authority (IANA). The most significant bit of Octet 1 is "1". For example, "000007c7" is the ID for Brocade Communications, Inc. in hexadecimal. With Octet 1 always equal to "1", the first four octets in the default engine ID is always "800007c7" (which is 1991 in decimal).
- Octet 5 is always 03 in hexadecimal and indicates that the next set of values represent a MAC address.
- Octets 6 through 11 form the MAC address of the lowest port in the management module.

**NOTE**

Engine ID must be a unique number among the various SNMP engines in the management domain. Using the default engine ID ensures the uniqueness of the numbers.

---

### Defining an SNMP group

SNMP groups map SNMP users to SNMP views. For each SNMP group, you can configure a read view, a write view, or both. Users who are mapped to a group will use its views for access control.

To configure an SNMP user group, enter a command such as the following.

```
FastIron(config)# snmp-server group admin v3 auth read all write all
```

**Syntax:**

```
[no] snmp-server group <groupname> v1 | v2 | v3 auth | noauth | priv [access <standard-ACL-id>] [read <viewstring> | write <viewstring>]
```

---
Using the user-based security model

NOTE
This command is not used for SNMP version 1 and SNMP version 2. In these versions, groups and group views are created internally using community strings. (refer to “Establishing SNMP community strings” on page 1667.) When a community string is created, two groups are created, based on the community string name. One group is for SNMP version 1 packets, while the other is for SNMP version 2 packets.

The group <groupname> parameter defines the name of the SNMP group to be created.

The v1, v2, or v3 parameter indicates which version of SNMP is used. In most cases, you will be using v3, since groups are automatically created in SNMP versions 1 and 2 from community strings.

The auth | noauth parameter determines whether or not authentication will be required to access the supported views. If auth is selected, then only authenticated packets are allowed to access the view specified for the user group. Selecting noauth means that no authentication is required to access the specified view. Selecting priv means that an authentication password will be required from the users.

The access <standard-ACL-id> parameter is optional. It allows incoming SNMP packets to be filtered based on the standard ACL attached to the group.

The read <viewstring> | write <viewstring> parameter is optional. It indicates that users who belong to this group have either read or write access to the MIB.

The <viewstring> variable is the name of the view to which the SNMP group members have access. If no view is specified, then the group has no access to the MIB.

The value of <viewstring> is defined using the snmp-server view command. The SNMP agent comes with the "all" default view, which provides access to the entire MIB; however, it must be specified when creating the group. The "all" view also allows SNMP version 3 to be backwards compatibility with SNMP version 1 and version 2.

NOTE
If you will be using a view other than the "all" view, that view must be configured before creating the user group. Refer to the section “SNMP v3 Configuration examples” on page 1682, especially for details on the include | exclude parameters.

Defining an SNMP user account

The snmp-server user command does the following:

- Creates an SNMP user.
- Defines the group to which the user will be associated.
- Defines the type of authentication to be used for SNMP access by this user.
- Specifies one of the following encryption types used to encrypt the privacy password:
  - Data Encryption Standard (DES) – A symmetric-key algorithm that uses a 56-bit key.
  - Advanced Encryption Standard (AES) – The 128-bit encryption standard adopted by the U.S. government. This standard is a symmetric cipher algorithm chosen by the National Institute of Standards and Technology (NIST) as the replacement for DES.
NOTE
AES encryption is supported starting in software release FSX 05.0.00. It is also supported for FGS, FLS, and FWS devices in software release FGS 04.3.02 and for FGS-STK and FLS-STK devices in release 05.0.02, and FCX devices running software release 06.0.00 and later.

NOTE
On Turbolron X Series devices, AES encryption is supported on devices running software release 04.2.00 and later.

Here is an example of how to create an SNMP User account.

FastIron(config)# snmp-s user bob admin v3 access 2 auth md5 bobmd5 priv des bobdes

The CLI for creating SNMP version 3 users has been updated as follows.

Syntax: [no] snmp-server user <name> <groupname> v3

[access <standard-ACL-id>]

[[encrypted] [auth md5 <md5-password> | sha <sha-password>]

[priv [encrypted] des <des-password-key> | aes <aes-password-key>]]

The <name> parameter defines the SNMP user name or security name used to access the management module.

The <groupname> parameter identifies the SNMP group to which this user is associated or mapped. All users must be mapped to an SNMP group. Groups are defined using the snmp-server group command.

NOTE
The SNMP group to which the user account will be mapped should be configured before creating the user accounts; otherwise, the group will be created without any views. Also, ACL groups must be configured before configuring user accounts.

The v3 parameter is required.

The access <standard-ACL-id> parameter is optional. It indicates that incoming SNMP packets are filtered based on the ACL attached to the user account.

NOTE
The ACL specified in a user account overrides the ACL assigned to the group to which the user is mapped. If no ACL is entered for the user account, then the ACL configured for the group will be used to filter packets.

The encrypted parameter means that the MD5 or SHA password will be a digest value. MD5 has 16 octets in the digest. SHA has 20. The digest string has to be entered as a hexadecimal string. In this case, the agent need not generate any explicit digest. If the encrypted parameter is not used, the user is expected to enter the authentication password string for MD5 or SHA. The agent will convert the password string to a digest, as described in RFC 2574.

The auth md5 | sha parameter is optional. It defines the type of encryption that the user must have to be authenticated. Choose between MD5 or SHA encryption. MD5 and SHA are two authentication protocols used in SNMP version 3.

The <md5-password> and <sha-password> define the password the user must use to be authenticated. These password must have a minimum of 8 characters. If the encrypted parameter is used, then the digest has 16 octets for MD5 or 20 octets for SHA.
NOTE
Once a password string is entered, the generated configuration displays the digest (for security reasons), not the actual password.

The `priv [encrypted]` parameter is optional after you enter the md5 or sha password. The `priv` parameter specifies the encryption type (DES or AES) used to encrypt the privacy password. If the `encrypted` keyword is used, do the following:

NOTE
All FastIron devices support the DES encryption type. The AES encryption type is supported on FastIron X Series devices running software release FSX 05.0.00 and later. On TurboIron devices, AES encryption is supported on devices running software release 04.2.00 and later.

- If DES is the privacy protocol to be used, enter `des` followed by a 16-octet DES key in hexadecimal format for the `<des-password-key>`. If you include the encrypted keyword, enter a password string of at least 8 characters.
- If AES is the privacy protocol to be used, enter `aes` followed by the AES password key. For a small password key, enter 12 characters. For a big password key, enter 16 characters. If you include the encrypted keyword, enter a password string containing 32 hexadecimal characters.

NOTE
AES encryption is supported starting in software release FSX 05.0.00.

### Defining SNMP views

SNMP views are named groups of MIB objects that can be associated with user accounts to allow limited access for viewing and modification of SNMP statistics and system configuration. SNMP views can also be used with other commands that take SNMP views as an argument. SNMP views reference MIB objects using object names, numbers, wildcards, or a combination of the three. The numbers represent the hierarchical location of the object in the MIB tree. You can reference individual objects in the MIB tree or a subset of objects from the MIB tree.

To configure the number of SNMP views available on the Brocade device, enter the following command.

```
FastIron(config)# system-max view 15
```

**Syntax:** `system-max view <number-of-views>`

This command specifies the maximum number of SNMPv2 and v3 views that can be configured on a device. The number of views can be from 10 – 65536. The default is 10 views.

To add an SNMP view, enter one of the following commands.

```
FastIron(config)# snmp-server view Maynes system included
FastIron(config)# snmp-server view Maynes system.2 excluded
FastIron(config)# snmp-server view Maynes 2.3.*.6 included
FastIron(config)# write mem
```

**NOTE**
The `snmp-server view` command supports the MIB objects as defined in RFC 1445.

**Syntax:** `[no] snmp-server view <name> <mib_tree> included | excluded`
The `<name>` parameter can be any alphanumeric name you choose to identify the view. The names cannot contain spaces.

The `<mib_tree>` parameter is the name of the MIB object or family. MIB objects and MIB sub-trees can be identified by a name or by the numbers called Object Identifiers (OIDs) that represent the position of the object or sub-tree in the MIB hierarchy. You can use a wildcard (*) in the numbers to specify a sub-tree family.

The `included | excluded` parameter specifies whether the MIB objects identified by the `<mib_family>` parameter are included in the view or excluded from the view.

**NOTE**
All MIB objects are automatically excluded from any view unless they are explicitly included; therefore, when creating views using the `snmp-server view` command, indicate which portion of the MIB you want users to access.

For example, you may want to assign the view called “admin” a community string or user group. The “admin” view will allow access to the Brocade MIBs objects that begin with the 1.3.6.1.4.1.1991 object identifier. Enter the following command.

```
FastIron(config)# snmp-server view admin 1.3.6.1.4.1.1991 included
```

You can exclude portions of the MIB within an inclusion scope. For example, if you want to exclude the `snAgentSys` objects, which begin with 1.3.6.1.4.1.1991.1.1.2 object identifier from the `admin` view, enter a second command such as the following.

```
FastIron(config)# snmp-server view admin 1.3.6.1.4.1.1991.1.1.2 excluded
```

**NOTE**
Note that the exclusion is within the scope of the inclusion.

To delete a view, use the `no` parameter before the command.

### SNMP version 3 traps

Brocade devices support SNMP notifications in SMv2 format. This allows notifications to be encrypted and sent to the target hosts in a secure manner.

#### Defining an SNMP group and specifying which view is notified of traps

The SNMP group command allows configuration of a viewname for notification purpose, similar to the read and write view. The default viewname is "all", which allows access to the entire MIB.

To configure an SNMP user group, first configure SNMP v3 views using the `snmp-server view` command. Refer to “SNMP v3 Configuration examples” on page 1682. Then enter a command such as the following.

```
FastIron(config)# snmp-server group admin v3 auth read all write all notify all
```

**Syntax:** `[no] snmp-server group <groupname>
  v1 | v2 | v3`
The **group** `<groupname>` parameter defines the name of the SNMP group to be created.

The **v1**, **v2**, or **v3** parameter indicates which version of SNMP to use. In most cases, you will use v3, since groups are automatically created in SNMP versions 1 and 2 from community strings.

The **auth | noauth | priv** parameter determines whether or not authentication will be required to access the supported views. If auth is selected, then only authenticated packets are allowed to access the view specified for the user group. Selecting **noauth** means that no authentication is required to access the specified view. Selecting **priv** means that an authentication password will be required from the users.

The **access <standard-ACL-id>** parameter is optional. It allows incoming SNMP packets to be filtered based on the standard ACL attached to the group.

The **read <viewstring> | write <viewstring>** parameter is optional. It indicates that users who belong to this group have either read or write access to the MIB.

The **notify** view allows administrators to restrict the scope of varbind objects that will be part of the notification. All of the varbinds need to be in the included view for the notification to be created.

The `<viewstring>` variable is the name of the view to which the SNMP group members have access. If no view is specified, then the group has no access to the MIB.

### Defining the UDP port for SNMP v3 traps

#### Platform Support:
- FastIron X Series devices
- FGS and FLS devices running software release 03.2.00 and later
- FWS devices running software release 04.3.00 or later
- TurboIron X Series devices running software release 04.1.00 and later
- FCX devices running software release 6.0 and later

The SNMP host command enhancements allow configuration of notifications in SMIV2 format, with or without encryption, in addition to the previously supported SMIV1 trap format.

You can define a port that receives the SNMP v3 traps by entering a command such as the following.

```
FastIron(config)# snmp-server host 192.168.4.11 version v3 auth security-name port 4/1 [no] snmp-server host <ip-addr> | <ipv6-addr> version [ v1 | v2c <community-string> | v3 auth | noauth | priv <security-name>] [port <trap-UDP-port-number>]
```

The `<ip-addr>` parameter specifies the IP address of the host that will receive the trap.

For **version**, indicate one of the following

For SNMP version 1, enter **v1** and the name of the community string (`<community-string>`). This string is encrypted within the system.
NOTE

The options "v2c" and "v3" are new in software release 03.0.00. If the configured version is v2c, then the notification is sent out in SMIv2 format, using the community string, but in cleartext mode. To send the SMIv2 notification in SNMPv3 packet format, configure v3 with auth or privacy parameters, or both, by specifying a security name. The actual authorization and privacy values are obtained from the security name.

For SNMP version 2c, enter v2 and the name of the community string. This string is encrypted within the system.

For SNMP version 3, enter one of the following depending on the authorization required for the host:

- v3 auth <security-name>: Allow only authenticated packets.
- v3 no auth <security-name>: Allow all packets.
- v3 priv <security-name>: A password is required

For port <trap-UDP-port-number>, specify the UDP port number on the host that will receive the trap.

Trap MIB changes

To support the SNMP V3 trap feature, the Brocade Enterprise Trap MIB was rewritten in SMIv2 format, as follows:

- The MIB name was changed from FOUNDARY-SN-TRAP-MIB to FOUNDARY-SN-NOTIFICATION-MIB
- Individual notifications were changed to NOTIFICATION-TYPE instead of TRAP-TYPE.
- As per the SMIv2 format, each notification has an OID associated with it. The root node of the notification is snTraps (OID enterprise.foundry.0). For example, OID for snTrapRunningConfigChanged is {snTraps.73}. Earlier, each trap had a trap ID associated with it, as per the SMIv1 format.

Backward compatibility with SMIv1 trap format

The Brocade device will continue to support creation of traps in SMIv1 format, as before. To allow the device to send notifications in SMIv2 format, configure the device as described above. The default mode is still the original SMIv1 format.

Restricting SNMP Access to an IPv6 node

You can restrict SNMP access so that the device (including IronView Network Manager) can only be accessed by the IPv6 host address that you specify. To do so, enter a command such as the following.

FastIron(config)# snmp-client ipv6 2001:efff:89::23

Syntax: snmp-client ipv6 <ipv6-address>

The <ipv6-address> must be in hexadecimal format using 16-bit values between colons as documented in RFC 2373.
Specifying an IPv6 host as an SNMP trap receiver

You can specify an IPv6 host as a trap receiver to ensure that all SNMP traps sent by the device will go to the same SNMP trap receiver or set of receivers, typically one or more host devices on the network. To do so, enter a command such as the following:

```
FastIron(config)# snmp-server host ipv6 2001:efff:89::13
```

**Syntax:** `snmp-server host ipv6 <ipv6-address>`

The `<ipv6-address>` must be in hexadecimal format using 16-bit values between colons as documented in RFC 2373.

SNMP v3 over IPv6

**Platform Support:**
- FastIron X Series devices running software release 02.4.00 and later
- FGS and FLS devices running software release 04.0.00 and later
- FWS devices running software release 04.3.00 or later

The above devices support IPv6 for SNMP version 3.

Restricting SNMP Access to an IPv6 Node

You can restrict SNMP access so that the Brocade device (including IronView Network Manager) can only be accessed by the IPv6 host address that you specify. To do so, enter a command such as the following:

```
FastIron(config)# snmp-client ipv6 2001:efff:89::23
```

**Syntax:** `snmp-client ipv6 <ipv6-address>`

The `<ipv6-address>` must be in hexadecimal format using 16-bit values between colons as documented in RFC 2373.

Specifying an IPv6 host as an SNMP trap receiver

You can specify an IPv6 host as a trap receiver to ensure that all SNMP traps sent by the Brocade device will go to the same SNMP trap receiver or set of receivers, typically one or more host devices on the network. To do so, enter a command such as the following:

```
FastIron(config)# snmp-server host ipv6 2001:efff:89::13
```

**Syntax:** `snmp-server host ipv6 <ipv6-address>`

The `<ipv6-address>` must be in hexadecimal format using 16-bit values between colons as documented in RFC 2373.

Viewing IPv6 SNMP server addresses

**Platform Support:**
- FastIron X Series devices running software release 02.4.00 and later
- FGS and FLS devices running software release 04.0.00 and later
Displaying SNMP Information

This section lists the commands for viewing SNMP-related information.

Displaying the Engine ID

To display the engine ID of a management module, enter a command such as the following.

FastIron# show snmp engineid
Local SNMP Engine ID: 800007c70300e05290ab60
Engine Boots: 3
Engine time: 5

Syntax: show snmp engineid

The engine ID identifies the source or destination of the packet.

The engine boots represents the number of times that the SNMP engine reinitialized itself with the same engine ID. If the engineID is modified, the boot count is reset to 0.

The engine time represents the current time with the SNMP agent.

Displaying SNMP groups

To display the definition of an SNMP group, enter a command such as the following.
Displaying SNMP Information

FastIron# show snmp group
groupname = exceptifgrp
security model = v3
security level = authNoPriv
ACL id = 2
readview = exceptif
writeview = <none>

Syntax: show snmp group

The value for security level can be one of the following.

<table>
<thead>
<tr>
<th>Security level</th>
<th>Authentication</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;none&gt;</td>
<td>If the security model shows v1 or v2, then security level is blank. User names are not used to authenticate users; community strings are used instead.</td>
</tr>
<tr>
<td>noauthNoPriv</td>
<td>Displays if the security model shows v3 and user authentication is by user name only.</td>
</tr>
<tr>
<td>authNoPriv</td>
<td>Displays if the security model shows v3 and user authentication is by user name and the MD5 or SHA algorithm.</td>
</tr>
</tbody>
</table>

Displaying user information

To display the definition of an SNMP user account, enter a command such as the following.

FastIron# show snmp user
username = bob
ACL id = 2
group = admin
security model = v3
group ACL id = 0
authtype = md5
authkey = 3aca18d90b8d172760e2dd2e8f59b7fe
privtype = des, privkey = 1088359afb3701730173a6332d406eec
genre ID= 800007c70300e052ab0000

Syntax: show snmp user

Interpreting varbinds in report packets

If an SNMP version 3 request packet is to be rejected by an SNMP agent, the agent sends a report packet that contains one or more varbinds. The varbinds contain additional information, showing the cause of failures. An SNMP manager application decodes the description from the varbind. The following table presents a list of varbinds supported by the SNMP agent.

<table>
<thead>
<tr>
<th>Varbind object Identifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.3.6.1.6.3.11.2.1.3.0</td>
<td>Unknown packet data unit.</td>
</tr>
<tr>
<td>1.3.6.1.6.3.12.1.5.0</td>
<td>The value of the varbind shows the engine ID that needs to be used in the snmp-server engineid command</td>
</tr>
<tr>
<td>1.3.6.1.6.3.15.1.1.0</td>
<td>Unsupported security level.</td>
</tr>
<tr>
<td>1.3.6.1.6.3.15.1.1.2.0</td>
<td>Not in time packet.</td>
</tr>
</tbody>
</table>
The following sections present examples of how to configure SNMP v3.

### Simple SNMP v3 configuration

```
FastIron(config)# snmp-s group admingrp v3 priv read all write all notify all
FastIron(config)# snmp-s user adminuser admingrp v3 auth md5 <auth password> priv
privacy password
FastIron(config)# snmp-s host <dest-ip> version v3 privacy adminuser
```

### More detailed SNMP v3 configuration

```
FastIron(config)# snmp-server view internet internet included
FastIron(config)# snmp-server view system system included
FastIron(config)# snmp-server community .... ro
FastIron(config)# snmp-server community ...... rw
FastIron(config)# snmp-server contact isc-operations
FastIron(config)# snmp-server location sdh-pillbox
FastIron(config)# snmp-server host 128.91.255.32 ....
FastIron(config)# snmp-server group ops v3 priv read internet write system
FastIron(config)# snmp-server group admin v3 priv read internet write internet
FastIron(config)# snmp-server group restricted v3 priv read internet

```
Enabling the Foundry Discovery Protocol (FDP) and Reading Cisco Discovery Protocol (CDP) Packets

Using FDP

The Foundry Discovery Protocol (FDP) enables Brocade devices to advertise themselves to other Brocade devices on the network. When you enable FDP on a Brocade device, the device periodically advertises information including the following:

- Hostname (device ID)
- Product platform and capability
- Software version
- VLAN and Layer 3 protocol address information for the port sending the update. IP, IPX, and AppleTalk Layer 3 information is supported.

A Brocade device running FDP sends FDP updates on Layer 2 to MAC address 01-E0-52-CC-CC-CC. Other Brocade devices listening on that address receive the updates and can display the information in the updates. Brocade devices can send and receive FDP updates on Ethernet interfaces.

FDP is disabled by default.

**NOTE**

If FDP is not enabled on a Brocade device that receives an FDP update or the device is running a software release that does not support FDP, the update passes through the device at Layer 2.

Configuring FDP

The following sections describe how to enable FDP and how to change the FDP update and hold timers.

**Enabling FDP globally**

To enable a Brocade device to globally send FDP packets, enter the following command at the global CONFIG level of the CLI.

```
FESX Router(config)# fdp run
```

**Syntax:** `[no] fdp run`

The feature is disabled by default.

**Enabling FDP at the interface level**

You can enable FDP at the interface level by entering commands such as the following.

```
FESX Router(config)# int e 2/1
FESX Router(config-if-2/1)# fdp enable
```
Syntax: [no] fdp enable
By default, the feature is enabled on an interface once FDP is enabled on the device.

Changing the FDP update timer

By default, a Brocade device enabled for FDP sends an FDP update every 60 seconds. You can change the update timer to a value from 5 – 900 seconds.

To change the FDP update timer, enter a command such as the following at the global CONFIG level of the CLI.

FESX Router(config)# fdp timer 120

Syntax: [no] fdp timer <secs>
The <secs> parameter specifies the number of seconds between updates and can be from 5 – 900 seconds. The default is 60 seconds.

Changing the FDP hold time

By default, a Brocade device that receives an FDP update holds the information until one of the following events occurs:

- The device receives a new update.
- 180 seconds have passed since receipt of the last update. This is the hold time.

Once either of these events occurs, the device discards the update.

To change the FDP hold time, enter a command such as the following at the global CONFIG level of the CLI.

FESX Router(config)# fdp holdtime 360

Syntax: [no] fdp holdtime <secs>
The <secs> parameter specifies the number of seconds a Brocade device that receives an FDP update can hold the update before discarding it. You can specify from 10 – 255 seconds. The default is 180 seconds.

Displaying FDP information

You can display the following FDP information:

- FDP entries for Brocade neighbors
- Individual FDP entries
- FDP information for an interface on the device you are managing
- FDP packet statistics

**NOTE**
If the Brocade device has intercepted CDP updates, then the CDP information is also displayed.

Displaying neighbor information

To display a summary list of all the Brocade neighbors that have sent FDP updates to this Brocade device, enter the following command.
Syntax: `show fdp neighbor [ethernet [<slotnum>/]<portnum>] [detail]`

The `ethernet [<slotnum>/]<portnum>` parameter lists the information for updates received on the specified slot/port.

The `detail` parameter lists detailed information for each device.

The `show fdp neighbor` command, without optional parameters, displays the following information.

### TABLE 265  Summary FDP and CDP neighbor information

<table>
<thead>
<tr>
<th>This line...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device ID</td>
<td>The hostname of the neighbor.</td>
</tr>
<tr>
<td>Local Int</td>
<td>The interface on which this Brocade device received an FDP or CDP update for the neighbor.</td>
</tr>
<tr>
<td>Holdtm</td>
<td>The maximum number of seconds this device can keep the information received in the update before discarding it.</td>
</tr>
<tr>
<td>Capability</td>
<td>The role the neighbor is capable of playing in the network.</td>
</tr>
<tr>
<td>Platform</td>
<td>The product platform of the neighbor.</td>
</tr>
<tr>
<td>Port ID</td>
<td>The interface through which the neighbor sent the update.</td>
</tr>
</tbody>
</table>

To display detailed information, enter the following command.

```plaintext
FESX RouterA# show fdp neighbor detail
Device ID: FastIronB configured as default VLAN1, tag-type8100
Entry address(es):
Platform: FastIron Router, Capabilities: Router
Interface: Eth 2/9
Port ID (outgoing port): Eth 2/9 is TAGGED in following VLAN(s):
  9 10 11
Holdtime : 176 seconds
Version : Foundry, Inc. Router, IronWare Version 07.6.01b1T53 Compiled on Aug 29 2002 at 10:35:21 labeled as B2R07601b1
```

The `show fdp neighbor detail` command displays the following information.
Displaying FDP entries

To display the detailed neighbor information for a specific device, enter a command such as the following.

```
FESX RouterA# show fdp entry FastIronB
Device ID: FastIronB configured as default VLAN1, tag-type8100
Entry address(es):
Platform: FastIron Router, Capabilities: Router
Interface: Eth 2/9
Port ID (outgoing port): Eth 2/9 is TAGGED in following VLAN(s):
    9 10 11
Holdtime : 176 seconds
Version : Foundry, Inc. Router, IronWare Version 07.6.01b1T53 Compiled on Aug 29 2002 at 10:35:21 labeled as B2R07601b1
```

Syntax: `show fdp entry * | <device-id>`

The `*` | `<device-id>` parameter specifies the device ID. If you enter `*`, the detailed updates for all neighbor devices are displayed. If you enter a specific device ID, the update for that device is displayed. For information about the display, refer to Table 266.

Displaying FDP information for an interface

To display FDP information for an interface, enter a command such as the following.

```
FESX RouterA# show fdp interface ethernet 2/3
FastEthernet2/3 is up, line protocol is up
    Encapsulation ethernet
    Sending FDP packets every 5 seconds
    Holdtime is 180 seconds
```
This example shows information for Ethernet port 2/3. The port sends FDP updates every 5 seconds. Neighbors that receive the updates can hold them for up to 180 seconds before discarding them.

**Syntax:** `show fdp interface [ethernet [<slotnum>/]<portnum>]

The `ethernet [<slotnum>/]<portnum>` parameter lists the information only for the specified interface.

**Displaying FDP and CDP statistics**

To display FDP and CDP packet statistics, enter the following command.

```plaintext
FESX RouterA# show fdp traffic
CDP/FDP counters:
  Total packets output: 6, Input: 5
 Hdr syntax: 0, Chksum error: 0, Encaps failed: 0
  No memory: 0, Invalid packet: 0, Fragmented: 0
  Internal errors: 0
```

**Clearing FDP and CDP information**

You can clear the following FDP and CDP information:

- Information received in FDP and CDP updates
- FDP and CDP statistics

The same commands clear information for both FDP and CDP.

**Clearing FDP and CDP neighbor information**

To clear the information received in FDP and CDP updates from neighboring devices, enter the following command.

```plaintext
FESX Router# clear fdp table
```

**Syntax:** `clear fdp table`

**NOTE**

This command clears all the updates for FDP and CDP.

**Clearing FDP and CDP statistics**

To clear FDP and CDP statistics, enter the following command.

```plaintext
FESX Router# clear fdp counters
```

**Syntax:** `clear fdp counters`
Reading CDP packets

Cisco Discovery Protocol (CDP) packets are used by Cisco devices to advertise themselves to other Cisco devices. By default, Brocade devices forward these packets without examining their contents. You can configure a Brocade device to intercept and display the contents of CDP packets. This feature is useful for learning device and interface information for Cisco devices in the network.

Brocade devices support intercepting and interpreting CDP version 1 and version 2 packets.

NOTE
The Brocade device can interpret only the information fields that are common to both CDP version 1 and CDP version 2.

NOTE
When you enable interception of CDP packets, the Brocade device drops the packets. As a result, Cisco devices will no longer receive the packets.

Enabling interception of CDP packets globally

To enable the device to intercept and display CDP packets, enter the following command at the global CONFIG level of the CLI.

FESX Router(config)# cdp run

Syntax: [no] cdp run

The feature is disabled by default.

Enabling interception of CDP packets on an interface

You can disable and enable CDP at the interface level.

You can enter commands such as the following.

FastIron(config)# int e 2/1
FastIron(config-if-2/1)# cdp enable

Syntax: [no] cdp enable

By default, the feature is enabled on an interface once CDP is enabled on the device.

Displaying CDP information

You can display the following CDP information:

- Cisco neighbors
- CDP entries for all Cisco neighbors or a specific neighbor
- CDP packet statistics
Displaying neighbors

To display the Cisco neighbors the Brocade device has learned from CDP packets, enter the following command.

```
FESX Router# show fdp neighbors
Capability Codes: R - Router, T - Trans Bridge, B - Source Route Bridge
                S - Switch, H - Host, I - IGMP, r - Repeater
                (*) indicates a Cisco device

Device ID     Local Int    Holdtm  Capability Platform    Port ID
------------- ------------ ------ ---------- ----------- ---------------
(*)Router     Eth 1/1      124    R          cisco RSP4     FastEthernet5/0/0
```

To display detailed information for the neighbors, enter the following command.

```
FESX Router# show fdp neighbors detail
Device ID: Router
Entry address(es):
    IP address: 207.95.6.143
Platform: cisco RSP4, Capabilities: Router
Interface: Eth 1/1, Port ID (outgoing port): FastEthernet5/0/0
Holdtime : 150 seconds
Version :
Cisco Internetwork Operating System Software
IOS (tm) RSP Software (RSP-JSV-M), Version 12.0(5)T1, RELEASE SOFTWARE (fc1)
Copyright (c) 1986-1999 by cisco Systems, Inc.
Compiled Thu 19-Aug-99 04:12 by cmong

FESX Router# show fdp neighbors ethernet 1/1
Device ID: Router
Entry address(es):
    IP address: 207.95.6.143
Platform: cisco RSP4, Capabilities: Router
Interface: Eth 1/1, Port ID (outgoing port): FastEthernet5/0/0
Holdtime : 127 seconds
Version :
Cisco Internetwork Operating System Software
IOS (tm) RSP Software (RSP-JSV-M), Version 12.0(5)T1, RELEASE SOFTWARE (fc1)
Copyright (c) 1986-1999 by cisco Systems, Inc.
Compiled Thu 19-Aug-99 04:12 by cmong
```

Syntax: `show fdp neighbors [detail | ethernet [slotnum]/portnum]`

Displaying CDP entries

To display CDP entries for all neighbors, enter the following command.
To display CDP entries for a specific device, specify the device ID. Here is an example.

FESX Router# show fdp entry *  
Device ID: Router  
Entry address(es):  
   IP address: 207.95.6.143  
Platform: cisco RSP4, Capabilities: Router  
Interface: Eth 1/1, Port ID (outgoing port): FastEthernet5/0/0  
Holdtime : 124 seconds  
Version :  
Cisco Internetwork Operating System Software  
IOS (tm) RSP Software (RSP-JSV-M), Version 12.0(5)T1, RELEASE SOFTWARE  
(fc1)  
Copyright (c) 1986-1999 by cisco Systems, Inc.  
Compiled Thu 19-Aug-99 04:12 by cmong

Syntax: show fdp entry * | <device-id>

**Displaying CDP statistics**

To display CDP packet statistics, enter the following command.

FESX Router# show fdp traffic  
CDP counters:  
   Total packets output: 0, Input: 3  
   Hdr syntax: 0, Chksum error: 0, Encaps failed: 0  
   No memory: 0, Invalid packet: 0, Fragmented: 0

Syntax: show fdp traffic

**Clearing CDP information**

You can clear the following CDP information:

- Cisco Neighbor information
- CDP statistics

To clear the Cisco neighbor information, enter the following command.

FESX Router# clear fdp table  
Syntax: clear fdp table

To clear CDP statistics, enter the following command.
FESX Router# clear fdp counters

Syntax: clear fdp counters
Reading CDP packets
This chapter describes how to display Syslog messages and how to configure the Syslog facility, and lists the Syslog messages that Brocade devices can display during standard operation.

**NOTE**  
This chapter does not list Syslog messages that can be displayed when a debug option is enabled.

### Overview

Brocade software can write syslog messages to provide information at the following severity levels:

- Emergencies
- Alerts
- Critical
- Errors
- Warnings
- Notifications
- Informational
- Debugging

The device writes the messages to a local buffer.

You also can specify the IP address or host name of up to six Syslog servers. When you specify a Syslog server, the Brocade device writes the messages both to the system log and to the Syslog server.

Using a Syslog server ensures that the messages remain available even after a system reload. The Brocade local Syslog buffer is cleared during a system reload or reboot, but the Syslog messages sent to the Syslog server remain on the server.

**NOTE**  
Starting in software release 02.5.00, you can enable the Brocade device to retain Syslog messages after a soft reboot (`reload` command). Refer to “Retaining Syslog messages after a soft reboot” on page 1702.

The Syslog service on a Syslog server receives logging messages from applications on the local host or from devices such as a Layer 2 Switch or Layer 3 Switch. Syslog adds a time stamp to each received message and directs messages to a log file. Most Unix workstations come with Syslog configured. Some third party vendor products also provide Syslog running on NT.

Syslog uses UDP port 514 and each Syslog message thus is sent with destination port 514. Each Syslog message is one line with Syslog message format. The message is embedded in the text portion of the Syslog format. There are several subfields in the format. Keywords are used to identify each subfield, and commas are delimiters. The subfield order is insensitive except that the text subfield should be the last field in the message. All the subfields are optional.
Displaying Syslog messages

To display the Syslog messages in the device local buffer, enter the `show logging` command at any level of the CLI. The following shows an example display output.

FastIron>show logging

Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
Buffer logging: level ACDMEINW, 3 messages logged
level code: A=alert C=critical D=debugging M=emergency E=error
I=informational N=notification W=warning

Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed

Dynamic Log Buffer (50 entries):
Dec 15 18:46:17:I:Interface ethernet 4, state up
Dec 15 18:45:21:I:Bridge topology change, vlan 4095, interface 4, changed state to forwarding
Dec 15 18:45:15:I:Warm start

For information about the Syslog configuration information, time stamps, and dynamic and static buffers, refer to “Displaying the Syslog configuration” on page 1696.

Enabling real-time display of Syslog messages

By default, to view Syslog messages generated by a Brocade device, you need to display the Syslog buffer or the log on a Syslog server used by the Brocade device.

You can enable real-time display of Syslog messages on the management console. When you enable this feature, the software displays a Syslog message on the management console when the message is generated. However, to enable display of real-time Syslog messages in Telnet or SSH sessions, you also must enable display within the individual sessions.

To enable real-time display of Syslog messages, enter the following command at the global CONFIG level of the CLI.

FastIron(config)#logging console

Syntax: [no] logging console

This command enables the real-time display of Syslog messages on the serial console. You can enter this command from the serial console or a Telnet or SSH session.

Enabling real-time display for a Telnet or SSH session

To also enable the real-time display for a Telnet or SSH session, enter the following command from the Privileged EXEC level of the session.

telnet@FastIron#terminal monitor
Syslog trace was turned ON

Syntax: terminal monitor
Configuring the Syslog service

Notice that the CLI displays a message to indicate the status change for the feature. To disable the feature in the management session, enter the `terminal monitor` command again. The command toggles the feature on and off.

telnet@FastIron#terminal monitor
Syslog trace was turned OFF

Here is an example of how the Syslog messages are displayed.

telnet@FastIron#terminal monitor
Syslog trace was turned ON
SYSLOG: <9>FastIron, Power supply 2, power supply on left connector, failed
SYSLOG: <14>FastIron, Interface ethernet 6, state down
SYSLOG: <14>FastIron, Interface ethernet 2, state up

Show log on all terminals

Platform Support:

- FGS and FLS devices running software release 04.1.00 and later
- FWS devices running software release 04.3.00 or later
- FastIron X Series devices running software release 04.1.00 and later – L2, BL3, L3
- Turbolron X Series devices running software release 04.1.00 and later
- FastIron CX devices running software release 06.0.00 and later

In software release versions prior to those listed above, log messages could only be sent to a single terminal logged on to a Brocade switch. The above software versions remove that limitation and permits any terminal logged on to a Brocade switch to receive real-time Syslog messages when the `terminal monitor` command is issued.

Configuring the Syslog service

The procedures in this section describe how to perform the following Syslog configuration tasks:

- Specify a Syslog server. You can configure the Brocade device to use up to six Syslog servers. (Use of a Syslog server is optional. The system can hold up to 1000 Syslog messages in an internal buffer.)

  **NOTE**
  For FLS devices, the Layer 2 internal buffer message limit is 100. For the Layer 3 image, the limit is 1,000.

- Change the level of messages the system logs.
- Change the number of messages the local Syslog buffer can hold.
- Display the Syslog configuration.
- Clear the local Syslog buffer.

Logging is enabled by default, with the following settings:

- Messages of all severity levels (Emergencies – Debugging) are logged.
- By default, up to 50 messages are retained in the local Syslog buffer. This can be changed.
• No Syslog server is specified.

Displaying the Syslog configuration

To display the Syslog parameters currently in effect on a Brocade device, enter the following command from any level of the CLI.

FastIron>#show logging
 Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
 Buffer logging: level ACDMEINW, 3 messages logged
     level code: A=alert C=critical D=debugging E=emergency M=emergency
                     E=error I=informational N=notification W=warning

Static Log Buffer:
 Dec 15 19:04:14:A:Fan 1, fan on right connector, failed

Dynamic Log Buffer (50 entries):
 Dec 15 18:46:17:I:Interface ethernet 1/4, state up
 Dec 15 18:45:21:I:Bridge topology change, vlan 4095, interface 4, changed
     state to forwarding
 Dec 15 18:45:15:I:Warm start

Syntax: show logging

The Syslog display shows the following configuration information, in the rows above the log entries themselves.

<table>
<thead>
<tr>
<th>TABLE 267 CLI display of Syslog buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field</strong>...</td>
</tr>
<tr>
<td>Syslog logging</td>
</tr>
<tr>
<td>messages dropped</td>
</tr>
<tr>
<td>flushes</td>
</tr>
<tr>
<td>overruns</td>
</tr>
<tr>
<td>level</td>
</tr>
<tr>
<td>messages logged</td>
</tr>
<tr>
<td>level code</td>
</tr>
</tbody>
</table>

Static and dynamic buffers

The software provides two buffers:
Configuring the Syslog service

- **Static** – logs power supply failures, fan failures, and temperature warning or shutdown messages
- **Dynamic** – logs all other message types

In the static log, new messages replace older ones, so only the most recent message is displayed. For example, only the most recent temperature warning message will be present in the log. If multiple temperature warning messages are sent to the log, the latest one replaces the previous one. The static buffer is not configurable.

The message types that appear in the static buffer do not appear in the dynamic buffer. The dynamic buffer contains up to the maximum number of messages configured for the buffer (50 by default), then begins removing the oldest messages (at the bottom of the log) to make room for new ones.

The static and dynamic buffers are both displayed when you display the log.

```
FastIron#show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
  Buffer logging: level ACDMEINW, 3 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
    I=informational N=notification W=warning

Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed
Dec 15 19:00:14:A:Fan 2, fan on left connector, failed

Dynamic Log Buffer (50 entries):
Dec 15 18:46:17:1:I:Interface ethernet 4, state up
Dec 15 18:45:21:1:I:Bridge topology change, vlan 4095, interface 4, changed
  state to forwarding
Dec 15 18:45:15:1:I:Warm start
```

Notice that the static buffer contains two separate messages for fan failures. Each message of each type has its own buffer. Thus, if you replace fan 1 but for some reason that fan also fails, the software replaces the first message about the failure of fan 1 with the newer message. The software does not overwrite the message for fan 2, unless the software sends a newer message for fan 2.

When you clear log entries, you can selectively clear the static or dynamic buffer, or you can clear both. For example, to clear only the dynamic buffer, enter the following command at the Privileged EXEC level.

```
FastIron#clear logging dynamic-buffer
```

**Syntax:** `clear logging [dynamic-buffer | static-buffer]`

You can specify `dynamic-buffer` to clear the dynamic buffer or `static-buffer` to clear the static buffer. If you do not specify a buffer, both buffers are cleared.

**Time stamps**

The contents of the time stamp differ depending on whether you have set the time and date on the onboard system clock:

- If you have set the time and date on the onboard system clock, the date and time are shown in the following format.
  
  `mm dd hh:mm:ss`
Configuring the Syslog service

where

- \( mm \) – abbreviation for the name of the month
- \( dd \) – day
- \( hh \) – hours
- \( mm \) – minutes
- \( ss \) – seconds

For example, “Oct 15 17:38:03” means October 15 at 5:38 PM and 3 seconds.

- If you have not set the time and date on the onboard system clock, the time stamp shows the amount of time that has passed since the device was booted, in the following format.

\(<num>d<num>h<num>m<num>s\)

where

- \(<num>d\) – day
- \(<num>h\) – hours
- \(<num>m\) – minutes
- \(<num>s\) – seconds

For example, “188d1h01m00s” means the device had been running for 188 days, 11 hours, one minute, and zero seconds when the Syslog entry with this time stamp was generated.

Example of Syslog messages on a device with the onboard clock set

The example shows the format of messages on a device where the onboard system clock has been set. Each time stamp shows the month, the day, and the time of the system clock when the message was generated. For example, the system time when the most recent message (the one at the top) was generated was October 15 at 5:38 PM and 3 seconds.

FastIron#show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
Buffer logging: level ACDMEINW, 38 messages logged
level code: A=alert C=critical D=debugging M=emergency E=error I=informational N=notification W=warning

Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed
Dec 15 19:00:14:A:Fan 2, fan on left connector, failed

Dynamic Log Buffer (50 entries):
Oct 15 17:38:03:warning:list 101 denied tcp 209.157.22.191(0)(Ethernet 18 0010.5af.77ed) -> 198.99.4.69(http), 1 event(s)
Oct 15 07:03:30:warning:list 101 denied tcp 209.157.22.26(0)(Ethernet 18 0010.5af.77ed) -> 198.99.4.69(http), 1 event(s)
Oct 15 06:58:30:warning:list 101 denied tcp 209.157.22.198(0)(Ethernet 18 0010.5af.77ed) -> 198.99.4.69(http), 1 event(s)

Example of Syslog messages on a device with the onboard clock not set

The example shows the format of messages on a device where the onboard system clock is not set. Each time stamp shows the amount of time the device had been running when the message was generated. For example, the most recent message, at the top of the list of messages, was generated when the device had been running for 21 days, seven hours, two minutes, and 40 seconds.
Disabling or re-enabling Syslog

Syslog is enabled by default. To disable it, enter the following command at the global CONFIG level.

```
FastIron(config)#no logging on
```

**Syntax:** [no] logging on [udp-port]

The `<udp-port>` parameter specifies the application port used for the Syslog facility. The default is 514.

To re-enable logging, enter the following command.

```
FastIron(config)#logging on
```

This command enables local Syslog logging with the following defaults:

- Messages of all severity levels (Emergencies – Debugging) are logged.
- Up to 50 messages are retained in the local Syslog buffer.
- No Syslog server is specified.

Specifying a Syslog server

To specify a Syslog server, enter a command such as the following.

```
FastIron(config)#logging host 10.0.0.99
```

**Syntax:** logging host <ip-addr> | <server-name>

Specifying an additional Syslog server

To specify an additional Syslog server, enter the `logging host <ip-addr>` command again, as in the following example. You can specify up to six Syslog servers.

```
FastIron(config)#logging host 10.0.0.99
```

**Syntax:** logging host <ip-addr> | <server-name>
Disabling logging of a message level

To change the message level, disable logging of specific message levels. You must disable the message levels on an individual basis.

For example, to disable logging of debugging and informational messages, enter the following commands.

```
FastIron(config)#no logging buffered debugging
FastIron(config)#no logging buffered informational
```

Syntax:  `[no] logging buffered <level> | <num-entries>`

The `<level>` parameter can have one of the following values:

- alerts
- critical
- debugging
- emergencies
- errors
- informational
- notifications
- warnings

The commands in the example above change the log level to notification messages or higher. The software will not log informational or debugging messages. The changed message level also applies to the Syslog servers.

Changing the number of entries the local buffer can hold

You also can use the `logging buffered` command to change the number of entries the local Syslog buffer can store. For example.

```
FastIron(config)#logging buffered 100
FastIron(config)#write mem
FastIron(config)#exit
FastIron#reload
```

Syntax:  `logging buffered <num>`

The default number of messages is 50. On most FastIron Layer 2 and Layer 3 switches, the buffer can hold up to 1000 entries.

**NOTE**

For FastIron LS devices running Layer 2 software, the syslog buffer limit is 100 entries. For FLS devices running the EPREM software image, the syslog buffer limit is 1000 entries.

**Configuration notes**

- In software releases FSX 02.5.00 and later, you must save the configuration and reload the software to place the change into effect. In releases prior to 02.5.00, the change takes effect immediately and does not require you to reload the software.
- If you decrease the size of the buffer, the software clears the buffer before placing the change into effect.
• If your device is running software release 02.4.00 and you increase the size of the Syslog buffer, the software will clear some of the older locally buffered Syslog messages.

## Changing the log facility

The Syslog daemon on the Syslog server uses a facility to determine where to log the messages from the Brocade device. The default facility for messages the Brocade device sends to the Syslog server is "user". You can change the facility using the following command.

### NOTE

You can specify only one facility. If you configure the Brocade device to use two Syslog servers, the device uses the same facility on both servers.

```
FastIron(config)#logging facility local0
```

**Syntax:** `logging facility <facility-name>`

The `<facility-name>` can be one of the following:

- **kern** – kernel messages
- **user** – random user-level messages
- **mail** – mail system
- **daemon** – system daemons
- **auth** – security or authorization messages
- **syslog** – messages generated internally by Syslog
- **lpr** – line printer subsystem
- **news** – netnews subsystem
- **uucp** – uucp subsystem
- **sys9** – cron/at subsystem
- **sys10** – reserved for system use
- **sys11** – reserved for system use
- **sys12** – reserved for system use
- **sys13** – reserved for system use
- **sys14** – reserved for system use
- **cron** – cron/at subsystem
- **local0** – reserved for local use
- **local1** – reserved for local use
- **local2** – reserved for local use
- **local3** – reserved for local use
- **local4** – reserved for local use
- **local5** – reserved for local use
- **local6** – reserved for local use
- **local7** – reserved for local use
Displaying Interface names in Syslog messages

By default, an interface slot number (if applicable) and port number are displayed when you display Syslog messages. If you want to display the name of the interface instead of its number, enter the following command:

```
FastIron(config)# ip show-portname
```

This command is applied globally to all interfaces on Layer 2 Switches and Layer 3 Switches.

**Syntax:** 
```
[no] ip show-portname
```

When you display the messages in the Syslog, you see the interface name under the Dynamic Log Buffer section. The actual interface number is appended to the interface name. For example, if the interface name is "lab" and its port number is "2", you see "lab2" displayed as in the example below:

```
FastIron# show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
  Buffer logging: level ACDMEINW, 3 messages logged
    level code: A=alert C=critical D=debugging M=emergency E=error
    I=informational N=notification W=warning
Static Log Buffer:
Dec 15 19:04:14:A:Fan 1, fan on right connector, failed
Dynamic Log Buffer (50 entries):
Dec 15 18:46:17:I:Interface ethernet Lab2, state up
Dec 15 18:45:15:I:Warm start
```

Displaying TCP or UDP port numbers in Syslog messages

The command `ip show-service-number-in-log` allows you to change the display of TCP or UDP application information from the TCP or UDP well-known port name to the TCP or UDP port number. For example, when this command is in effect, the Brocade device will display `http` (the well-known port name) instead of `80` (the port number) in the output of show commands, and other commands that contain application port information. By default, Brocade devices display TCP or UDP application information in named notation.

To display TCP or UDP port numbers instead of their names, enter the following command.

```
FastIron(config)#ip show-service-number-in-log
```

**Syntax:** 
```
[no] ip show-service-number-in-log
```

Retaining Syslog messages after a soft reboot

You can configure the FastIron X Series device to save the System log (Syslog) after a soft reboot (`reload` command). In releases prior to 02.5.00, the device clears the messages from the System log when the `reload` command is issued.

**Configuration considerations**

- If the number of entries that the Syslog buffer can hold was set to a lower value using the CLI command `logging buffered`, the System log will be cleared after a soft reboot, even when the `logging persistence` feature is in effect. To prevent the device from clearing the System log, either leave the number of entries allowed in the Syslog buffer unchanged, or increase the number of entries allowed in the Syslog buffer.
• This feature does not save Syslog messages after a hard reboot. When the Brocade device is power-cycled, the Syslog messages are cleared.

• If logging persistence is enabled and you load a new software image on the device, you must first clear the log file if you want to reload the device. (Refer to “Clearing the Syslog messages from the local buffer” on page 1703.)

To configure the device to save the System log messages after a soft reboot, enter the following command.

```
FastIron(config)#logging persistence
```

**Syntax:** `[no] logging persistence`  
Enter `no logging persistence` to disable this feature after it has been enabled.

### Clearing the Syslog messages from the local buffer

To clear the Syslog messages stored in the local buffer of the Brocade device, enter the following command.

```
FastIron#clear logging
```

**Syntax:** `clear logging`

### Syslog messages for hardware errors

**Platform Support:**

• FastIron chassis devices running software release 04.2.00 and later

FastIron Chassis devices support the display of hardware read and write errors encountered on a slot or module during bootup and during normal system operations. There are four types of errors, which may cause the system to disable or power down the modules on which they occur:

• Configuration read error  
• Configuration write error  
• Memory read error  
• Memory write error

The following shows examples of some hardware errors in the `show logging` display output.
Syslog messages

Syslog messages (alerts) for hardware errors are listed in Table 268 on page 1704.

<table>
<thead>
<tr>
<th>Message level</th>
<th>Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert</td>
<td>&lt;num-modules&gt; modules and 1 power supply, need more power supply!!</td>
<td>Indicates that the chassis needs more power supplies to run the modules in the chassis. The &lt;num-modules&gt; parameter indicates the number of modules in the chassis.</td>
</tr>
<tr>
<td>Alert</td>
<td>Fan &lt;num&gt;, &lt;location&gt;, failed</td>
<td>A fan has failed. The &lt;num&gt; is the fan number. The &lt;location&gt; describes where the failed fan is in the chassis.</td>
</tr>
<tr>
<td>Alert</td>
<td>ISIS MEMORY USE EXCEEDED</td>
<td>IS-IS is requesting more memory than is available.</td>
</tr>
</tbody>
</table>
### Brocade Syslog messages (Continued)

<table>
<thead>
<tr>
<th>Message level</th>
<th>Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert</td>
<td>MAC Authentication failed for <code>&lt;mac-address&gt;</code> on <code>&lt;portnum&gt;</code></td>
<td>RADIUS authentication was successful for the specified <code>&lt;mac-address&gt;</code> on the specified <code>&lt;portnum&gt;</code>; however, the VLAN returned in the RADIUS Access-Accept message did not refer to a valid VLAN or VLAN ID on the Brocade device. This is treated as an authentication failure.</td>
</tr>
<tr>
<td>Alert</td>
<td>MAC Authentication failed for <code>&lt;mac-address&gt;</code> on <code>&lt;portnum&gt;</code> (Invalid User)</td>
<td>RADIUS authentication failed for the specified <code>&lt;mac-address&gt;</code> on the specified <code>&lt;portnum&gt;</code> because the MAC address sent to the RADIUS server was not found in the RADIUS server users database.</td>
</tr>
<tr>
<td>Alert</td>
<td>MAC Authentication failed for <code>&lt;mac-address&gt;</code> on <code>&lt;portnum&gt;</code> (No VLAN Info received from RADIUS server)</td>
<td>RADIUS authentication was successful for the specified <code>&lt;mac-address&gt;</code> on the specified <code>&lt;portnum&gt;</code>; however, dynamic VLAN assignment was enabled for the port, but the RADIUS Access-Accept message did not include VLAN information. This is treated as an authentication failure.</td>
</tr>
<tr>
<td>Alert</td>
<td>MAC Authentication failed for <code>&lt;mac-address&gt;</code> on <code>&lt;portnum&gt;</code> (Port is already in another radius given vlan)</td>
<td>RADIUS authentication was successful for the specified <code>&lt;mac-address&gt;</code> on the specified <code>&lt;portnum&gt;</code>; however, the RADIUS Access-Accept message specified a VLAN ID, although the port had previously been moved to a different RADIUS-assigned VLAN. This is treated as an authentication failure.</td>
</tr>
<tr>
<td>Alert</td>
<td>MAC Authentication failed for <code>&lt;mac-address&gt;</code> on <code>&lt;portnum&gt;</code> (RADIUS given vlan does not exist)</td>
<td>RADIUS authentication was successful for the specified <code>&lt;mac-address&gt;</code> on the specified <code>&lt;portnum&gt;</code>; however, the RADIUS Access-Accept message specified a VLAN that does not exist in the Brocade configuration. This is treated as an authentication failure.</td>
</tr>
<tr>
<td>Alert</td>
<td>MAC Authentication failed for <code>&lt;mac-address&gt;</code> on <code>&lt;portnum&gt;</code> (RADIUS given VLAN does not match with TAGGED vlan)</td>
<td>Multi-device port authentication failed for the <code>&lt;mac-address&gt;</code> on a tagged port because the packet with this MAC address as the source was tagged with a VLAN ID different from the RADIUS-supplied VLAN ID.</td>
</tr>
</tbody>
</table>
| Alert         | Management module at slot `<slot-num>` state changed from `<module-state>` to `<module-state>`. | Indicates a state change in a management module. The `<slot-num>` indicates the chassis slot containing the module. The `<module-state>` can be one of the following:  
  - active  
  - standby  
  - crashed  
  - coming-up  
  - unknown |

<td>Informational</td>
<td>DOT1X : port &lt;portnum&gt; - mac &lt;mac address&gt; This device doesn't support ACL with MAC Filtering on the same port</td>
<td>The RADIUS server returned a MAC address filter while an IP ACL was applied to the port, or returned an IP ACL while a MAC address filter was applied to the port.</td>
</tr>
</tbody>
</table>
Informational | DOT1X Port <portnum> is unauthorized because system resource is not enough or the invalid information to set the dynamic assigned IP ACLs or MAC address filters | 802.1X authentication could not take place on the port. This happened because strict security mode was enabled and one of the following occurred:
• Insufficient system resources were available on the device to apply an IP ACL or MAC address filter to the port
• Invalid information was received from the RADIUS server (for example, the Filter-ID attribute did not refer to an existing IP ACL or MAC address filter)

Informational | DOT1X: Port <portnum> currently used vlan-id changes to <vlan-id> due to dot1x-RADIUS vlan assignment | A user has completed 802.1X authentication. The profile received from the RADIUS server specifies a VLAN ID for the user. The port to which the user is connected has been moved to the VLAN indicated by <vlan-id>.

Informational | DOT1X: Port <portnum> currently used vlan-id is set back to port default vlan-id <vlan-id> | The user connected to <portnum> has disconnected, causing the port to be moved back into its default VLAN, <vlan-id>.

Informational | DOT1X: Port <portnum>, AuthControlledPortStatus change: authorized | The status of the interface controlled port has changed from unauthorized to authorized.

Informational | DOT1X: Port <portnum>, AuthControlledPortStatus change: unauthorized | The status of the interface controlled port has changed from authorized to unauthorized.

Informational | Enable super | port-config | read-only password deleted | added | modified from console | telnet | ssh | web | snmp OR Line password deleted | added | modified from console | telnet | ssh | web | snmp | A user created, re-configured, or deleted an Enable or Line password through the Web, SNMP, console, SSH, or Telnet session.

Informational | ERR_DISABLE: Interface ethernet <port-number>, err-disable recovery timeout | Errdisable recovery timer expired and the port has been reenabled.

Informational | ERR_DISABLE: Interface ethernet 16, err-disable recovery timeout | If the wait time (port is down and is waiting to come up) expires and the port is brought up the following message is displayed.

Informational | ERR_DISABLE: Link flaps on port ethernet 16 exceeded threshold; port in err-disable state | The threshold for the number of times that a port link toggles from “up” to “down” and “down” to “up” has been exceeded.

Informational | Interface <portnum>, line protocol down | The line protocol on a port has gone down. The <portnum> is the port number.

Informational | Interface <portnum>, line protocol up | The line protocol on a port has come up. The <portnum> is the port number.

Informational | Interface <portnum>, state down | A port has gone down. The <portnum> is the port number.

Informational | Interface <portnum>, state up | A port has come up. The <portnum> is the port number.

</table>
### Notification

OSPF intf authen failure, rid `<router-id>`,
inf addr `<ip-addr>`,
pkt src addr `<src-ip-addr>`,
error type `<error-type>`, pkt type `<pkt-type>`

Indicates that an OSPF interface authentication failure has occurred.
The `<router-id>` is the router ID of the Brocade device.
The `<ip-addr>` is the IP address of the interface on the Brocade device.
The `<src-ip-addr>` is the IP address of the interface from which the Brocade device received the authentication failure.
The `<error-type>` can be one of the following:
- bad version
- area mismatch
- unknown NBMA neighbor
- unknown virtual neighbor
- authentication type mismatch
- authentication failure
- network mask mismatch
- hello interval mismatch
- dead interval mismatch
- option mismatch
- unknown

The `<packet-type>` can be one of the following:
- hello
- database description
- link state request
- link state update
- link state ack
- unknown

Network Monitoring

This appendix describes the remote monitoring features available on Brocade products.

Basic management

The following sections contain procedures for basic system management tasks.

Viewing system information

You can access software and hardware specifics for a Brocade Layer 2 Switch or Layer 3 Switch. For software specifics, refer to “Determining the software versions installed and running on a device” on page 83.

To view the software and hardware details for the system, enter the `show version` command. The following shows an example output.
Basic management

FastIron#show version

==========================================================================
Active Management CPU [Slot-9]:
  SW: Version 04.3.00b17T3e3 Copyright (c) 1996-2008 Brocade Communications, Inc., Inc.
  Compiled on Sep 25 2008 at 04:09:20 labeled as SXR04300b17
    (4031365 bytes) from Secondary sxr04300b17.bin
  BootROM: Version 04.0.00T3e5 (FEv2)
  HW: ANR-Chassis FastIron SX 1600-PREM (PROM-TYPE SX-FIL3U)
  Serial #: TE35069141

SL 3: SX-FI424C 24-port Gig Copper
  Serial #: CY13073008
  P-ASIC 4: type 00D1, rev D2 subrev 00
  P-ASIC 5: type 00D1, rev D2 subrev 00

SL 9: SX-FI8GMR4 8-port Management
  Serial #: CH37080003
  P-ASIC 16: type 00D1, rev D2 subrev 00

SL 14: SX-FI42XGW 2-port 10G LAN/WAN
  Serial #: Invalid
  P-ASIC 26: type 01D1, rev 00 subrev 00
  P-ASIC 27: type 01D1, rev 00 subrev 00

Active Management Module:
  660 MHz Power PC processor 8541 (version 32/0020) 66 MHz bus
  512 KB boot flash memory
  16384 KB code flash memory
  512 MB DRAM
  The system uptime is 2 minutes 13 seconds
  The system started=warm start reloaded=by "reload"
  *** NOT FOR PRODUCTION ***
  *** AUTO SHUTDOWN IS OFF. PLEASE ACTIVATE WITH auto-shutdown ***

The following hardware details are listed in the output of the show version command:
- Chassis type
- PROM type (if applicable)
- Chassis serial number
- Management and interface module serial numbers and ASIC types

For a description of the software details in the output of the show version command, refer to “Determining the software versions installed and running on a device” on page 83.

Syntax: show version

Viewing configuration information

You can view a variety of configuration details and statistics with the show option. The show option provides a convenient way to check configuration changes before saving them to flash.

The show options available will vary for Layer 2 Switches and Layer 3 Switches and by configuration level.
To determine the available show commands for the system or a specific level of the CLI, enter the following command.

FastIron#show ?

Syntax: show <option>

You also can enter “show” at the command prompt, then press the TAB key.

Viewing port statistics

Port statistics are polled by default every 10 seconds.

You can view statistics for ports by entering the following show commands:

- show interfaces
- show configuration
- show statistics

To display the statistics, enter a command such as the following.

FastIron#show statistics ethernet 1/3

Syntax: show statistics [ethernet [stack-unit] / <slotnum> / <portnum>]

The stack-unit parameter is required on FastIron GS and LS devices running software release 02.5.00 or later, and FastIron GS-STK and FastIron LS-STK devices running software release 05.0.00 and later.

The slotnum parameter is required on chassis devices and on FastIron GS devices running software release 02.5.00 or later.

The portnum parameter is a valid port number.

Table 269 lists the statistics displayed in the output of the show statistics command.

</table>
VIEWING STP STATISTICS

You can view a summary of STP statistics for Layer 2 Switches and Layer 3 Switches. STP statistics are by default polled every 10 seconds.

To view spanning tree statistics, enter the `show span` command. To view STP statistics for a VLAN, enter the `span vlan` command.

CLEARING STATISTICS

You can clear statistics for many parameters with the `clear` option.
To determine the available **clear** commands for the system, enter the following command.

```
FastIron#clear ?
```

**Syntax:** `clear <option>`

You also can enter “clear” at the command prompt, then press the TAB key.

---

**NOTE**
Clear commands are found at the Privileged EXEC level.

---

### Traffic counters for outbound traffic

You can configure traffic counters (also called transmit counters) that enable the Brocade device to count the following packet types on a port or port region:

- broadcast packets
- multicast packets
- unicast packets
- dropped packets due to congestion and egress filtering

Depending on the parameters specified with the traffic counter configuration, traffic counters record the number of outbound packets from any combination of the following sources:

- a specific port or all ports in a specific port region
- a specific VLAN or all VLANs
- a specific 802.1p priority queue or all priority queues

---

**Configuration notes**

Consider the following rules when configuring traffic counters for outbound traffic.

- This feature is supported in the Layer 2, base Layer 3, and full Layer 3 codes.
- This feature applies to physical ports only, including 10 Gbps Ethernet ports and trunk ports. It does not apply to virtual interfaces.
- Once the enhanced traffic counters are read using the `show transmit-counter values` command, the counters are cleared (reset to zero).
- For each port region, you can enable a maximum of two traffic counters, regardless of whether traffic counters are enabled on individual ports or on all ports in the port region.
- Traffic counters increase for bridged filtered outbound traffic when any of the following conditions occur:
  - The port is disabled or the link is down.
  - The port or port region does not belong to the VLAN specified in the transmit counter configuration.
  - A Layer 2 protocol (e.g., spanning tree) has the port in a Blocked state.
  - The source port needs to be suppressed for multi-target packets.
  - The priority queue specified in the traffic counter is not allowed for some other reason.
  - Unknown unicast and unregistered multicast packets are filtered.
**Configuration syntax**

This section provides the syntax and configuration examples for enhanced traffic counters.

**Example**

To configure traffic counters for outbound traffic on a specific port, enter a command such as the following.

```
FastIron(config)#transmit-counter 4 port 18 only vlan 1 prio 7 enable
```

The above command creates and enables traffic counter 4 on port 18. The device will count the number of packets sent out on port 18 that are in VLAN 1 and have a priority queue of 7.

**Example**

To configure traffic counters for outbound traffic in a specific port region, enter a command such as the following.

```
FastIron(config)#transmit-counter 1 port 1 region vlan all prio all enable
```

The above command creates and enables traffic counter 1 on all ports that are in the same port region as port 1. The device will count the number of packets transmitted in this port region that belong to any VLAN and have any assigned priority queue.

**Syntax:**

```
[no] transmit-counter <counter-ID> port [<slotnum>/<port-num>] only | region vlan <vlan-ID> | all priority <priority-queue> | all enable
```

Enter the `no` form of the command to remove the outbound traffic counter.

The `<counter-ID>` parameter identifies the traffic counter. You can configure up to 64 traffic counters. Enter a number from 1 – 64.

The `<slotnum>` parameter is required on chassis devices.

The `<port-num>` parameter is the port number to which enhanced traffic counters will apply. Enter the port number followed by `only` to apply the enhanced traffic counter to a specific port, or enter the port number followed by `region` to apply the enhanced traffic counter to all of the ports in the port region.

The `<vlan-ID>` parameter identifies the VLAN ID for which outbound traffic will be counted. Enter a number from 0 – 4095 or enter `all` to indicate all VLANs.

The `<priority-queue>` parameter identifies the 802.1p priority queue for which traffic will be counted. Enter a number from 0 – 7 or enter `all` to indicate all priority queues.

**Displaying enhanced traffic counter profiles**

To display the details of the traffic counters configured on your device, enter the `show transmit-counter profiles` command. The following shows an example output.

```
FastIron#show transmit-counter profiles
Tx Counter Port(s) Vlan Id Priority Device Set
  1   1 -   12   All   All   Dev 0   Set0
  4          18         1         7   Dev 1   Set0
 10   13 -   24    100       All Dev 1   Set1
```
Displaying enhanced traffic counter statistics

To display the traffic counters for outbound traffic, enter the `show transmit-counter profiles` command.

**NOTE**
Once the enhanced traffic counters are displayed, the counters are cleared (reset to zero).

The following shows an example output.

```
FastIron#show transmit-counter values 1
Transmit Queue Counter Values for Counter 1:
Transmitted Frames:
  Known Unicast   : 17204
  Multicast & Unknown Unicast : 2797
  Broadcast       : 5
Dropped Frames:
  Bridge Egress Filtered : 2
  Congestion Drops      : 0
FastIron#show transmit-counter values 4
Transmit Queue Counter Values for Counter 4:
Transmitted Frames:
  Known Unicast : 124
  Multicast & Unknown Unicast : 2752
  Broadcast     : 0
Dropped Frames:
  Bridge Egress Filtered : 37
  Congestion Drops      : 0
```

**Syntax:** `show transmit-counter values <number>`

where `<number>` identifies a valid enhanced traffic counter and is a value from 1 – 64.

**TABLE 270** Outbound traffic counter statistics

**RMON support**

The Brocade RMON agent supports the following groups. The group numbers come from the RMON specification (RFC 1757):

- Statistics (RMON Group 1)
- History (RMON Group 2)
- Alarms (RMON Group 3)
- Events (RMON Group 9)

The CLI allows you to make configuration changes to the control data for these groups, but you need a separate RMON application to view and display the data graphically.

**Maximum number of entries allowed in the RMON control table**

You can specify the maximum number of entries allowed in the RMON control table, including alarms, history, and events. The default number of RMON entries allowed in the RMON control table is 1024 on the FESX, and 2048 on the TIX, FSX, FSX 800, and FSX 1600. The maximum number of RMON entries supported is 32768.

To set the maximum number of allowable entries to 3000 in the RMON history table, enter commands such as the following.

```
FastIron(config)#system-max rmon-entries 3000
FastIron(config)#write mem
FastIron(config)#exit
FastIron#reload
```

**NOTE**

You must save the change to the startup-config file and reload or reboot. The change does not take effect until you reload or reboot.

**Syntax:** `system-max rmon-entries <value>`
where <value> can be:

- 1536 – 32768 for TIX, FSX, FSX 800, and FSX 1600 devices
- 128 – 32768 for FESX devices

Statistics (RMON group 1)

Count information on multicast and broadcast packets, total packets sent, undersized and oversized packets, CRC alignment errors, jabbers, collision, fragments and dropped events is collected for each port on a Brocade Layer 2 Switch or Layer 3 Switch.

No configuration is required to activate collection of statistics for the Layer 2 Switch or Layer 3 Switch. This activity is by default automatically activated at system start-up.

You can view a textual summary of the statistics for all ports by entering the following CLI command.

```
FastIron#show rmon statistics
Ethernet statistics 1 is active, owned by monitor
Interface 1/1 (ifIndex 1) counters
    Octets          0
    Drop events          0
    Broadcast pkts          0
    CRC alignment errors          0
    Oversize pkts          0
    Jabbers          0
    64 octets pkts 0 65 to 127 octets pkts 0
    128 to 255 octets pkts 0 256 to 511 octets pkts 0
    512 to 1023 octets pkts 0 1024 to 1518 octets pkts 0
```

Syntax: show rmon statistics [[<slotnum>/]<portnum>]

The <portnum> parameter specifies the port number. You can use the physical port number or the SNMP port number. The physical port number is based on the product. If you specify a physical port on a chassis device, you must also enter the slot number:

- If the product is a Stackable device, the ports are numbered sequentially starting with 1.
- If the product is a Chassis device, the ports are numbered according to slot and port. For example, the first port in slot 1 is 1/1. The third port in slot 7 is 7/3.

The SNMP numbers of the ports start at 1 and increase sequentially. For example, if you are using a Chassis device and slot 1 contains an 8-port module, the SNMP number of the first port in slot 2 is 9. The physical port number of the same port is 2/1.

This command shows the following information.
<table>
<thead>
<tr>
<th>This line...</th>
<th>Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Octets</td>
<td>The total number of octets of data received on the network. This number includes octets in bad packets. This number does not include framing bits but does include Frame Check Sequence (FCS) octets.</td>
</tr>
<tr>
<td>Drop events</td>
<td>Indicates an overrun at the port. The port logic could not receive the traffic at full line rate and had to drop some packets as a result. The counter indicates the total number of events in which packets were dropped by the RMON probe due to lack of resources. This number is not necessarily the number of packets dropped, but is the number of times an overrun condition has been detected.</td>
</tr>
<tr>
<td>Packets</td>
<td>The total number of packets received. This number includes bad packets, broadcast packets, and multicast packets.</td>
</tr>
<tr>
<td>Broadcast pkts</td>
<td>The total number of good packets received that were directed to the broadcast address. This number does not include multicast packets.</td>
</tr>
<tr>
<td>Multicast pkts</td>
<td>The total number of good packets received that were directed to a multicast address. This number does not include packets directed to the broadcast address.</td>
</tr>
<tr>
<td>CRC alignment errors</td>
<td>The total number of packets received that were from 64 – 1518 octets long, but had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a non-integral number of octets (Alignment Error). The packet length does not include framing bits but does include FCS octets.</td>
</tr>
<tr>
<td>Undersize pkts</td>
<td>The total number of packets received that were less than 64 octets long and were otherwise well formed. This number does not include framing bits but does include FCS octets.</td>
</tr>
<tr>
<td>Fragments</td>
<td>The total number of packets received that were less than 64 octets long and had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a non-integral number of octets (Alignment Error). It is normal for this counter to increment, since it counts both runts (which are normal occurrences due to collisions) and noise hits. This number does not include framing bits but does include FCS octets.</td>
</tr>
<tr>
<td>Oversize packets</td>
<td>The total number of packets received that were longer than 1518 octets and were otherwise well formed. This number does not include framing bits but does include FCS octets.</td>
</tr>
<tr>
<td>Jabbers</td>
<td>The total number of packets received that were longer than 1518 octets and had either a bad FCS with an integral number of octets (FCS Error) or a bad FCS with a non-integral number of octets (Alignment Error). <strong>NOTE:</strong> This definition of jabber is different from the definition in IEEE-802.3 section 8.2.1.5 (10BASE5) and section 10.3.1.4 (10BASE2). These documents define jabber as the condition where any packet exceeds 20 ms. The allowed range to detect jabber is between 20 ms and 150 ms. This number does not include framing bits but does include FCS octets.</td>
</tr>
<tr>
<td>Collisions</td>
<td>The best estimate of the total number of collisions on this Ethernet segment.</td>
</tr>
<tr>
<td>64 octets pkts</td>
<td>The total number of packets received that were 64 octets long. This number includes bad packets. This number does not include framing bits but does include FCS octets.</td>
</tr>
<tr>
<td>65 to 127 octets pkts</td>
<td>The total number of packets received that were 65 – 127 octets long. This number includes bad packets. This number does not include framing bits but does include FCS octets.</td>
</tr>
</tbody>
</table>

### History (RMON group 2)

All active ports by default will generate two history control data entries per active Brocade Layer 2 Switch port or Layer 3 Switch interface. An active port is defined as one with a link up. If the link goes down the two entries are automatically deleted.

Two history entries are generated for each device:

- A sampling of statistics every 30 seconds
- A sampling of statistics every 30 minutes

The history data can be accessed and displayed using any of the popular RMON applications.

A sample RMON history command and its syntax is shown below.

FastIron(config)#rmon history 1 interface 1 buckets 10 interval 10 owner nyc02

**Syntax:** `rmon history <entry-number> interface [<slotnum>/]<portnum> buckets <number> interval <sampling-interval> owner <text-string>`

You can modify the sampling interval and the bucket (number of entries saved before overwrite) using the CLI. In the above example, owner refers to the RMON station that will request the information.

**NOTE**

To review the control data entry for each port or interface, enter the `show rmon history` command.

### Alarm (RMON group 3)

Alarm is designed to monitor configured thresholds for any SNMP integer, time tick, gauge or counter MIB object. Using the CLI, you can define what MIB objects are monitored, the type of thresholds that are monitored (falling, rising or both), the value of those thresholds, and the sample type (absolute or delta).

An alarm event is reported each time that a threshold is exceeded. The alarm entry also indicates the action (event) to be taken if the threshold be exceeded.

A sample CLI alarm entry and its syntax is shown below.
FastIron(config)#rmon alarm 1 ifInOctets.6 10 delta rising-threshold 100 1 falling threshold 50 1 owner nyc02

Syntax:  rmon alarm <entry-number> <MIB-object.interface-num> <sampling-time> 
<sample-type>  
<threshold-type> <threshold-value> <event-number> <threshold-type> <threshold-value> 
<event-number>  
owner <text-string>

Event (RMON group 9)

There are two elements to the Event Group—the event control table and the event log table.
The event control table defines the action to be taken when an alarm is reported. Defined events
can be found by entering the CLI command, show event. The Event Log Table collects and stores
reported events for retrieval by an RMON application.

A sample entry and syntax of the event control table is shown below.

FastIron(config)#rmon event 1 description ‘testing a longer string’ log-and-trap public owner nyc02

Syntax:  rmon event <event-entry> description <text-string> log | trap | log-and-trap owner 
<rmon-station>

sFlow

sFlow is a standards-based protocol that allows network traffic to be sampled at a user-defined rate
for the purpose of monitoring traffic flow patterns and identifying packet transfer rates on
user-specified interfaces.

When sFlow is enabled on a Layer 2 or Layer 3 switch, the system performs the following
sFlow-related tasks:
• Samples traffic flows by copying packet header information
• Identifies ingress and egress interfaces for the sampled flows
• Combines sFlow samples into UDP packets and forwards them to the sFlow collectors for
  analysis
• Forwards byte and packet count data, or counter samples, to sFlow collectors

sFlow is described in RFC 3176, “InMon Corporation's sFlow: A Method for Monitoring Traffic in
Switched and Routed Networks”.

NOTE
When sFlow is enabled on a FastIron X Series switch or Turbolron X Series switch, or Fastiron CX
switch, QoS will support 7 priority queues rather than 8. This is because QoS queue 1 is reserved
for sFlow and does not get used for other types of traffic. Any non-sFlow packets assigned to QoS
queue 1 will be redirected to QoS 0. On the FastIron GS, QoS queue 1 can be used for priority traffic,
even when sFlow is enabled on an interface.
Support for sFlow version 5

sFlow version 5 enhances and modifies the format of the data sent to the sFlow collector. sFlow version 5 introduces several new sFlow features and also defines a new datagram syntax used by the sFlow agent to report flow samples and interface counters to the sFlow collector.

sFlow version 5 adds support for the following:

- sFlow version 5 datagrams
- Sub-agent support
- Configurable sFlow export packet size
- Support for the new data field and sample type length in flow samples
- Configurable interval for exporting Brocade-specific data structure

sFlow version 5 is backward-compatible with sFlow version 2. On devices that support sFlow version 5, the sFlow agent exports sFlow version 2 flow samples by default, but you can configure the device to export the data in sFlow version 5 format. You can switch between sFlow version 2 and sFlow version 5 formats. The sFlow collector automatically parses each incoming sample and decodes it based on the version number.

The configuration procedures for sFlow version 5 are the same as for sFlow version 2, except where explicitly noted. Configuration procedures for sFlow are in the section “Configuring and enabling sFlow” on page 1746. The features and CLI commands that are specific to sFlow version 5 are described in the section “Configuring sFlow version 5 features” on page 1753.

sFlow support for IPv6 packets

The Brocade implementation of sFlow features support IPv6 packets. This support includes extended router information and extended gateway information in the sampled packet. Note that sFlow support for IPv6 packets exists only on devices running software that supports IPv6.

The configuration procedures for this feature are the same as for IPv4, except where the collector is a link-local address on a Layer 3 switch. For details refer to “Specifying the collector” on page 1747.

Extended router information

IPv6 sFlow sampled packets include the following extended router information:

- IP address of the next hop router
- Outgoing VLAN ID
- Source IP address prefix length
- Destination IP address prefix length

Note that in IPv6 devices, the prefix lengths of the source and destination IP addresses are collected if BGP is configured and the route lookup is completed. In IPv4 devices, this information is collected only if BGP is configured on the devices.

Extended gateway information

If BGP is enabled, extended gateway information is included in IPv6 sFlow sampled packets, including the following BGP information about a packet destination route:

- The autonomous system (AS) number for the router
• The source IP AS of the route
• The source peer AS for the route
• The AS patch to the destination

NOTE
AS communities and local preferences are not included in the sampled packets.

To obtain extended gateway information, use “struct extended_gateway” as described in RFC 3176.

IPv6 packet sampling
IPv6 sampling is performed by the packet processor. The system uses the sampling rate setting to selectively mark the monitoring bit in the header of an incoming packet. Marked packets tell the CPU that the packets are subject to sFlow sampling.

Configuration considerations
This section lists the sFlow configuration considerations on Brocade devices.

Hardware support
• Brocade devices support sFlow packet sampling of inbound traffic only. These devices do not sample outbound packets. However, Brocade devices support byte and packet count statistics for both traffic directions.
• sFlow is supported on all Ethernet ports (10/100, Gbps, and 10 Gbps)

CPU utilization
Enabling sFlow may cause a slight and noticeable increase of up to 20% in CPU utilization. In typical scenarios, this is normal behavior for sFlow, and does not affect the functionality of other features on the switch.

Source address
The sampled sFlow data sent to the collectors includes an agent_address field. This field identifies the IP address of the device that sent the data:
• On a Layer 2 Switch, agent_address is the Layer 2 Switch management IP address. You must configure the management IP address in order to export sFlow data from the device. If the switch has both an IPv4 and IPv6 address, the agent_address is the IPv4 address. If the switch has an IPv6 address only, the agent_address is the global IPv6 address.
• On a Layer 3 Switch with IPv6 interfaces only, sFlow looks for an IPv6 address in the following order, and uses the first address found:
  • The first IPv6 address on the lowest-numbered loopback interface
  • The first IPv6 address on the lowest-numbered VE interface
  • The first IPv6 address on any interface
• On a Layer 3 Switch with both IPv4 and IPv6 interfaces, or with IPv4 interfaces only, sFlow looks for an IP address in the following order, and uses the first address found:
  • The IPv4 router ID configured by the ip router-id command
sFlow

- The first IPv4 address on the lowest-numbered loopback interface
- The first IPv4 address on the lowest-numbered virtual interface
- The first IPv4 address on any interface

**NOTE**
The device uses the router ID only if the device also has an IP interface with the same address. Router ID is not supported on IPv6 devices.

**NOTE**
If an IP address is not already configured when you enable sFlow, the feature uses the source address 0.0.0.0. To display the agent_address, enable sFlow, then enter the `show sflow` command. Refer to “Enabling sFlow forwarding” on page 1751 and “Displaying sFlow information” on page 1756.

**NOTE**
Starting with the introduction of sFlow version 5, you can set an arbitrary IPv4 or IPv6 address as the sFlow agent IP address. Refer to “Specifying the sFlow agent IP address” on page 1754.

**Sampling rate**

The **sampling rate** is the average ratio of the number of packets incoming on an sFlow enabled port, to the number of flow samples taken from those packets. sFlow sampling can affect performance in some configurations.

Note that on the FastIron and Turbolron X Series devices, the configured sampling rate and the actual rate are the same. The software does not adjust the configured sampling rate as on other Brocade devices.

**Port monitoring and sFlow**

- The FastIron GS supports sFlow and port monitoring together on the same port.
- On the FastIron GS, you can use QoS queue 1 for priority traffic, even when sFlow is enabled on the port. This differs from the FastIron X Series. When sFlow is enabled on the FESX, FSX, and FWSX, these devices support seven priorities instead of eight because QoS queue 1 is reserved for sFlow and is not used by other packets. Any non-sFlow packets assigned to QoS queue 1 will be directed to QoS queue 0:
  - FESX and FWSX devices running software release 02.2.01 or later support port monitoring and sFlow together on the same device. The caveat is that these features cannot be configured together within the same port region.
  - FSX devices running software release 02.2.00 or later support port monitoring and sFlow together on the same device. The caveat is that these features cannot be configured together within the same port region.

**Configuring and enabling sFlow**

**NOTE**
The commands in this section apply to sFlow version 2 and sFlow version 5. CLI commands that are specific to sFlow version 5 are documented in “Configuring sFlow version 5 features” on page 1753.
To configure sFlow, perform the following tasks:

- Optional – If your device supports sFlow version 5, change the version used for exporting sFlow data
- Specify collector information. The collector is the external device to which you are exporting the sFlow data. You can specify up to four collectors.
- Optional – Change the polling interval
- Optional – Change the sampling rate
- Enable sFlow globally
- Enable sFlow forwarding on individual interfaces
- Enable sFlow forwarding on individual trunk ports
- If your device supports sFlow version 5, configure sFlow version 5 features

**NOTE**
If you change the router ID or other IP address value that sFlow uses for its agent_address, you need to disable and then re-enable sFlow to cause the feature to use the new source address.

### Specifying the Collector

sFlow exports traffic statistics to an external collector. You can specify up to four collectors. You can specify more than one collector with the same IP address if the UDP port numbers are unique. You can have up to four unique combinations of IP addresses and UDP port numbers.

**IPv4 devices**

To specify an sFlow collector on an IPv4 device, enter a command such as the following.

```
FastIron(config)#sflow destination 10.10.10.1
```

This command specifies a collector with IPv4 address 10.10.10.1, listening for sFlow data on UDP port 6343.

**Syntax:** [no] sflow destination <ip-addr> [<dest-udp-port>]

The `<ip-addr>` parameter specifies the IP address of the collector.

The `<dest-udp-port>` parameter specifies the UDP port on which the sFlow collector will be listening for exported sFlow data. The default port number is 6343.

The sampled sFlow data sent to the collectors includes an agent_address field. This field identifies the device that sent the data. Refer to “Source address” on page 1745.

**IPv6 devices**

To specify an sFlow collector on an IPv6 device, enter a command such as the following.

```
FastIron(config)#sflow destination ipv6 2003:0::0b:02a
```

This command specifies a collector with IPv6 address 2003::0b:02a, listening for sFlow data on UDP port 6343.

**Syntax:** [no] sflow destination ipv6 <ip-addr> [<dest-udp-port>]

The `<ip-addr>` parameter specifies the IP address of the collector.

The `<dest-udp-port>` parameter specifies the UDP port on which the sFlow collector will be listening for exported sFlow data. The default port number is 6343.
If the IPv6 address you specify is a link-local address on a Layer 3 switch, you must also specify the `outgoing-interface ethernet <port-num>` or the `ve <port-num>`. This identifies the outgoing interface through which the sampled packets will be sent.

The sampled sFlow data sent to the collectors includes an agent_address field. This field identifies the device that sent the data. Refer to “Source address” on page 1745.

**Changing the polling interval**

The polling interval defines how often sFlow byte and packet counter data for a port are sent to the sFlow collectors. If multiple ports are enabled for sFlow, the Brocade device staggers transmission of the counter data to smooth performance. For example, if sFlow is enabled on two ports and the polling interval is 20 seconds, the Brocade device sends counter data every ten seconds. The counter data for one of the ports are sent after ten seconds, and counter data for the other port are sent after an additional ten seconds. Ten seconds later, new counter data for the first port are sent. Similarly, if sFlow is enabled on five ports and the polling interval is 20 seconds, the Brocade device sends counter data every four seconds.

The default polling interval is 20 seconds. You can change the interval to a value from 1 to any higher value. The interval value applies to all interfaces on which sFlow is enabled. If you set the polling interval to 0, counter data sampling is disabled.

To change the polling interval, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)#sflow polling-interval 30
```

**Syntax:** `[no] sflow polling-interval <secs>

The `<secs>` parameter specifies the interval and can be from 1 to any higher value. The default is 20 seconds. If you specify 0, counter data sampling is disabled.

**Changing the sampling rate**

The sampling rate is the average ratio of the number of packets incoming on an sFlow-enabled port, to the number of flow samples taken from those packets.

You can change the default (global) sampling rate. You also can change the rate on an individual port, overriding the default sampling rate of 512. With a sampling rate of 512, on average, one in every 512 packets forwarded on an interface is sampled.

**Configuration considerations**

The sampling rate is a fraction in the form 1/N, meaning that, on average, one out of every N packets will be sampled. The `sflow sample` command at the global level or port level specifies N, the denominator of the fraction. Thus a higher number for the denominator means a lower sampling rate since fewer packets are sampled. Likewise, a lower number for the denominator means a higher sampling rate because more packets are sampled. For example, if you change the denominator from 512 to 128, the sampling rate increases because four times as many packets will be sampled.

**NOTE**

Brocade recommends that you do not change the denominator to a value lower than the default. Sampling requires CPU resources. Using a low denominator for the sampling rate can cause high CPU utilization.
**Configured rate and actual rate**

When you enter a sampling rate value, this value is the *configured rate*. The software rounds the value you enter to the next higher odd power of 2 to obtain the *actual rate*. This value becomes the actual sampling rate. For example, if the configured sampling rate is 1000, then the actual rate is 2048 and 1 in 2048 packets are sampled by the hardware.

**Change to global rate**

If you change the global sampling rate, the change is applied to all sFlow-enabled ports *except* those ports on which you have already explicitly set the sampling rate. For example, suppose that sFlow is enabled on ports 1/1, 1/2, and 5/1. If you configure the sampling rate on port 1/1 but leave the other two ports using the default rate, then a change to the global sampling rate applies to ports 1/2 and 5/1 but not port 1/1. sFlow assumes that you want to continue using the sampling rate you explicitly configured on an individual port even if you globally change the sampling rate for the other ports.

**Module rate**

While different ports on a module may be configured to have different sampling rates, the hardware for the module will be programmed to take samples at a single rate (the module sampling rate). The module sampling rate will be the highest sampling rate (i.e. lowest number) configured for any of the ports on the module.

When ports on a given module are configured with different sampling rates, the CPU discards some of the samples supplied by the hardware for ports with configured sampling rates which are lower than the module sampling rate. This is referred to as subsampling, and the ratio between the port sampling rate and the module sampling rate is known as the subsampling factor. For example, if the module in slot 4 has sFlow enabled on ports 4/2 and 4/8, and port 4/2 is using the default sampling rate of 512, and port 4/8 is configured explicitly for a rate of 2048, then the module sampling rate will be 512 because this is the highest port sampling rate (lowest number). The subsampling factor for port 4/2 will be 1, meaning that every sample taken by the hardware will be exported, while the subsampling factor for port 4/8 will be 4, meaning that one out of every four samples taken by the hardware will be exported. Whether a port’s sampling rate is configured explicitly, or whether it uses the global default setting, has no effect on the calculations.

You do not need to perform any of these calculations to change a sampling rate. For simplicity, the syntax information in this section lists the valid sampling rates. In addition, the software will round the value you enter up to the nearest value listed. You can display the rates you entered (the configured rates) as well as the rates rounded up to by the software (the actual rates) for the default sampling rate, module rates, and all sFlow-enabled ports by entering the `show sflow` command. Refer to “Displaying sFlow information” on page 1756.

**Sampling rate for new ports**

When you enable sFlow on a port, the port’s sampling rate is set to the global default sampling rate. This also applies to ports on which you disable and then re-enable sFlow. The port does not retain the sampling rate it had when you disabled sFlow on the port, even if you had explicitly set the sampling rate on the port.

**Changing the default sampling rate**

To change the default (global) sampling rate, enter a command such as the following at the global CONFIG level of the CLI.

```
FastIron(config)#sflow sample 2048
```

**Syntax:** `[no] sflow sample <num>`
The <num> parameter specifies the average number of packets from which each sample will be taken. The software rounds the value you enter to the next higher odd power of 2. This value becomes the actual default sampling rate and is one of the following:

- 2
- 8
- 32
- 128
- 512
- 2048
- 4096
- 8192
- 32768
- 131072
- 524288
- 2097152
- 8388608
- 33554432
- 134217728
- 536870912
- 2147483648

For example, if the configured sampling rate is 1000, then the actual rate is 2048 and 1 in 2048 packets are sampled by the hardware.

**Changing the sampling rate of a module**
You cannot change a module sampling rate directly. You can change a module sampling rate only by changing the sampling rate of a port on that module.

**Changing the sampling rate on a port**
You can configure an individual port to use a different sampling rate than the global default sampling rate. This is useful in cases where ports have different bandwidths. For example, if you are using sFlow on 10/100 ports and Gbps Ethernet ports, you might want to configure the Gbps ports to use a higher sampling rate (and thus gather fewer samples per number of packets) than the 10/100 ports.

To change the sampling rate on an individual port, enter a command such as the following at the configuration level for the port.

```bash
FastIron(config-if-1/1)#sflow sample 8192
```

**Syntax:** `[no] sflow sample <num>`

The <num> parameter specifies the average number of packets from which each sample will be taken. The software rounds the value you enter up to the next odd power of 2. The actual sampling rate becomes one of the values listed in “Changing the default sampling rate”.

**Changing the default sampling rate**

- 2
- 8
- 32
- 128
- 512
- 2048
- 4096
- 8192
- 32768
- 131072
- 524288
- 2097152
- 8388608
- 33554432
- 134217728
- 536870912
- 2147483648
Changing the sampling rate for a trunk port

You can configure an individual static trunk port to use a different sampling rate than the global default sampling rate. This feature is also supported on LACP trunk ports starting in release FSX 04.3.00. However, it is not supported on LACP trunk ports on TurboIron X Series devices. This feature is useful in cases where ports have different bandwidths. For example, if you are using sFlow on 10/100 ports and Gbps Ethernet ports, you might want to configure the Gbps ports to use a higher sampling rate (and thus gather fewer samples per number of packets) than the 10/100 ports.

To change the sampling rate on an individual trunk port, enter commands such as the following.

```
FastIron(config)#trunk e 4/1 to 4/8
FastIron(config-trunk-4/1-4/8)#config-trunk-ind
FastIron(config-trunk-4/1-4/8)#sflow-subsampling e 4/2 8192
```

Syntax:

```
[no] sflow-subsampling ethernet [<slotnum>/]<portnum> <num>
```

OR

```
[no] sflow sample ethernet [<slotnum>/]<portnum> <num>
```

**NOTE**

Use the command `sflow sample` (instead of `sflow-subsampling`), if your device is running software release FSX 05.1.00 or later. Starting with software release FSX 05.1.00, the CLI command `sflow-subsampling` was replaced with `sflow sample`. The command is automatically updated in the `running configuration` when the software is upgraded from pre-release FSX 05.1.00, to release FSX 05.1.00 or later. It is also updated in the `startup configuration` after the command `write memory` is issued.

The `<num>` parameter specifies the average number of packets from which each sample will be taken. The software rounds the value you enter up to the next odd power of 2. The actual sampling rate becomes one of the values listed in “Changing the default sampling rate”.

Enabling sFlow forwarding

sFlow exports data only for the interfaces on which you enable sFlow forwarding. You can enable sFlow forwarding on Ethernet interfaces.

To enable sFlow forwarding, perform the following:

- Globally enable the sFlow feature
- Enable sFlow forwarding on individual interfaces
- Enable sFlow forwarding on individual trunk ports

**NOTE**

Before you enable sFlow, make sure the device has an IP address that sFlow can use as its source address. Refer to “Source address” on page 1745 for the source address requirements.

**NOTE**

When you enable sFlow forwarding on an 802.1X-enabled interface, the samples taken from the interface include the username used to obtain access to either or both the inbound and outbound ports, if that information is available. For information about 802.1X, refer to Chapter 42, “Configuring 802.1X Port Security”. 
Command syntax
This section shows how to enable sFlow forwarding.

Globally enabling sFlow forwarding
To enable sFlow forwarding, you must first enable it on a global basis, then on individual interfaces or trunk ports, or both.

To globally enable sFlow forwarding, enter the following command.

FastIron(config)#sflow enable

You can now enable sFlow forwarding on individual ports as described in the next two sections.

Syntax: [no] sflow enable

Enabling sFlow forwarding on individual interfaces
To enable sFlow forwarding enter commands such as the following.

FastIron(config)#sflow enable
FastIron(config)#interface ethernet 1/1 to 1/8
FastIron(config-mif-1/1-1/8)#sflow-forwarding

These commands globally enable sFlow, then enable sFlow forwarding on Ethernet ports 1/1 – 1/8. You must use both the `sflow enable` and `sflow-forwarding` commands to enable the feature.

Syntax: [no] sflow enable

Syntax: [no] sflow-forwarding

OR

Syntax: [no] sflow forwarding

Note
Use the command `sflow forwarding` (without the dash), if your device is running software release FSX 05.1.00 or later. Starting with software release FSX 05.1.00, the CLI command `sflow-forwarding` was replaced with `sflow forwarding`. The command is automatically updated in the `running configuration` when the software is upgraded from pre-release FSX 05.1.00, to release FSX 05.1.00 or later. It is also updated in the `startup configuration` after the command `write memory` is issued.

Enabling sFlow forwarding on individual trunk ports
This feature is supported on individual ports of a static trunk group. It is also supported on LACP trunk ports starting in release FSX 04.3.00. However, it is not supported on LACP trunk ports on TurboIron X Series devices.

Note
When you enable sFlow forwarding on a trunk port, only the primary port of the trunk group forwards sFlow samples.

To enable sFlow forwarding on a trunk port, enter commands such as the following.

FastIron(config)#sflow enable
FastIron(config)#trunk e 4/1 to 4/8
FastIron(config-trunk-4/1-4/8)#config-trunk-ind
FastIron(config-trunk-4/1-4/8)#sflow-forwarding e 4/2

These commands globally enable sFlow, then enable sFlow forwarding on trunk port e 4/2. You must use both the `sflow enable` and `sflow-forwarding` commands to enable the feature.
**Syntax:** [no] sflow enable

**Syntax:** [no] sflow-forwarding

**OR**

**Syntax:** [no] sflow forwarding

---

**NOTE**

Use the command `sflow forwarding` (without the dash), if your device is running software release FSX 05.1.00 or later. In software release FSX 05.1.00, the CLI command `sflow-forwarding` was replaced with `sflow forwarding`. The command is automatically updated in the running configuration when the software is upgraded from pre-release FSX 05.1.00, to release FSX 05.1.00 or later. It is also updated in the startup configuration after the command `write memory` is issued.

---

**Configuring sFlow version 5 features**

---

**NOTE**

The commands in this section are supported when sFlow version 5 is enabled on the device. These commands are not supported with sFlow version 2. sFlow version 5 also supports all of the sFlow configuration commands in “Configuring and enabling sFlow” on page 1746.

When sFlow version 5 is enabled on the device, you can do the following:

- Specify the sFlow version (version 2 or version 5)
- Specify the sFlow agent IP address
- Specify the maximum flow sample size
- Export CPU and memory usage Information to the sFlow collector
- Specify the polling interval for exporting CPU and memory usage information to the sFlow collector
- Export CPU-directed data (management traffic) to the sFlow collector

---

**Egress interface ID for sampled broadcast and multicast packets**

For broadcast and multicast traffic, the egress interface ID for sampled traffic is always 0x80000000. When broadcast and multicast packets are sampled, they are usually forwarded to more than one port. However, the output port field in an sFlow datagram supports the display of one egress interface ID only. Therefore, the sFlow version 5 agent always sets the output port ID to 0x80000000 for broadcast and multicast packets that are sampled.

---

**Specifying the sFlow version format**

If your device supports sFlow version 5, you can optionally specify the version used for exporting sFlow data. Refer “Specifying the sFlow agent IP address”.

---
Specifying the sFlow agent IP address

The sampled sFlow data sent to the collectors includes an agent_address field. This field identifies the device (the sFlow agent) that sent the data. By default, the device automatically selects the sFlow agent IP address based on the configuration, as described in the section “Source address” on page 1745. However, starting in software release FSX 05.1.00, you can configure the device to instead use an arbitrary IPv4 or IPv6 address as the sFlow agent IP address.

To specify an IPv4 address as the sFlow agent IP address, enter a command such as the following.

```
FastIron(config)#sflow agent-ip 10.10.10.1
```

**Syntax:** 

```
[no] sflow agent-ip <ipv4-addr>
```

The `<ipv4-addr>` specifies the address of the device that sent the data.

To specify an IPv6 address as the sFlow agent IP address, enter a command such as the following.

```
FastIron(config)#sflow agent-ip FE80::240:D0FF:FE48:4672
```

**Syntax:** 

```
[no] sflow agent-ip <ipv6-addr>
```

The `<ipv6-addr>` specifies the address of the device that sent the data.

Specifying the version used for exporting sFlow data

By default, when sFlow is enabled globally on the Brocade device, the sFlow agent exports sFlow data in version 2 format. If your device supports sFlow version 5, you can change this setting so that the sFlow agent exports data in version 5 format. You can switch between versions without rebooting the device or disabling sFlow.

**NOTE**

When the sFlow version number is changed, the system will reset sFlow counters and flow sample sequence numbers.

To specify the sFlow version used for exporting sFlow data, enter the following command.

```
FastIron(config)#sflow version 5
```

**Syntax:** 

```
[no] sflow version 2 | 5
```

The default is 2.

Specifying the maximum flow sample size

With sFlow version 5, you can specify the maximum size of the flow sample sent to the sFlow collector. If a packet is larger than the specified maximum size, then only the contents of the packet up to the specified maximum number of bytes is exported. If the size of the packet is smaller than the specified maximum, then the entire packet is exported.

For example, to specify 1024 bytes as the maximum flow sample size, enter the following command.

```
FastIron(config)# sflow max-packet-size 1024
```

**Syntax:** 

```
[no] sflow max-packet-size <size>
```

For both sFlow version 2 and version 5, the default maximum flow sample size is 256 bytes.
For sFlow version 5, the maximum flow sample size is 1300 bytes.

**Exporting CPU and memory usage information to the sFlow collector**

With sFlow version 5, you can optionally configure the sFlow agent on the Brocade device to export information about CPU and memory usage to the sFlow collector.

To export CPU usage and memory usage information, enter the following command.

```
FastIron(config)# sflow export system-info
```

**Syntax:** `[no] sflow export system-info`

By default, CPU usage information and memory usage information are not exported.

**Specifying the polling interval for exporting CPU and memory usage information to the sFlow collector**

The polling interval defines how often sFlow data for a port is sent to the sFlow collector. With sFlow version 5, you can optionally set the polling interval used for exporting CPU and memory usage information.

For example, to set the polling interval for exporting CPU and memory usage information to 30 seconds, enter the following command.

```
FastIron(config)# sflow export system-info 30
```

**Syntax:** `[no] sflow export system-info <seconds>`

You can specify a polling interval from 5 seconds to 1,800 seconds (30 minutes). The default polling interval for exporting CPU and memory usage information is 300 seconds (5 minutes).

**Exporting CPU-directed data (management traffic) to the sFlow collector**

You can select which and how often data destined to the CPU (for example, Telnet sessions) is sent to the sFlow collector.

CLI commands allow you to do the following:

- Enable the sFlow agent to export CPU-directed data
- Specify the sampling rate for exported CPU-directed data

**Enabling the sFlow agent to export CPU-directed data**

To enable the sFlow agent on a Brocade device to export data destined to the CPU to the sFlow collector, enter the following command.

```
FastIron(config)# sflow export cpu-traffic
```

**Syntax:** `[no] sflow export cpu-traffic`

By default, this feature is disabled. The sFlow agent does not send data destined to the CPU to the sFlow collector.
Specifying the sampling rate for exported CPU-directed data
The sampling rate is the average ratio of the number of packets incoming on an sFlow-enabled port, to the number of flow samples taken from those packets. You can optionally set the sampling rate for CPU-directed data exported to the sFlow collector. For example, to set this sampling rate to 2048, enter the following command.

```
FastIron(config)# sflow export cpu-traffic 2048
```

**Syntax:** `[no] sflow export cpu-traffic <rate>`

The default sampling rate depends on the Brocade device being configured. Refer to “Changing the sampling rate” on page 1748 for the default sampling rate for each kind of Brocade device.

Displaying sFlow information
To display sFlow configuration information and statistics, enter the following command at any level of the CLI.
FastIron#show sflow
sflow version:5
sFlow services are enabled.
sFlow agent IP address: 123.123.123.1
4 collector destinations configured:
Collector IP 192.168.4.204, UDP 6343
Collector IP 192.168.4.200, UDP 6333
Collector IP 192.168.4.202, UDP 6355
Collector IP 192.168.4.203, UDP 6565
Polling interval is 0 seconds.
Configured default sampling rate: 1 per 512 packets
Actual default sampling rate: 1 per 512 packets
The maximum sFlow sample size:512
exporting cpu-traffic is enabled
exporting cpu-traffic sample rate:16
exporting system-info is enabled
exporting system-info polling interval:20 seconds
10552 UDP packets exported
24127 sFlow samples collected.
sFlow ports: ethe 1/2 to 1/12 ethe 1/15 ethe 1/25 to 1/26 ethe 4/1 ethe 5/10 to 5/20 ethe 8/1 ethe 8/4

Configuring a utilization list for an uplink port

You can configure uplink utilization lists that display the percentage of a given uplink port bandwidth that is used by a specific list of downlink ports. The percentages are based on 30-second intervals of RMON packet statistics for the ports. Both transmit and receive traffic is counted in each percentage.

NOTE
This feature is intended for ISP or collocation environments in which downlink ports are dedicated to various customers' traffic and are isolated from one another. If traffic regularly passes between the downlink ports, the information displayed by the utilization lists does not provide a clear depiction of traffic exchanged by the downlink ports and the uplink port.

Clearing sFlow statistics

To clear the UDP packet and sFlow sample counters in the show sflow display, enter the following command.

FastIron#clear statistics

Syntax: clear statistics

This command clears the values in the following fields of the show sflow display:

- UDP packets exported
- sFlow samples collected

NOTE
This command also clears the statistics counters used by other features.

TABLE 272  sFlow information  (Continued)

<table>

</tr>
<tr>
<td></td>
<td>• disabled</td>
</tr>
<tr>
<td>exporting system-info polling interval</td>
<td>Specifies the interval, in seconds, that sFlow data is sent to the sFlow collector.</td>
</tr>
<tr>
<td>UDP packets exported</td>
<td>The number of sFlow export packets the Brocade device has sent.</td>
</tr>
<tr>
<td></td>
<td>NOTE: Each UDP packet can contain multiple samples.</td>
</tr>
<tr>
<td>sFlow samples collected</td>
<td>The number of sampled packets that have been sent to the collectors.</td>
</tr>
<tr>
<td>sFlow ports</td>
<td>The ports on which you enabled sFlow.</td>
</tr>
<tr>
<td>Module Sampling Rates</td>
<td>The configured and actual sampling rates for each module. If a module does not have any sFlow-enabled ports, the rates are listed as 0.</td>
</tr>
<tr>
<td>Port Sampling Rates</td>
<td>The configured and actual sampling rates for each sFlow-enabled port. The Subsampling factor indicates how many times the sampling rate of the port's module is multiplied to achieve the port's sampling rate. Because of the way the actual sampling rates are computed, the Subsampling factors are always whole numbers.</td>
</tr>
</tbody>
</table>
Each uplink utilization list consists of the following:

- Utilization list number (1, 2, 3, or 4)
- One or more uplink ports
- One or more downlink ports

Each list displays the uplink port and the percentage of that port bandwidth that was utilized by the downlink ports over the most recent 30-second interval.

You can configure up to four bandwidth utilization lists.

**Command syntax**

To configure an uplink utilization list, enter commands such as the following. The commands in this example configure a link utilization list with port 1/1 as the uplink port and ports 1/2 and 1/3 as the downlink ports.

```
FastIron(config)#relative-utilization 1 uplink eth 1/1 downlink eth 1/2 to 1/3
FastIron(config)#write memory
```

Syntax:

```
[no] relative-utilization <num> uplink ethernet [<slotnum>/]<portnum> [to <slotnum>/]<portnum>... downlink ethernet [<slotnum>/]<portnum> [to <slotnum>/]<portnum>...]
```

The `<num>` parameter specifies the list number. You can configure up to four lists. Specify a number from 1 – 4.

The `uplink ethernet` parameters and the port numbers you specify after the parameters indicate the uplink ports.

The `downlink ethernet` parameters and the port numbers you specify after the parameters indicate the downlink ports.

**Displaying utilization percentages for an uplink**

After you configure an uplink utilization list, you can display the list to observe the percentage of the uplink bandwidth that each of the downlink ports used during the most recent 30-second port statistics interval. The number of packets sent and received between the two ports is listed, as well as the ratio of each individual downlink port packets relative to the total number of packets on the uplink.

To display an uplink utilization list, enter a command such as the following at any level of the CLI.

```
FastIron#show relative-utilization 1
uplink: ethe 1
30-sec total uplink packet count = 3011
packet count ratio (%)
  1/ 2:60  1/ 3:40
```

In this example, ports 1/2 and 1/3 are sending traffic to port 1/1. Port 1/2 and port 1/3 are isolated (not shared by multiple clients) and typically do not exchange traffic with other ports except for the uplink port, 1/1.

Syntax: `show relative-utilization <num>`

The `<num>` parameter specifies the list number.
NOTE
The example above represents a pure configuration in which traffic is exchanged only by ports 1/2 and 1/1, and by ports 1/3 and 1/1. For this reason, the percentages for the two downlink ports equal 100%. In some cases, the percentages do not always equal 100%. This is true in cases where the ports exchange some traffic with other ports in the system or when the downlink ports are configured together in a port-based VLAN.

In the following example, ports 1/2 and 1/3 are in the same port-based VLAN.

```
FastIron#show relative-utilization 1
uplink: ethe 1
30-sec total uplink packet count = 3011
packet count ratio (%)
   1/2:100   1/ 3:100
```

Here is another example showing different data for the same link utilization list. In this example, port 1/2 is connected to a hub and is sending traffic to port 1/1. Port 1/3 is unconnected.

```
FastIron#show relative-utilization 1
uplink: ethe 1
30-sec total uplink packet count = 2996
packet count ratio (%)
   1/2:100   1/ 3:---
```
Configuring a utilization list for an uplink port
## IEEE compliance

Brocade devices support the following standards.

1. The FWSX and TIX do not support Layer 3 features.
The following table lists the RFCs supported by Brocade devices.

**NOTE**
Some devices support only a subset of the RFCs. For example, Layer 2 Switches do not support router-specific RFCs. For a list of features supported on your device, refer to the data sheet or the software release notes for the version of software running on your device.

1. The FWSX and TIX do not support Layer 3 features.
In addition to the RFCs listed in “RFC support” on page 1764, Brocade devices support the following Internet drafts:

- ietf-idmr-dvmrp version 3.05, obsoletes RFC 1075 (not supported on TIX)
- draft-ietf-magma-igmp-proxy.txt
- draft-ietf-pim-dm-05 (V1) (not supported on TIX)
- draft-ietf-pim-v2-dm-03 (V2) (not supported on TIX)
- draft-katz-yeung-ospf-traffic-03.txt (not supported on TIX)
- TACACS+ Protocol version 1.78
Internet drafts
Some Brocade devices have passed the Common Criteria (CC) certification testing. This testing is sponsored by the National Information Assurance Partnership (NIAP) - Common Criteria Evaluation and Validation Scheme (CCEVS). For more information regarding the NIAP-CCEVS certification process refer to the following link: http://www.niap-ccevs.org/.

In an effort to maintain a proper level of security as it relates to access to network infrastructure resources, Brocade recommends that all Brocade hardware be installed within a secure location that is accessible by approved personnel only.

### NIAP-CCEVS certified Brocade equipment and Ironware releases

The following Brocade devices have been NIAP-CCEVS certified. The following IronWare software release must be used to remain compliant with this certification:

<table>

Web-Management access to NIAP-CCEVS certified Brocade equipment

All Brocade networking devices that are to remain in compliance with the NIAP-CCEVS certification must disable all remote access through the integrated Web management graphical user interface (GUI). In accordance with NIAP-CCEVS this functionality is considered a security risk and must be disabled.

Please refer to the Brocade Configuration Guides associated with each product listed in the table “NIAP-CCEVS certified Brocade equipment and IronWare software releases”, for detailed instructions on how to disable the Web Management Interface feature.

Local user password changes

Please note that if existing usernames and passwords have been configured on a Brocade Device with specific privilege levels (super-user, read-only, port-config), and if you attempt to change a user’s password by executing the following syntax:

```plaintext
Brocade-Device(config)# user fdryreadonly password <value>
```

The privilege level of this particular user will be changed from its current value to "super-user". The “super-user” level username and password combination provides full access to the Brocade command line interface (CLI). To prevent this from occurring, use the following syntax:

```plaintext
Brocade-Device(config)# user fdryreadonly privilege <value> password <value>
```
